As regards the selection of cases for treatment, it is desirable, though not essential, that one lung should be sound. In the event of both lungs being affected, there must, of course, be sufficient healthy substance in the "sound" lung to carry on the functions of respiration. It is quite astonishing how little apparently healthy lung is necessary for this purpose. Fig. 1 well illustrates this point; it will be seen from this skiagram that an artificial pneumothorax has been produced on the right side. The left lung is largely involved by fibroid phthisis. Yet this patient has been able to walk from ten to twelve miles a day, and has just indulged in a winter's hunting.

It was formerly thought that by producing a pneumothorax in a bilateral case with quiescent limited disease on the "sound" side one ran a great risk of lighting up the disease afresh by throwing additional work on the "sound" side. This has not proved to be the case in practice. Indeed, if the pathological state of affairs is considered, it is seen that rather than exciting the disease to fresh activity one is in reality bringing about a condition of affairs which is conducive to arrest. When one lung is extensively involved and the other slightly so, a considerable amount of compensatory emphysema takes place in the "sound" lung. The alveoli are enlarged and the capillaries dilated; subsequently the capillaries become thrombosed and atrophied and *post mortem* the lung presents a swollen and anaemic appearance. Now when an artificial pneumothorax is produced the emphysematous lung is subjected to pressure, and consequently compression is brought to bear on the vessels and some obstruction to the circulation in that lung is produced. This in turn produces venous stasis, a condition which obtains, but to a much more marked degree, in a case of mitral stenosis. Thus there is produced in the "sound" lung the essentials aimed at in Bier's treatment of tuberculosis by passive hyperaemia, a condition of the lung which tends to bring about arrest rather than excitation of the disease. The radiographic appearance of an emphysematous lung is well illustrated in Fig. 2, while Fig. 3, from the same case, taken after the production of an artificial pneumothorax on the left side, shows the compression to which the right lung has been subjected.

The position taken up by the collapsed lung is naturally dependent on the presence or absence of adhesions to the pleura. Figs. 5 and 6 well illustrate two common positions taken up by the lung in the absence of adhesions. Fig. 5 shows the lung collapsed in the shape of a ball round the pulmonary root, whilst in Fig. 6 it is seen lying along the bodies of the vertebrae.

The sudden drop of temperature claimed to be brought about by the production of an artificial pneumothorax in pyrexial cases has only occurred once in my practice (Chart A). I have found in my cases that the temperature usually for two or three weeks after the operation remains on much the same level as before, with frequently a tendency to a lowering of the morning temperature. After this period it gradually subsides, with an occasional temporary exacerbation, and by the end of six weeks or so the temperature has once more assumed a normal curve. In nearly all my cases there has been an immediate and permanent drop in the daily amount of expectoration, after an initial rise of three or four days' duration due to the squeezing out of secretion from the compressed lung.

There is one other point, but by no means the least in practical importance. It is never possible to predict before making the attempt whether or not one will be able to produce an artificial pneumothorax. Whilst I have failed after repeated attempts in cases which to the ordinary methods of investigation seemed to be entirely free from adhesions, I have likewise failed in cases in which I regarded such a possibility as remote. The moral of this is not to be too encouraging to the patient as to the results to be attained by this method of treatment, as if one is too optimistic and fails in the performance of the operation on account of adhesions, the disappointment and sense of depression produced by failure will require all the tact and ingenuity at one's command to counteract the ill effects produced and prevent a detrimental influence being brought to bear on the progress of the disease.

I will now relate a few selected cases, each of which presents some points of interest.

CASE I.

A young lady, aged 22, who developed phthisis in the summer of 1911. Lassitude and loss of weight were the initial symptoms. She was admitted to this sanatorium on October 11th, 1911. The condition then present was induration, with crepitations, over the whole of the right upper lobe and apex of the right lower lobe. Left lung healthy, tubercle bacilli abundant in sputum. Improvement took place during the winter of 1911-12, and in June, 1912, the patient returned to her home to continue treatment under home conditions for the summer months. She returned in October with a recrudescence in the right lung. There was also evidence of the disease having com-

CHART A.—Case I. B = 500 c.cm. N; G = 600 c.cm. N; S = 750 c.cm. N.

menced in the left lower lobe. She remained under treatment during the summer of 1912-13. The disease on the left side became arrested, and improvement took place in the right lung. During the summer of 1913 the patient was able to take exercise to the extent of walking four miles daily, but in December an exacerbation of the disease occurred in the right lung, accompanied by pyrexia, sweating, and loss of weight. Matters did not improve. Accordingly, at the beginning of March, 1914, it was decided to attempt collapse of the right lung by means of artificial pneumothorax. On March 5th the intrapleural space was found showing a pressure of -16 – -10 cm. of water; 600 c.cm. of nitrogen were introduced, raising the pressure to -4 – 0 . Refills were given on subsequent days (vide Chart A), until on March 10th the intrapleural pressure had been raised to $+12$ – $+7$. Physical examination of the chest revealed the absence of breath sounds on the right side and a skiagram taken the following day (Fig. 5) shows the lung well collapsed. During this period the temperature and pulse-rate had both fallen to within normal limits.

On March 16th the patient was allowed to sit up in bed for an hour. On March 18th a further refill was given, and the following day the patient was allowed to sit up in a chair for two hours. All seemed to be going on well, and a successful result from the treatment was anticipated. During the night of March 21st–22nd the patient complained of restlessness and

CHART B.—Case II. A = 1,000 c.cm. N; B = 500 c.cm. N; C = 950 c.cm. N; D = 1,000 c.cm. N; E = 900 c.cm. N.

increasing shortness of breath. Some cyanosis was present, and the pulse-rate had increased to 120. Examination of the chest revealed a diffuse commencing pneumonia of the left lung, fine crepitations being audible from apex to base. The dyspnoea rapidly increased, and as the patient's condition was rapidly becoming critical I decided to release the right lung in an attempt to give the patient more aerating surface with which to carry on respiration and also to relieve any mechanical embarrassment of the heart. Accordingly a Saugmann's needle was introduced, one limb of which was connected by rubber tubing to a Potain's aspirator pump, the other to the manometer. The clip was released, and the tap shut. The nitrogen was in this way extracted from the right side of the chest. Readings were taken on the manometer between every two or three strokes of the pump by clipping and opening the tap. The intrapleural pressure was reduced until a negative pressure of -4 – -2 was produced. During these operations the pulse was not materially affected, and no additional distress was manifest. The Saugmann needle was withdrawn and the chest auscultated. The breath sounds were immediately audible over the whole of the right lung, and in character were much the same as before the initial collapse sixteen days previously. Unfortunately the hope of improvement entertained was not realized, and the patient died from heart failure twenty-four hours later in spite of the free use of oxygen.

The points of interest in this case are: First, the almost immediate improvement in the temperature and pulse-rate subsequent to the collapse of the diseased right lung (Chart A). Secondly, the performance of the operation for decompression under conditions of emergency; and, lastly, the rapidity with which the collapsed lung expanded under the release of the pressure.

CASE II.

A man, aged 34, weighing 13½ st. and standing 6 ft. 2 in., was admitted on February 13th, 1914, with a history of haemoptysis six weeks previously. Examination of the chest showed a limited lesion in the right upper lobe with evidence of induration. The left lung was normal. As the temperature was slightly raised, the patient was kept at rest in bed. Cough was a prominent symptom, accompanied by mucopurulent sputum, to the extent of 150 c.cm., daily. Ten days after admission the temperature began to rise steadily (Chart B), sweating at night commenced, and the patient soon became acutely ill. Auscultation of the chest revealed evidence of increased activity in the right upper lobe.

This state of affairs continued without much change for a fortnight, when, on March 13th, a severe haemorrhage occurred, which continued at intervals for the next two days, in spite of treatment on the usual lines. A particularly severe haemorrhage occurred on March 15th, and as the patient's condition was rapidly deteriorating and the haemorrhage showed no signs of abating, it was decided to attempt the production of an artificial pneumothorax as a means of checking the haemorrhage by pressure; 1,000 c.cm. of nitrogen were introduced at the first sitting, raising the intrapleural pressure from -10 to -2 cm. of water. This had the effect of controlling the haemorrhage to a great extent, but as bright red expectoration persisted the following morning a further 1,000 c.cm. of nitrogen were introduced, raising the intrapleural pressure to $+4$. This had the desired effect of stopping the bleeding. The patient showed no signs of distress as the result of these two large injections of nitrogen, and, as the disease appeared to be running such an acute course, it was decided to continue the treatment and produce a complete pneumothorax. Accordingly refills of 500, 950, and 1,000 c.cm. were given within the next five days (vide Chart B), and the intrapleural pressure was eventually raised to $+18$ cm. of water, at which it has been kept by periodical refills for upwards of a year. The progress of this case has been most satisfactory. The temperature and pulse-rate quickly dropped, and the patient was soon able to lie up and about, and has been taking daily walking exercise to the extent of six miles without fatigue, whilst the physical signs and symptoms indicate quiescence of the disease, and it

is hoped that ultimate permanent adhesion will be obtained. In this case there are evidently some adhesions on the posterior surface of the upper lobe, as, although breath sounds were inaudible in front, there was evidence of feeble tubular breathing over a small area behind. This is borne out by the appearance in the skiagram taken but not shown in this paper. The case is interesting as showing the value of this form of treatment in cases of alarming and uncontrollable haemorrhage.

CASE III.

A young man developed phthisis in the left lung in January, 1910, at the age of 26. He received sanatorium treatment for a period of six months, during which time considerable improvement took place, and in the autumn of the same year he was recommended to take up residence in Anstrath. He spent four years abroad, during which time he had many ups and downs, and towards the end of that period had several severe haemoptyses. He returned to England in 1914, and on the voyage home he was sent to this sanatorium by a London physician with the request that an attempt should be made to produce an artificial pneumothorax, though the physician did not hold out much hope of a successful issue on account of the duration of the disease and the undoubted presence of pleural adhesions. On examination it was found that the left lung was involved throughout by tuberculous disease, with evidence of cavitation in the upper lobe. The right lung showed evidence of a quiescent lesion at the apex of the upper lobe. Fig. 2 shows the radiographic appearance on admission—extensive left-sided disease with much compensatory emphysema in the right lower lobe. On November 10th three attempts were made, at different sites, to find a free pleural space, but without success. On November 12th a further trial was made, and at the second

GEOFFREY LUCAS: TREATMENT OF PHTHISIS BY NITROGEN COMPRESSION.

FIG. 1.—Showing a complete pneumothorax on the right side with extensive disease on the left.

FIG. 2.—Shows Case III immediately before operation. Note the emphysematous condition of the right lung.

FIG. 3.—Shows Case III during the process of the production of complete pneumothorax. Note the altered appearance of the right lung owing to the compression of the left lung.

FIG. 4.—Shows Case III with the lung finally collapsed. Note the shadows of the two lines of attachment of the pleura to the chest wall—*a*, to the anterior wall; *b*, to the posterior wall.

FIG. 5.

FIG. 6.

Figs. 5 and 6 show two common positions assumed by a collapsed lung free from adhesions.

attempt the needle encountered a free space in the sixth intercostal space in the posterior axillary line. The manometer oscillations were small but definitely negative 4, -2, accordingly 500 c.cm. of nitrogen were introduced, which had the effect of producing positive pressure of +3+1. It was therefore obvious that one had entered a pleural sac. However, hope was entertained that one might be able to gradually break down pleural adhesions and eventually produce an effective pneumothorax. Frequent refills of small amounts were subsequently given until eventually a very satisfactory pneumothorax was produced without any pain or untoward symptoms. A pressure of +18 was reached and has been maintained. Figs. 2, 3, and 4 show three stages in the course of treatment. Fig. 3 shows extremely well the effects of compression of the left lung on the emphysematous right lung. A careful scrutiny of Fig. 4 shows that the left lung is partly bound down by adhesions to both the anterior and posterior chest wall. The faint line of shadow indicated by the arrow (a) marks the line of attachment to the anterior wall, while; the arrow (b) shows the line of attachment to the posterior wall. The lung is evidently compressed inwards towards the mediastinum in the shape of a gutter between the two lines of adhesion. This case is at present doing well. The general condition is excellent, and the patient is living an ordinary life under home conditions, the compression being kept up by means of refills at varying intervals of approximately a month. The case is interesting as illustrating how even adhesions of long standing may be harmlessly broken down by the exercise of caution and perseverance in the treatment.

In conclusion I should like to express my indebtedness to Mr. T. R. Watson, radiographer to this sanatorium, for the production of the skiagrams illustrating this paper.

THE PATHOLOGY AND TREATMENT OF GUNSHOT WOUNDS OF THE SMALL INTESTINE.

By OWEN RICHARDS, M.Ch., F.R.C.S.,

PROFESSOR OF CLINICAL SURGERY, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE; TEMPORARY CAPTAIN R.A.M.C., BRITISH EXPEDITIONARY FORCE, FRANCE.

FOUR months' work in a casualty clearing station have given me the opportunity of observing a number of these cases, and though my experience is not wide enough to warrant any final conclusions, yet some points have struck me which may be of interest to others who have to deal with cases of this class.

PATHOLOGY.

Whereas in wounds of the colon and duodenum the chief feature is the progressive escape of contents followed by a more or less localized peritonitis, in the small intestine such an escape usually does not occur at all, and if it does so slight as not to be an essential feature in the case. The cause of death in wounds of the small intestine is more frequently intestinal obstruction due to paralysis and distension spreading upwards from the injured coil. To make this contrast clear, I have appended notes of examples of cases of both classes.

In Case 1 there was a wound of the colon; the chief symptoms were general distension and localized pain. On opening the abdomen a large collection of faeces was found localized under pressure in a cavity formed by adherent intestines. Faeces continued to be discharged from this wound for five days.

Similarly, when the colon is wounded extraperitoneally, faeces are expelled under pressure into the surrounding connective tissue spaces to an almost unlimited extent. I have seen a wound of the colon on the left side (verified *post mortem*) cause faecal infiltration extending into the right loin and discolouring the skin on the right side of the abdomen before death.

In Cases II and III similar localized collections of intestinal contents under pressure followed wounds of the second and third portions of the duodenum respectively.

In wounds of the jejunum and ileum this progressive escape of contents has not occurred in those cases which I have seen.

Of course, if a full coil of intestine is widely opened, it stands to reason that the contents in it at the time must escape. Some undoubtedly escaped in Case IX. But where the coil is empty or the perforations small there is no escape even at the time; in any case, there is no progressive escape later, such as is seen in wounds of the duodenum or colon. The neighbouring coils and the omentum

rapidly become adherent, the injured portion becomes inflamed, immobilized, and shut off, and, although it becomes full, it is only when it is lifted from its bed at operation that the contents are discharged.

Case IV illustrates this point. The injured coil had retracted from the wound area, and was missed at the time of operation. At the autopsy, although it presented four fairly large wounds, it was so securely wrapped in omentum that no general coiling or inflammation of the peritoneum had occurred, although the coil itself was then quite full.

In Case V, where there were three wounds due to a fragment of shell, the condition was the same. In Case VI there was no escape till the coil was lifted from its bed, when the fluid contents spouted out freely.

In Case VII the injured coil was full of liquid faeces which had not escaped, and the same is true of Case VIII.

In Case IX, where the intestine was nearly divided, there was a limited escape, but no general fouling such as would be present after the rupture of an ulcer. A week later there was found a fairly widespread adhesive peritonitis with no suppuration.

So that it seems that the usual course of gunshot wounds of the small intestine, even when multiple and fairly large, is that they are sealed off at once in such a way that there is only a very small escape of contents, not enough to produce a general peritonitis or even a localized collection of faeces. All that is produced at the time is a very limited local peritonitis.

After this has occurred the intestine at and between the wounds becomes inflamed, immobilized, and paralysed; it slowly fills up and constitutes a functional block. The bowel above it becomes progressively distended, paralysed, and poisoned, just as it does in any other form of intestinal obstruction. The patient after a time develops distension and bilious vomiting, and ultimately dies.

This point is illustrated by Case VII, where the bowel was resected two and a half days after the injury, when bilious vomiting had already set in. The dilated intestine above the injury was emptied at the time of operation, and this gave temporary relief, but the symptoms recurred, and the patient died. *Post mortem* the bowel above the junction was found very much distended, that below it empty and contracted, and this although there was no physical obstruction whatever.

In Case IV, where the injured coil was not dealt with, the same condition was found at the autopsy.

The clinical course of these cases is in agreement with this view. Many of them—by no means all, but a large proportion—remain free from symptoms and apparently well for two or three days on starvation and morphine. At the end of this time, which often coincides with their transfer to a clearing hospital, they rapidly develop distension and vomiting, and ultimately die.

If these symptoms were due to an immediate escape of contents, one would expect immediate pain, rigidity, rising pulse, and vomiting. But the course they actually follow and the symptoms they present are rather those of an obstruction of gradual onset than those of a prompt general peritonitis.

The explanation of these differences in the behaviour of wounds of the duodenum and colon on the one hand, and of those of the mobile part of the small intestine on the other, is probably twofold. In the first place, the small intestine is so situated that it is very readily sealed off by omentum and adjacent coils. In the second place, it seems to be the case that the movements of the small intestine are more readily paralysed by injury and inflammation than those of either the colon or the stomach. So that although a passive dilatation occurs, there is no driving force behind it which could lead to escape of contents under pressure. If such a force were present recent adhesions would not prevent leakage, though they might limit its extent.

TREATMENT.

If the course of events is usually such as is suggested above, the bearing of it on treatment is obvious. For it is clear that simple suture of wounds of the duodenum and colon is both necessary and sufficient. If this is efficiently done the contents will be driven along their proper course; if it is not done, they will be continually forced either into the peritoneum or into the extraperitoneal tissue. In

neither case will there be stasis. The essential thing is to close the leak—there is no danger of obstruction.

In the jejunum and ileum, on the other hand, simple closure of the wound would be both unnecessary and inefficient. As regards the escape of contents, it would merely effect, with a certain amount of shock, disturbance, and fouling of the peritoneum, what Nature had already done. As regards paralytic obstruction, it would do much to increase it.

The proper course in such a case would be to resect not only the injured portion, but also as much bowel above it as is likely to remain out of action and constitute a functional obstruction. The point is not a new one; it was emphasized by Barker in relation to strangulated hernia, and is equally sound whether the obstruction is physical or functional. The longer the obstruction has existed the more important it becomes.

The amount to be removed depends, first, on the number and relative position of the wounds; apart from this it increases with delay, since the condition which makes resection necessary is one which progresses gradually and regularly upwards. In Case vii the resection of 12 in. after two and a half days was not enough to prevent stasis in the bowel above, as was evident *post mortem*. The patient probably died for that reason.

In Case ix, operated on ten hours after injury, the removal of 7 in. was sufficient to restore the function of the intestine. In Case v, where 2½ ft. were removed after thirty-six hours, the patient made a good recovery.

In Case vi, where 4½ ft. were resected after eighteen hours, the amount may have been unnecessarily great, but it was a fault on the right side, and did not interfere with the patient's recovery.

A sound principle can, of course, be made absurd easily enough by carrying it to extremes, and the earlier the operation the less the need for wide resection. But it is doubtful if the difference in shock is very great; and whereas the risk of an insufficient resection is death, that of an excessive resection is more likely to be indigestion.

TECHNIQUE AND AFTER-TREATMENT.

In view of the fact that injured intestine may move away from the wound and so be missed (as in Case iv), and that the course of the bullet is often unknown, it is wise to place the incision near the mid-line and inspect the whole of the small intestine. It is a disadvantage to include the wound in the incision.

After operation the sooner the bowels move the better. Enemas and divided doses of calomel are useful, and pepsin sometimes acts like a charm. Apart from these points, the technique and after-treatment are those of a similar operation in civil practice.

The recovery of one case (vi) was interrupted by an acute dilatation of the stomach, and all three surviving cases had a varying degree of diarrhoea, which in one (v) amounted to a serious dysentery.

SELECTION OF CASES.

The majority of cases reach us after a varying period of rest in a field ambulance. The condition of some is so bad that operation is out of the question; in others the presumed intestinal injury is accompanied by others which render interference inadvisable.

In the rest the presence or occurrence of definite symptoms of injury in the intestinal area is a sound indication for operating at once. Some patients recover without any such symptoms, and to open all wounded abdomens as a routine measure would probably do more harm than good. But once symptoms become manifest there is not much margin for delay. If these cases are placed under observation in a clearing hospital soon enough after the injury, it should be possible to seize the opportunity when it occurs, provided always that the surgeon has the necessary equipment and experience for dealing with any condition he may find.

The common practice of withholding water from such patients causes much suffering. In cases of internal haemorrhage and during transport it is probably necessary. Once in hospital, if a man is definitely dying, no good purpose is served by adding thirst to his other sufferings, while if he has an injury which requires operation, the worst that water in reasonable quantities is likely to do is

to hasten the time at which he develops symptoms and is radically dealt with. The sufferings these patients endure from thirst cannot be doubted by any one who has ever seen them. The only consideration which could weigh against them is proof that men who would ultimately have lived have actually died because they were given water in hospital some time after the injury. As far as I know this proof is lacking.

Water does not produce flatus; it probably never reaches the wounded area, and if it does it is unlikely, for reasons already given, to cause any escape of contents.

RESULTS.

Makins (*Surgical Experiences in South Africa*, p. 460) concludes as follows: "Perforating wounds of the small intestine are very fatal injuries. Every patient in whom this condition was *certainly* diagnosed died." In dealing with such an injury it is not so much a question of how many cases will be lost, but rather whether any can be saved.

I have appended notes of the only cases, 5 in number, in which I have opened the abdomen and resected intestine in this hospital (Cases v, vi, vii, viii, and ix).

Of these cases viii died almost at once from recurrent bleeding, and vii after thirty-six hours with intestinal stasis, due, I believe, to an insufficiently free resection.

Case ix recovered and lived for a week, during which time he improved in condition and had his bowels open freely and often. He died at the end of this period from secondary haemorrhage from an artery outside the abdomen.

Case v recovered and was transferred to the base three weeks after operation.

Case vi recovered, was transferred to another hospital, and seventeen days after operation was reported well and on ordinary diet, on his way to the base in a barge.

The results thus are that out of 5 cases, 2 died outright, 2 recovered completely, and 1 recovered from the operation but died a week later from another cause.

The two who recovered completely happen to be those in which the largest amounts of bowel were removed (2½ ft. and 4½ ft. respectively).

CONCLUSIONS.

1. Death in uncomplicated cases of gunshot wounds of the small intestine is not usually due to escape of faeces and general peritonitis, but to a progressive intestinal paralysis and distension spreading upwards from the injured coil.

2. Operation in such a case should include the resection of the injured portion together with as much bowel above it as would otherwise remain in a condition of paralysis.

3. If this be done sufficiently early there is a prospect of saving a fair proportion of cases.

I wish to repeat that these conclusions are based on a small number of cases, those of which notes are given. Wider experience or the experience of other surgeons may perhaps modify or contradict them; meanwhile their practical importance at this time seems to me to justify their publication.

In conclusion I wish to express my great obligation to Captain H. T. M. Wilson, R.A.M.C., for his help with nearly all these cases, and for many valuable practical suggestions.

CASE I.—Wound of Colon: Localized Escape of Faeces: Drainage: Death from Secondary Haemorrhage Six Days later.

Private D., 2nd Scots Fusiliers. Shrapnel wound three days ago. Entry near navel; no exit. Distension, poor pulse, retention of urine, acute localized uncontrollable pain. No vomiting. March 15th, operation undertaken chiefly to relieve the pain. Incision near wound, splitting rectus. On opening the peritoneum semi-solid faeces came out under great pressure, issuing from a blackened cavity formed by adherent intestine, into which faeces were discharged from a wound of the colon. Faeces came away through the wound for the next five days. The pain was less, the general condition poor. On March 20th an enema was given and solid faeces were passed per rectum. Secondary haemorrhage then began, increased, and proved fatal on the 21st. As fighting was then going on no autopsy was made.

CASE II.—Wound of the Duodenum: Localized Escape of Contents: Drainage: Death.

Private H., East Lancs. Wound in the right flank three days ago. Bilious vomiting, very acute local pain, no signs of general peritonitis. Operation March 7th; Incision vertical in

upper part of right rectus, viscera adherent round a collection of dirty grey fluid and gas, which issued from a hole deep down in the inflamed lining of the cavity. This hole could not be closed. Drainage through the wound of entry; closure of the operation wound. Vomiting and pain ceased at once; the next morning the patient was reading the paper. Discharge free, reddening the surrounding skin; no faecal smell. The patient was transferred to the base six days later. While there the discharge diminished and ceased to be irritating, but he gradually sank and died.

CASE III.—Wound of Duodenum or Beginning of Jejunum: Localized Collection of Fluid; Drainage; Death in Five Days.

Lieutenant C. J., 2nd Leicesters. Sharpnel wound left loin between the half and one hour before No. 1 symptoms till the night before admission, then vomiting, pulse 120, hicough, and pain referred to testes. Operation May 24th: Incision splitting left rectus. On opening the peritoneum a dirty fluid, fetid though the odour was not faecal, issued under pressure from a cavity formed by adherent viscera. The hole in the intestine could not be demonstrated but lay apparently in the duodeno-jejunal flexure. A sharpnel bullet was found lying in the mesentery of the jejunum close to the bowel which was here intact. Closure in layers with a lumbar drain.

May 25th. The discharge is practically pure bile. This fluid, later on, reddened and excoriated the surrounding skin; the patient vomited a good deal, grew weaker, and died May 29th.

CASE IV.—Injury to a Coil of Intestine which Retracted from the Wound and was Missed at Operation; Death from Haemorrhage.

Private M., 2nd Leicesters. Wound in left iliac fossa; pulse 120. Operation May 17th: Vertical incision over the wound, large collections of clot inside and outside the peritoneum, that inside smells slightly faecal. Colon intact, two small punctures in the wall of the coil at the site of the suture. A coil of jejunum of ricochet bullet found loose. The patient died on May 19th.

Post mortem: Abdomen full of blood, wound of omentum. In the umbilical region, at some distance from the wound, lay a coil of jejunum completely wrapped in omentum, with four biggish holes. No escape of contents, no general peritonitis. The injured coil and the bowel above it much distended, the intestine below empty and shrunken.

CASE V.—Resection of 2½ ft. of Small Intestine; Dysentery; Recovery.

Corporal M., R.Y.R. Shell wound through right ilium thirty-six hours before in direction of pelvis. Slight abdominal distension; no pain on vomiting. Urine normal. Operation March 18th: Incision in the middle line. Three wounds found in the coil of the ileum at the site of the suture. No escape of contents. The missile, a square piece of shell about 1 in. across, lay in the lumen of the gut. Two and a half feet of intestine resected, end-to-end suture, suprapubic drain. Two days later the bowels were moved with calomel, enemata, and pituitrin. A week after operation he developed diarrhoea, which later became a definite dysentery, with passage of blood and mucus. Treated with morphine, sulph. hour, recovery. Transferred to base April 9th, three weeks after operation.

CASE VI.—Wounds of Small Intestine; Resection of 4½ ft.; Acute Dilatation of Stomach; Recovery.

Lieutenant C. F. P., 6th Duke of Wellington's. Entry wound—ricochet bullet—right iliac fossa. After eighteen hours, onset of local pain, rigidity. Bullet thought to be in wall. Operation May 24th: Incision vertical, crossing the wound. A coil of ileum found wrapped in the omentum, perforated near the mesenteric border in two places about 5 in. apart. There had been no escape of faeces, but the coil was full, and as soon as it was lifted from its bed the liquid contents spouted out. Intestine above much dilated with gas and liquid faeces, that below practically empty. A piece of bullet casing lying loose. Rest of contents of the rectum normally in situ. No general peritonitis; 53 in. of bowel resected from just below the injury upwards; it was all dilated and inflamed. Bowel above emptied. End-to-end suture in healthy bowel. Inflamed omentum tied off. Suprapubic drain.

May 25th. Poor pulse. No vomiting.
May 26th. Enema—solid faeces. While this was acting half a pint of clear, negligible serum was discharged from the drain, and three measured pints of watery green fluid vomited. No further vomiting.

May 27th. Epigastric pain and distension, stomach felt swollen and tense, rest of abdomen lax. Stomach tube drew off 3 pints green fluid. In the evening same condition, about 1½ pints brownish sour-smelling fluid drawn off. Bowels moved naturally in the night; no further distension. Later there was a troublesome diarrhoea.

Our hospital moved away a few days later, and the patient was left in the care of Captain Frankau, R.A.M.C.T., who tells me that he sent him to the base in a barge on June 10th (seventeen days after operation). He was then on ordinary diet and doing well.

CASE VII.—Excision of 12 in. of Intestine; Death Thirty-six Hours later.

Private H., 4th Liverpools. Shot from roof of penis to right lower ribs two and a half days ago. Bullet (sharpnel) felt under the skin. Bilious vomiting, rigidity, pain. Operation March 15th: Incision in right rectus. Small intestine wounded in two places, full of liquid faeces of which none had escaped.

Resected a foot and emptied the bowel above. The next morning the patient was better, later bilious vomiting came on again and he sank and died.

Post mortem: No other injury was found. No general peritonitis; no haemorrhage. The bowel above the union very much distended, that below it empty and contracted.

CASE VIII.—Resection of 9 in. of Small Intestine; Death a Few Hours later from Recurrent Haemorrhage.

Private D. B., 2nd Yorks. Bullet wound crossing abdomen from a point 2 in. left of the navel to the right loin. Operation January 28th: Median incision. The wound of exit lay just outside the ascending colon. The peritoneal surface of this was apparently intact, but the discharge from the exit wound smelt slightly faecal. The whole of the small intestine was inspected. In one place there was a complete perforation, mucous membrane protruded and blocked both entry and exit. There was no escape of contents. About 2 in. of the injured portion was excised and the intestine joined by end-to-end suture. Death took place some hours later.

Post mortem: The peritoneum was full of free blood, derived either from the omentum, which was slightly injured, or from the region of the exit wound.

CASE IX.—Resection of 7 in. of Bowel; Recovery; Death a Week later from Secondary Haemorrhage from the Gluteal Artery.

Private C., 2nd Gordons. Shell wound in right buttock ten hours before; vomiting, rigidity. A wide track leads directly through the ilium into the pelvis. Operation February 7th: Median incision. Bladder and rectum intact; a good deal of free blood and some peritonitis. The small intestine had four wounds, two of which neatly divided it. Missile not found. Seven inches resected. Closure with drain in entry wound. The patient nearly died after the operation, but rallied, grew stronger, and lived for a week, the bowels opening frequently. On February 15th he began to bleed from the drain, the bleeding recurred and increased, and proved fatal on the 14th.

Post mortem: Intestinal tract all sound, but generally adherent. Scarcely any blood in the abdomen. Bleeding had evidently come from the wound in the buttock, presumably from the gluteal artery.

"TRENCH BACK" TREATED BY SODIUM SALICYLATE IONIZATION.

By JOHN D. SANDES, CAPTAIN I.M.S.,

OFFICER IN CHARGE OF ELECTRO-THERAPEUTIC INSTITUTE, KITCHENER INDIAN HOSPITAL, BRIGHTON.

"TRENCH BACK" is the term applied to a variety of conditions arising from injury to the back in the lumbar or sacral regions. The injury is usually caused by the impact of large and heavy masses of matter, such as a quantity of earth or sandbags.

As the condition is of great importance on account of its frequency and the prolonged disability it usually entails, I venture to bring forward the following method of treatment, although the number of cases so far treated does not justify any dogmatic statement as to its utility or allow any final conclusion to be drawn.

The cases almost invariably come from the trenches. They complain of pain and rigidity in the dorsal-lumbar region. Various degrees of disability are represented—some can get about, others have to be carried on stretchers. Those who can walk do so with a pronounced stoop, and use a stick. Tenderness is generally present. Some cases show anaesthesia, and in these there is probably spinal injury. In the milder cases the clinical picture is that of marked lumbago, and would be indistinguishable except for the history. All cases of this condition should be examined by x rays before being treated in the manner suggested, and all cases of injury to the spine and pelvis excluded. Cases with anaesthesia of the lumbar and sacral regions are unsuitable for ionization, as they are very liable to be badly blistered during treatment. The majority have no spinal lesion, the symptoms being due to contusion or sprain of the muscles and fasciae alone. It is for cases of this class that I advocate ionization. In a certain proportion a pronounced psychical factor can be traced, and these cases present features similar in many respects to the condition known as "railway spine," and are always difficult to treat.

The cases that have come under my notice in the Electro-Therapeutic Institute of the Kitchener Indian Hospital, Brighton, have, as a rule, been medically treated in the wards for some time. I selected a number and treated them by ionization with sodium salicylate, and obtained good results in a short time.

I now apply the treatment to all cases of trench back

coming to the department, and the results so far have been satisfactory. It is applied as follows: A 1 per cent. solution of sodium salicylate is prepared. (This can be conveniently done with Burroughs and Wellcome's solids for ionic medication.) A large pad sufficient to stretch right across the back, and 8 or 10 in. broad, is saturated with the solution. The pad must be composed of at least six layers of lint. The patient is placed face downwards on a couch, and the pad is laid over the painful area. A mail chain electrode is placed on top of the pad, and the whole firmly bound on with a bandage. The mail chain electrode is connected with the negative pole of a battery or electric machine. The "multostat," if available, is very convenient, as the current can be regulated to a nicety and all fear of severe shocks obviated. An indifferent electrode is then placed upon some other region, say the upper dorsal, moistened with sodium chloride solution, and connected with the positive pole. The current is gradually turned on and treatment continued for about fifteen minutes. Applications are carried out twice weekly, and improvement often occurs after the first. Some cases are cured in two or three applications.

Certain points in the practical application of the treatment deserve notice. The indifferent electrode (the positive) should be at least as large as the active (the negative). There should be at least half a dozen layers of lint between the mail electrode and the skin; this will allow higher doses to be given without blistering. A 1 per cent. solution of sodium salicylate is quite sufficient, as the concentration of the solution has little or no effect on the amount of the drug absorbed. The dosage is regulated almost entirely by the amount of the current traversing the circuit, hence a milliampere-meter is necessary; 30 milliamperes is the usual amount to be given at the initial treatment. At subsequent applications this can be increased until the patient is taking 100 milliamperes, or even more. Some cases tend to blister readily even with low dosages, and allowances must be made for individual differences. As a general rule the higher the milliamperage that can be borne, the better and quicker will be the results, always remembering that the size of the electrodes must be proportionately increased. The current should be introduced very gradually and also turned off very gradually, as a rapid increment or rapid diminution causes severe shock. Pure distilled water should always be used for making the solutions, as, if other salts are present in the water they also will be ionized, and will interfere with the treatment.

CASE I.—Sepoy F. G., admitted to hospital with trench back on May 14th. Came to electrical department on May 25th. He had severe pain and stiffness in his back muscles and pain down back of left thigh, and was unable to stand upright or walk without a stick. After five applications of salicylate ionization he was walking easily, and had no pain whatever.

CASE II.—H., admitted May 14th with trench back, came to electrical department on May 25th. Very severe pain in lumbar and sacral region. Patient quite unable to walk and brought on a stretcher. Slight movement caused severe pain. After seven applications patient is getting freely about, pain is almost gone, and he complains only of slight stiffness in back muscles.

CASE III.—Sepoy M. B. K., came with severe pain in lumbar region, and inability to straighten back or walk without a stick. After four applications of sodium salicylate ionization the patient was quite cured.

CASE IV.—Lance Naik F. D. came with much pain and stiffness in his back. Had to use a stick to get along. After three applications he was cured.

CASE V.—Sepoy N., came to the department using a stick. He was unable to stand straight, and complained of great pain in the lumbar region. After three applications of sodium salicylate ionization he was quite well.

On July 30th a silver tray and Chippendale clock were presented by the present and past members of the staff of the Leeds Public Health Department to Dr. J. S. Cameron, who recently retired from the position of medical officer of health owing to ill health. Dr. Dennison, chairman of the Sanitary Committee, referred to the great sanitary improvements that had taken place in Leeds, most of which, he said, owed their inception and completion to the medical officer of health. They had helped to decrease the death-rate of the city from a previous average of 22 per 1,000 to the low rate of 15 per 1,000. Dr. Cameron, in acknowledging the presentation, spoke of the loyalty and co-operation of his staff, without which, he said, it would have been impossible for these larger measures of sanitary reform to be carried out.

STOMOXYS, THE STABLE-FLY.

BY

A. E. SHIPLEY, Sc.D., F.R.S.,
MASTER OF CHRIST'S COLLEGE, CAMBRIDGE.

Fly! Thy brisk unmeaning buzz
Would have roused the man of Uz;
And, besides thy buzzing, I
Fancy thou'rt a stinging fly.
Fly—'who'rt peering, I am certain,
At me now from yonder curtain:
Eezy, curious, thirsty fly
(As thou'rt clept, I well know why)—
Cease, if only for a nicety
Hour, to make my being tingle!
Flee to some loved haunt of thine;
To the valleys where the kine,
Udder-deep in grasses cool,
Or the rusby-margined pool,
Strive to lash thy murrinus kin
(Vainly) from their dappled skin!
Calverley: "The Poet and the Fly."

The common names for common insects in English are confusing. Not only are the same insects frequently known by different names on different sides of the Atlantic, but in many cases quite different insects, insects even belonging to different genera, are connoted by the

Fig. 1.—The insect that is believed to transmit infantile paralysis. Original drawing of the biting stable-fly (*Stomoxys calcitrans*, Linn.), by Ignaz Matasch. (From the *American Museum Journal*.)

same common name. In this respect matters are different in Germany, partly perhaps because the Germans on the whole are more scientifically inclined than we are, but partly, I suspect, because the German language lends itself more easily to express in one word—however long—the characteristics of any given insect.

Fig. 2.—Stable-fly, *Stomoxys calcitrans* (× 5). Antenna. Natural size, resting position. (From *Flies in Relation to Disease: Non-blood-sucking Flies*. By G. S. Graham Smith, M.D. Cambridge University Press, 1914.)

The genus *Stomoxys* is generally called in Great Britain the "stable-fly," but there are other "stable-flies." One of the commonest species, *Stomoxys calcitrans*, is a two-winged muscid fly, not at all unlike the common domestic fly, *Musca domestica*, but there

are one or two points which readily distinguish it from the commoner insect. To begin with—it has a hard, firm, chitinous, piercing proboscis, which when at rest stretches forward in front of the head, and when in action is pressed down at right angles to the longitudinal axis of the body; then, again, when resting its wings diverge, those of the house-fly approximate. Like other flies, the *Stomoxys* varies somewhat in length, between 5.5-7 mm. The thorax has on its back four longitudinal, dark stripes, broken by a transverse suture; and, as the accompanying figure shows, the third of the great, long veins which traverse the wing is much more slightly bent than is the case in *Musca domestica*. Further, whereas the hinder edge of the eye in the house-fly is straight that of the stable-fly is concave, and the antennae bear hairs on the upper side only and not above and below as they do in the domestic fly.

As a biting fly and a blood-sucking fly, the habits of

Fig. 3.—Wing of the house-fly (*Musca domestica*) above, and of the stable-fly (*Stomoxys calcitrans*) below. Note the sharp elbow in the third long wing vein of *Musca* and the less bent vein of *Stomoxys*. Drawing by Ignaz Matusch. (From the *American Museum Journal*.)

Stomoxys naturally differ from those of *Musca domestica*, but, like the latter, its distribution is almost world-wide. It is found in all temperate and tropical countries, and extends as far north as Lapland. But it is perhaps most abundant, or shall we say it has been most observed, in temperate climates and during the summer months?

In any farm or country house large numbers of *Stomoxys*

calcitrans are found in and about the cowsheds and stables, and in warm weather the same is true wherever cattle are grazing in the field. Later in the year, at the beginning of autumn, they are frequently found indoors, and in some "fly counts" they have furnished quite 50 per cent. of the flies of a country house, the remaining 50 per cent. being made up of many other species and genera. When resting on a vertical surface *Stomoxys* generally has its head pointing upwards, whereas, as a rule, the house-fly rests upside down. The adult fly feeds upon any decaying matter, but whenever it can it sucks the blood of vertebrates, and at times is a real nuisance to animals as well as human beings. So voracious are they that should a well-fed one be injured, the others immediately attack it and suck up every drop of blood which it had secured for its own food.

It has often been disputed whether a meal of blood is essential to the female mosquito before oviposition, but it seems perfectly clear that the female *Stomoxys* can produce fertilized eggs without having had a meal of blood.

The female lays a number of white, banana-shaped eggs a few inches below the surface of any decaying organic matter; fermenting grass from the lawn, decaying garden

stuff, stable manure—each forms a favourable nidus. The eggs are laid in a heap like those of the house-fly, each heap containing from fifty to seventy. The egg is

Fig. 5.—*Stomoxys calcitrans*. Eggs (after Newstead). (From *Flies in Relation to Disease: Blood-sucking Flies*. By Edward Hindle.)

1 mm. in length and has a grooved side, through the thicker end of which the larva escapes when the egg-shell splits.

The issuing larva is almost transparent. It not only has no head but the anterior end dwindles almost to a point. When fully grown it attains a length of 11 mm., and the larval stage usually lasts from two to three weeks, but development may be retarded by adverse circumstances up to eleven or twelve weeks, and in such cases the full-grown larvae are often stunted in size. In these circumstances the pupae they produce are markedly smaller than those which have followed a more normal course of development. As is true of the egg and of the larva, the pupa resembles the pupa of the house-fly, being barrel-shaped and of a chestnut brown colour; it is 5 to 5.5 mm. in length. The pupa stage lasts from nine to thirteen days, but this period is prolonged by cold.

On emerging from the pupa case the insect has to push its way to the surface of the rotting vegetation in which it has been produced. This it does partly by the alternate inflation and deflation of the so-called "frontal sac," and by actively pushing forward the body by means of its legs. Once on the surface the

Fig. 6.—Acephalous larva of *Stomoxys calcitrans* (x 7) (after Newstead). (From *Flies in Relation to Disease: Blood-sucking Flies*. By Edward Hindle.)

insect begins to clean itself, pumps air into its body, forces it along the tracheae in the wings, which expand and ultimately harden; in the processes of unfolding they are aided by the hind legs. For a time the insect is immobile, gradually stiffening, but when the integument has hardened it flies off to explore the outer world. Under normal conditions the whole life-cycle varies from twenty-seven to thirty-seven days.

The chief interest of *Stomoxys* to the public rests upon the fact that it is a very potent carrier of disease. There are certain forms of *Trypanosoma* which, under experimental conditions, are undoubtedly transferred by this species. But opinion is still unsettled

as to whether the transference of these protozoa occur in nature. The *Serra* diseases of horses and camels is, according to some authorities, transferred by *Stomoxys*,

Fig. 7.—Coarctate pupa of *Stomoxys calcitrans* (after Newstead). (From *Flies in Relation to Disease: Blood-sucking Flies*. By Edward Hindle.)

and so is the *Surra* disease of cattle; and there are others, all fully set forth in Mr. Hindle's work on *Flies and Disease*.

Certain threadworms—for instance, *Filaria labiata-papillosa*—which occur in the peritoneal cavity and sometimes in the eyes of cattle and deer in India are undoubtedly conveyed by *Stomoxys calcitrans*. The superficial vessels of the cattle swarm with the larvae of these threadworms, which readily pass through the proboscis of the insect into its stomach. They then wriggle through the walls of the stomach and make their way into the thoracic muscles: here they undergo a "rest-cure," and after a time they are readily transferred to a new and uninfected host.

But by far the worst infection which is attributed to this fly is acute epidemic poliomyelitis, or infantile paralysis. That this disease occurs in epidemics has been known, especially in Scandinavia, for some time, and eight years ago it attracted serious attention in North America and in our country. In 1907 there were many local outbreaks in the United States and Canada, and it is thought that the infection was first introduced from Scandinavia along the Atlantic coast, and later inland as far as the State of Minnesota, by the numerous Scandinavian immigrants that settle there.

The disease is one of those which are apparently due to a protozoan too small to be visible under the highest power of the microscope, and so small as to be able to pass through a Berkefeld filter. It can readily be artificially transmitted to monkeys. It is thought that the disease is by no means transmitted only by means of the biting *Stomoxys*, and that it may be directly transmitted from one person to another without the aid of any intermediate host. But there seems little doubt that it can be, and is, transmitted by *Stomoxys*, and therefore it is of the highest importance to reduce the number of these insects.

The most efficient way of controlling this pest is to destroy or put out of action its breeding places. All decaying vegetable matter should be either removed or burnt or buried, or covered with some agent which will prevent the larvae living. In fact, the methods that have been advocated for the common house-fly are applicable to *Stomoxys*. If stable manure were carefully removed, from May to October, at least every seven days, the number of flies would be materially reduced. Where this is impracticable, manure heaps should be covered with some insecticide, so as to destroy the eggs and larvae. Experiments are still being made with the view of finding a substance capable of killing the eggs, larvae, and pupae, which will be at once cheap and unharmed to the fertilizing value of the manure. The American experts recommend borax or colemanite (crude calcium borate), calcined, powdered, and applied by a flour-dredger. The proportions which seem most effective are 0.62 lb. of borax and 0.75 lb. of colemanite to 10 cubic ft. or 8 bushels of manure. Two or three gallons of water should then be sprinkled over the manure heap.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF MYELOMA OF THE STERNUM TREATED BY RADIUM.

A MALE, aged 32, suffering from a large myeloma of the sternum, was recommended to me with a view to radium treatment in the Royal Infirmary, Edinburgh, by Professor Gulland, on March 9th, 1915. The tumour had first been noticed two years before after an attack of pleurisy; it had since steadily increased in size, and now consisted of a firm adherent growth about the size of a large coconut in front of the sternum. The circumference of the chest over the growth measured $37\frac{1}{2}$ in. An x-ray examination suggested involvement of the mediastinum. The patient suffered from increasing weakness, from constriction of the chest, and shortness of breath. A consultation was held with Mr. Miles, who considered the case inoperable. In view of the size of the growth, and of the limited amount of radium at the disposal of the Royal

Infirmary, I did not think that much benefit would result from radium applications, but I said that if he were admitted to the wards, a vigorous course of treatment would be tried.

This consisted in the introduction by Mr. Miles of four aluminium tubes containing 10 to 20 mg. each of pure radium bromide into the right hemisphere of the growth, while at the same time external applications through silver shields, 0.5 mm. in thickness, were made. Thus the right hemisphere of the tumour was subjected to an energetic crossfire of rays. The plan of treatment was to transfer at the end of a few days the internal tubes to the left hemisphere, but owing to the rapid diminution in the size of the growth it was not found practicable to introduce more than two of the tubes. The total dose amounted to 13,200 mg. hours.

A month after the treatment the growth had entirely disappeared. Professor Gulland remarked, in regard to this case, "that he had watched the tumour growing during the past eighteen months, that it was of very large size—quite as big as two fists—that he had been rather a sceptic as regards the value of radium in malignant disease, but that he was now quite converted. The growth was a myeloid sarcoma."

The patient has regained his health and strength, and is back at his work.

No tumour, in my experience, is so amenable to radium as a myeloid sarcoma. When energetically treated they melt away in an extraordinary fashion.

DAWSON TURNER,

Officer in Charge of the Radium Treatment at
the Royal Infirmary, Edinburgh.

COMPLETE INVERSION OF UTERUS WITHOUT COLLAPSE OR SHOCK: CONCEALED DELIVERY.

I HAVE read two articles on cases of inversion, in the JOURNAL of April 17th, pp. 676, 677, in both of which there was severe collapse. In the following instance collapse was entirely absent.

I was asked one morning to attend a village woman in labour. On arrival I found a young, healthy-looking woman of about 25 years of age who would not allow anybody else to remain with me in her room. She was lying on a couch, but there was no sign of recent or impending delivery about her. She informed me, on promise of secrecy, that she had given birth to a dead immature fetus during the early part of the previous night and thrown it away, and that all I could do for her was to keep my promise. But as soon as I came out of the room I was shown the body with placenta attached and entire. The household were very anxious to impress upon me that there were no marks of violence on it. I asked them to send for a midwife and left. Three hours later I was called again to attend the same woman. The midwife had arrived, and found something unusual outside the vagina. I thought I should have told the household that the patient had refused any medical aid from me at my first visit. The swelling was the uterus, which had undergone complete inversion. I reduced the organ quite easily and put in a plug to keep it up. Recovery was uneventful.

The outstanding feature in this case was the absence of collapse or shock. There was no collapse, in part, no doubt, because there had been no haemorrhage. Shock, according to Crile, may be produced by exposure of abdominal viscera. In Dr. Oag's case exposure for two hours caused shock and death. In my case more than twelve hours' exposure of the interior of the uterus did not produce the slightest constitutional disturbance. I think that the difference in my patient's case can be explained by the state of her mind. Soldiers in the heat of a struggle and consequent mental excitement are said to receive very severe wounds which off the battlefield would have produced instant collapse and shock. My patient was greatly worried by the prospect of possible loss of reputation. The extreme state of excitement of thought centres may have had a reflex influence, and prevented inhibition of vasomotor centres and consequent shock.

Dumbulla.

C. G. KRIEN, M.B. Edin.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

At a meeting on July 15th. Dr. J. J. PRINGLE, President, who was in the chair, showed a Turkish bath shampooer, aged 40, who presented an *Erythematous, circinate, and gyrate eruption of very large pattern on the trunk and limbs of more than six weeks' duration.* The case was discussed by Dr. H. G. ADAMSON, Dr. GRAHAM LITTLE, Mr. J. E. R. McDONAGH, Dr. J. M. H. MACLEOD, and Dr. J. H. STOWERS, and considerable differences of opinion were expressed as to the diagnosis, but the general feeling seemed to be in favour of its being an instance of the rare disease described by Darier as *pityriasis rosca gigantea.* Dr. GRAHAM LITTLE exhibited: (1) A female patient, aged 66, with extremely numerous small tumours over the arms, neck, trunk, and thighs, of two and a half years' duration, accompanied by irritation and urticarial attacks. Their contents consisted of sebaceous-like matter, and the exhibitor regarded them as *Traumatic implantation or inclusion cysts.* The PRESIDENT thought the case was probably identical with a disease described by Dubreuilh of Bordeaux in 1896 as "fat-containing cysts of the sweat glands" or of the condition described by Bosellini of Bologna and by himself in 1899 under the name of "steatoma multiplex." The case was discussed by Mr. WILLMOTT EVANS, Dr. ADAMSON, Dr. MACLEOD, and Mr. McDONAGH, who supported Dr. Little's views and confirmed his microscopic observations. (2) A case of *Pigmentation around the mouth* of a boy, aged 12, from Trinidad, apparently resulting from the application of tincture of iodine used for the treatment of a streptococcal infection of the lips. Dr. MACLEOD and Dr. PARKES WEBER discussed the case. (3) A middle-aged woman presenting very extensive *Angioma serpiginosum* with haemorrhagic pigmentation on the legs, thighs, and abdomen associated with joint pains. The relationship to or identity with the condition known as "Schauberg's disease" were discussed by Dr. DUDLEY CORBETT, the PRESIDENT, and Dr. PARKES WEBER, while Dr. G. PENNET suggested the possibility of a syphilitic origin. Dr. G. F. STEBBING brought forward (1) a case of *Atrophic sclerodermia and sclerodactylia* in a woman, aged 70, with enormous masses of calcification almost completely surrounding the left shoulder-joint, as demonstrated by skiagrams. Dr. PARKES WEBER remarked upon the comparative immunity of the feet from sclerodermia. (2) A middle-aged woman with *Congenital multiple tumours on the extensor surface of the right arm.* The PRESIDENT, Mr. McDONAGH, and Dr. PARKES WEBER commented upon the resemblance of the tumours to leiomyoma, and advocated biopsy to settle the point. Dr. GRAHAM LITTLE suggested a possible diagnosis of *urticaria pigmentosa.* Dr. H. W. BARBER brought forward a middle-aged woman suffering from severe *Lupus erythematosus* of the face and arms, apparently of about sixteen years' duration. She also had myxoedema, and had been treated with thyroids. Mr. H. C. SAMUEL showed two sisters, both suffering simultaneously from severe *Lichen planus of circinate type* of the legs and trunk. Dr. GRAHAM LITTLE and Dr. STOWERS reported similar incidents of *lichen planus* in sisters. Dr. S. E. DORE exhibited a young woman, aged 23, suffering from *Graves's disease* of two years' duration, the most marked symptoms of which were enlarged thyroid, tachycardia, and fine tremors. During the same period she had had dystrophies of the nails with intermittent cheilopompholyx. The feet were not affected. He commented on the admitted occasional occurrence of nail changes in Graves's disease, and thought cheilopompholyx played no part in their production. Dr. PARKES WEBER did not associate the nail conditions with Graves's disease, but Dr. PENNET and the PRESIDENT shared the exhibitor's views. Dr. DUDLEY CORBETT exhibited a case of *Sclerodermia* in an old woman with much telangiectatic change over the clavicular regions somewhat resembling an x ray burn.

SECTION OF ELECTRO-THERAPEUTICS.

A STENOGRAPHER of this Section, appointed to recommend a *Standard opaque meal for radiographic examination of the alimentary canal,* has presented the following report:

1. The standard meal should consist of either bread and milk, or porridge (Note 1).
2. The total bulk of the meal should be about half a pint.
3. The meal should be mixed with 2oz. of barium sulphate or 2oz. of bismuth oxychloride.
4. The meal should be taken as nearly as possible on an empty stomach.
5. No aperient or other medicine should be taken within thirty-six hours of the first examination, and if the bowels are not opened naturally, an enema should be given on the morning of the examination.

Note 1.—(A) Preparation of bread and milk: 2 oz. of white bread, without crust, cut into small cubes, are placed in the bowl from which the meal is to be taken. 8 oz. of ordinary or malted milk are boiled in a separate vessel with 2 oz. of bismuth oxychloride or 2 oz. of barium sulphate; this mixture is stirred and poured over the bread. Sugar is added to taste.

(B) Preparation of porridge: 1 oz. of porridge made from the finest oatmeal are mixed with 2 oz. of bismuth oxychloride or 2 oz. of barium sulphate, and sufficient milk to make the total bulk up to 10oz. The patient adds as much brown sugar as he likes.

Note 2.—(A) Bismuth carbonate neutralizes about 22 per cent. of the free nature of the stomach, but there is no evolution of gas, as the carbon dioxide is dissolved as rapidly as it is produced (H. Finneborn and A. E. Barclay). The reduction in the acidity of the gastric contents tends to reduce the motor activity of the stomach and to interfere with the normal action of the pylorus.

(B) Bismuth oxychloride is slightly more opaque to the x-rays than bismuth carbonate (R. Morton).

(C) Bismuth oxychloride is about one and a half times as opaque to x-rays as an equal weight, and twice as opaque as an equal bulk of barium sulphate (R. Morton).

Note 3.—Barium sulphate is preferable, at any rate for hospital use, as it is very much cheaper than bismuth oxychloride and equally good for radiographic examinations. By using barium sulphate, Guy's Hospital has saved about £50 per annum.

(Signed) A. E. BARCLAY,
A. F. HERTZ,
REGINALD MORTON,
S. GILBERT SCOTT.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

At a meeting on July 13th, Dr. JANE WALKER in the chair, Dr. MARY SCHARLEB read notes of the following cases: (1) An unmarried woman, aged 58, had complained of backache and slight loss five years after the menopause. Diagnostic curettement was performed, the generative organs appearing normal on examination. In the scanty curettage a mass, the size of a very small pea, was found, which on microscopic examination proved to be an *Adenocarcinoma.* Panlysterectomy with removal of appendages was performed, and the only abnormality proved to be a small cancerous patch at the uterine opening of the left Fallopian tube, where the nodule had been scraped off. The diagnosis was thus made solely on the pathological findings. (2) A woman, aged 66, twice married, but never pregnant, complained of steady increase in the size of the abdomen for four years. The abdomen was the size of a twin pregnancy at full term. On operation a large *Multilocular cyst of each ovary* was found, both cysts burrowing deeply into the broad ligament. They proved to be benign papillomata. (3) This case showed the stimulation of maternity on dermoid cysts. The woman was recently married and very anxious to have a child. She complained of uncomfortable coitus. Examination showed a mass, the size of a small orange, in Douglas's pouch, behind a normal uterus. Operation was postponed to give her a chance of becoming pregnant, but six weeks later the tumour filled the abdomen up to the umbilicus, and *Bilateral multilocular dermoid cysts* were removed, a fragment of ovary being left. Dr. JANE WALKER had seen an identical case operated on by Mrs. Boyd; in this case also a fragment of ovary was left, and the woman subsequently gave birth to premature twins. Dr. LUCIA ALDRICH BLAKE read notes of the following cases: (1) A girl, aged 20, had for three consecutive winters suffered from a catching pain in the back, and now complained of a swelling there. This had the characters of a chronic abscess; there was no curvature and little pain, and x-ray examination showed an indefinite fusiform shadow. The abscess was widely opened, emptied, and sewn up three times at short intervals, and after the third operation a skiagram showed *Disease of the ninth intervertebral disc and the head of the tenth rib.* The latter was removed, and much tuberculous pus

extended from the posterior mediastinum; a further operation was necessary, after which the wound healed up, and after a year the patient had a straight back, and there had been no recurrence. (2) An unmarried woman, aged 46, complained of loss of flesh, abdominal pain, swelling, and nausea for two weeks. Examination showed fullness on the left side of the abdomen, and a *Hard lump in the sigmoid region*, which did not disappear on evacuation of the bowels; there were no symptoms of constriction. Operation showed the sigmoid to be adherent to the anterior abdominal wall, to the loop of the small bowel, and to a mass of glands in the meso-sigmoid. The whole adherent mass was excised, and the patient made a good recovery. A fistula was present between the mass of glands and the sigmoid, through which brownish pus exuded. There was no evidence of malignant disease, nor of tuberculosis, nor of a foreign body. The cause of the condition remained obscure. (3) A married woman, aged 49, complained of enlargement of the abdomen and a profuse offensive discharge; menstruation was regular and profuse. The abdomen measured 35 in. round the umbilicus, and a firm, rounded swelling could be felt a handbreadth below the xiphi-sternum. The pelvis was blocked by the mass, and the uterus seemed flattened out over it. The discharge was exceedingly profuse, and increased by pressure on the abdomen. Operation showed the mass to be a large *Degenerated cervical fibroid* situated below the peritoneum and opening into the uterus. After its removal the patient made a rapid recovery. (4) A married woman, aged 53, complained of continuous loss for twelve weeks preceded by amenorrhoea for nine months. A mass was felt in the right iliac fossa and was diagnosed as a cervical fibroid. Hysterectomy was performed and the patient made a good recovery. Pathological examination showed a polypoid mass in the body of the uterus giving the appearance of a *Fibromyoma undergoing hyaline degeneration*; the surrounding nuclei stained intensely and suggested sarcoma. Six months later the patient returned having a mass larger than the original, fixed and inoperable. Dr. ELIZABETH BOLTON read notes of the following cases: (1) A married woman, aged 57, who complained of a dull aching pain in the hepatic area, constant for eighteen months. There was occasional vomiting and nausea, no jaundice. The liver extended nearly to the umbilicus, was smooth, with a prominence on the surface connected with the left lobe. Laparotomy showed *Hyalid disease*, the cavity partly in the liver and tracking thence in three directions upwards under the diaphragm. The cysts were dissected out and the patient made a good recovery. (2) A single woman, aged 48, who had always been well. While on holiday she bathed and dived much, and during one dive was seized with acute abdominal pain and vomiting, and for twelve hours could not pass water. The temperature was 100° and pulse 80, and the abdomen very tender. She became worse and laparotomy revealed *Torsion of a fibroid*. Supravaginal hysterectomy was performed and a good recovery was made. Dr. KATE PLATT showed plans of the *New Lady Harbinger Women's College and Hospital at Delhi*. Accommodation was arranged for 100 students—Indians, Anglo-Indians and Europeans—and for 160 patients. The students would take the M.B., B.S. degree of Lahore University. About 20 had entered for the first year. The PRESIDENT read a communication from Dr. ROSA BALE on a case of *Heart-block* in a woman aged 57. In an alarming and almost fatal attack, in which the pulse rate was 20, and there were violent spasms of Cheyne-Stokes breathing, the patient responded to 4-hourly doses of strychnine given hypodermically and recovered completely after six injections.

MR. JOHN MURRAY has published a booklet by Helen Donald-Smith entitled, *War Distress and War Help*. It is a short catalogue of the leading war help societies, showing their scope and objects and the addresses of their offices. The purpose of the address is to enable any one to ascertain quickly the particular war help society or association which deals with a particular class of distress. To ensure the trustworthiness of the information supplied a proof has been submitted to all the chief societies mentioned in it, and the compiler has received valuable assistance from foreign embassies and consulates. Such a list is invaluable at the present time. Any profits from its sale will be given to the Officers' Families Fund.

Reviews.

DENTAL ANATOMY AND SURGERY.

IN *An Introduction to Dental Anatomy and Physiology* Mr. HOWELL SMITH has allowed his enthusiasm to loose a rein, and has sometimes obscured his subject and even his meaning by argument round about it. He has tried to make dental anatomy a "live" subject, and to a large extent he has succeeded, especially in his chapter on the teeth and their functions, in which the food habits of various peoples, phonation, and the "ornamental" uses of teeth are described, together with what he groups as the minor functions of teeth, though it may be doubted whether "prehension" be a minor function. He fails, however, to infuse life into the discussion on the evolution of the mammalian crown, and leaves the tribituberculous theory as difficult reading as ever. The description of the human teeth is not altogether satisfactory, perhaps from a desire on the part of the author to vary his language. He wonders at the loss of the three tubercles on the cutting edges of the incisors after a few years' use! There is no account of the common variations; thus the second upper permanent molar is described as four-cusped, though a later figure of the base of the human skull shows the common three cusped variation; there is no comment on this. The remarks on the sensitiveness of teeth are of considerable interest, both in themselves and in view of Mr. Howard Mumme's recent demonstration of non-medullated nerve fibrils in the dentine; it is difficult, however, to agree with the author that the cementum of the root is sensitive. The whole book suffers from the author's delight in foreign words and from his tendency to overstate his points. Yet it is one that will find a ready welcome. As with his other works, with but one or two exceptions (radiographs) the illustrations are excellent.

Mr. UNDERWOOD'S *Aids to Dental Anatomy and Physiology*² is an excellent summary, lacking little except illustrations. It will assist the student of dental surgery in acquiring a scientific knowledge of his speciality, and, as the author is a recognized authority on the subject, we may add that the physician and surgeon may read it with profit. It is far better in composition than most compilations entitled "Aids," which are too often assistants to cramming rather than to knowledge. The chapter on the teeth of man is excellent, and comparative anatomy is introduced with judicious limitations. The author devotes a few paragraphs to the missing teeth in *Homo* and to the dentition of ancient man, about which so much has been discovered and described, even since the death of Barnard Davis, Flower, and the great French and German anthropologists of the nineteenth century. Mr. Underwood states that only one instance of a mandible with any truly simian character has been discovered so far, and that is the fragment lately found at Piltdown. It is well that a dentist of some authority should remind us that it is a great error to believe that Darwin discovered the "missing link" and that others have unearthed quite a chain of such links between man and the anthropoid apes. We have not even turned up a set of human teeth with a distinct diastema, constant in the quadrumanus. Mr. Underwood adds Mr. J. Howard Mumme's important monograph on the process of calcification in enamel and dentine. It appears in its original form, complete, as it was only published last year in the *Philosophical Transactions*, too late to be incorporated in the text.

HEALTH VISITORS IN MUNICIPAL SERVICE.

The employment of lay visitors in the service of the municipal tuberculosis dispensaries that are springing up throughout the country is not an unmixed blessing. Fact and sympathy in dealing with erring fellow-creatures are not granted to every one, and if knowledge also is

¹ *An Introduction to Dental Anatomy and Physiology*. By A. Howell-Smith, L.R.C.P. Lond., M.R.C.S. Eng., L.D.S. Eng., Lecturer on Dental Anatomy and Dental Surgery, Royal Dental Hospital, London. London: J. and A. Churchill, 1913. (Slop. rope, 8vo., pp. 372; 340 illustrations, 18s. net.)

² *Aids to Dental Anatomy and Physiology*. By A. S. Underwood, M.R.C.S., L.D.S., Third edition. London: Baillière, Tindall, and Cox, 1914. (Fcap. 8vo., pp. 136. Cloth, 2s. 6d. net; paper, 2s. net.)

lacking, the visit may cause more irritation than assistance in the tuberculous home. To provide them with a little knowledge of the subject, Dr. Brunon, tuberculosis officer for the borough of Deptford, has written a small *Tuberculosis Handbook*² for health visitors and nurses, and for lay workers in general, who may be called upon to deal with sufferers from tuberculosis in any of its forms. Tuberculosis of other organs than the lungs, however, is but little recognized by the average layman, and hence consumption and its treatment are chiefly considered. The etiological and pathological aspects of the disease are only lightly touched upon. Infectivity is described by the transcript in full of the manifesto issued by the Royal College of Physicians in April, 1914. The use of tuberculin for diagnostic purposes is shortly explained, but no stress is laid upon it as a therapeutic agent. The pneumothorax treatment of the advanced disease is briefly mentioned and the apparatus used for it is figured, presumably for the benefit of nurses who might possibly be called upon to assist in the operation.

Sanatorium treatment and the working of the tuberculosis dispensary are considered at greater length, many useful details being insisted upon, especially with regard to home visiting. A final chapter deals with legislation as applied to tuberculosis. The small work, well printed and illustrated, is worthy of the attention of the class of readers for whom it has been prepared, as enabling them to take a more intelligent interest in their work and to avoid the common errors arising from simple ignorance.

LOUPING-ILL OR TREMBLING IN SHEEP.

The Edinburgh and East of Scotland College of Agriculture is doing no small service to comparative pathology and public health by its encouragement of such investigations as that into the mysterious malady in sheep known as "louping-ill," or "trembles," which has been conducted by J. P. MCGOWAN, M.A., M.D., B.Sc., Assistant Superintendent of the Royal College of Physicians' Laboratory, Edinburgh. Dr. McGowan's researches upon "braxy" in sheep were recently noticed in this JOURNAL (June 12th, 1915, p. 1017), and from them the conclusion was drawn that braxy was due primarily to the *Bacillus bipolaris septicus orium*, and he has now reached the opinion, expressed in the pamphlet entitled *Investigation into "Louping-ill" or "Trembling,"*³ that the same microorganism is the cause of "louping-ill." He thus runs counter to the view held by the late Professor Hamilton of Aberdeen, who ascribed it to the *Bacillus choreae paralytica ovis*, a microbe which McGowan groups with the *post-mortem* putrefactive agents which appear in sheep, no matter what be the cause of their death. The difference in severity between braxy and louping-ill—the former is always fatal, whilst recoveries from the latter are not uncommon—is to be explained on the hypothesis that louping-ill is the less fulminant and less fatal form of the same malady.

"Louping-ill" simply means "leaping-ill," and, indeed, it was at one time known under the latter name in Scotland. It got its name from the characteristic symptom, the leaping of the animal into the air when startled, as by the sudden appearance of a dog. After jumping up it falls down, kicks a little while, and then dies, or it may lie kicking and then rise up and walk away staggering; or, finally, it may continue to lie and exhibit a more or less paralysed state, and may then ultimately recover the use of its limbs in part or die. Other diseases, however, have been confused with louping-ill, and so Dr. McGowan distinguishes a "true" from a "pseudo" form. Under the latter he places the diseases of lambs (lameness, abscesses, paralysis, and deformities) due to ticks, navel-ill, joint-ill, and woolball in the stomach; each of these must be prevented or treated according to its cause, as by the extermination of the tick, the doing away with fixed lambing pens, the application of tincture of iodine and tar to the navel immediately after birth, and perhaps the opening of abscesses. True louping-ill, or true "trembling" (to give it another name often applied to it),

includes "stagers," and may be subdivided into several varieties; of these braxy is one, and grass sickness of lambs is another, and both of these are very acute forms. The primary cause, both in braxy and in true louping-ill, is the same, namely, the *Bacillus bipolaris septicus orium*, but the secondary one differs, being the eating of frosted succulent food in braxy and extreme variations of outside temperature in true louping-ill. Other differences are that braxy attacks the most thriving sheep in the flock, but true louping-ill does not necessarily do so; that braxy is most common in autumn, but louping-ill in spring; and that while braxy is the result of a sudden violent chill, louping-ill is due to a less violent one. Louping-ill has for a long time and by many authorities been regarded as associated with the presence of ticks, but there is much evidence against this conclusion, whilst, as has been stated above, pseudo-louping-ill is most probably connected with them, the grass ticks, by the irritation they cause at the points bitten, setting up swelling of lymphatic glands and consequent lameness, pyæmia and abscesses, and joint affections.

Dr. McGowan makes certain suggestions for the prevention of true louping-ill; indeed, he is not hopeless about the possibility of getting a vaccine for purposes of cure as well. So far as prevention is concerned he would recommend the provision on all hills of shelter-belts; the avoidance of over-stocking; the separation of the leaner and ill thriving ewes from the others in the early spring; the wide burning of both heather and white land; the draining of the land and the application of lime to it; the careful and gentle performance of wether-locking, and the avoidance of hounding with dogs. The actual treatment is largely symptomatic; the administration of a purgative, keeping the animal quiet in a sheltered place on young grass, stimulants (whisky, digitalis, strophanthus) in cases of heart failure, and potassium bromide and chloral in cases of actual fits and violent nervous symptoms.

It is to be understood that Dr. McGowan's investigation deals with louping-ill as it exists in Scotland; it may be identical with the diseases known in England as twitch, trembles, moss-illness, dizzy, and "turn in the head," with the cheluna of Patagonia, and with certain maladies described in French and German textbooks, but he has not extended his inquiries to these matters. The whole subject invites further research in various directions, and it may yet turn out that these maladies come into touch with human maladies at one point or another; meanwhile Dr. McGowan and the East of Scotland College of Agriculture are to be thanked for breaking comparatively new ground.

PUBLIC HEALTH TEXTBOOKS.

The appearance of a sixth edition of Dr. Kenwood's *Public Health Laboratory Work*⁴ is good evidence that it continues to fulfil what is required of a practical handbook of the subject. Not many changes have been made from the fifth edition, the principal being the omission of the section of bacteriology by Dr. Savage; a few pages on the bacteriological examination of water are introduced into the chapter on "the opinion on water samples," but apart from this bacteriological matters generally are omitted, in view of the existence of several practical books suitable for the public health student's needs in that subject. The examination of water, sewage and sewage effluent, soil and air occupy about half the book, the remainder being devoted to the examination of the principal kinds of food, the detection and estimation of arsenic in various articles, and the testing of disinfectants. Medical men taking up public health work will find Dr. Kenwood's manual an excellent one for guiding and assisting their practical work.

A second edition of the *Treatise on Hygiene and Public Health*,⁵ by Drs. B. N. Gross and J. L. Das, has reached

² *Public Health Laboratory Work*. By Henry R. Kenwood, M.B., F.R.S. Edin., D.P.H., F.C.S. Sixth edition. London: H. K. Lewis, 1914. (Demy 8vo, pp. 430; 4 plates, 87 figures. 10s. net.)

³ *A Treatise on Hygiene and Public Health with Special Reference to the Tropics*. By Barendra Nath Ghosh, L.M.S. (Cal. Univ.) and Jobar Lal Das, L.M.S. (Cal. Univ.), with an introduction by Colonel K. Macleod, M.D., LL.D., F.R.C.S., L.M.S. (ret.). Second edition. Calcutta: Hilton and Co. London: Sunplein, Marshall, Hamilton, Kent, and Co. Limited, 1914. (Cr. 8vo., pp. 415; 48 figures. 6s. net.)

⁴ *The Tuberculosis Handbook*. By A. H. G. Burton, M.D., etc. London: The Scientific Press, Ltd., 1914. (Cr. 8vo., pp. 67; illustrated. 2s. 6d. net.)

⁵ *Investigation into "Louping-ill" or "Trembling."* By J. P. McGowan, M.A., M.D., M.R.C.P.E. Edinburgh: William Blackwood and Sons, July, 1915. (Pp. 51.)

us. The first edition was received so recently (JOURNAL, October 4th, 1913, p. 870) that there is little to add to the commendation then bestowed on the book. It makes no claim to originality, but, as the authors state, is founded on the standard works on the subject, keeping in view its special object, to adapt the principles of these works to the conditions which prevail in India. The new edition has been carefully revised, and in some places extended, to bring it up to date, and with the same view the number of illustrations has been somewhat increased. We may say that the book fulfils its object satisfactorily. But the fact that a second edition has been called for less than two years after the publication of the first is the best evidence that the book has met a want.

SURFACE TENSION.

ALTHOUGH many of the phenomena included under the term "capillarity," or "capillary action," such as the rise of a liquid in a narrow tube when one end of it is introduced below the surface, or the absorption of a liquid by a porous substance of which a small portion only is dipped into the liquid, are familiar to most persons, probably very few, except those who have made a special study of the subject, would be able to explain such phenomena or to give any account of the theoretical considerations deducible from them. In a little book entitled *Surface Tension and Surface Energy*, Messrs. R. S. WILLOWS and E. HATSCHEK give a succinct account of the general subject of surface energy of which capillary action is one manifestation. The five chapters of the book represent a series of articles which appeared originally in the *Chemical World*, and are based on a course of lectures delivered at the Sir John Cass Technical Institute by one of the authors. Mr. Hatschek is the author of a work on colloids which has been previously noticed in our columns, and the present subject is very closely connected with what may be termed colloidal chemistry. In a so-called colloidal solution solid matter exists in a state of extreme subdivision, and, therefore, with a great development of surface for a given mass; the particular properties of surfaces due to their being the boundaries between dissimilar substances therefore play a very large part in determining the peculiar properties of such quasi-solutions. The phenomenon known as adsorption is also a particular case of the results of surface energy, and a general summary of the whole subject is, therefore, to be welcomed. The book under notice, being originally designed for the use of chemists, assumes a fair general knowledge of chemistry and physics, and to a reader possessing such knowledge it is an excellent presentation of the subject, but more general readers would probably find the treatment too condensed to be easily followed. The use of mathematical formulæ and calculations is, of course, inevitable, but the mathematical treatment is confined to what is essential, and very few details are given of the experimental work which is described. The book will be found a useful summary, suitable for those who desire to obtain correct general ideas on the subject, either for the sake of its bearing on other subjects or as a preliminary to a more detailed study of it.

Surface Tension and Surface Energy and their Influence on Chemical Phenomena. By R. S. Willows, M.A., D.Sc., and E. Hatschek. London: J. and A. Churchill, 1915. (Cr. 8vo, pp. 88; 17 figures. 2s. 6d. net.)

MEDICAL AND SURGICAL APPLIANCES.

A Tourniquet.

MR. J. M. CARVELL, M.R.C.S. (West Kensington, W.), writes: For some time past in connexion with ambulance work the need has been felt for a more efficient form of tourniquet than those in general use, that is, the india-rubber or the pad and strap varieties; the drawbacks being, in the case of the former, that when applied the circulation of the limb is completely restricted, and that the rubber soon perishes. In the case of the latter there are three distinct weaknesses: (1) When the strap is tightened the pad is pulled out of place, owing to pressure being exerted on one side of the pad or block only; (2) owing to the means to secure the appliance being a spiked buckle, some relaxation of the band takes place, and it is difficult to remove or adjust; and (3) the strap being pierced by the buckle spikes, is weakened, and soon wears

out. Messrs. Hatrick and Co., of 70, St. John Street, Clerkenwell, have made for me a tourniquet which overcomes these drawbacks, and possesses other advantages which are absent in other tourniquets. It consists of a pad or block of vulcanite (or other suitable material) which is affixed to a metal plate, one end of which forms an eye and the other an open hook. To the eye is permanently attached a special form of spiked buckle, and a similar detachable buckle engages over the hook of the metal plate when the instrument is in use. Through the two runs the strap of the tourniquet, which consists of two lengths of webbing placed one over the other, and stitched across at frequent intervals, the ends of the webbing being thickened so that it cannot be detached from the buckles. To apply the tourniquet the loose clip is removed from the hook, the block is placed in position, the strap is passed round the limb, the loose clip replaced over the hook. Pressure is then exerted on both ends of the strap, and the block is forced directly downwards, the strap automatically holding at the point of greatest pressure. To remove the tourniquet the release tongues (marked) are pulled with an upward motion, when pressure is instantaneously relaxed. An additional lock is provided for use only in cases in which a patient may have to be transported a considerable distance and possibly loaded and unloaded *en route*. This is secured by inserting pencils, or anything similar, through the loops formed by the two lengths of webbing composing the strap immediately outside the clips, when the tourniquet is in position. When this is done, the appliance is secured even if the release tongues should be inadvertently pulled.

MOTOR CARS FOR MEDICAL MEN.

LIGHT CAR DEVELOPMENTS.

By H. MASSAC BUIST.

THE situation in regard to the supplies of British-built motor cars that I outlined in the JOURNAL of May 29th is emphasized by the appointment of Mr. Lloyd George to the ministry of munitions and Dr. Addison as parliamentary secretary. Further investigations at first hand of the position in the Midlands reveals that in effect all our best makers of cars of all powers, sizes, and prices are now busy on Government work; therefore there is no time to be lost by the medical man who contemplates placing an order for a new car. These remarks must be taken as applying not only to medium size, but also to the smaller sorts of vehicles, including light cars, with certain developments in connexion with which I propose to deal in these notes.

I cannot, perhaps, make a better beginning than by drawing attention to a new craze, whereby a large section of light car users are not content with the extraordinarily rapid manner in which the manufacturers are developing these machines, but fancy that perchance they can also improve their qualities by experimenting on them. Take, for example, the practice not infrequently advocated for owners of light machines to drill holes in the connecting rods for lightness, or to lighten the pistons by drilling and turning on the inside of them, or cutting the cans to increase the valve lift, or taking metal off the bottoms of the cylinder castings to increase the compression pressure. Some amateurs with a turn for mechanics take a delight in this sort of thing, with the result that for a space their vehicles become very showy in the matter of speed, and envy is created in the bosoms of owners of non-mechanical mind of similar light cars, who are tempted to engage some local mechanic to fittivate their machines on similar lines for a few pounds.

PRACTICES TO BE AVOIDED.

The medical man, to whom reliability is essential and the total cost of whose motoring is a material item, will be well advised to have nothing to do with any such practices. Those who advise or suggest them are false

educators of the robbing public, because they would inculcate quite wrong principles. It should be had in mind that the average light car of to-day is, proportionately to its weight, a powerfully engined vehicle. The transmission and other mechanical details are worked out by the manufacturer in strict relation to the power the motor develops as furnished by him. Increase that power by ever so little and you upset all the careful calculations on which the machine as a whole was designed. Apart from this the product is a machine which has never been tested by the maker as a unit because his experiments, which usually extend over at least a season before he presents a model, are all conducted with that vehicle in the form in which it is ultimately evolved and standardized. In these days of keen competition, when the majority of buyers are too much influenced in their choice by the quality they call liveliness, the medical man may rest assured that no maker markets a car with more material in it and with a less powerful engine than his exhaustive tests have shown him to be necessary.

THE ALTERNATIVES.

It will be observed as a rule, moreover, that all these seductive receipts for faking light cars are concerned with paring away the material furnished by the maker in the standard products. Thus, the engine itself is made to produce more power with less material to stand the strains of the greater impulses.

As many a medical man lives in hilly districts the temptation to succumb to what is almost becoming a vogue may be considerable. If, however, in spite of the extra cost in tyres involved, he wants to negotiate the rises more speedily there are open to him two alternatives: He may either spend his money in acquiring in the original instance a larger and more powerful vehicle which he will run on strictly standardized conditions, or ferret about and discover which maker or agent can give him one or other of the light cars that have been produced for speed and other competitions, and the more vital parts of which are fashioned of special steels, tested to stand the additional stresses. The latter alternative, however, is not to be recommended unless the medical man chances to make a hobby of the mechanism of his car, in that the more these vehicles depart from the strictly standard product the more liable are the details of them to get out of adjustment; and the results sought can be attained only when every detail is perfectly in tune with the rest.

A POCKET-SAVING LESSON FROM ABROAD.

Nearly every private advocate of the practice of "putting more ginger" into his light car innocently believes himself to have discovered things of which the industry is in complete ignorance, whereas the very practices he exploits have been indulged in since motors were. Far better, because more profitable in every way, is it to take thought as to the manner in which you drive your light car. There is a great contrast between motor drivers of all classes of vehicles in this country and the French, Italians, and Americans, for example. In these islands we have made a fetish of the idea of doing as much of our journeying as possible on the top speed. If the average owner had the least realization of the manner in which he strains his vehicle by doing this and the slower speed he really makes by hanging on to the top gear to the last gasp of the engine, he would cease the practice. Every foreign driver, whether professional or amateur, is taught that engine revolutions represent horse-power; consequently he always changes down to a lower speed when his engine begins to slow and before it has lost any appreciable number of revolutions.

Moreover, any one who had time and opportunity to study the car testers round about Coventry and Birmingham would observe that, though the average of those concerned with light cars certainly seem bent on destroying the chassis before they have any chance of being placed on the market, nevertheless, they are never guilty of attempting to make an engine of 1,000 or 1,500 c.m. travel at 5 miles an hour on top gear, or pick up on top at practically no miles an hour after rounding a corner. On the contrary, whenever they want the car to accelerate after it has been

slowed, they drop into a lower speed and open the throttle fully for a few yards. That way the engine, transmission, and all the rest of the mechanism is saved, and also the speed at which it is desired to travel is attained much more quickly than by hanging on to the top gear.

THE EVERYTHING-AT ONCE POLICY.

One of the troubles of the light car proposition to-day is the impatience not only of a large number of would-be owners, but also of a number of manufacturers. They want everything at once. Thus, before we have had reasonable time in which to complete to its full possibilities the development of the two-seater with an occasional third seat, four-seater light cars with tonneau bodies are already being standardized and coach-making departments blamed for not producing luxuriously-equipped limousine bodies for these chassis, with miniature engines. There would seem to be a mad race to put on the market a showy-looking vehicle for two hundred odd pounds, embodying all the features of a six-cylinder Rolls-Royce. Already the light car owner has electric lighting and generating sets standardized complete, and there have been introduced this year electric mechanical engine-starting sets for light cars.

Though all those developments admittedly add to the weight and absorb horse-power, one has to admit a case for the dependable mechanical starter for the light car, especially when employed for doctors' service. The reason is that the little magneto fitted are designed so that at present they only give an efficient spark when the engine is turning very much faster than is possible by any hand cranking. This present difficulty is common to the majority of light cars. It could, of course, be obviated by employing dual ignition, taking the accumulator current from the batteries of the lighting set. Speaking of my own experience, however, I do not advise this under the heading of reliability.

MECHANICAL ENGINE STARTERS FOR LIGHT CARS.

The average medical man has occasion to stop his car very frequently, consequently if anybody should get value out of a mechanical starter, he is the one. I would therefore take as an illustration of the latest developments the electrical light car starter now standardized by the firm of C. A. Vandervell that made its mark in connexion with electric lighting sets for cars. Connected with the battery and the starter motor is a plunger switch. When the switch is in its normal position, the circuit is open and the starter is electrically disconnected from the battery. When the plunger switch is depressed or pushed down, the starting circuit is closed and current passes from the battery to the electric starter. The firm itself has facilities for fitting cars at short notice at its London, Birmingham, and Manchester premises, so that there need be no uncertainty of the thing being bungled by inexperienced installation.

In winter especially, and for night work, the mechanical engine starter is an accessory much to be recommended to the medical man, since few things are more fatiguing than the strains of winding an engine rapidly.

THE FOUR-SPEED LIGHT CAR.

But with motors thus taxed to carry extra loads and to generate the electrical energy necessary for starting and lighting purposes, and with increases of weight also in coach work, so that some light cars scale 1½ cwt. ready for the road, either larger motors or more gears must be employed.

About the finest scheme of a light car that shall be well up to its work is the Coventry Premier 10.4-h.p. 4-cylinder model, wherein we see a recognition of these points, for, on the one hand, the engine is 65 mm. by 120, giving a volume of 1,592 c.c.m., and, on the other, the gear-box provides four forward speeds, so that there is nothing undue in the chassis weighing 12 cwt. War is unfortunately interfering with the output, and the car will not be ready for the market just yet, but the product must be noted as representing a notable line of development, because, in addition, the rear suspension is on the free cantilever principle, as distinct from quarter elliptic springs, which, by some mysterious process, are generally catalogued as cantilever ones when they are applied to

light cars. This design also reveals the possibility of making a light car wherein the seats are well between the axles, the wheelbase being proportionately as long and the centre of gravity as low as in a six-cylinder large car.

LONGER WHEELBASES THIS YEAR.

This brings us to another point in light car development this year. In the beginning the centre of gravity of most light cars was high and the track narrow—as instance the earlier Morris-Oxford models. By most makers this tendency has been remedied by widening the axles with a gain in lateral stability. But the average light car will probably have the seating line an inch or two lower in a season or so.

What is more important in the meantime is the observed tendency to lengthen the wheelbase in the 1915 models. In some this measure as much as 8 ft. 3 in. These longer wheelbases make for easier riding, and undoubtedly enable the machines to hold the road better. The standard wheelbase last year averaged 7 ft. 6 in., though many vehicles were made shorter, one well-known type being not more than 6 ft. 9 in. Thus the increase to an average wheelbase measurement of 8 ft. 3 in. represents an appreciable advance this year, though that extra 9 to 18 in. of course entails considerable addition of weight by reason of the frame, propeller-shaft, and kindred details having to be elongated. Undoubtedly the increased comfort and stability of the 1915 cars thoroughly justifies the departure.

A NEW MAKE OF LIGHT CAR.

A newcomer to the light car industry this year is one long familiar by name to road users in the Raleigh Cycle Company of Lenton, Nottingham, which made a tentative effort at motor manufacturing in the early days of the industry in this country, but whose present 11 h.p. four-cylinder vehicle really represents its start in the motor industry. This machine scales 13 cwt. complete, and has a block cast four-cylinder engine with a bore of 67 mm. and a piston travel of 95 mm., giving a volume of 1,340 c.c.m., so that again we have an example of providing something not so highly stressed as an 1,100 c.c.m. engine must be when used on vehicles so completely equipped as the best sorts of light cars. The Raleigh is standardized with Rotax dynamo and electric lighting set, the generating plant being protected from dust and wet by a shield. A Thomson-Bennett British-made magneto with fixed firing point is used, and the cooling is by the natural circulation of the water, but the engine oiling is by the big ends dipping into pump-fed troughs, the pistons and cylinders being supplied by splash. The gate-controlled gearbox gives three speeds forward, and the drive is by an overhead worm above the back axle, which is equipped with three-quarter elliptic springs.

THE BABY PEUGEOT LIMOUSINE.

A somewhat quaint light-car novelty is the Baby Peugeot miniature limousine-compé, which has been designed and built by one of the agents of the famous firm of Peugeot (England) Limited, 10, Brompton Road, London, S.W., and is sold complete with accumulator lighting set and lamps for £250. The problem presented to the coachbuilder, of course, has consisted in how to give plenty of room to the passengers on so small a chassis; it has certainly been tackled with considerable ingenuity. All the windows, including three oval ones, are of plate glass, and the door is hinged in two halves, the window portion opening independent of the lower part. The interior can be lit up at night, the main colour scheme of its decoration being light brown, while the exterior of this limousine-in-little is painted mustard colour, with black wings and details.

Other light car developments will form the subject of a future article.

ACCORDING to the *Medical Record*, a recently issued bulletin of the Census Bureau states that blindness is less common in America than in most other countries, and is apparently decreasing among the young. Indians suffer much more than other races from the affliction, and blindness is much more prevalent among negroes than among whites, and among men than women. The blind population of the United States in 1910 numbered 57,272, or £2.3 to each 100,000 of population. Trades taught in schools or workshops have prepared 1,500 blind persons for total or partial self-support.

BRITISH DENTAL ASSOCIATION.

ANNUAL MEETING.

The thirty-fifth annual meeting was held on July 24th, in the hall of the Medical Society of London.

Retiring President's Address.

In delivering his valedictory address, the retiring President (Mr. W. GUY, F.R.C.S., L.D.S. Edin.) said the war had given the dental profession the chance of rendering splendid service to the country in the treatment of recruits and soldiers, and an enormous amount of work was done in that way. In the matter of army dental treatment, however, the war found them unprovided with a definite scheme, and emergency measures became necessary. Commissions as temporary lieutenants were conferred on about seventy dentists, who were now doing duty either with the Expeditionary Forces or at home stations. The War Office circular of January 22nd authorised a scale of payment for civilian dentists in providing treatment necessary to render a non-commissioned officer or man fit for service in the field. He believed the work of the army dentists was of the most arduous character, and the authorities were fully aware of its value. But what were seventy amongst so many? The present system might be improved by instituting effective control and supervision by dental staff officers, but the only logical and efficient method of coping with the great problem of dental treatment for the men of our armies would be found in the establishment of an army dental corps. In conclusion, Mr. Guy paid a tribute to the memory of five dentists and two dental students who had already fallen at the front. He also mentioned that he had personally operated on more than 1,000 patients at the 1st Scottish General Hospital, Craigleith, and considerably more than double that number had passed through his hands at the Edinburgh Dental Hospital.

A hearty vote of thanks was passed to the retiring president, on the motion of Mr. REES PRICE (formerly of Glasgow), seconded by Mr. W. G. CAMPBELL (of Dundee).

Installation of New President.

Mr. W. H. DOLAMORE, M.R.C.S., L.R.C.P., L.D.S. Eng., was then inducted as president, and delivered an address, in which he said that never, perhaps, had the disasters which may follow the neglect of teeth been more apparent than now. It needed but an inspection of the teeth of many soldiers invalided home to prove what an important factor neglected teeth were in producing or predisposing to the development of general disease. It was no secret that the army authorities first refused men with bad teeth. When the need of men and more men was felt, these were admitted irrespective of the condition of their teeth. But, having been admitted, it was found that either their teeth must be treated or these men would not be available for foreign service. It was the recognition of the lamentable condition of the teeth which led dentists in the early days of last August to offer voluntarily to do what they could for our gallant men, both in our hospitals and in their own consulting rooms. But the task was too great for efficiency unless properly co-ordinated, and with greater financial backing than they could give or procure. Tardily the War Office undertook the work. But the delay, some four or five months, caused, he was told, this serious position: Troops, passed as fit some months earlier, were paraded and inspected previous to foreign service. Then, and not till then, it was discovered that many men needed dental treatment. Now arose this difficulty: Either the work had to be done in a hurry, and frequently dentures inserted long before the mouth had healed sufficiently for them to be serviceable even for a year, or the men had to be kept back at home for some three or four months. Further, the War Office having recognized the obligation to provide dental treatment in the interest of efficiency, it was a matter of regret that it did not appoint a committee, on which dentists conversant with the matter had a seat, to advise, and to supervise the carrying out of the arrangements.

He believed that if there were such a committee, two points especially would have come early under discussion. First, the need of effective supervision over the dental

work which was being done. Secondly, the need of dental aid in the treatment of injuries of the jaws. The principle of supervision was admitted, for all this work was signed for and approved by members of the R.A.M.C. But there was no real supervision.

With regard to the second suggestion, the treatment of fractures of the jaw, and especially the designing and fixing of splints after extensive injury, was a very special work, and experience was only gained after many years with special opportunities. The men who had been appointed dental lieutenants were most excellent men, but they were young, and, with perhaps some few exceptions, had not had this experience. From what they heard many of these fractures and injuries were not treated by means of splints at all, and dental aid was sought only when some permanent deformity, beyond treatment, had resulted. That surely was wrong. Deformity, by immediate and correct treatment, could be avoided, and although many of these wounds were horribly septic, he would urge that a properly made splint would not increase but diminish septicity. The splint, by holding the parts immovably fixed, allowed the mouth to be opened freely and painlessly, so that an antiseptic treatment could be thoroughly carried out. Further, the parts were kept in a state of rest, saving pain and hastening the healing of the wounds. He thought a certain number of more senior men qualified to supervise, and, in the case of injuries of the jaws, qualified to treat, should be appointed. He believed it would be possible to find such men. A few were already serving in the R.A.M.C., but not utilized for dental work. But even if higher rank were given, men could only accept such posts at much self-sacrifice. Many had responsibilities at home which would preclude their volunteering, but there were others who could do so. The example of those medical men, including many who practised dentistry, who had sacrificed their positions at home to carry on work for the R.A.M.C. in various ways, justified the belief that they not only could, but would.

Business Meeting.

In the afternoon the annual meeting of the Benevolent Fund was held, followed by the annual business meeting of members. At the latter the report and accounts were adopted, and Mr. Frank J. Pearce was cordially re-elected honorary secretary.

SHORTAGE OF MEDICAL OFFICERS IN VOLUNTARY HOSPITALS.

AN informal conversation on the shortage of medical officers in the voluntary hospitals took place at Charing Cross Hospital on July 30th. The gathering was convened by the British Hospitals Association, and Mr. H. WADE DEACON, Chairman of the Liverpool Royal Infirmary, presided. Mr. J. COURTNEY BUCHANAN, Secretary and House Governor of the Metropolitan Hospital, who opened the proceedings with a short paper, said that the present "race for residents" was common to nearly all the hospitals. Inquiries addressed to fifty institutions revealed the fact that the expenditure on residents was very greatly in excess of that which was incurred in normal times. For hospitals with medical schools a scheme (see *infra*) had been arranged with the War Office for granting early commissions to resident medical officers, and so far as these institutions were concerned, the difficulty was practically at an end. Hospitals without medical schools, however, were in difficulties, which would be more serious were it not for the loyalty of the visiting staff. It was not strange if a young man did not desire to go on working at a hospital in civilian obscurity at a salary of £150 or £200 a year when his professional brethren in khaki uniform were in receipt of a salary of approximately £500 a year. What sort of attraction could a hospital hold out to prospective residents which would be anything like so effective as the honor of military service, accompanied as it was by considerable material advantage? Then, again, what substitutes were available? General practitioners in the neighbourhood of hospitals might be induced to extend their generosity still further, but as a rule they were very closely engaged in their own practices. Graduates of foreign universities might be engaged, subject to registra-

tion by the General Medical Council, but an imperfect knowledge of English was frequently a fatal drawback. So far as doctors from the United States were concerned, the difficulty was one of registration, and there was no reciprocity between England and America in this matter of qualification. Civil hospitals had given up a great deal of their in-patient accommodation for sick and wounded soldiers, and in this and other ways had established some sort of right to special consideration in the matter of residents. It would be a thousand pities if anything militated against their permanent interests.

Sir WILLIAM COLLINS formulated two considerations which ought to be kept before them—first, anything that they did or said with regard to the War Office was not intended to embarrass the Army medical department; secondly, the voluntary hospitals of London had ground for asking for just consideration in this matter of the shortage of resident officers. Was it possible to increase the supply? It was easier to turn the civilian into a soldier than to turn the layman into a doctor. There could be no such thing as honorary war degrees in the medical faculty. Something might be done in the way of reducing fees and speeding up examinations, but no great increase in supply could be looked for. The lady graduate, again, had come into her own, and he hoped would be increasingly utilized. Then there were our Indian fellow-subjects. Only a few days previously he had met a Parsee who had come to this country anxious to obtain a house-surgery, and had found the colour bar against his services being utilized. He hoped that the ancient prejudice against the "black doctor" would disappear. There remained the general practitioner. He had had in his hands a list of medical men in the neighbourhood of Hampstead who had offered to serve the Hampstead General Hospital a certain number of mornings or afternoons a week. Perhaps such arrangements might be the means of breaking down the lines of caste between the consulting officer and the general practitioner. When all these possible sources of supply had been considered, however, they had to face the fact that it was the War Office which had "spoilt the market" for resident officers. In twenty-six London hospitals which in July, 1914, had 104 resident officers, there were now only 81. In one hospital with which he was connected there was no resident medical officer at all, and another had to depend upon a gentleman of foreign birth who was not quite familiar with the English language. It would be well to discover, first, whether all the available supply was being used, and then to endeavour to bring about co-operation between the military authorities and the voluntary hospitals so as to ensure the most effective distribution.

Mr. E. W. MORRIS, Secretary of the London Hospital, sent a letter in which he gave particulars of the arrangements which had been made at that institution to cope with the difficulty:

1. The War Office has agreed that all men newly qualified shall apply direct to the War Office for a commission if suitable, but they shall be referred back to the hospital, if they have qualified from the hospital, to do three months' practical work in house appointments before being called up.
2. All present holders of house appointments shall be given a commission at once, but shall be liable to be called up at forty-eight hours' notice when required for training, but not more than five shall be called up at any one time.
3. When they so call up the residents they shall replace them by lending R.A.M.C. qualified men to fill the vacancy.

Mr. Morris added that at the London Hospital for the last five weeks they had been served by seven Canadian doctors, who had done splendid work, and when these were suddenly called up the Bethnal Green military hospital at once offered the services of four or five of their doctors to tide over the difficulty until the arrival of the reinforcements.

Mr. G. ACTON DAVIS, Treasurer of St. Bartholomew's Hospital, said that the arrangement which his hospital had come to with the War Office was similar to the one obtaining at the London, with the exception of the last condition (that of the lent R.A.M.C. men), which in their case did not apply.

Sir GABRIEL THOMAS said that at the Royal Gwent Hospital at Newport they had got the advanced medical students to help them, and the experiment had proved very successful. In addition, two of the consulting staff—he was one of them—were doing casualty work.

Dr. T. JENNER VERRALL said that although the policy of

the War Office in tapping the sources of newly qualified graduates, who were the very men the hospitals wanted, was quite justifiable from their point of view, it was incumbent upon the military authorities to see that as little damage as possible was done to the hospitals. The plan of temporary commissions was an excellent one. He could speak for his Committee of the British Medical Association when he said that, in their negotiations with the War Office, while necessarily the needs of the army came first, they would do their best to see that the needs of the civilian hospitals were a good second.

Dr. ALFRED Cox, Medical Secretary of the British Medical Association, was of opinion that the source of supply represented by the local practitioners had not been used as it might have been, either for the needs of the War Office or for the civilian population. This fact had been brought home to them in the Association while compiling the war register. One speaker had suggested that many of the medical men in the army were wasting their time. This was a matter upon which strong and divergent views were current. There were those who maintained that there was no real wastage, and others also pointed out the importance of the men being at hand, even if they were not fully employed, so that the authorities could reach them. At the same time, he thought it quite possible for the War Office to allow some of these men whose time was not fully occupied to do hospital work until actually wanted.

Major JAMES GALLOWAY thought that the principle of "seconding" might very well be extended to a greater degree. He had come across numbers of medical officers from the Dominions, some of whom jumped at the idea of taking up work in connexion with the London hospitals.

Mr. BUCHANAN, after replying on the discussion, moved:

That it be referred to the Executive Committee (of the British Hospitals Association) to collect information with a view to securing that all possible means of supply of resident medical officers are made available, and also to endeavour to bring about co-operation between the War Office and Admiralty and the voluntary hospitals in effecting such redistribution of medical officers as may be mutually advantageous.

Sir WILLIAM COLLINS seconded, and this was agreed to.

REPORT OF THE MURRAY COMMITTEE ON DISABLEMENT.

In a leading article in this issue we deal with the question of providing for the disabled soldier, both in its general aspects and in its relation to the Naval and Military War Pensions Bill, which has been hung up by the House of Lords. As opposition was offered to the bill on account of the machinery which it proposes to set up, it may be useful to summarize the arguments and findings of the Committee¹ appointed by the Local Government Board in February last to report upon the provision of employment for sailors and soldiers disabled in the war; the bill placed before Parliament was framed to a greater or smaller degree upon their recommendations. The Committee, of which Sir George Murray was chairman, proceeded with their inquiry from the premise that the care of the men who had been disabled was an obligation which should fall primarily upon the State, and that the award of a pension did not extinguish the liability. At the same time, it was agreed that the best results of State action could only be secured with the co-operation of voluntary associations and individuals who take an interest in the welfare of the men.

The first of the Committee's suggestions was that the State should take a more liberal view of its duties on discharging men from the navy or army. The discharge is governed generally by the evidence of unfitness for any future return to active service, and with it ceases the responsibility of the naval and military authorities so far as further medical or surgical treatment is concerned. In the opinion of the Committee, the State should assume the responsibility for further treatment when this is likely to improve the condition of the case. Some of the men

are discharged from the hospital still suffering from such conditions as heart disease or rheumatism, and these should have the prolonged or special after-treatment which may be necessary when there is a reasonable prospect of their restoration to health and resumption of a civil occupation. Sufferers from tuberculous disease, if not eligible for sanatorium benefit under the National Insurance Act, should be dealt with in a residential institution. With regard to those who are mentally affected, the extreme measure of confinement in a lunatic asylum should be taken only when it is clear that treatment in some other institution less prejudicial to the man's industrial future is unavailing or attended by circumstances of danger. There remains that large class of cases in which, owing to loss of limbs or other cause, surgical appliances are required before civil employment can be entered upon. In a list of 3,000 discharges for all forms of disablement covering the first eight months of war, the proportion of cases in which amputation of leg, arm, or hand was necessary was 13.6 per cent. The present practice by which the disabled are supplied with surgical appliances is, in the opinion of the committee, sufficiently liberal, although they think that greater advantage might be taken of recent advances in orthopaedic surgery. Their recommendation is that instead of the appliance being prescribed by the doctor in attendance on the patient, any man requiring an artificial limb should be seen by an orthopaedic surgeon, who would prescribe the appliance best suited to the requirements of the individual and his prospective occupation.

A proportion of the disabled will be permanently and completely incapacitated, a further proportion will find employment without assistance. The number to be dealt with from the point of view of employment, therefore, is not so great as the casualty lists might lead one to suppose. In many cases, however, the disabled man, from the nature of his disability or other cause, will be unable to resume the occupation he was following before the war. In that event he should be given the opportunity of learning a new trade, his training to take place, if possible, in the neighbourhood of his home. In the larger towns the training might be undertaken through the existing polytechnics and trade schools. Before being discharged all disabled men should be registered at the labour exchange of the district into which they are going. The work of dealing with these men along the threefold line of restoration to health, provision of training facilities, and finding of employment, should be undertaken through a committee system. The report suggests the setting up of a central committee, which would include representatives of various Government departments, employers of labour, trade unions, and voluntary agencies; with branch committees for Scotland and Ireland, and subsidiary local committees in areas where, owing to the numbers of disabled, these appear to be desirable. The committee would refer tuberculous and other cases needing medical treatment to the National Health Insurance Joint Committee, and the mentally affected to the Home Office or Local Government Board; in orthopaedic cases the proposed committee would act in conjunction with the Admiralty and War Office, as it is held to be desirable that these cases should remain under the charge of the naval and military departments. Such a machinery might even be used more widely, and deal generally with the resettlement of the soldier in civilian life, but the application to other than cases of disablement does not come within the terms of reference. At the time of the report (May) it was estimated that the discharges for disablement by the present date at the end of twelve months of war would be 7,000, and this makes it evident that some organization should be set up with the least possible delay.

DR. H. LEGRAND, of Alexandria, formerly *in tunc* of the Paris hospitals, has been appointed physician to the Sultan of Egypt.

THE death of Count de Siniéy, Doctor of Medicine and Member of the Paris Jockey Club, is announced in *Le Journal*.

THE French Ministry of Commerce has established in the Paris Ecole Supérieure de Pharmacie a department for the study of questions of chemical manufacture, with special reference to the war. The director is Professor Béhal, of the Academy of Medicine.

¹ Report of the Committee appointed by the Local Government Board upon the Provision of Employment for Sailors and Soldiers Disabled in the War. (Cd. 1125) 114.

British Medical Journal.

SATURDAY, AUGUST 7th, 1915.

THE CARE OF DISABLED SOLDIERS.

It is, of course, impossible to say what proportion of the wounded in the present war will be more or less permanently disabled—40 per cent. has been mentioned in the House of Commons—but in any case it is certain that the halt and maimed will be numerous. The number of wounded in the South African war has already been exceeded in the Dardanelles alone. Every feeling of gratitude and humanity will prompt a generous provision in such cases, but even if these sentiments could be ruled out, there would still remain good economic reasons why the men should be cared for and industrially habilitated as far as possible. We cannot have the broken soldier of "The Deserted Village" again dependent on the casual bounty of the parson or of anybody else; and, save when he is completely disabled, the man had far better be in receipt of a wholly or partially self-supporting wage than of a pension, if only because the effort to earn his living will in many cases be the means of saving him from moral collapse.

Under existing arrangements, the rate of State pension in the case of men discharged partially disabled is from 3s. 6d. to 17s. 6d. a week, according to the degree of disability and the domestic responsibilities of the claimant, together with half a crown (discretionary) for each child. In the case of a lost limb the minimum is 10s. 6d. We understand that by agreement between the National Relief Fund, the Soldiers' and Sailors' Families Association, and the Incorporated Soldiers' and Sailors' Help Society, it has been arranged for the last-named body to take over the case immediately on discharge, and to make up the income to 15s. in the case of single men and 25s. in the case of a married man, with 2s. extra for each child, until the recipient is fit for work. These allowances are subject to a medical certificate at any time, and cease at the end of three months unless a very definite medical certificate is forthcoming as to continued unfitness.

The care and employment of the discharged soldier hitherto has been the object of a good deal of voluntary effort, willingly assisted by Government departments, such as the Post Office, and by large employers of labour. There are seven or eight societies whose purpose it is to find work for him, whether he be able-bodied or disabled. Some of them promote emigration, and one other encourages land settlement in this country. In addition to these, the British Red Cross Society has recently announced that the care of the totally incapacitated soldier is work properly to be undertaken by the society so far as its funds allow. Only one body, however, so far as we can gather, provides actual industrial training on any extensive scale for partially disabled service men, and this body, the Soldiers' and Sailors' Help Society, is now opening up large workshops in different districts

for teaching the men a trade, the scheme being a memorial to Lord Roberts. At the present time the society is looking after the needs of some 30,000 men who are on sick furlough or have been discharged disabled.

The critical period for the ex-soldier's industrial future is that of convalescence, particularly its later stage, when, if he has lost a limb, he is getting accustomed to his artificial appliance. It should be said that artificial limbs are supplied free, either through Chelsea Hospital or the Admiralty, up to a certain cost (we believe up to about £15). There are cases, however, in which it may be desirable to equip a man with an artificial limb at a cost exceeding the Government allowance, and in these voluntary assistance is being given, and it is hoped to obtain the State grant in part payment. Two or three months may elapse after the operation before the stump will permit of the limb being fitted, and even when the case is ready there may still be a further delay owing to the large number of waiting cases with which the instrument maker has to deal. Sir Arthur May recently stated that 1,000 men at the present time are waiting for their limbs; from inquiries we have made, we gather that the medical Director-General of the navy was including both the services. In many cases the man is discharged from the naval or military hospital and sent home, the limb perhaps arriving some weeks later; in other cases he is discharged already fitted with the limb, but is faced with the task of getting accustomed to it without skilled aid. In addition to this, it frequently happens that he is the subject of neurasthenia. We have been informed that a large proportion of the men who have been taken in hand by the Soldiers' and Sailors' Help Society show symptoms of this trouble, which gradually disappears as confidence in the future returns.

It is hoped to deal with all cases of amputation and special orthopaedic cases ultimately through Queen Mary's Convalescent Auxiliary Hospitals. As a beginning two houses, together capable of accommodating 300 cases, have been acquired at Roehampton, near London, and a movement is on foot to establish similar hospitals in Scotland and Ireland, where a number of cases are already under supervision. The necessary condition is that the hospitals shall be established near to such cities as Edinburgh or Dublin, so that the orthopaedic surgeons on the consulting staff may be frequently in attendance. Their advice is to be placed at the service of the men, so that they may not have to depend solely upon the advice, no doubt highly skilled, of the instrument makers. It is the purpose of these hospitals, working in conjunction with the societies, to find employment for the men when they have sufficiently regained their strength.

What is known as the educative convalescence which has been instituted in the Princess Louisa Military Wards at Chailey deserves a special notice on account of certain features which, through lack of opportunity, can hardly have been adopted elsewhere. Here, in the heart of Sussex, there was established some years ago the Heritage Schools of Arts and Crafts for Crippled Children as a development of the Guild of Brave Poor Things and the Guild of Play. The association of a colony of handicrafts with an orthopaedic hospital in miniature seemed to make this centre a peculiarly suitable one for the reception of wounded soldiers, and accordingly the military authorities fixed upon this place for convalescent quarters to which men from the London Hospital could be sent down. The

experience has meant much more to the men than a mere stay in a pleasant guest chamber, with dispensary and massage rooms attached, and it has meant even more than instruction in experimental craft classes—rug making, by the way, has proved to be of great recuperative value for shattered nerves. The main point is that the soldiers have been helped on their way to independence by association with the child cripples, whose motto is "Happy in my lot." To each limbless man an orderly has been assigned in the shape of a boy similarly handicapped, and thus the sheer force of example has assisted the soldier to wrestle successfully with crutches, to rise above the swinging, empty sleeve, and "to walk serene in the shadows cast by his depression."

The ideal to be aimed at in all this work for the soldier is that these men should not remain in special workshops after they have become skilled, but should take their individual places in the industrial life of the country. To neutralize their physical handicap so far as it affects their industrial ability is not impossible in a very large proportion of cases, but it is, nevertheless, a great task which will require all the skill that State and voluntary organization can bring to bear upon it. The combination of State and voluntary assistance is likely to be affected considerably by the Naval and Military War Pensions Bill, which was founded, more or less, on the report of the committee appointed by the Local Government Board last February to consider and report upon the methods to be adopted for providing employment for soldiers and sailors disabled in the war. This committee advised that the care of soldiers and sailors disabled in the war was a duty which should be assumed by the State. This care would include the restoration of the man's health where practicable, the provision of training facilities if he desired to learn a new trade, and the finding of employment for him when he stood in need of such assistance. The committee advised that a central committee and local committees should be appointed, and the bill proposes to set up a Statutory Committee of the Royal Patriotic Fund containing representatives of the Crown, the Treasury, the Admiralty, the Army, the Insurance Joint Committee, and the Local Government Boards in England and Wales, Scotland and Ireland, as well as the Fund itself. The bill as originally drafted proposed to include also representatives of the governing body of the National Relief Fund (commonly called the Prince of Wales's Fund) and the Soldiers' and Sailors' Families Association, but as some members of the National Relief Fund did not think they were justified in handing over the funds entrusted to them by the public to be administered by any other body the representatives of the Fund and of the Association were omitted from the bill as it was passing through the House of Commons. The bill proposes that the local committees shall inquire into cases referred to them, distribute grants made by the statutory committee, and collect and distribute funds locally.

This arrangement has been strongly criticized, and, indeed, the measure is regarded unfavourably by many, if not all, of the voluntary organizations which are concerned for the welfare of the soldier. The fact that some such measure is advisable, even inevitable, is admitted, but the misgiving on the part of the voluntary organizations is due to the possibility that, without a greater leavening of voluntary representation, a system may be set up having all the unyielding officialism of labour bureaux, whereas a more personal interest and sympathetic treatment

may rightfully be claimed on behalf of those who have suffered so grievously for their country. The bill has now been hung up by the House of Lords, partly on the ground that there had not been sufficient time for its consideration, partly because it excluded the representatives of voluntary associations from the central statutory committee.

PLAGUE, CHOLERA, AND YELLOW FEVER IN 1913.

The large number of readers who studied Dr. Bruce Low's valuable reports on the dissemination of plague and cholera throughout the world, which have been published by the Local Government Board during the last sixteen years, will be glad to learn that Dr. Low's retirement has not led to the discontinuance of the practice of issuing such a return.

The report now issued, which is the work of Dr. R. W. Johnstone,¹ differs from its predecessors in being a separate publication, instead of an appendix to the annual report of the Board's medical officer, but the manner in which the information is presented follows the general lines of previous reports.

So far as plague is concerned, the state of affairs in 1913 did not differ markedly from that recorded in 1912. In India, which has borne the brunt of the attacks which commenced in 1894 and have spared so few parts of the globe, there was a considerable decline in the number of recorded deaths—217,145 in 1913 as against 306,088 in 1912. Unfortunately 1914 has been less favourable, 227,149 deaths having been returned for the first nine months of that year. The work carried out under the auspices of the Advisory Committee for Plague Investigations in India has considerably increased our knowledge of the disease both in its epidemiological and bacteriological aspects, but the practical difficulties of sanitary administration in such a country as India are enormous, and should be borne in mind by armchair critics.

No case of plague in man occurred in England and Wales during 1913. Seven plague-infected rats out of 4,359 examined in the Port of London, and 1 out of 4,218 in the Port of Liverpool, were the only manifestations of the disease in the great shipping centres. On the other hand, the restricted area of East Suffolk, which has been of so much interest to epidemiologists since 1911, had not reverted to its normal condition. Two plague-infected rats were found on a farm in the Samford rural district, while 3 out of 5 ferrets, which had died after feeding on a rat in the Woodbridge rural district, were shown to be infected.

In some places there was an unusual mortality among rats, while elsewhere there were complaints of much illness and many deaths among ferrets. Some keepers lost all their ferrets in this way. It appears probable that the original source of the infection was the landing of infected rats from grain ships in the port of Ipswich, although strict proof is lacking. The sequence of events illustrates the well known epidemiological truth that a concurrence of several favouring events is necessary for the development of an epidemic. A still more striking illustration is the failure of a widespread prevalence of plague among the ground squirrels (*Citellus beecheyi*) of California to generate an epidemic.

Passing to the subject of cholera, there has again to be recorded an absolutely heavy mortality in India,

¹ Reports to the Local Government Board on Public Health and Medical Subjects. New series, No. 104. Dr. R. W. Johnstone's Report to the Local Government Board on *The Progress and Diffusion of I. Plague, II. Cholera, III. Yellow Fever, throughout the World during the year 1913*. London, 1915. (3s.)

296,000 deaths in the eleven provinces for which the returns were complete when Dr. Johnstone's report was being prepared. The rate is, however, below that of 1912 (1.71 per mille in 1912, 1.21 in 1913). Bengal, Bihar and Orissa, and the United Provinces of Agra and Oudh, with 52 per cent. of the population under notice, contributed 71 per cent. of the deaths from cholera.

As Dr. Johnstone points out, all the circumstances likely to favour the development of cholera are to be found in India. Thus the congregation of multitudes of pilgrims in places affording inadequate sanitary accommodation, shelter and water supply must be a fruitful source of danger, while the ordinary level of hygienic knowledge is still, notwithstanding the efforts of the Central and Provincial Governments, deplorably low.

Japan had little cholera in 1913—78 cases with 22 deaths, as compared with 2,728 cases, 1,678 fatal, in 1912. This is a repetition of the experience of 1910 and 1911, the latter being a year of slight and the former of relatively heavy cholera mortality. In Europe, apart from the Balkan war zone, there was a widespread epidemic in Roumania, 5,680 attacks with 2,926 deaths coming under official observation. This may have been, to some extent, an aftermath of the Balkan war, a remark which also applies to the recrudescence of the disease in Austria-Hungary, since the earliest cases in that empire were reported from frontier districts abutting on Serbia and Roumania. The cases in Austria proper were scattered. About 1,200 seem to have occurred in Hungary. In European Russia 469 cases with 228 deaths were notified, fewer than in any of the six preceding years, except 1912. No cases of cholera were reported in England during 1913, although some occurred in ships bound for this country.

The most interesting section of the report relative to yellow fever is that which touches on Nigeria. During 1913 some 29 cases were notified in Lagos, the first person attacked being a European who had arrived two days before from Abeokuta, a town fifty miles to the north. At least two cases at Lagos occurred on ships, and the exact total for the colony cannot be stated. Dr. H. Seidelin was sent to assist in the investigation of the disease, and he confirmed the results of Drs. J. W. Scott Macfie and J. E. L. Johnston as to the presence in the blood of patients of certain bodies with which the name of Dr. Seidelin is associated, and which he regards as the specific parasites of yellow fever. The workers at Lagos found these bodies in practically every case; they experimentally infected dogs, white rats, and guinea-pigs, and found very similar bodies in the blood of two stray native dogs. If these results are confirmed, Sir Patrick Manson's suggestion that possibly dogs or other animals might act as reservoirs of the yellow fever virus will be verified. That human carriers may be of importance is also suggested by Dr. Seidelin, who has found the "yellow fever bodies" in the blood of apparently healthy persons. The whole subject is engaging the attention of a Colonial Office Commission, and the time has not yet come for a final judgement. As usual, the incidence of yellow fever in 1913 was practically confined to certain areas of Central and South America and to that portion of the West Coast of Africa which is between Senegal and French Congo.

Among the minor calamities of the great war must be reckoned the fact that the report for 1914 will hardly be comparable with Dr. Johnstone's survey for 1913.

HERBALISTS AND DEATH CERTIFICATES.

The action of the registrar of births and deaths at Westleigh in refusing to accept a "death certificate" signed by an unqualified practitioner named Charles C. Abbott, styling himself a medical botanist, is much to be commended. Upon this refusal the death was reported as "uncertified" to the coroner, who very properly issued his order for an inquest. From the report of the inquest in the *Livings Chronicle* of July 30th it appears that the deceased was a child, aged 11 months, the daughter of a collier. The child had been attended at various times by the herbalist, and on July 6th last, being ill, was seen by Abbott, who diagnosed inflammation of the lungs and brain. He continued attending until July 21st, when the child died, and a certificate was given and signed by him stating that death was due to bronchial pneumonia and meningitis, and giving the duration of the illness as fifteen days. At the inquest Dr. Pickup gave evidence that he had made a *post-mortem* examination and that death was the result of bronchial pneumonia and heart failure; he expressed the opinion that had the child been attended by a qualified practitioner it would have had a better chance of life. The coroner pointed out to the jury that "a herbalist had a smattering of knowledge which might be dangerous and might do no end of harm and lessen a child's chances of life. Medical men had special knowledge. . . . He wished some one would take the case up." The jury returned a verdict of "Death from natural causes." It is quite clear that in this case an offence under the Apothecaries Act, 1815, has been committed; and if other cases could be brought forward in which it could be proved that Abbott had prescribed and dispensed for patients suffering from medical, as opposed to surgical, diseases a prosecution by the Master and Wardens of the Society of Apothecaries should be instituted. We note that the coroner stated in his summing up that the mother "might be morally liable for not calling in a doctor, but she was not legally nor criminally liable." We venture to differ from the learned coroner on this point; under the Children Act, "failure to provide adequate food, clothing, medical aid, or lodging, is deemed to be neglect in a manner likely to cause injury to health." In this case it is clear that, according to the medical evidence, the child's chance of recovery was imperilled by the failure to provide adequate medical aid; and a prosecution under the Act would follow this neglect. In 1909 Dr. Niven, the Medical Officer of Health of Manchester, in a report upon the Act prepared for the Infant Life Protection Committee of that city, pointed out the importance of this section, and took legal opinion as to its bearing upon the question of unqualified attendance and the carrying out of the advice given. Failure to secure medical aid (and by this is meant qualified medical attendance) is therefore a penal offence under the Act, and its provisions should be enforced against parents where such aid is procurable and not afforded to the child whose condition requires it. It may also be noted that the unqualified practitioner who attends children can himself be prosecuted for aiding and abetting in the neglect. In the BRITISH MEDICAL JOURNAL of July 3rd, 1909, we commented upon the prosecution of a woman named Hannah Forrest, who treated a child who had been seriously burnt. The magistrate fined her 20s. and costs. The prosecution was carried out under the Accessories and Abettors Act, 1861, section 8, which enacts that any one who shall aid, abet, counsel, or procure the commission of any misdemeanour either at common law or by virtue of any Act passed or to be passed is liable to be tried, indicted, and punished as a principal. This Act might with advantage to the public well be put in operation more often against quacks and unqualified practitioners, who, by their attendance, lull parents to a false sense of security and thus prevent qualified advice being sought in time to save life.

ANTITYPHOID INOCULATION IN FRANCE AND ELSEWHERE.

COMMENTING on the fact that it is only quite recently that the inhabitants of Paris have ceased to entertain unnecessary fears about the alleged dangers of antityphoid inoculation, Landonzy¹ describes a series of 600 antityphoid injections administered to a hundred and fifty men, women, and children (mostly adolescents) at the Léon Bourgeois dispensary of the Laënnec Hospital. Each patient received four hypodermic injections at intervals of a week, generally in the subcutaneous tissue between the border of the left scapula and the spine, at 9 a.m. Two cachets of aspirin were handed to the patient, to be taken at noon and 6 p.m. if necessary; they were, however, only exceptionally required. Sometimes the effect of the inoculation was to make the shoulders feel bruised or the arms heavy, but it rarely prevented the patient from working; on one occasion a patient fainted for a short time immediately after the injection, and in four instances there was fever over 102° F. lasting from six to forty-eight hours. In no case was there evidence of local inflammation; the occurrence of menstruation is no contraindication to the inoculation. Chantemesse,² discussing Landonzy's paper, added that at the hospital of the Polytechnic School he had inoculated 3,722 persons between the ages of 2 and 55 against typhoid fever since August, 1914. There had been no abscesses, no septicaemias, no fainting fits, and no deaths as a result of the inoculations. In most cases he had vaccinated or revaccinated the patients to protect them from small-pox, at the same time, inoculating one arm and vaccinating the other. He warmly recommends the practice, because the inconveniences of the inoculation, if there are any inconveniences, manifest themselves within a period of three to five hours, whereas the vaccination gives rise to no discomfort before the fourth day. He continues to employ the heated cultures for antityphoid inoculation, similar to those first employed by himself and Widal in 1888. These cultures contain the typhoid bacilli intact, and as they are intact the absorption by the patient of the toxic substances they contain is necessarily a slow process, and thus the danger of anaphylactic symptoms is minimized. If the typhoid cultures are sterilized, not by heat but by chloroform or some analogous substance, the bodies of the bacteria may be broken up and their toxins set free in the fluid used for injection, increasing to an undesirable extent the rapidity with which they are absorbed by the patient and the danger of unpleasant reactions. On this point Chantemesse differs from Castellani,³ who employs for immunizing inoculations phenolized emulsions of bacteria grown on agar, rather than broth cultures sterilized by heat, arguing that his emulsions give rise to less painful local reactions than do the broth cultures. For the last ten years Castellani has employed combined bacterial vaccines for immunizing human beings against infectious disorders. Chantemesse, as has been stated above, has vaccinated many patients against both typhoid fever and small-pox at the same time. Castellani goes very much further in the same direction. His mixed typhoid + paratyphoid A + paratyphoid B vaccine, introduced in 1905, and his typhoid + paratyphoid A + paratyphoid B + cholera vaccine, are now being employed, he says, in both Switzerland and Italy, and give excellent practical results. The second of these vaccines contains per cubic centimetre 500 million typhoid bacilli, 250 million each of paratyphoid A and B, and 1,000 or 2,000 million cholera vibrios; the first dose is 0.5 to 0.6 c.c.m.; the second and third injections, given subsequently at intervals of a week, are twice as large. Another of his compound vaccines contains the bacteria of cholera + plague + typhoid + paratyphoid A and B + Malta fever;

a fourth, even more complex, immunizes simultaneously against infection with typhoid + paratyphoid A and B + Shiga Kruse dysentery + Flexner dysentery + Hys Y dysentery + Flexner-simile No. 1 dysentery + Flexner-simile No. 2 dysentery. His animal experiments show that rabbits, at any rate, cannot as a rule be satisfactorily vaccinated with more than three varieties of bacteria at once. In man, however, the above vaccine prescriptions, and others like them, do give satisfactory results. Castellani adds that the presence of 0.5 per cent. of phenol in his vaccines suffices to sterilize them, usually in twenty-four hours. Other writers, however, refer to his antityphoid vaccine, prepared as is described above, as a vaccine of living bacteria. Thus Carlo Fulle,⁴ in a synthetic review of antityphoid inoculation in armies, describes all Castellani's vaccines as containing living bacteria. Fulle gives the official statistics of the antityphoid inoculations carried out in the armies of Europe, Japan, and the United States of America, during the last few years.

ECONOMY IN FOOD.

We have received from the Board of Education a pamphlet entitled *Economy in Food*,⁵ which gives information very similar to that furnished in the Board's circular relating to meals for school children, but is adapted to the needs of families. Examples of one and two course dinners are given, the quantities being those deemed sufficient, with $\frac{1}{4}$ lb. bread, for a family consisting of father, mother, and four or five children, and notes on cooking are added. The information provided should be of value, but we are bound to say that in some respects the pamphlet bears marks of hasty preparation. Thus, as we have said, the quantities are stated to be sufficient for "one meal for a family consisting of father, mother, and four or five children." This is surely a very loose statement. Again, in the preface, signed by the Minister for Education, it is said that the whole matter can be summed up in the precepts: (1) Buy economically; (2) prepare carefully; (3) avoid all waste. To some extent information is furnished which will be useful in enabling the reader to conform to the two latter precepts, but no suggestions of value are made as to economical marketing, although it is notorious that one of the great difficulties of the poor is that their ordinary methods of purchasing food are extremely costly. The Board has also issued a circular to local authorities on the same subject, advocating, among other things, the organization of further instruction, and, in addition, special regulations for grants in aid of such instruction for housewives in economical cookery are promulgated. The Board is undoubtedly taking a step in the right direction; whether much progress will be made so long as the poor have before their eyes the spectacle of waste on an enormous scale to which we recently directed attention in the case of the troops, is a question to which we are not prepared to give a dogmatic answer.

QUACKERY IN THE EIGHTEENTH CENTURY.

QUACKERY is as old as human credulity, and that is as old as mankind itself. The methods of the pretenders who profess to cure all diseases remain essentially the same, because the mind of this foolish compounded clay man accepts their promises with all the greater readiness the more loudly and confidently they are made. Steele, in the *Spectator* of July 30th, 1712, says: "There is hardly a man in the world, one would think, so ignorant as not to know that the ordinary quack-doctors who publish their great abilities in little brown billets distributed to all that pass by are to a man impostors and murderers; yet such is the credulity of the vulgar and the impudence of these professors that the affair still goes on and new promises of

what was never done before are made every day. What aggravates the jest is that even this promise has been made as long as the memory of man can trace it, yet nothing performed, and yet still prevails." He proceeds to give examples which read very like the quack advertisements of the present day, though the style is coarser and there is a less subtle display of pseudo-scientific knowledge. The eighteenth century quack states, without any flourishes of language, that he "cureth all diseases incident to men, women or children"; he specially mentions "the yellow jaundice, green sickness, scurvy, dropsy, long sea voyages, campaigns, and women's miscarriages, lying in, etc." Surely an odd enough medley of afflictions without the strange appeal that follows: "as some people that has (sic) been lame (!) these thirty years can testify." Another grounds his pretensions to cure cataract on the fact that he has lost an eye in the emperor's service; while another claims the possession of special skill in the cure of "bursten" children by declaring that his father and grandfather were both "bursten." Had he said that he had cured himself of rupture such a statement might have seemed to have some show of reason, on the principle that "who drives fat oxen should himself be fat." A correspondent has sent us a copy of *The Daily Advertiser* of September 7th, 1753, containing advertisements which show the impudence of the eighteenth century quack, and also the prevalence of venereal diseases. Mingled with announcements of the publication of a *Life of Joseph Addison, Esq.*, and a *Defence of the Most Essential Articles of Christian Belief against the Caricatures of Modern Atheists*, we find a proclamation by one Dr. Cam "a graduate physician" who announces himself as the author and vendor of several treatises on venereal diseases, of the efficacy of his "short and easy method of curing the Grand Pox, without salivating, vomiting, or any other irksome operation by a true specific lately discover'd, which performs the cure without any disorder, sickness, confinement, or alteration of diet; and is so wonderfully easy in its operation that persons emaciated and weaken'd by the distemper or other tedious or unsuccessful courses are hereby miraculously relieved." The difficulty about salvarsan and the substitutes suggested for it under the stress of war might have been avoided if Dr. Cam's specific had not been allowed to die out of human memory. In another advertisement the pensive public is solemnly warned against "the woman that imposes at the Royal Exchange her counterfeits of the remedies belonging to Dr. Chamberlen's only right and true famous anodyne necklace for children's teeth, fits, fevers, convulsions, etc." "The cheat," it is stated, "is easily discover'd if you have not got the *Family Almanack*, the treatises on the gout and rheumatism and venereal distemper and a gleet and all the author's other books given you gratis along with your medicines." What, one cannot help wondering, was the *Family Almanack*? Was it given away to sell the treatises on gleet, as it was the fashion a short time ago to tempt purchasers of a pound of tea? The advertiser, Mr. Bradshaw, who describes himself as Dr. Chamberlen's servant, insists that his customers must get the genuine article. "When," he asks with withering satire, "shops will take in and sell what the owners of such shops positively know to be downright counterfeits and take them into their shops to catch mistaking customers, how are they to be depended on for the Duffy's and Stoughton's Elixirs, Heart Burn Lozenges, Hungary Water and other things they sell?" How indeed? Probably the people who doctored themselves with Duffy's elixir and Hungary water did not suffer much from taking "counterfeits." Where are these things now? *Où sont les neiges d'antan?* But however completely even the memory of such specifics may perish, others will take their place. Laws and learning may die, but quackery will thrive till it fades into nothingness before the spread of the light of scientific truth.

PUBLIC HEALTH IN AUSTRALIA.

The evolution of hygiene and public health in Australia was the subject of a lecture delivered a short time ago to the Royal Sanitary Institute by Dr. W. Perrin Norris, chief medical officer of the Medical Bureau of the Commonwealth. Hygiene, he said, had uses both for scavenger and statesman, and in its name not only might the food adulterator be indicted, but also the pedagogue who injured the people by inculcating a lie; while health, he insisted, was a positive quality, consisting largely in a capacity of adjustment to circumstances, and was incomplete without that joy of life which he claimed as an Australian characteristic. So joyous was the Australian temperament, indeed, that one observer had pronounced it Gallic; doubtless it was partly the result of the most pacific and equable climate of all the continents. Dr. Norris then surveyed the political and social history of Australia from the first British settlement, previous to which, he said, Australia was entirely free from the communicable diseases of the Old World. The early settlers brought with them certain results of their distinctly unhygienic environment, and also, for both better and worse, their national and local traditions. British they were, however, and British Australia still was—97 per cent. of her. The first definite evidence of any movement in the direction of preventive medicine was in 1803, when the Governor of New South Wales asked the Colonial Office for a supply of vaccine. In 1828 the first ship known to be infected was placed in quarantine. Since that time small-pox had obtained a temporary foothold on twelve occasions, and each time the disease had been stamped out by preventive measures. Up to the present it could not be said that small-pox was endemic in Australia. Coming to the legislation more particularly of the last twenty years, Dr. Norris said that the public health policy in Australia differed from that in Great Britain by reason of the definite power and activity of the centralized authorities in the daughterland. They had realized that municipal boundaries might not coincide with public health needs, and the tendency had been to take action irrespective of such boundaries. The practice of amending and tinkering old Acts had been superseded by the system of making new laws to meet special circumstances. The object had been formation rather than reformation, as became a country which was in the course of rapid self-construction. Dr. Norris instanced the regulations as to food purity, which, he said, were enforced not by inspectors, who might earn distinction by the number of scalps they carried in their belt, but by supervisors, whose care it was to reduce adulteration by educational measures among others. Australia had the highest natural increase of population of all countries in the world except one, and the proportion of males to females—male preponderance being at one time enormous—was being satisfactorily adjusted; it was now 107:100. The death-rate for 1911-12 was 10.35, the lowest in the world except that of the sister dominion of New Zealand, and the infant mortality was now below 70, and in one State only 60. There were still lions in the path to the kingdom of hygiene, even in Australia, and of these he instanced an insufficient quickness of the social conscience, and the danger of an unmoralized commercialism. As furnishing the key to still more important hygienic advances he looked to the science of eugenics, now in the course of development.

THE RATION OF THE FRENCH SOLDIER.

In recent sessions of the Academy of Medicine the service rations of the French army have been subjected to criticism by several distinguished authorities. At the meeting of July 6th, M. Armand Gautier presented a paper entitled "Dans la ration actuelle du soldat en campagne, il faut diminuer la viande et augmenter les légumes et le vin."¹

¹ *Bulletin de l'Académie de Médecine*, 1915, No. 27.

M. Gautier began by pointing out that while analysis of the dietaries of labourers in France and Belgium had established the fact that an energy equivalent of 3,900 calories in summer and 4,300 in winter should be furnished, the official active service ration provided but 3,200. He held that the official diet was already somewhat too rich in animal protein and advocated the provision of mixtures of cooked and preserved vegetables and meat on the lines proposed by MM. Basset, Pietre, and Goulut. One suitable formula gives for each tin 300 grams chopped beef, 20 grams fat, 100 grams carrots, 12.5 grams onions, 40 grams concentrated bouillon, 3 grams pepper and spices. The calculation refers to the ingredients in the uncooked state. In this way a daily addition of 400 to 500 calories could be made. Of the remaining 500 to 600 calories required, a certain quantity, some 200, could be provided by the addition of sugar, preferably in the form of chocolate, but this would be the maximum permissible addition without violating the rule that the daily consumption of sugar ought not to exceed 80 grams. The remaining calories needed should, in M. Gautier's opinion, be furnished by the addition of 50 centilitres of wine at 10° C., making the total daily issue of wine 75 centilitres. M. Gautier is a strong advocate of the use of natural wine in this way; he emphasizes the advantage of rapidity of absorption and the beneficially stimulating effects upon the nervous system which he claims for it, and points out that such advantages are not possessed by an equivalent quantity of alcohol given in the form of strong spirit. At the following session of the Academy² MM. Vidal and Landouzy energetically supported M. Gautier's proposition, and argued that the most efficient weapon in the campaign against alcoholism was to be found in the judicious use of the natural wine of the country. It was pointed out that, in general, the districts in which alcoholism was rampant were not the vine-raising areas, and the enormous evils of spirit drinking were emphasized. M. Vidal and other members desired to have these conclusions expressed in a formal resolution of the Academy, but the perpetual secretary having pointed out that to do so would infringe a rule of the Academy, the proposals were remitted to a commission charged with the preparation of a report. The two arguments in favour of the use of wine—(1) the dietetic argument, (2) the argument for its use as a prophylactic against alcoholism—are logically quite distinct, and it will probably be thought that, simply on the evidence presented in these communications, the case in favour of the second is the more cogent. On the dietetic side, the ordinary physiological objections, namely, increased heat loss due to cutaneous vaso-dilatation and the hypnotic effect following the transitory stimulation, are not dealt with, not to speak of the practical point raised by Major Lclean in the valuable lectures reported in our columns and since published in book form,³ namely, the danger that men will purchase the alcohol rations of tectotal comrades, and consequently that some individuals may obtain a grossly unhygienic amount. The question of wine rations is not, perhaps, one which has much direct importance for our own service, but its indirect importance is great and the findings of the commission will be awaited with interest.

WAR EMERGENCY COMMITTEE.

THE new special War Emergency Committee has already met twice, and has appointed Dr. T. Jenner Verrall as its Chairman, Dr. A. E. Shipley, F.R.S. (Master of Christ's College, Cambridge), and Mr. E. B. Turner as Vice-Chairmen, and Mr. Bishop Harman and the Medical Secretary as Secretaries of the Committee. Professor Harvey Littlejohn, Dean of the Faculty of Medicine, Edinburgh University, has been co-opted as a member, and other prominent members of the profession have been

invited to accept membership. A conference has been held with Sir Alfred Keogh, who has cordially welcomed the proffered services of the new Committee, and has promised it his active support and co-operation. The Committee proposes at the earliest possible moment to place the immediate necessities of the War Office for a large supply of medical officers before all members of the profession not at present giving whole-time military service.

Medical Notes in Parliament.

Territorial Medical Officers.—Lord Newton, in replying to a question by Lord Harris in the House of Lords on July 27th, explained that the position as between the Territorial Force medical officer and the civilian practitioner who had been granted a temporary commission since mobilization was as follows: The Territorial Force officer was paid at the same rate as the Regular R.A.M.C. officer, except that unembodied service did not count for increase of pay in the same rank. Both Territorial and Regular officers of junior rank were paid less than civilian surgeons commissioned as lieutenants and serving on a special war contract. The inequality had existed since the date of mobilization, and he was afraid it was inevitable in war. It was very difficult to see how the inequality or injustice could be rectified, but he would remind his noble friend that a concession of some value had been made to the Medical Corps in view of the admirable service performed, lieutenants of six months' service having been promoted to the rank of captain. He believed the question was still under the consideration of the Treasury and the War Office.

Dental Surgeons.—Mr. Tennant, in replying to Sir Henry Norman on July 28th, said that there were no consultants in dentistry to the forces abroad. There were forty-eight qualified dental surgeons serving abroad and forty-eight at home with the rank of lieutenant. There were also ninety-three honorary consulting dental surgeons at home. These numbers did not include the dental surgeons employed by local military authorities at home nor those doing duty with Colonial troops. Sir Henry Norman subsequently asked if it was intended to add to the somewhat meagre number of dentists with the forces abroad, and Mr. Tennant said that he had heard no complaint that there was any requirement to that effect.

Royal Assent.—The following were among the measures which received the Royal Assent prior to the adjournment of the House of Commons on July 29th till September 14th: Notification of Births (Extension) Act, 1915, Milk and Dairies (Consolidation) Act, 1915, and the Scottish Universities (Emergency Powers) Act, 1915.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

THE following subscriptions to the Fund have been received by the Treasurer, Dr. Des Voeux:

Thirty-fifth List.

	£ s. d.	£ s. d.
North of England Branch of Fund (per Dr. Jas. Don and Mr. A. S. Percival, Hon. Secs.) (eighteenth donation, total 2771 18s. 9d.)	1 1 0	7 12 6
Dr. S. Robson	1 1 0	
Northumberland Pharmacists' Society (per Mr. G. R. Patterson)	1 1 0	100 0 0
Warrington Pharmacists, collected by Mr. H. M. S. Hill (per Dr. Murray, Hon. Sec., Warrington Division, B.M.A.)		
Pharmaceutical Society of New Zealand (per Mr. C. M. Nielsen, Registrar)		

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

² *Bulletin de l'Académie de Médecine*, 1915, No. 28.

³ *Sanitation in War*. By Major P. S. Lclean, R.A.M.C. (Churchill).

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

TREATMENT OF FRACTURES.

KIPLING says there are many different ways of constructing tribal lays, and each and every one of them is right. A like statement would apply with almost equal force to methods of dealing with fractures, and consequently references to this subject in these notes have been rare. Only when a newly-devised method meets a desideratum not included in the aims of already approved methods or not secured by them, can one be justified in drawing attention to it. Methods that come within the limits of this stipulation are of necessity rare, but there is one now in use at a stationary hospital for dealing with fractures of the thigh and upper arm, including the elbow.

In the case of the thigh the effect of applying the method—apart from securing absolute immobility of the fractured ends—is as follows: (1) The patient can move himself about in bed quite freely, that is to say, he can let himself down towards the bottom of the bed or pull himself up towards the top; he can move his pelvis right off the bed to a height of 5 or 6 inches; or he can leave his pelvis on the bed and assume a sitting posture. (2) If the fracture is compound the wound can be efficiently dressed without interfering with the splint, and the latter need not be changed even if the patient has to be sent on a journey. The mobility of the patient is secured by attaching the splint by several weighted pulleys to a trolley which runs to and fro, as the patient pleases, on a frame above the bed. This part of the appliance is in fact a reproduction in miniature of the very simple but effective machinery by which heavy weights, such as girders, are moved about in engineering workshops.

On the other hand, the immobility of the fractured ends of the bone is secured by a splint whose general character will perhaps best be suggested by a series of comparisons. It resembles a Thomas's knee-splint because it causes the same force to operate in two opposite directions—*vis a fronte* in the case of the fractured bone, *vis a tergo* in the case of two rigid bars, which are thus driven firmly against an immovable part of the patient's body. It resembles a Wallace because the upward driven bars are parallel and the force is applied by means of a screw-pin cross-bar. Finally, it resembles a Max Page because the portion of the splint which impinges on the tuber ischii is not a loop but a segment of a circle. But while it presents all these resemblances to the splints named, there are so many differences that it is not to be regarded either as a modification of any of them, or even as a combination of all three.

For instance, unlike any of them, the side bars are placed at the level not of the middle but of the upper third of the circumference of the limb. The screw-pin cross-piece, through which the extending and driving force is applied, is operated, not as in the Wallace, by a one-sided lever handle—every movement of which almost inevitably tilts the limb one way or the other—but by a double-grip lever which distributes the screwing force equally on both sides. Unlike the Max Page, the splint is suspended by a counterweight, and this counterweight acts not as in the Thomas and Wallace, from a single point, but is distributed so as to form four independent overhead counterpoises, each of which is self-adjusting. Finally, the bed of the splint is not a series of strips of flannel bandage, but a continuous layer of perforated zinc. This is sufficiently thin to be moulded by the hand, and, thanks to the high level of the side bars to which it is attached, its general form is that of a deep gutter, not a groove. The amount of additional support that it affords is therefore very considerable, while, of course, zinc never sags.

Should it be necessary to evacuate the patient, the suspension apparatus is detached and the splint fixed for the journey to a wooden support.

The general idea of the upper arm and elbow appliance is of much the same order, but the principle of the suspension apparatus is that of a quay-side crane instead of an overhead trolley. The splint itself, moreover, more

closely resembles an ordinary elbow-joint Thomas, except that a zinc bed is substituted for flannel strips.

But the net effect is not less valuable. The injured part is kept steady, the wound is accessible, and the patient is not confined to one position—he can sit up, lie back, or turn on his side.

The use of perforated zinc is not, it should be noted, peculiar to the splints here described. A good many surgeons are now replacing it by the flannel strips otherwise employed with splints of the Hodgett and Thomas types. It has the advantage of never sagging, and, practically speaking, it does not seem to soil. If desired an opening can readily be cut in it for the passage of a drainage tube, but in any case a metal surface is not congenial to microbes.

The only splint of the general order in question to which I have not yet seen it applied is the Max Page. Here, too, a zinc instead of flannel strip bed would probably be a useful modification when this splint is being used, not only at the beginning but throughout the treatment of the case. This is another splint which seems certain to outlive the war. It meets the desiderata of prolonged treatment less completely than the one just described, but is excellently suited to country practice and the purposes to which it is at present mainly being turned. It "caught on" very rapidly at the casualty clearing stations, where it is indeed a blessing to have a means of converting a broken thigh into a painlessly movable limb within the space of a very few minutes. The upper and lower halves can be kept ready and clipped together quickly as soon as the length of the limb to be treated has been ascertained, and the material of which it is built is so light and easily carried that it is never likely to lose its place in the splint boxes of military formations.

I have heard it said that the Max Page tends to slip down the thigh during transport, but this can be the case only when the extension has been carelessly adjusted in the first instance and when the surgeon has failed to take advantage of the fact that the side "irons" can be squeezed in laterally, so as to take the shape of the limb. Another mistake sometimes made is placing the foot support close to the heel, instead of at about the level of the junction of the middle and lower thirds of the leg. In such case there is just a possibility of the side irons bending slightly after long use.

RIDING CLASSES.

The equivalent of a riding school was established a little time ago at one of the remount camps. It is at some little distance from Boulogne, but a motor omnibus has been told off to take out those authorized to attend the classes. The latter are for the most part temporary officers in the Royal Army Medical Corps. All these are liable to be detailed for duty at the front, and their efficiency when thus employed is enhanced by ability to ride. Equestration is one of the subjects in which the regular officers of the Royal Army Medical Corps have to qualify while still in the probationary period of their career, but not until they reach the rank of major do they become entitled to the usual allowance for the upkeep of a horse. Meantime, however, they may have to ride if attached to a field ambulance unit which has been mobilized for the purpose of taking part in training manoeuvres, or if they are placed during such training in medical charge of a cavalry or infantry unit. During actual war operations it is only when employed in like positions that riding is required of medical officers of the rank of captain or lieutenant, but the number of posts which then have to be filled is relatively much greater. Apart from the greater size of a fighting army every large unit, including cavalry regiments, infantry battalions, artillery brigades and analogous bodies of troops, has allotted to it a medical officer. In fact, in war time there is a partial return to the old regimental system. At the present time the phase through which warfare is passing and the circumstances of the moment are combining to reduce—almost to abolish—any immediate necessity for riding on the part of officers of almost every branch of the army, but it is very important not to overlook the fact that at any moment there may be a return to the normal. In that case the mobility of medical officers in charge of fighting troops will automatically again become a matter vital to the general organization for the

prevention of disease in the army as also to the welfare and rapid succour of the wounded during actual battle operations.

Besides this it is of personal advantage to a medical officer to be able to ride even though when at the base he may be able to do the whole of his work without ever mounting a horse. Flanders is not an ideal country for horse exercise—it is too closely cultivated—but in slack times, for instance, when the unit to which a medical officer is attached is resting in billets, an afternoon ride makes a pleasant break.

CASES FROM THE DARDANELLES TREATED ON A HOSPITAL SHIP.

MAJOR W. A. CHAPPEL, M.D., R.A.M.C., sends us the following notes of 71 out of 635 cases. All the cases, with one exception of possible gastric ulcer, were due to wounds or injuries inflicted during the operations at the Dardanelles. The voyage took ten days. (1) There was one case of tetanus; the first symptoms showed on the fourteenth day. Treatment consisted in opening up pockets in the wound and excising away all granulations and sloughing material, applying packs of hydrogen peroxide at first every four, then every eight hours, the injection intrathecally of 6,000 units of antitetanic serum within the first twenty-four hours and intramuscular injections every four hours, then every six, and latterly every eight, of 10 minims of a 1 in 40 solution of carbolic acid. Relapse occurred on the fourth day of treatment, when spasm of the jaw and neck returned, and 2,000 units were again injected intrathecally. The man was quite out of danger on landing, and the temperature had been normal for four days. (2) A violent secondary haemorrhage of the femoral artery at 1 a.m. was met by ligation of this vessel in Hunter's canal. (3) An aneurysm of the femoral had developed five weeks after a bullet wound in the lowest one-third of the thigh. The artery had been tied in Hunter's canal and gangrene had supervened, owing, apparently, to injury done by the bullet to the anastomotic and other vessels upon which collateral circulation would depend. The gangrene extended nearly to the knee, leaving no area of healthy tissue sufficient to cover a stump at the site of election. A Lister's amputation was done at the lowest third, and an uninterrupted recovery followed.

In all, fifteen operations under a general anaesthetic were necessary in the 71 cases; four were for the extraction of bullets revealed by a very excellent x-ray apparatus; four were for cellulitis; three for the removal of necrosed bone; two for abscesses; one for secondary haemorrhage; and one for resetting a simple fracture of the femur.

All the cases improved very markedly on the voyage, which was made in smooth seas. All were cut cases to begin with, but fully half were able to be on deck during the latter half of the journey. The surgical equipment was complete and as satisfactory as in any small modern hospital.

Only two cases will require further surgical treatment immediately—bullets lodged in the spinal column, producing grave peripheral symptoms. If smooth seas could be ensured, the conditions of surgical treatment would be as good as those of most base hospitals. Not more than one third will be fit for further war service, and these only after periods of convalescence ranging from six weeks to six months. In loyalty to the high example of the King and Lord Kitchener, no alcoholic beverage was given during the voyage, and no case arose suggesting its use to which the resources of the dispensary were not equal.

FRENCH WOUNDED IN THE DARDANELLES.

In the *Gazette hebdomadaire des sciences médicales de Bordeaux* of August 1st, Dr. René Celles gives an account of his surgical experiences as principal medical officer of the French hospital ship *Burligata* in the Dardanelles. From what he has seen in a nine months' experience the wounds in the Dardanelles fighting differ from those seen at the Western front. Whilst in France the majority of wounds are inflicted by shells, in the Dardanelles the injuries are mostly caused by bullets. This he attributes to the fact that the Turks are not well supplied with artillery. The wounded men, 500 in number, were all

French or French-Colonial troops, and were hurt in the fighting at Sedd-al-Bahr on May 8th. As a rule, they were seen from four to twelve hours after the infliction of the wounds. The average duration of their stay in the ship was five days. Owing to the shorthandedness of the surgical staff it was possible to make notes of only 170. In 26 per cent. of that number the first dressing was applied by a comrade on the field of battle, in 2.6 by an army medical officer, while the rest were dressed at the ambulances behind the firing line. All reached the ship with wounds relatively clean and in good condition. Almost all had received an injection of antitetanus serum. It has been said that the majority of the wounds were caused by bullets, the proportions being approximately as follows: Bullet wounds, 77.8 per cent.; shell, 11.1; fragment of stone, 1; wounds caused by agents impossible to recognize, 11.1. Many of these wounds were very serious and were much lacerated, especially at the aperture of exit. Dr. Celles says that nearly all the soldiers insisted that the wounds had been caused by explosive bullets. He is convinced, however, that this was seldom the case, although it was impossible to deny that dum-dums were not sometimes used. He instances particularly a case of wound of the testicle, where no hard body could have been struck in the passage of the projectile into the body. The gravity of the wounds he attributes to the excellent shooting of the Turks and to the nearness of the combatants to each other. A rough classification of the seats of injury is given as follows:—Wounds of limbs: (a) Not affecting the joints, 48 per cent. Among these was a considerable number of compound fractures; most frequently both bones of a limb were broken, sometimes all three. Beside the fractured bones there were often large gaping wounds at the bottom of which a large artery could be seen pulsating or bleeding. (b) Penetrating wounds of joints, 14.7 per cent.; most of these were of the knee. Wounds of thorax: (a) Non-penetrating, 4.5 per cent.; (b) penetrating, 11.5 per cent. The organ most frequently injured was the lung. In two cases the heart was wounded; one patient died two hours after receiving the wound; the other survived till the following day. In that case the bullet entered at the level of the right seventh intercostal space slightly outside the nipple line; after passing horizontally through the thorax it came out at the level of the left intercostal space, also slightly outside the nipple line. Through the latter orifice projected a considerable quantity of pre-pericardial fatty tissue. In 4 of 18 penetrating wounds of the chest death occurred within twenty-four hours. Wounds of the abdomen were less frequent (9.6 per cent.), but almost all were penetrating. Among 15 patients four deaths occurred in twenty-four hours. In 3 cases both the thorax and the abdomen were wounded by the same projectile; one died. Wounds of the skull were less frequent. Of these 2.1 per cent. were superficial; they were always accompanied by haematoma and oedema when the face was struck. Of penetrating wounds the percentage was 2.1; in these exposed the underlying brain, which could be seen beating and bleeding. Sometimes there was a cerebral hernia. One man amused himself, till he was restrained, by fingering about in his skull and extracting a foul mixture of blood and brain substance. Three secondary complications are particularly to be dreaded in war surgery—haemorrhage, gangrene and tetanus. Although haemorrhage is frequent, the prognosis is not bad, provided proper treatment can be applied; the best procedure is ligation of the main artery of the limb. Gangrene is very rare. Among the 500 cases there were only two cases. In one there was gas gangrene of the hand and the forearm, coming on three days after a bullet wound; its course was very rapid, and amputation had to be performed at once. Dr. Celles says the only instruments he had at his disposal were a bad bistoury, a dissecting forceps, and a ligature needle; a saw had to be borrowed from the ship's carpenter. Nevertheless, the patient recovered without any complication.

As regards tetanus, of which he saw a great deal in the early months of the war in Europe, there was not a single case in the batch of 500. This he attributes largely to the general use of antitetanus serum.

Speaking of the arrangements for dealing with the wounded, Dr. Celles says the French had two regular hospital ships, the *Canada* and the *Duguay-Trouin*,

specially and comfortably fitted up. These received the wounded in front of the Gallipoli peninsula and took them to Europe, Algeria, and Egypt. During the passage the surgeons could apply all necessary treatment and perform such operations as were urgent. In addition to these, there were several accessory ships—the *Burdigala*, the *Lorraine*, the *Ceylon*, and others—transports or trading vessels requisitioned or mobilized, which took wounded on board if none of the regular hospital ships were available. These accessory ships had no proper equipment and no adequate staff. When the 500 wounded had to be taken on board on the night of May 8th, Dr. Celles had to deal with them single-handed, without even a nurse to help him. The difficulties under which he had to work, owing to the lack of instruments, may be gathered from his account of the amputation for which he had to use a carpenter's saw.

He suggests that a base hospital should be established at some place within a comparatively short distance of the fighting line—for instance, at Lennos—which can be reached in three hours. This should be properly equipped and staffed, and the wounded would be more quickly attended to, and would be saved long sea passages and transshipments, which are very fatiguing and dangerous for those wounded in the abdomen or the chest. The hospital ships would act as transports, and would not lose five or six days in voyages to Europe.

CASUALTIES IN THE MEDICAL SERVICES.

NAVY.

Wounded.

Staff Surgeon E. B. Kenny, R.N., Dardanelles.

ARMY.

Wounded.

Captain P. B. Bharucha, I.M.S. (Persian Gulf),
Lieutenant (temporary) J. Cattinagh, R.A.M.C. (Dardanelles).

Lieutenant (temporary) C. D. Roberts, R.A.M.C. (Flanders).

Lieutenant (temporary) J. S. Stewart, R.A.M.C. (Flanders).

There are two temporary Lieutenants of the name of J. S. Stewart in the R.A.M.C., with commissions dated August 10th and October 5th, 1914, respectively.

DEATHS AMONG SONS OF MEDICAL MEN.

Five such cases have been reported recently, to which are added three older cases.

Concanon, G. L. B., Captain, 2nd Battalion Australian Infantry, killed in the Dardanelles on March 25th, was the only son of Dr. William A. Concanon of Toowoomba, Queensland. He was educated at the Leys School and King's College, Cambridge.

Harley, John, Lieutenant 13th Battalion Worcester Regiment, only son of John Harley, M.D., of Beedings, Fulbrough, killed at the Dardanelles on June 4th. He was born in 1880, educated at Charterhouse and at Trinity College, Oxford, where he took the degree of M.A. He was called to the Bar in 1906, but never practised, devoting himself to research work in the Record Office, and became a Fellow of the Society of Antiquaries. He enlisted in the Artists' Rifles at the beginning of the war, got a commission in the Worcester Regiment on February 8th, 1915, and went to the Dardanelles on May 10th, attached to the King's Own Scottish Borderers.

Irvine, Christopher Theodore Corrie, Lieutenant Indian army, youngest son of the late Surgeon-General G. J. Irvine, R.N., killed in the Dardanelles on June 28th, aged 26. He was born on January 27th, 1889, got his first commission in the Comaught Rangers on December 11th, 1909, became Lieutenant on March 11th, 1912, and joined the Indian army on August 15th, 1914. He was in the 25th Punjab, but when killed was attached to the 69th Pmjabis.

Macpherson, Duncan Stuart Ross, Lieutenant Indian army, only son of Surgeon-General W. G. Macpherson, C.B. He entered the army on April 20th, 1911, and was in the 7th Gurkhas, but was attached to the Black Watch from August 25th, 1914.

Mactier, Henry Mackinnon, Major Indian army, son of the late Surgeon-Major W. F. Mactier, I.M.S. (retired), killed at Nevee Chapelle on March 16th. He was born on July 21st, 1856, joined the Royal Sussex Regiment on December 21st, 1889, and the Indian army on July 2nd, 1891, becoming Captain in 1898, and Major on December 21st, 1907. He served on the North-Eastern Frontier of India, in the Burma and Lushai campaigns of 1892, medal with clasp; in the Chin Hills in 1892-3, clasp; and on the North-West Frontier in the Tirah campaign of 1897-8, medal with two clasps. He was second in command of the 23rd Gurkhas.

Oldham, Leslie William Series, Major Royal Engineers, only son of the late Brigade Surgeon C. F. Oldham, I.M.S., killed in

action July 28th. Major Oldham attained that rank on July 27th, 1909. He commanded the 63rd Field Company of Royal Engineers. He served in the Chitral campaign of 1895 as commanding Royal Engineers of the relief force from Gilgit, was present in the action of Chakalwat and Nisa Gai, was mentioned in dispatches, and received the medal.

Pollard, Edward Branch, Lieutenant King's Own Scottish Borderers, attached to Royal Engineers, son of Dr. Pollard of Moffat, wounded in the head near La Bassée on July 7th, and died in hospital in France on July 26th. His commission was dated December 3rd, 1914.

Thomson, Duncan Turner, Private 9th Battalion Highland Light Infantry (Glasgow Highlanders), second son of Dr. Thomson of 8, Hamilton Park Terrace, Hillhead, Glasgow, died on July 30th at the General Hospital, Northampton, of wounds received in France on June 19th, aged 26.

MEDICAL STUDENTS.

Boyd, R. M. Stewart, Lieutenant 6th Battalion Highland Light Infantry, fifth son of Mr. James Boyd of Athole Gardens, Glasgow, killed in the Dardanelles, was a final-year student of medicine at Glasgow. He got his first commission on May 4th, 1914, and was at first reported as wounded and missing.

Erskine, Thomas Baillie, Second Lieutenant 4th Battalion Argyll and Sutherland Highlanders, attached to the Gordon Highlanders, killed in Flanders, was a medical student at Glasgow. His first commission was dated August 15th, 1914.

NOTES.

SERBIA.

Proposed Establishment of a Baby Hospital.

According to the *Journal of the American Medical Association* the American Red Cross has made arrangements for the establishment of a baby hospital in Serbia, which will be known as the Mabel Grouitch Baby Hospital, in recognition of the Red Cross activities of Mme. Slavko Grouitch, wife of the Under Secretary for Foreign Affairs of Serbia. The hospital will be in charge of Dr. Louise Taylor Jones, Washington, and Dr. Catherine H. Travis, New Britain, Conn., who sailed on the Greek steamer *Constantine* from New York for the Piræus, July 19th. Dr. Jones will act as medical director of the hospital, and expects to return to Washington in October, leaving the hospital in charge of Dr. Travis.

MEDICAL OFFICERS WANTED.

2nd Line Welsh Border Mounted Brigade.

Four medical officers are required immediately for service with the Shropshire Royal Horse Artillery, Cheshire Yeomanry, Denbighshire Yeomanry and Field Ambulance, respectively, of the above brigade. Pay and allowances as in the regular army. Further particulars can be obtained on application to Lieutenant-Colonel D. C. Leyland Orton, Senior Medical Officer, 2nd Line Welsh Border Mounted Brigade, Lambton Park Camp, Chester-le-Street, co. Durham.

1st Wessex (S) Casualty Clearing Station, R.A.M.C.(T.).

Medical officers are required to complete the establishment of this unit. Two should be operating surgeons, preferably holding F.R.C.S. All must be prepared for both home and foreign service. Those recently qualified acceptable. Ambulance workers specially welcome. Applications to the Officer Commanding, 1st Wessex (S) Casualty Clearing Station, R.A.M.C.(T.), Evelyn House, Salisbury.

England and Wales.

THE TUBERCULOSIS CAMPAIGN IN WALES.

The Welsh National Memorial Association.

The annual meeting of the Governors of the King Edward VII Welsh National Memorial Association for the prevention and abolition of tuberculosis was held at Llandudno on July 31st.

Mr. D. S. Davies, High Sheriff of Denbighshire and one of the treasurers of the association, who presided, referred with regret to the fact that the Pembrokeshire County Council had maintained its refusal to come into the scheme, which embraced all the rest of Wales. Notwithstanding this, the association had hitherto treated dependants of insured persons in that county as well as other non-insured members of the community, and, by agreement with the Insurance Committee, the treatment of insured persons had been provided for. Mr. D. W. Evans (General Director) said that the failure of the county council to make its contribution involved the loss to the association of an equivalent amount from the Treasury.

It was announced that the honorary casualty surgeons, Mr. J. Lynn Thomas, C.B. (Cardiff), and Mr. Robert Jones (Liverpool), had carefully considered the suggestion to establish one large central hospital in Wales for the treatment of surgical tuberculosis, but, finding it to be, for geographical reasons, impracticable, had recommended

two hospitals—one for South Wales, at Glan Ely, near Cardiff, and the other to form part of the North Wales Sanatorium, which is being erected on an admirable site, given by Mr. D. S. Davies, on rising ground at Llangwyfan, on the east side of the Vale of Clwyd, a few miles from Denbigh. It was mentioned that during the year the association had received two valuable gifts, which would greatly facilitate its work in Monmouthshire. Sir Garrad Thomas (Chairman of the Medical Committee) and his family had given a house in Newport, and Mr. J. C. Hanbury seven acres of land near Pontypool Junction, on which a tuberculosis hospital with 100 beds would be erected.

President's Address.

In the absence of the President, Lieut.-Colonel David Davies, M.P., on military duty, his annual address was read to the meeting. After discussing the attitude of the County Council of Pembrokeshire, and explaining the general financial situation of the association, he said that the number of persons who had received treatment through it in an institution, either a sanatorium or a hospital, had risen from 2,073 in 1913-14 to 3,003 in 1914-15. The capital expenditure down to March, 1915, had amounted to £100,452. The Charity Commissioners had recently approved the scheme for the administration of the association, and in consequence the Treasury was about to sanction the payment, through the Welsh Insurance Commission, of the contribution authorized by Section 64 of the Insurance Act, 1911.

The Sanatoriums.

The work the association had set out to do had progressed during the year in all departments quite satisfactorily, except that there had been unavoidable delay in completing the building contracts now in force. In March, 1914, there were 87 beds in hospitals owned by the association. On March 31st, 1915, the number was 185. The total hospital beds at the disposal of the association this time last year were 332; on March 31st, 1915, there were 418. Since March 31st the new hospital at Llangefni had been opened, the alterations to the structure at Tregarren were proceeding apace, and the permanent annex at Glan Ely was approaching completion.

In March, 1914, the association had 299 sanatorium beds. Of that number 228 were in buildings owned or leased by the association, and 71 in institutions over which the association had no control. On March 31st, 1915, it had 257 beds in buildings owned or leased by it, and 128 beds in other institutions, making a total of 385, or an increase of 86 beds. Having regard to the extraordinary circumstances, the buildings of the North Wales sanatorium at Llangwyfan, near Brecon, and of the South Wales sanatorium at Pontywal, near Brecon, were progressing satisfactorily.

Number of Patients and Results.

The association had started with the intention of raising a capital sum of £300,000, and up to date it had received, in money and in kind, £220,000. At the institutes or visiting stations, now numbering 101 in various districts, 8,868 persons had been examined by the tuberculosis physicians during the war; these persons included 3,121 men and 2,460 women, the remainder being children. The number of women applying had shown a slight increase, which was satisfactory, as the death-rate from tuberculosis among men and women was practically the same. The percentage of women applicants found to be tuberculous had fallen from 72 to 52. The number of children examined had increased, and might be expected to increase still further when the scheme of the association became still more closely connected with the medical inspection of school children. The number of contacts examined had risen from 1,484 in 1913-14 to 1,808 in 1914-15, and the number found tuberculous from 360 to 416. Of the number discharged from sanatoriums no less than 69 per cent. of pulmonary cases and 80 per cent. of non-pulmonary cases were discharged as fit for work. These were most gratifying figures, and the President hoped these cases would be followed up from time to time to ascertain whether the improvement manifest upon their being discharged from a sanatorium had been maintained. No fewer than 250 patients were discharged during the year from hospitals as being fit for work. More satisfactory still was the fact that 836 patients

attending from time to time at the tuberculosis institutes and visiting stations had been discharged from treatment as being fit for work. This was a valuable phase of treatment of tuberculosis, and the results went to show that residence in an institution was not absolutely necessary in every case of tuberculosis. With reference to the educational campaign, no fewer, he said, than 76,538 scholars and teachers attended lectures delivered in elementary and secondary schools during the year.

Surgical Tuberculosis.

At the invitation of the Chairman, Mr. Robert Jones made some observations on the importance of providing adequate treatment for adults suffering from surgical tuberculosis. Tubercle of bones and joints in children, he said, might almost be called benign, but in adults it was malignant, and many pitiable cases occurred which it was quite impossible to treat adequately in their own homes. Nor were such cases suitable for treatment in general hospitals, in fact he had refused to treat tuberculous cases in such hospitals. Continuous open-air treatment, the patient sleeping out of doors, was essential, and the greatest benefit occurred during the winter months. With adequate treatment deformity after tuberculosis could be avoided. The scheme for treating surgical tuberculosis in Wales should not be parochial but national. Treatment should be begun at central hospitals, and the patients retained in them until they could safely be sent to convalescent annexes.

After transacting some further business, including a resolution to pay the expenses of representative members in attending meetings of the Board of Governors, the Council, and the Committees, a hearty vote of thanks to the chairman was adopted, and the meeting came to an end.

TUBERCULOSIS DISPENSARIES FOR LONDON.

At its last meeting before the recess, the London County Council, through its Public Health Committee, approved as part of the comprehensive scheme for the treatment of tuberculosis in London, dispensary schemes prepared by three of the metropolitan borough councils. The three boroughs concerned are Bermondsey, Hackney, and Stoke Newington, the total annual cost in the case of Bermondsey being £200 (in respect of uninsured persons only), and in the other two cases estimated at £1,840 and £420 respectively. The maximum amount of the Council's contribution cannot be fixed until the date on which the scheme comes into operation is known.

It has also been decided to continue, as far as possible, the arrangements for reserving beds in residential institutions for the reception of uninsured tuberculous persons under the Council's scheme. It is not possible in all cases to reserve a definite amount of accommodation owing to the abnormal conditions prevailing, but the arrangements for adults include 20 beds at the Royal Chest Hospital, City-road, and 20 at Maltings Farm Sanatorium, as well as 50 to be allotted, if available, by the authorities of the Brompton Hospital, either in the hospital itself or in Frimley Sanatorium. Some 170 beds are also to be kept open for children at various institutions, including 38 beds at Queen Mary's Hospital at Carshalton, which have been placed at the Council's disposal by the Metropolitan Asylums Board.

RIGHT OF OLD AGE PENSIONERS TO MEDICAL ASSISTANCE.

The Local Pension Committee of the London County Council has had its attention drawn to the fact that many old age pensioners who become ill do not seem to appreciate that "medical or surgical assistance (including food or comforts)" supplied by or on the recommendation of a Poor Law medical officer does not disqualify them for a pension. The consequence is that pensioners frequently refrain quite unnecessarily from applying to the Poor Law authorities for medical and surgical assistance. The Board of Customs and Excise has not seen its way to agree to the committee's suggestion that a short statement of the law on the subject should be printed on each pension order book, and the committee is now suggesting to the Local Government Board (the central pension authority under the Acts) that it might with advantage draw the attention of the various boards of guardians to the law on the subject.

Ireland.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION FOR
IRELAND.

The twenty-third annual general meeting of the Royal National Hospital for Consumption for Ireland was held in Dublin on July 29th, Major E. H. C. Wellesley, J.P., Chairman of the Board of Governors, in the chair.

The Chairman, in moving the adoption of the report, said that while they regretted that they must still wait for a detailed statement of the medical work of the hospital during the year—which, however, he believed was of an entirely satisfactory and encouraging condition—he thought they would all sympathize with, and be proud of, the circumstances which occasioned the delay. Their two resident medical officers, Dr. Hanan and Dr. Crosbie, had obeyed their country's call and placed their services at the disposal of, one the naval, and the other the military, medical authorities, and were now serving in these branches of the national service. Their places were efficiently filled at present by Dr. Kennedy and Dr. Gordon, but these gentlemen, further embarrassed as they had been by the absence of one laboratory assistant with the Reserves and the illness of his successor, had not had time to deal with and compile the statistics with sufficient detail to admit of the results being tabulated in time for the board's report adopted on July 8th. The effects of the war had also been felt in falling income and increased cost of food. On the other hand, when they looked at the work carried on at the hospital, there was every reason for thankfulness and satisfaction. They had during the period since the last annual meeting increased the number of beds to 125. He had offered to place at the disposal of the Insurance Commissioners in connexion with the military authorities twenty-five beds for soldiers discharged from the army suffering from tuberculosis. They were still receiving insured patients for treatment from Insurance Committees throughout Ireland, of whom several had acquired a definite number of contract beds, and other county authorities—these, of course, in addition to patients recommended by subscribers and donors—and the board had good reason to know that the high standard of efficiency existing at the hospital, both medical, nursing, and administrative, was well appreciated by those who had been brought into contact with it. The board desired to express its thanks to Dr. Crofton, visiting physician, Dr. Hanan and Dr. Crosbie, the late—and Dr. Kennedy and Dr. Gordon, the present—resident medical officers, and to Miss Taylor, lady superintendent, and the nursing staff generally. Mr. Wellington Darley, J.P., seconded, and the report was adopted.

Dr. Crofton, in returning thanks, said that although they had not been able to have ready a detailed medical report on the results of the treatment of patients at the Royal National Hospital for Consumption for Ireland during the year 1914, he had, with the help of the assistant resident medical officer, Dr. Crosbie, at present serving in the Royal Army Medical Corps in Dublin, been able to draw up a preliminary report giving the broad results. Of the total number of patients discharged during 1914, exclusive of those in whom no diagnosis of consumption could be made, 15.5 per cent. were "very much improved" or "apparently cured," 20.7 per cent. were "much improved," 21.2 per cent. "improved," 37.3 per cent. "*in statu quo*," 3.1 per cent. were worse, and 2.2 per cent. died. In 1913 the figures were 12.8, 15.9, 23.4, 31.8, 12.5, 3.4; while in 1912 the figures were 6.6, 21.3, 24.9, 27.3, 19.2, and 0.60—a favourable comparison, he thought, in spite of having only 10.8 per cent. of Group I (early) cases to deal with in 1914 as compared with 43.1 per cent. in 1912. Owing to the breaking up of the staff in consequence of the war, for all practical purposes the method of treatment for which he was responsible—namely, the chemotherapy of the disease by iodoform dissolved in ether given intravenously, accompanied by immunization against the catarrhal microbes and then immunization against the tubercle bacilli—had to be abandoned early in August. In order, therefore, to get some idea of the results obtained while the treatment was in full swing he had estimated the results for the first six months of 1914. The figures were: 17.6, 23.7, 22.3, 32.4, 3.4, and 0.6. It would be

noted that those patients who entered the hospital in June could have had very little treatment, so that the figures were not so good as they might have been. Of Group I, 10.9 per cent. were apparently cured in 1912, 22.4 per cent. in 1913, 35.7 per cent. in 1914. In Group II the figures were 6.6 per cent. in 1912, 4.2 per cent. in 1913, 21.6 per cent. in 1914; in Group III, 0 per cent. in 1912, 3.1 per cent. in 1913, 5.6 per cent. in 1914. There could be no doubt whatever that the cases they had apparently cured had been cases of consumption, and they did not consider cases "very much improved" or "apparently cured" unless they had lost all their physical signs, and had been proved to have no tubercle bacilli in their sputum after several examinations. He called attention to the third-stage cases, in which the whole of one lung or a large area of both lungs was infected; these, of course, were most unfavourable cases, many of them absolutely untreatable. Of Group III cases, 40 per cent. of the whole that entered in 1914, about 30 per cent. were absolutely untreatable, so that they were very proud of having "apparently cured" 5.6 per cent. of this group. He did not consider a sanatorium a suitable place for the treatment of these third-stage cases, especially during the winter, since they ought to be protected from extremes of temperature, etc., until they were sufficiently convalescent to stand them. Special hospitals near cities and large towns were urgently needed for the treatment of such cases; these hospitals would also provide accommodation for the incurable cases.

He had been advocating for many years the use of preventive inoculation against tuberculosis. That measure not only had the advantage of increasing individual resistance to the disease, but reaction after an injection would show the nature of the disease and enable treatment to be instituted while the case was comparatively easily curable. The disease as a whole would not be properly combated until every dispensary doctor held a tuberculosis dispensary once or twice a week, until each province had a laboratory for clinical research attached to a larger central hospital, and, lastly, until a properly equipped tuberculosis research institute was established in the country.

Professor McWeaney said that in view of the large number of advanced cases that had been sent in the results achieved by Dr. Crofton and the resident medical staff were in the highest degree satisfactory. His view was that every effort should be made to diagnose consumption before the bacilli appeared. This could be accomplished by refined clinical methods, including the injection of tuberculin. These were the cases that responded really well to sanatorium treatment, and it was a great pity to see so many patients in the incurable stage sent in by the Insurance Committees. Dr. Crofton had been entrusted by the Research Committee of the National Insurance with important research work on the chemotherapy of tubercle, and Dr. McWeaney ventured to express the hope that the trials which were being made on animals of new antiseptic compounds would soon yield results that might be applied to the treatment of the disease as it occurred in human beings.

NEW RESERVE OF R.A.M.C.

Last week a public meeting, under the auspices of the St. John Ambulance Association (Territorial Branch) was held in the Royal Dublin Society's lecture theatre, to obtain volunteers for service in the Military Home Hospitals Reserve, of whom there is at present urgent need. Mr. Justice Ross, P.C., presided over a large attendance, principally composed of members of local units of the association. Dr. Lumsden made a statement of the work accomplished by the St. John Ambulance Association. He said that when the war broke out they were able to place 4,000 men at the disposal of the R.A.M.C., and since then 14,000 had been supplied. From Dublin they had sent 250, most of whom were serving with the Expeditionary Forces. Their St. John Ambulance Brigade had been progressing most satisfactorily during the last few months. They now had units all over the county and city of Dublin, and several large industrial firms in the city had their own unit. He read a letter he had received from Sir Richard Temple asking for volunteers for the Military Home Hospitals Reserve. He pointed out that there was no age limit provided a man was over 19 years

and fit for home service. For service abroad the age limits were 19 to 40. One of the most remarkable features of the war so far, he said, had been the splendid services of the R.A.M.C. He hoped within the next few weeks they would be able to send forward a long list of names of men who were prepared to come forward when required. Sir John William Moore, M.D., moved a resolution:

"That the Military Home Hospitals Reserve was deserving of the support of all 'first-aiders,' who were now given an opportunity of serving their King and country in the military hospitals, either at home or abroad, thus setting free the existing men in the R.A.M.C. for the Expeditionary Force.

DISPENSARY MEDICAL OFFICERS AT THE FRONT.

At the last meeting of the Edenderry Board of Guardians the question of the terms of leave to medical officers volunteering for service at the front came up for discussion. At present three of the union medical officers are with His Majesty's Forces on six months' leave, their salaries and substitutes being paid in full for that term. One of the guardians pointed out that in Mullingar not a single doctor had gone, whereas in Edenderry they were paying at the rate of £655 a year for substitutes for their doctors, and that it was not fair that the ratepayers in one area should get off scot free, while in another area they should be so severely taxed. A resolution was unanimously adopted that in future leave be given on the condition that the doctors pay their own substitutes, their positions being kept open, and the substitutes to reside in the respective districts. This order to apply to the three doctors who have already gone to the front when their term of six months has expired. This question, which is undoubtedly a difficult one, will have to be faced by many of the boards of guardians in Ireland, though it is not likely that there are many unions who have lost as many as three of their medical officers. If it is fair to continue the payment of full salary in addition to the payment of a substitute—and this is authorized by the Local Government Board—it might be suggested that the additional burden should be pooled and met out of a demand on all the unions in Ireland according to valuation. These men, of course, are being paid by the Government for their services, and fairly well paid, too; in most instances this pay should at least make up for the temporary loss of their private practice. In some cases, especially if the doctor has no family, he may even be better off by the substitution of army or navy pay for his private practice. Though it may seem hard, therefore, on the union to have to pay the salaries of both the absent doctor and his substitute, still the boards of guardians in Ireland have not been so generous in the matter of salaries to their medical officers as to make the medical profession sympathize with their present trouble.

ROYAL HOSPITAL FOR INCURABLES.

The annual meeting of the supporters of the Royal Hospital for Incurables was held recently and the 171st annual report of the governors (for the year ended March 31st, 1915) was read. The governors stated that the new wings were now rapidly nearing completion. The expenditure to date amounted to £18,147 18s. 9d., and the receipts to meet this outlay during the past year totalled £975 11s. Already investments to the amount of £12,050 had had to be sold (much below their original cost), in order to reduce the heavy debt due to the bank, and the income of the hospital was permanently diminished by this reduction of capital. On April 1st, 1914, there were 213 patients in the hospital: 123 candidates applied for admission during the year, and of these 35 were elected—6 afflicted with consumption, 10 with cancer, 9 with paralysis and nervous diseases, 4 with cardiac and vascular diseases, 2 with rheumatism and arthritis, and 4 with other forms of disease. The ordinary income showed a decrease of £334 16s. 6d. as compared with the previous year, mainly due to a decreased revenue from invested funds and a reduced subscription list, while the ordinary expenditure had increased by over £200. The cost of maintaining a bed for the year was £38 1s. 5½d., which was 17s. 2d. in excess of the cost in the previous year. It was to be feared, however, that owing to the increased cost of living, as the result of the war, there would be a substantial increase under this head during the present year.

Scotland.

ADDITIONAL COURSE IN CLINICAL MEDICINE IN EDINBURGH INFIRMARY.

Since there is no post-graduate teaching going on in the wards of the Edinburgh Royal Infirmary this autumn on account of the war, a great deal of clinical material is available. This is being utilized in providing instruction in clinical medicine to senior students to enable them to graduate a little earlier and also to give opportunities for work to undergraduates who have returned from the front. The course is being given at the request and under the auspices of the University and the Royal Colleges, and will qualify both for the university degree and for the triple qualification. The teachers who are actively engaged are Dr. F. D. Boyd, Dr. R. A. Fleming, and Dr. Harry Rainy (physicians), and Dr. Edwin Bramwell (assistant physician). The course will count as a regular one in every respect.

India.

ANNUAL MEETING OF THE ST. JOHN AMBULANCE ASSOCIATION.

The annual general meeting of the St. John Ambulance Association in India was held at the Viceregal Lodge, Simla, on June 24th, His Excellency the Viceroy presiding. The Commander-in-Chief, chairman of the Indian Council of the association, said the Indian Ambulance Department of the association had ably maintained the best traditions of the ancient Order of St. John, the oldest military medical organization in the world, and the army in India was fortunate in having this great society ready to come to the assistance of its wounded on the outbreak of this terrible war.

General Sir Pardee Lanks, in presenting the report to the meeting, said he had much pleasure in announcing that His Highness the Maharaja of Scindia had intimated his intention of presenting them with a further gift of five hundred units for the use of British troops, thus bringing the total amount of the generous donation up to one thousand ten-bed units, of an estimated value of over two lakhs. Three motor boats had now been sent to the Persian Gulf, and, in addition to these three, they hoped to be able to supply ten more of light draft and suitable for river work, and they had already received from Her Highness the Begum Sahiba of Bhopal a sum of Rs. 14,000 for the purchase of two such boats. Thanks to Lady Earle, they had now received an offer of two more motor ambulances from the ladies of Assam, thus bringing the total for that province up to four, three of which had been given by the ladies of Assam and one by Her Highness the Rani of Bijnr. The military authorities had accepted the association's offer to equip and staff for a period of at least one year a special war hospital to be worked in connexion with the *o-ray* institute at Dehra Dun. The estimated total cost of the upkeep of the hospital for one year was half a lakh of rupees, and the cost per bed was Rs. 2,000.

Sir Arthur Ker, honorary treasurer of the association, in presenting the statement of accounts of the general fund of the Indian Head Quarters and of the St. John Ambulance Red Cross War Fund for India, said that the Indian Council had kept its general and war funds separate, and that it aimed at an endowment reserve fund, which would ensure its permanency. This reserve fund was now Rs. 45,000, which showed steady progress when they recalled that some five years ago the total assets of the Indian branch were only Rs. 300. The annual Government grant was Rs. 5,000, which, though helpful, was only a fraction of their annual expenditure, which was roughly about a quarter of a lakh. A much larger endowment reserve fund was required if the future of the association was to be definitely assured.

Colonel Blackburn, general secretary, speaking of the reorganization of the three provincial centres, said that in order to make units of manageable size and to encourage the development of local interest in the work it was sought to form centres of the association in the various geographical subdivisions of India. These provincial centres were

designated to be administrative rather than executive bodies, and it was their duty to subdivide territory into district centres, which, under local administration, carried out the executive work, educational, and Red Cross of the association. More than 200 centres on these lines had been formed in every corner of India and also in Burma.

Certain members having been elected councillors, the Viceroy decorated Colonel H. Hendley, I.M.S., with the badge of honorary associate.

His Excellency then delivered an address in which he said he had now had the honour of presiding at three annual meetings of the St. John Ambulance Association, and this was probably the last occasion on which he would have the pleasure of being present at a meeting of the Indian branch. Few people in India realized that on the outbreak of the war this association, whose growth in India had just been dealt with by Sir Pardee Lukis, would promptly take up the rôle of a Red Cross Society and discharge its functions with such resource and ability. After briefly recapitulating the achievements of the association, he referred to the great liberalities of the ruling chiefs of India. They had heard from Sir Pardee Lukis the latest example of the unparalleled generosity of His Highness the Maharaja of Scindia, and he took this opportunity of announcing that another friend, His Highness the Maharaja of Jaipur, in sending a message asking to be excused from attending this meeting, had most generously forwarded a donation of Rs. 5,000 to the funds of the association to be allocated in any way he (the Viceroy) might think fit. In accepting with gratitude this noble contribution he had decided to hand it over to the Executive Committee with an instruction that it should be devoted to the maintenance of beds at the Dchra Dun War Hospital. He would like to mention the enormous output of work by the ladies both European and Indian of a Western presidency under distinguished and energetic auspices, but he was reluctant to do so lest he should fail to do justice to the magnificent efforts that had been put forth in another presidency under other high auspices and indeed in every part of the Indian Empire. There in Simla he spoke of his own knowledge, and he had been filled with admiration at the way in which various committees and numerous working parties had laboured and slaved in the common cause. But all this self-sacrificing labour would have been thrown away if it had not been wisely organized and directed. Their thanks were due not only to the General Secretary who had worked so hard, but also to the Chairman of the Executive Committee under whose guidance he had worked, and that was to Sir Pardee Lukis himself. He could remember smiling at the enthusiasm of the General Secretary when at the first meeting over which he presided that gentleman expressed the conviction that in a few years there would hardly be a hamlet from Tonk to Trichinopoly and from Bombay to Bhamo where the association was unknown. That day was not so far distant as it seemed to them then, and the Indian Council might reasonably claim that the association had taken firm and healthy root in every corner of the Indian Empire.

Correspondence.

HEMERALOPIA OR NYCTALOPIA.

SIR,—I read with pleasure Dr. Guthrie's letter in this week's BRITISH MEDICAL JOURNAL on the meaning of nyctalopia. I take the liberty of sending you a reprint of an article which I wrote about thirty-five years ago and which was published in the *Royal London Ophthalmic Hospital Reports* in 1882.

My attention was first specially directed to the matter about forty years ago, when plans were prepared for the first edition of *Quain's Dictionary of Medicine*, for which I was asked to write some definitions, and among them "Nyctalopia." After much thought I came to the conclusion that the true meaning of the word "nyctalopia" was night-blindness, though this opinion ran counter to practically all existing literary authorities and that of all the friends I consulted.

A few years later the late Dr. Greenhill and I published two articles on the subject in the tenth volume of *Oph-*

thalmic Hospital Reports, of which I was then editor. As a result of our endeavours the articles relating to nyctalopia in Liddell and Scott's *Lexicon* were rewritten and the word *nyctalopia* was inserted for the first time. The College of Physicians also accepted our view and altered the definition it had hitherto given of the words "hemeralopia" and "nyctalopia" in the ensuing edition of its *Nomenclature*.

Dr. Greenhill and I hoped we had settled the question for ever, but since we wrote a new generation has sprung up, to whom our labours seem to be unknown.—

I am, etc.,

JOHN TWEEDY.

SIR,—Since the appearance of my letter in your issue of July 31st, Sir John Tweedy has drawn my attention to papers by himself and the late Dr. W. A. Greenhill (*Royal London Ophthalmic Hospital Reports*, vol. x, part iii, 1882) in which the whole question was fully discussed and decided in favour of the view that "hemeralopia" means day-blindness and "nyctalopia" night-blindness. Had I been aware of these important and learned treatises, and of the fact that we owe to the labours of Sir John Tweedy and Dr. Greenhill that correct definitions of the terms have been inserted in recent editions of Liddell and Scott's *Lexicon* and in *Quain's Dictionary of Medicine*, 1882, I should not have ventured to trespass on your space. I do not, however, regret having done so, as it is evident that heresy still exists on the subject, and I now have an opportunity of enlightening others who, like myself, were unaware that Sir John Tweedy and Dr. Greenhill had settled the point in dispute for ever, more than thirty years ago.

The fact that in Germany "hemeralopia" is still used in the sense of night-blindness needs no comment.—

I am, etc.,

LEONARD GUTHRIE.

TEMPORARY COMMISSIONS FOR MEDICAL MEN UNDER 40.

An Irish Committee.

SIR,—An appeal was recently made to the medical profession, through the British Medical Association, by Sir Alfred Keogh, K.C.B., the Director-General of Army Medical Services, for whole-time medical officers under 40 to serve with the troops wherever they might be sent abroad, and for men over 40 for service in the United Kingdom.

Sir Alfred Keogh said: "I would urge all those who are under 40 years of age and who are fit for active service to apply for temporary commissions in the R.A.M.C. if their civil obligations will allow them to do so. Such men would have an opportunity of seeing active service on the Continent or elsewhere where we have fighting armies. We are especially in need of young general practitioners who are willing to go anywhere and do anything in the way of duty with troops or with medical units." There is therefore an urgent need of young men for service with the troops, and it will naturally be more easy for men who have qualified in recent years to offer their services than those who are established in practice.

The Director-General further stated that the civil medical profession had already given the army so much generous and self-sacrificing assistance since the outbreak of the war that he regretted to be compelled to make further demands on it. But it was necessary to make adequate provision to safeguard the health of the home army when the Expeditionary Force was increased in strength to such an extent that every commissioned medical officer fit for active service would be required for service on the Continent.

In response to this urgent appeal the British Medical Association, through its local machinery, is trying to make arrangements to facilitate those doctors who are in a position to do so to join the R.A.M.C., and in assisting them to do so by providing substitutes acceptable to them for the conduct of their practices during their absence.

With the latter objects in view a committee has been formed in Dublin consisting of:

- Dr. J. C. McWalter and Dr. H. Mason (Apothecaries' Hall),
- Dr. D. J. Coffey and the Right Hon. M. F. Cox (National University),
- Dr. J. McDowell Cosgrave and Dr. J. O'Carroll (Royal College of Physicians),

Dr. Conway Dwyer and Dr. W. Taylor (Royal College of Surgeons).
 Professor A. F. Dixon and Professor A. C. O'Sullivan (Trinity College).
 Colonel Hearn, R.A.M.C.
 Dr. T. Hennessy.
 Dr. M. R. J. Hayes (Honorary Secretary).

In order that the existence of such a body may be generally known amongst the profession, I am directed to request you to publish this letter.

About 500 Irish doctors have already responded to the call of duty since the outbreak of the war, and it is satisfactory to note that such a large proportion of the Irish medical profession are serving with the troops, but it is believed that there are still a good many medical men under 40 who, if they could see their way clear, would accept temporary commissions for either home or foreign service, and Sir A. Keogh's words leave no room for doubt that it is the duty of such men to volunteer and the duty of their colleagues to make it possible for them to do so.

My committee will therefore be glad—

1. To receive the names of those who are willing to join the R.A.M.C., stating if they require to be provided with substitutes during their absence, and

2. The names of qualified practitioners, including those who have retired from practice who are willing to act as locumtenents for those who volunteer.

As regards whole-time home service in the United Kingdom the physical examination of candidates is less searching than that of an ordinary soldier. The work which home service entails is not more strenuous than that undergone by men in private practice.—I am, etc.,

35, Upper Fitzwilliam Street,
 Dublin, Aug. 2nd.

M. R. J. HAYES,
 Honorary Secretary.

THE STERILIZATION OF THE SKIN WITH TINCTURE OF IODINE.

SIR,—With reference to a communication in the JOURNAL of May 22nd, I wish to ask if Mr. Stretton has any grounds for claiming to be the originator of this method?

Early in 1909 I read an abstract of an account of Grossich's work in the ERYTHRE. It appealed to me so strongly that I performed the last thirty operations I did in the Colchester Military Hospital with iodine as the skin disinfectant, and I wrote a paper which was published in the JOURNAL of February 6th, 1909. I made no claim to originality. Since then I have noticed that at least two London surgeons have laid claim to having originated this method.

Mr. Stretton's technique only differs from that of Grossich in that he uses a weaker solution of iodine, but most of us quickly discovered that 10 per cent. strength was not necessary and was sometimes injurious.

"Give honour to whom honour is due"; but in this instance it is, I think, due to Grossich. He has greatly simplified the problem of skin disinfection, and laid all operating surgeons under a deep debt of obligation to him.—I am, etc.,

F. J. W. PORTER, Major R.A.M.C. (ret.),

H3 derabad, June 17th.

SCHOOL MEDICAL INSPECTION.

SIR,—In the JOURNAL of July 3rd appeared a memorandum approved by the British Medical Association and the National Union of Teachers concerning the method of school medical inspection.

I do not expect that many school medical officers will pay much heed to this *modus vivendi*. This for at least two reasons:

1. The agreement should have been drawn up between the National Union of Teachers and the Society of Medical Officers of Health to which the whole-time school medical officers belong. Few practitioners are taking part in this work, the intricacies of which (I may add with all respect) the British Medical Association does not understand.

2. I already have much more done by the teachers than the memorandum suggests, namely: Name, date of birth, age, address, school, and parents' occupation; also date of inspection, standard, regularity of attendance, clothing, footwear, cleanliness of body and clothing, and intelligence.

The teacher is the only person who knows the usual condition of the child attending school, as opposed to his or her "polished" condition produced for inspection day only.—I am, etc.,

August 3rd.

S.M.O.

ON THE CURVE OF THE EPIDEMIC.

SIR,—I sent my full address with my criticism of Dr. Percival's solution, but, in accordance with the convention of your correspondence columns, this was not printed.

As a solution of a differential equation in y and t must necessarily consist of a relation between y and t , and as $y = a \cos^2(mt - a)$ was the only relation between y and t given by Dr. Percival in the letter of June 12th, in which he presented his solution, I naturally took this to be his solution. I am quite prepared, however, to examine separately on its merits any solution he meant to put forward, if he will only state what it is.

A relation between the variables y and t , like $y = a \cos^2(mt - a)$, is not a transformation for the purposes of facilitating integration, but a test solution. A transformation must replace at least one of the old variables y and t by a new one. A test solution will be a correct solution if substitution in the original equation produces an identity. Dr. Percival challenges me to substantiate my statement that the result of substituting $y = a \cos^2(mt - a)$, that is,

$$-2m \tan(mt - a) = \log CD - \log \frac{a CD}{2N} \left[t + \frac{1}{m} \sin mt \cos \overline{mt - 2a} \right]$$

is not an identity. Before doing so he would naturally agree to my correcting the error in it due to the slip in his work of reduction, to which I referred, and which he wishes me to indicate.

The amended form is:

$$-2m \tan(mt - a) = \log \left[CD - \frac{a CD}{2N} \left(t - \frac{1}{m} \sin mt \cos \overline{mt - 2a} \right) \right]$$

and the slip in Dr. Percival's form is that he has taken the logarithm of the difference of

$$CD \text{ and } \frac{a CD}{2N} \left(t + \frac{1}{m} \sin mt \cos \overline{mt - 2a} \right)$$

to be the difference between their logarithms.

To prove that the above is not an identity I proceed as follows.

If it is an identity the constants can be so determined that it is true for all values of t . Taking the exponential of each side, making certain transferences from one side of the resulting equation to the other, and dividing each side by

$$\frac{a CD}{2N} e^{-2m \tan(mt - a)}$$

must therefore be true for all values of t .

Give then to t the successive values

$$T, T + \frac{\pi}{m}, T + \frac{2\pi}{m}, \dots, T + \frac{r\pi}{m}, \dots$$

The right hand side remains the same, that is,

$$\frac{2N}{a} \frac{1}{m} \sin m T \cos(mT - 2a) - \frac{2N}{a CD} e^{-2m \tan(mT - a)}$$

as these values are put in. The left hand assumes the values

$$T, T + \frac{\pi}{m}, T + \frac{2\pi}{m}, \dots, T + \frac{r\pi}{m}, \dots$$

Hence, subtracting the left hand and right hand sides of

any consecutive pair of equations, we get $\frac{\pi}{m} = c$, which is not true for any choice of m having a finite value.—I am, etc.,

London, N.W., July 22nd.

H. L. TRACHTENBERG.

DIAGNOSIS OF GOUT.

SIR,—In the BRITISH MEDICAL JOURNAL of July 31st, p. 177, I have read with much interest Dr. J. B. Berkart's article on gout. I consider it a very valuable contribution to our knowledge. If I have read it correctly, he relies on a deposit of urates in the joint for a correct diagnosis. Personally, I firmly believe that gout is due to a specific micro-organism. Several observers have isolated one resembling the anthrax bacillus, but proof is lacking. Until the specific germ is definitely isolated, I for one shall not believe we have any infallible means of diagnosing gout. The changes described by Dr. Berkart

K.C.V.O., M.D., Alfred Milne Gossage, M.D., Sir John Francis Harpin Broadbent, Bt., M.D., Harold Batty Shaw, M.D.; Midwifery and Diseases peculiar to Women, Henry Williamson, M.B. Camb., Cuthbert H. J. Lockyer, M.D., Thomas George Stevens, M.D., Gay Bellingham Smith, M.B., F.R.C.S., John Benjamin Helliell, M.D., Public Health: Part I, Wilfred W. O. Beveridge, D.S.O., M.B.; Part II, Sydney A. Monckton Copeman, M.D., Tropical Medicine: Bacteriology, John Charles Grant Ledingham, M.B., Diseases and Hygiene of the Tropics, Fleming Mait Sandwith, M.D., Murchison Scholarship, John Fawcett, M.D., Alfred Ernest Russell, M.D.

Communications.

The following communications were received: (1) From the Secretary of the Royal College of Surgeons of England, dated May 17th, June 11th, and July 9th, reporting proceedings of the Council of that College on May 13th, June 10th, and July 8th respectively; (2) from the Dean of the Faculty of Medicine, University of Edinburgh, reporting that the Murchison Scholarship had been awarded by the Faculty to Charles George Lambie, M.B., Ch.B.

Harveian Commemoration.

It was resolved that on the occasion of the Harveian Commemoration on October 18th next the usual dinner should not be held.

Election of Representatives and Members of Committee.

Sir Wilnot Herringham, M.D., was re-elected a Representative of the College on the Court of Governors of Sheffield University.

Dr. Sidney Martin and Dr. Newsholme were re-elected Members of the Executive Committee of the Cancer Research Fund.

Sir Thomas Barlow, Bt., M.B., was elected an additional Member of the Executive Committee of the Imperial Cancer Research Fund.

The Weber-Parkes Prize.

A report from the Adjudicators upon the Essays for the Weber-Parkes Prize, 1915, was received. It was resolved that the prize should be awarded to Dr. Noel Dean Bardwell.

Award of Medals.

On the recommendation of the Council, the Baly Medal was awarded to Dr. F. Gowland Hopkins, F.R.S., and the Moxon Medal to Professor J. J. Dejerine of Paris.

Reports from Committee of Management.

A report was received and adopted from the Committee of Management, dated June 23rd, 1915. The report recommended that the following institutions having fulfilled the requirements of the Board, should be added to the list of institutions recognized by the Examining Board in England for instruction in chemistry and physics—namely, North-Eastern County School, Barnard Castle; Bootham School, York; and Queen Elizabeth Grammar School, Wakefield.

A second report, dated July 13th, from the same committee, was received and adopted. The report was as follows:

1. That St. Chad's College, Denstone, Staffordshire, which is already recognized for instruction in Chemistry and Physics, be also recognized for instruction in Biology.
2. That the examination for the Diploma in Tropical Medicine be discontinued for the duration of the war.
3. That the extra examination in Part I for the Diploma in Public Health, held during recent years in the month of April, be discontinued for the duration of the war.

After some further formal business, the President dissolved the Comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council was held on July 29th, when Sir W. Watson Cheyne, President, was in the chair.

Leave of Absence.

Leave of absence was granted to Mr. Thorburn during his period of service in Malta as Consulting Surgeon to the Mediterranean Expeditionary Force.

The late Mr. Edmund Owen.

The following resolution was passed by the Council:

That the Council hereby express their deep regret at the death of their former colleague, Mr. Edmund Owen, whom they highly esteemed as an able surgeon, and for whom they entertained the warmest feelings of personal friendship; and they desire to offer their sincere sympathy to the members of his family in the loss which they have sustained.

The Council desire, also, to record their appreciation of Mr. Owen's many services to the College as a Vice-President and Member of the Council and Member of the Court of Examiners, of the keen interest which he displayed in all matters relating to the welfare of the profession, and of his energy and devotion on behalf of the wounded. His ready sympathy and cheery presence will be sadly missed in the large circle of friends which his many admirable qualities gathered around him.

Issue of Diplomas.

Diplomas of Membership were granted to 113 candidates found qualified at the recent examinations.

Diplomas in Public Health were granted, jointly with the College of Physicians, to five candidates found qualified at the recent examinations.

A Diploma in Tropical Medicine and Hygiene was granted,

jointly with the College of Physicians, to one candidate found qualified.

Report of Committee of Management.

The recommendations as given in the report of the Comitia of the Royal College of Physicians, were adopted.

Removal of a Member.

A member whose name had been previously removed from the Medical Register, was removed from being a member of the College.

Imperial Cancer Research Fund.

Sir John Bland-Sutton was elected a Member of the Executive Committee of the Imperial Cancer Research Fund in the place of Sir Rickman J. Godlee.

CONJOINT BOARD IN ENGLAND.

The following candidates have received the following diplomas indicated from the Royal College of Physicians and the Royal College of Surgeons respectively:

M.R.C.S., L.R.C.P.—J. G. Ackland, C. G. Ainsworth, D. R. Alexander, J. S. Alexander, E. H. R. Altonway, T. Ansell-Davies, G. C. G. Baldini, E. B. Barnes, J. V. Bales, C. W. W. Baxter, J. J. O. Bevan, R. S. Bines, E. Biddle, J. A. Blinling, D. A. Blount, C. W. Boland, C. C. Brewis, F. H. Butcher, F. V. Cant, J. C. Cavenagh, L. A. Celestin, J. E. Clark, S. J. Cowell, H. McW. Daniel, E. M. Densart, W. J. Dearden, D. H. Berry, R. G. Eades, S. E. Y. Elliott, D. T. Evans, R. G. Fairbairn, R. K. Ford, Charlotte I. Fox, O. Gleeson, G. R. Goltharke, R. C. Gow, A. P. Green, J. A. C. Greene, G. D. Gripper, G. H. Haines, H. W. Hales, N. H. H. W. Holman, G. H. G. Hughes, H. R. W. Huxford, W. W. Isaacs, L. G. Jacob, H. C. Jennings, F. A. Knott, R. D. Legg, David-Kelham, W. N. Leak, C. G. Leary, J. B. Leather, P. W. Ken Liang, S. J. L. Lindeman, C. G. Lindler, F. D. Lindow, V. E. Lloyd, W. H. Lloyd, S. D. Lodge, G. S. R. Long, J. E. C. Macnamara, S. A. S. Malkin, G. S. Marshall, A. D. Marston, J. B. McFarlane, W. G. McKenzie, C. H. Medlock, T. W. Melnish, R. G. Michelson, D. S. Mearns, P. M. Mearns, A. S. Morgan, J. E. Scott, J. H. Morris, I. Moutard, W. L. Partridge, N. S. Paruck, R. C. V. Pasco, L. G. Phillips, W. H. Pickup, T. L. Price, R. A. W. Proctor, A. L. Puncch, K. N. Purkis, G. J. Randall, R. M. Rigall, E. S. Rowbotham, E. Schuyler, G. H. Selous, N. J. C. Smith, Shah, E. W. L. Sharp, T. W. Sheldon, S. A. Sittampalam, J. B. R. Skelton, E. Siewera, F. R. Storrage, T. C. Summers, R. R. Syquia, C. Underhill, C. R. Taylor, M. J. D. Wallis, A. H. Warble, W. T. Warwick, T. T. B. Watson, F. L. Webster, W. R. White-Cooper, B. Whitehead, N. J. Wigrau, G. L. Wilkinson, A. Willatt, H. Williamson.

* Under the Medical Act, 1876.

D.P.H.—Ravi Das, S. Y. Gupta, W. B. H. Heddy, E. A. A. Saunders, N. G. Wilson.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE (Part I Chemistry, Part II Physics)—S. Akeley, W. H. Alast, F. T. Allen, H. Auldham, F. Barker, F. W. E. Barnes, W. Beaumont, B. F. Behman, R. A. D. J. Bernhardt, Frederic M. Bradley, Anna B. Broman, N. E. D. Cardledge, Marjorie C. G. Campbell, M. J. S. Ellison, J. L. Farquharson, K. Galsbury, Marion B. Gray, E. Hardy, J. W. Hulme, T. James, K. C. J. Jones, S. Kadinsky, J. Kendall, A. A. Knappman, P. Lindsey, E. R. Lloyd, Kathleen M. B. McArthur, D. B. Mearns, J. A. Mearns, A. S. Morgan, J. E. Scott, J. H. Morris, I. Moutard, W. L. Partridge, N. S. Paruck, R. C. V. Pasco, L. G. Phillips, W. H. Pickup, T. L. Price, R. A. W. Proctor, A. L. Puncch, K. N. Purkis, G. J. Randall, R. M. Rigall, E. S. Rowbotham, E. Schuyler, G. H. Selous, N. J. C. Smith, Shah, E. W. L. Sharp, T. W. Sheldon, S. A. Sittampalam, J. B. R. Skelton, E. Siewera, F. R. Storrage, T. C. Summers, R. R. Syquia, C. Underhill, C. R. Taylor, M. J. D. Wallis, A. H. Warble, W. T. Warwick, T. T. B. Watson, F. L. Webster, W. R. White-Cooper, B. Whitehead, N. J. Wigrau, G. L. Wilkinson, A. Willatt, H. Williamson.

* Passed in Part I only. † Passed in Part II only.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE—G. A. Barry, J. P. Pousner, M. Barden, D. P. Clein, E. J. Connolly, J. J. Fieane, N. A. Filose, C. G. Fitzgibbon, J. Forbes, E. Kinn, B. McMahon, E. F. Miallin, J. S. E. Manley, M. F. Moloney, J. O'Brien, T. P. O'Loughlin, F. G. Phillips, F. J. Ryan, W. H. Shipley.

SECOND COLLEGE—M. J. Broderick, T. F. Broderick, J. Danaher, T. L. Dolan, N. A. Filose, M. J. Griffin, J. A. Hamilton, L. M. Leventon, Miss N. McCormick, R. G. J. McCullagh, J. A. MacSweeney, M. R. Morris, M. O'Brien, C. O'Connor, B. F. O'Reilly, C. Rowan, G. R.

THIRD COLLEGE—J. H. Barrett, M. Pricece, G. H. M. Crofts, E. M. T. Crymble, R. D'Alton, H. W. Hackett, Miss M. McMillan, H. Mooney, M. J. P. O'Connell, J. P. O'Connell, J. F. O'Connell, A. P. O'Connell, C. E. Brennan, S. Brown, T. A. Buchanan, S. J. M. Cairns, G. A. Campbell, T. M. Cronin, B. J. Cusack, W. E. R. Dimond, J. C. Ferguson, C. E. H. Gater, N. H. Gray, J. Gray, P. J. McGuire, W. G. D. McCall, F. R. H. Mollan, M. Moran, J. A. Musgrave, C. J. O'Carroll, P. J. D. O'Malley, L. M. Rowlette, E. A. Ryan, T. H. Sarsfield, T. A. Watson, P. L. Wigoder, H. J. Villiers.

D.P.H.—S. Hessel, P. J. Tinney.

* Passed with Honours.

APOTHECARIES' HALL OF IRELAND.

The following candidates have been successful in the subjects indicated:

Primary Examination.—J. McCarthy, successful in Physics and in Chemistry; D. McCarthy and F. J. Fitzpatrick in Physics and Biology; W. G. C. Reavy in Biology; and J. T. Apperton in Chemistry.

Inter-mediate Examination.—D. J. Crowley passed in Pathology; J. H. McKenna and P. A. Sullivan in Pathology and in Medical Jurisprudence; and J. T. McDonnell in Medical Jurisprudence.
Final Examination.—J. B. Ellwood passed in Medicine; J. A. Sullivan in Medicine, Surgery, Midwifery, and in Pharmacy; A. Hegarty in Surgery; and J. H. McKenna in Midwifery and in Pharmacy.
Completed Primary Examination.—Completed Intermediate Examination. *Completed Final Examination.*

Obituary.

THE LATE MR. EDMUND OWEN.

The cremation of the remains of Mr. Edmund Owen took place at Golder's Green on Thursday, July 29th. The attendance at the ceremony was large, and the service was conducted by the Reverend William Walker of St. Augustine's, Leytonstone. Among those present were, in addition to Mr. Owen's brothers, Sir Douglas Owen and Mr. Owen, the Earl of Plymouth, Lord Savile, Sir Rickman Godlee, Sir David Ferrier, Sir Henry Morris, Colonel Sir Herbert and Lady Perrott, and Sir John Hewett. The College of Surgeons was represented by Sir W. Watson Cheyne and Professor Arthur Keith; St. Mary's Hospital by the Chairman, Mr. E. Ruffer, and the Secretary, Mr. Pondepeyre; the Hampstead General Hospital by Mr. Albert Langton; the King George V Hospital by Dr. Hammond and Dr. Miles; the St. John Ambulance Brigade to which Mr. Owen was surgeon-in-chief by Colonel Tyrell, Commissioner, and Assistant Commissioner Winn; the British Red Cross Society by the Hon. Arthur Stanley (Chairman), Sir Frederick Treves, Sir Benjamin Franklin, and the Secretary, Mr. Frank Hastings; the Medical Society by the President, Sir J. Bland-Sutton; and the British Medical Association by Mr. Guy Elliston.

Dr. FOSTER PALMER (London) writes: Twice only have I come in contact with Owen, and both times in relation to his gift of speech, which I see referred to several times in the obituary notice in the JOURNAL. He is spoken of as "an incisive speaker," with a "marvellous store of apt illustration," as a "pungent and witty after-dinner speaker," and one of his speeches is described as "full of wit and good humour" and a "masterpiece of persuasive eloquence." About seventeen years ago he came to the first annual dinner of the Chelsea Clinical Society and responded for the "Guests" in an eloquent speech. More recently, only a few years ago, he wrote an anonymous letter to the JOURNAL complaining of the distress he suffered from nervousness or stage-fright before making a speech. Having given some attention to this subject, I wrote in reply stating that I believed it to be almost universal with good speakers, that the excellence of a speech is often in direct ratio to the degree of stage-fright, and that I was sure that the writer, whoever he might be, was an eloquent speaker. I received a letter from Owen thanking me for my remarks and for the encouragement they gave him. There is presumably no longer any reason for anonymity. That men of Celtic origin have frequently the gift of eloquence is well known. What is, perhaps, not so well known is that they also suffer severely from stage-fright. The same condition of the nerve centres which results in fluency of speech also produces an almost abnormal sensitiveness as to its possible reception. (The most graphic description I have ever read of a case of stage-fright and its cure is contained in a novel by Rider Haggard called *Mr. Meeson's Will*.)

Dr. R. P. SMALLWOOD (Chelmsford) writes: In the notices of Edmund Owen's death in the JOURNAL there does not appear to be one by any one who acted as his house-surgeon, and it is for that reason that I send these few lines. Owen always treated his house-surgeons with the greatest liberality and allowed them to do numerous operations. He was always punctual and expected every one else to be so, and any one who was late or appeared to be slack in any way was very likely to hear of it, generally in a witty and pleasantly sarcastic manner. On one occasion a dresser, in cutting off a bandage from a head on the operation table, made a small cut in the patient's ear. "And the servant's name was Malchus," was Owen's comment when he saw it. On another occasion a

"chronic" on the well-known front bench surprised Owen by answering a question, and he, forgetting that silence is golden, said, "You seem surprised, sir." "So was Balaam," replied Owen. He hated abbreviations, such as pot. iod., liq. hyd. perchlor., and his opinion of drugs was not a high one, and one day, at a consultation, he remarked to one of the physicians, "Drugs are no use, are they?" "Not unless you know how to use them," was the unexpected reply he got. Owen never minded owing to a mistake, and I well remember telephoning to him to come and trephine a case of what I thought was a ruptured meningeal artery. From my account he thought it was not, and so did not come. The man died, and the *post-mortem* examination proved I was right, and Owen gave a lecture on his mistake in not operating, which was much more than most men would have done. There must be hundreds of men who learnt most of their surgery on the front bench, and he spared no trouble with any one who was willing to learn. He was a fine man physically, a bold and rapid operator, a splendid teacher, and one who will long be remembered gratefully by those who came in contact with him.

We regret to have to record the death on July 15th, after a short illness, of Dr. EDWARD A. CLARKE, of Dukinfield, at the age of 51. After studying at Owens College, Manchester, and the London Hospital, he took the diploma of I.S.A. in 1887, and was for a time house-surgeon to the General Infirmary, Wrexham. In 1891 he took the diploma of M.R.C.S.Eng., and settled in Dukinfield. He had a large practice, and was also medical inspector of schools in the borough. He was for several years representative of the Ashton-under-Lyne Division at the Representative Meetings of the British Medical Association, and worked very hard during the Insurance bill controversy. The Division presented him with a clock as a mark of recognition for his services. Dr. Clarke, who was J.P. for Cheshire, took a great interest in the St. John Ambulance movement, and was for many years a lecturer on first aid. He was a great personality at all the divisional meetings, and was held in high esteem by all who knew him. Dr. Clarke leaves a widow and one daughter.

In the issue of the JOURNAL for July 10th a review was published of Dr. Giordano's book on the physiology, pathology, and hygiene of the sulphur miners of Sicily. News has just been received of the death of Dr. Giordano on July 15th. A patient worker and a close observer of his fellow men, no one was better acquainted with the habits, the weaknesses, and the diseases of the sulphur miners, or more fully cognizant of the faults in their social surroundings, than the writer of the treatise referred to. An extern professor of the University of Palermo, and lecturer on the diseases of miners, Giordano spent his life in Lerccara, an old, quiet, out-of-the-way town, some miles from a railway station, and in the heart of the sulphur-mining industry of the island. His opinion upon the health conditions of the sulphur miners was frequently asked by the Italian Government. In an unobtrusive manner Giordano, by voice and pen, did much to improve the lot of the people amongst whom he lived. To have met Giordano, and to have discussed with him problems of industrial and mining hygiene, remains one of the pleasant memories in the life of the writer of these lines. In addition to the book referred to, Giordano published several papers on ankylostomiasis and other subjects. He was an honorary member of several of the learned societies of his own and other countries.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. R. D. Coale, for many years dean of the medical school of Maryland, aged 57; Dr. Jacob Michaux, professor of materia medica and therapeutics in the University College of Medicine, Richmond, Virginia, from its foundation in 1893 till 1912, aged 63; Dr. Rédier, for many years professor of surgical pathology in the Catholic Faculty of Medicine at Lille; Professor Soumenber, surgeon-in-chief of the Moabit Hospital, Berlin, aged 66; Dr. Sherman Voorhes, of New York, a well-known specialist in diseases of the eye, ear, and throat, aged 48; and Dr. F. W. Weisse, for many years

professor of anatomy, surgical pathology and oral surgery at the New York College of Dentistry, and author of a treatise, entitled *Practical Human Anatomy*, published in 1896, and of many other contributions to the literature of medical science, aged 72.

The Serbics.

TERRITORIAL FORCE.

EXCHANGE DESIRED.

CAPTAIN EDGAR V. PHILLIPS, R.A.M.C.(T.), at present attached to the Leicester 1st Royal Horse Artillery, stationed at Diss, Norfolk, wishes to exchange back to his original unit, the 5th Northern Hospital, and would be glad to hear from any medical man able to ride well who would be willing to take his place in the battery.

Medical News.

In the three weeks ending July 31st twenty cases of plague with twenty deaths occurred in Hong Kong.

THE *Archivio Italiano di Ginecologia* has suspended publication for the time on account of the war. We hope to see this valuable periodical come to life again before very long.

It is announced that Professor Dr. B. Fischer, Director of the Hygiene Institute of Kiel University, has died of heart failure in hospital on the German front near Ypres. He was 63 years of age.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held at Brighton on September 3rd and 4th, 1915. The chair will be taken each day at 10.30 a.m. by Sir Henry Tanner, C.B., Chairman of the Council of the Institute. There will be discussions on Indian sanitation, camp sanitation, maternity and child welfare, and the final report of the Royal Commission on Sewage Disposal.

A CONFERENCE was held at Oxford, under the auspices of the Oxfordshire Association for the Prevention of Tuberculosis, on July 17th. Representatives of sanitary authorities, Insurance Committees and other bodies attended. Sir William Osler, who presided, moved resolutions urging that the retention of the dispensing system should be regarded as essential in any scheme for dealing with tuberculosis in the county; that no tuberculosis scheme in the county could be considered complete or adequate which did not make provision for co-operation with a voluntary-care and after-care association on the lines suggested by the medical officers of the Local Government Board; and that the Conference desired to impress upon the responsible authorities the urgent need existing in the county for provision for advanced cases of tuberculosis unable to secure sufficient isolation and attention in their own homes. These resolutions were adopted.

An investigation was made during the past year into the state of the St. Lawrence river water, as the typhoid rate is high in several towns which it supplies. It was found that the water contained colon bacilli in varying degree according to the season of the year and the weather conditions, and that it was not fit to be used for domestic purposes unless adequately purified. A certain amount of pollution, brought down from the watershed, is inevitable; however, it is due chiefly to the discharge of untreated excreta from vessels, and from the places situated on the banks of the river. The population on lake vessels during the season of 1906 was estimated by the United States bureau of census as 14,000,000 persons! In some towns the pollution is largely the result of short-circuiting of their own sewage. It may be possible for some places to obtain their water supply from artesian wells, and experiments are being conducted with this object in view. Where this is not possible, the water will be chlorinated.—For instance, at Kingston, Brockville, and Gananoque; in other places a filtration plant will be installed. It seems difficult to guard against carelessness and irregularity in chlorinating the water supply. In Brockville the practice has been in force for two years, but typhoid epidemics continue to arise, and 82 cases were reported in the month ending January 26th. A false feeling of security is also given by the knowledge that in some places the water is fairly free from contamination most of the time, and it is forgotten that a serious epidemic may be caused by pollution which may be the result of certain weather conditions.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL unless the contrary be stated.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attingham, Westrand, London*; telephone, 2511, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2520, Gerrard. (3) GENERAL SECRETARY, *Westrand, Westrand, London*; telephone, 2534, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUESTIONS.

CORPUS VILE writes: In my search for an aperient to be used in cases of loss of consciousness, post-anaesthetic, etc., I have been experimenting upon myself with the hypodermic use of codeia. I hope to submit results for publication shortly. In the meanwhile, can any of your readers inform me what is the maximum safe hypodermic dose of codeia salts, and how they are eliminated? What untoward after-effects have been noted in chronic or acute overdosage?

DR. JAMES ARTHUR (Wingate, Co. Durham) writes: On July 26th a girl of 8 years was brought to me with a dislocation of the left elbow, both bones backward. On 31st the child was again brought to me with a similar dislocation of the right elbow, also by a fall on a kerb. Neither had occurred before, both were well marked, and reduction was easy. Was this due to unusual looseness of ligaments, and is it of rare occurrence?

ANSWERS.

KELOID.

DR. HERBERT P. TAYLER (Exmouth) writes, in reply to "J. W. W.": Some years ago I had as patient a child who developed a keloid condition of scars of a scald on the neck. Acting on the advice of the late Sir T. Smith, I painted these with contractile collodion, applying a new coat as soon as the first one scaled off. After many months the scars quite disappeared. Care must be taken to be sure that the collodion is contractile. The solution should be fairly thick.

NOTES.—There is no better work for coloured drawings of sections than Braune's original Atlas. Bellamy's translation is merely an abridgement with plain plates. Hugo Sellheim's *Topographischer Atlas zur normalen und pathologischen Anatomie des weiblichen Beckens*, published by Georgi, Leipzig, 1900, contains very fine coloured sections of the female pelvis.

HARE-LIP.

DR. H. FERGIE WOODS (Golder's Hill) writes that Dr. J. C. Burnett's book, *On the Prevention of Hare-lip, Cleft Palate, and other Congenital Defects*, might be useful to "R."

LETTERS, NOTES, ETC.

IODINE IN CHOLERA.

WE are indebted to Dr. May Thorne for the opportunity of reading a letter from Jolo, stating that tincture of iodine has been useful in the treatment of cholera. Five drops of 10 per cent. solution of iodine in alcohol is given in a tumbler of water every two hours.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words

All remittances by Postal Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-reste letters addressed either in initials or numbers.

ON THE IMMEDIATE EFFECTS OF THE
INHALATION OF CHLORINE GAS.

[WITH SPECIAL PLATE.]

BY SIR EDWARD SCHÄFER, F.R.S.,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF EDINBURGH.

THE mode of action of chlorine seems to be little known. In textbooks of pharmacology it is dismissed in few words. But in view of the illegitimate use which has been made of it by our foes in the present war it is desirable, as a preliminary to the adoption of measures for antagonizing its effects, that its physiological action—as distinguished from the pathological changes ultimately produced by inhalation—should be investigated. The present research deals with the immediate and fatal effects caused in cats, rabbits, and dogs by its inhalation, the animals having been in every case anaesthetized with chloroform or ether.

From the chemical nature of chlorine it seems evident that its immediate action must be local. For it is scarcely possible to imagine that it can exist in the free state in such a fluid as blood, which contains many bodies with which it would immediately combine, and which would—unless it were introduced in immense quantities—at once render it innocuous. But it is rarely safe to assume anything in physiology. To put the matter to the test of experiment I have injected into the veins of animals Ringer's solution saturated with the gas. If only a small quantity is thus introduced no effect is seen, and if a larger quantity, spread over a certain interval of time so that the fluid becomes well mixed with the blood, is injected the only result (Fig. 5) is to produce a quite temporary diminution of blood pressure (preceded by a slight rise) and a slight increase in the depth of the respirations. The fall is probably due, as we shall see, to obstruction of the pulmonary vessels; the diminution in volume of the kidney which is shown in the top tracing is doubtless passive. These results were produced by the introduction into the jugular vein of a rabbit of 10 c.c.m. of Ringer's fluid saturated with chlorine, the injection being spread over twenty seconds. On one occasion only—in which the same amount was injected more rapidly and presumably mixed imperfectly with the blood—a suddenly fatal result similar to that obtained by inhalation of a strong mixture of the gas with air was produced; in this case probably occlusion of the pulmonary vessels was produced.²

With inhalation the result is always serious. Even with air containing only 1 per cent. of chlorine—although at this dilution no special effect upon either the blood pressure or respiration may be visible for some minutes—a profound change ultimately occurs, and this may show itself with great suddenness (Fig. 6). In the case illustrated, the respirations, which had been quite regular and apparently of normal depth and rate for about four minutes, became suddenly very deep and in another minute convulsive, prior to complete arrest; whilst the blood pressure (which in the first period rose gradually, although not to any great extent, the rise being due probably to the irritation of the sensory nerves of the pulmonary mucous membrane) fell rapidly, and with the cessation of respiration, tumultuously, whilst there was at the same time marked slowing of the pulse. On substituting air for the gaseous mixture, respiration and blood pressure rapidly recovered, the blood pressure rising temporarily to a much greater height than before.

As soon as recovery seemed to be complete the 1 per cent. mixture was again substituted for air, and the animal was allowed to inhale the mixture for another seven minutes, during all which time very little effect on the blood pressure or respiration was produced. But at the end of that period there again ensued a sudden fall of blood pressure and cessation of respiration, which this time was not recovered from.

In Fig. 7 are shown the effects on a rabbit of inhalation of a mixture containing 2 parts of chlorine gas to 100 of air (the middle part of the tracing is omitted). As with the 1 per cent. mixture there is at first a gradual but slight rise of blood pressure, with but little change in the respiration. After four minutes the respirations had become

slower and rather deeper, and the heart was beating more slowly, although the blood pressure was well maintained. At five and a half minutes the respirations became suddenly convulsive, and the blood pressure showed corresponding irregularities. At six and a half minutes the respirations ceased abruptly, and the blood pressure failed suddenly. Respiration was not resumed, but the heart continued to beat for several minutes, the blood pressure gradually approaching zero. Artificial respiration was commenced two and a half minutes after the cessation of natural respiration, and whilst the heart was still beating well, but produced no effect upon the blood pressure, and there was no sign of recovery.

With a mixture of 1 part of chlorine gas to 20 of air (Fig. 8), and with all in excess of this (Figs. 9, 10, 11) a fatal result is rapidly and inevitably produced. The fall of blood pressure begins in less than half a minute, and in most instances is so fast as to reach zero within three or four minutes, whilst the respirations—which at once become slower, but may not be deeper, or may even be shallower except for an occasional gasp—cease in from one to three minutes. After this there are sometimes a few intermittent respiratory movements, but they are entirely ineffectual, and do not influence the blood pressure. Whilst the blood pressure is falling the heart is beating slowly and regularly; in the experiment on the dog illustrated in Fig. 11 the regularity is very striking during part of the time. In this case the effects on blood pressure and respiration are somewhat belated as compared with the experiments on the cat. This was partly due to the greater capacity of the dog's lungs, compared with those of the cat, relatively to the reservoir which contained the gaseous mixture inhaled, so that, although in this case a 10 per cent. mixture was employed, less effect was produced than with a 20 per cent. mixture in the cat; but it may also be connected with the fact that, as Evans¹ has remarked, pulmonary oedema is much more easily produced in the cat than in the dog.

In no case in which a strong mixture (5 per cent. or more) was employed was it possible to produce any recovery by artificial respiration.

As we have seen, these effects must be due to something happening locally in the lung, since the chlorine which is inhaled cannot be carried to the tissues in a free state. There is, moreover, abundant evidence that the tissues retain their vitality even after inhalation of the strongest mixture; for when the body is opened after death, the muscles contract briskly on excitation either directly or through their nerves, and the heart is also responsive to stimulation, and is, indeed, usually seen—especially the auricles—beating spontaneously if somewhat weakly. The only visible change is in the lungs, which even after the shortest exposure to a fatal dose are intensely red and congested, either all over or in innumerable patches. They are less shrunken than usual, and have a more solid feel, with but little crepitation; nevertheless, even small pieces float in water.

In the photograph (Fig. 1) the intensely dark colour presented by a cat's lungs after three minutes' inhalation of a 20 per cent. mixture of chlorine gas with air is manifest. The appearance presented was no doubt extreme, although the congestion may be quite as marked with weaker mixtures. Sometimes it is less apparent on the surface, although on cutting into the lung the section is always deep red in colour, and the tissue seems to be full of blood. There is usually some froth in the trachea and larger bronchi, but not nearly as much as is seen in cases of drowning.

The effects which might be produced locally in the lung by an irritant gas like chlorine are various. It may directly affect the bronchial musculature or the vascular musculature; it may stimulate the mucus-secreting mechanism of the air tubes; it may influence the coagulability or viscosity of the blood within the pulmonary vessels; or it may produce reflex effects by exciting the endings of afferent nerves within the lungs.

It is not possible in the space at my disposal fully to discuss all these points. In the meantime it may be stated that there is strong evidence for the opinion that the fatal result is due to obstruction in the pulmonary vessels rendering it impossible for the blood to pass freely to the left auricle and ventricle.

It appears to be the common opinion that an irritant gas like chlorine must necessarily produce constriction of

¹ The lungs show on microscopic examination (Fig. 4) the engorgement of pulmonary vessels and oedema which are characteristic of the lungs of animals which have inhaled chlorine.

the bronchioles. I have attempted to test the correctness of this view in various ways—namely: (1) By alternately driving air and a mixture of air with chlorine at a constant pressure through “surviving” lungs the surfaces of which have been pricked or incised to allow the air to perfuse through the lung, the perfused air being collected and measured; the time being recorded for a given amount of air to pass through the lung under these alternative circumstances. The result of experiments carried out in this manner has been to show that there is usually no diminution in the amount of air perfused when the perfused air has chlorine gas mixed with it, but rather the reverse. (2) Another method which suggested itself was to perfuse warm Ringer’s fluid through the “surviving” lung in the same manner as was done with the air in the last-mentioned experiment, and at a given moment to inject into the perfusion tube a certain amount of Ringer’s fluid containing dissolved chlorine gas. In various ways this method proved unsatisfactory, and the results were discordant; in some experiments there appeared to be contraction resulting from chlorine, in others no effect was produced, in others again there was a marked increase in flow. (3) The method which was finally adopted was similar to (1), but instead of employing the “surviving” lung, the experiment was performed on the living animal. The advantage of this is that any reflex effect which might be produced would be shown, as well as the local result. The experiments were carried out by the employment of positive ventilation with a Brodie pump, which delivered a constant quantity at each stroke through a bottle of the capacity of 100 c.c.m.; a perfectly similar bottle containing a mixture of air and chlorine being so arranged that at a given moment the stream of air from the pump could be sent through this bottle into the lungs instead of through the other. Most of the pumped-in air escaped as usual through the side tube of the tracheal cannula. To gauge the permeability of the bronchial tubes an opening was made in the thorax,

and one of the lungs was pricked in several places with a needle so as to permit the escape of a small amount of the pumped-in air. This was collected in an inverted measuring glass filled with Ringer, the body of the animal being immersed in warm Ringer’s solution. Fig. 12 is a record of such an experiment. It shows that the moment chlorine gas is mixed with the ventilation air there is a marked increase in the amount of air which passes out by the punctures in the lung; therefore the bronchial tubes have become more permeable. It remained to determine the effect of chlorine upon the pulmonary vessels. This is comparatively simple, for it is only necessary to tie a cannula into the pulmonary artery of an animal which has just been killed and to perfuse the pulmonary vessels with warm Ringer, collecting the outflow by means of a cannula tied into the left auricle. The lungs are in the meantime regularly inflated in the usual way by a Brodie pump (positive ventilation). The action of chlorine is determined by injecting, by means of a hypodermic syringe, into the supply tube passing from the Mariotte bottle of the perfusion apparatus a small quantity of Ringer’s fluid containing chlorine in solution. It is found that even if so little as 1 c.c.m. of 1 in 10 chlorine Ringer is thus injected a profound effect is produced upon the pulmonary circulation, the flow through which becomes greatly slowed almost to complete cessation.²

It may be mentioned that chlorine Ringer perfused in a dilute form through the blood vessels of the pithed frog also produces marked constriction.

As a variant on this experiment, the chlorine has been occasionally conveyed to the lungs through the air used for ventilating them, a similar effect being obtained.

We conclude, therefore, from the result of these experiments that chlorine produces its fatal results by causing obstruction of the pulmonary vessels, amounting in some cases to complete stasis, and not by causing contraction of the bronchioles.

Confirmation of this conclusion is obtained as the result of microscopic examination of the lungs of the “gassed” animals. A section of such a lung is shown in Fig. 2, which is a microphotograph magnified 200 diameters. The gas in this case was applied by allowing the chlorine to pass into the chloroform mask over the snout of the animal, so that the percentage inhaled is not known, but from the length of time—nine minutes—which elapsed before a fatal result ensued, the mixture must have been less than 1 per cent. The photograph reproduced in Fig. 3 is from a section of the lung shown in Fig. 1, in which case death ensued after three minutes’ inhalation of 1 in 5 mixture. It is magnified 500 diameters.

In both cases the pulmonary capillaries are gorged with blood, and there is an extraordinary amount of oedema in the interstitial tissue of the lung. In the second case the oedema-fluid has passed more freely into the alveoli, many of which are full of coagulated lymph; some contain blood. Presumably the oedema is secondary to the vascular obstruction, but even if this is so it must set up a vicious circle by increasing the obstruction, and this again will increase the oedema; so that in cases of survival the oedematous condition must tend to increase, at any rate for some time.

Apart from the extreme congestion of the vessels and the oedema, the tissues of the “gassed” lung are normal; the epithelium cells of the bronchial tubes are well preserved, and there is usually little increase of mucus within them. That secretion of mucus does not play an important part in connexion with the fatal inhalation of chlorine is evident from the fact that death results just as inevitably and rapidly after a prior dose of atropine (Figs. 8 and 10) as without it (Fig. 9).

So far as the other organs are concerned, we have already noted that the heart retains its excitability for some time after death, although its contractions are weak. The right side, especially the auricle, is fuller than the left, but not engorged with blood as in ordinary asphyxia. The liver and abdominal organs have a normal appearance; they are not specially congested, indeed, the intestines are usually bloodless, although the veins at the back of the abdomen are full of blood. (The precaution was always taken of tying the vena cava before removing the heart and lungs, in order to prevent escape of blood from the abdominal viscera.)

I have performed a few experiments with bromine vapour which have served to show that, although much more irritating to the conjunctival mucous membrane, bromine is less deleterious to the respiratory organs than chlorine, the fulminating effect of which appears to be absent in the case of bromine. It has, however, not hitherto been possible to complete these observations on bromine, and publication of the results must be deferred.

In conducting the experiments recorded in this paper—especially those on perfusion—I have received valuable assistance from Dr. Harold Pringle.

DESCRIPTIONS OF FIGS. 11 AND 12 IN SPECIAL PLATE.

Fig. 11.—Dog (about 10 kilos). Effect on blood pressure and respiration of inhalation of air containing 10 per cent chlorine gas during three and a half minutes. Notice that the heart, which becomes very slow, continues to beat several minutes after cessation of respiration. Artificial respiration, although followed by a few slow gasping natural respirations, failed to effect recovery, the blood pressure steadily falling to zero. *a*, Blood pressure curve; *b*, respirations; *c*, absence of blood pressure; *d*, time in 10 seconds; *e*, signal.

Fig. 12.—Cat. Experiment showing that chlorine inhalation does not produce obstruction in the bronchial tubes. An aperture was made in the thorax and one of the lungs pricked with a needle. Artificial respiration was maintained by pumping a definite amount of air at a regular rhythm into the lungs, the excess escaping by a side tube attached to the trachea tube. A small proportion of the air escaped through the punctures in the lung, and this was collected and measured in an inverted cylindrical measure, the trunk of the animal being immersed in warm Ringer’s solution. Every 25 c.c.m. thus collected was marked on the lowest line of the tracing. At the place indicated by the arrow 100 c.c.m. of air containing 20 per cent. chlorine was pumped in, and the experiment was then continued with ordinary air. Notice the much increased rate at which the air is escaping from the punctured lung after administration of the chlorine. This dose of chlorine, although contained within the limits of a single stroke of the pump, and although a very large proportion must have escaped at the side tube, produced an instant fall of blood pressure, and death ensued in six minutes in spite of the fact that artificial respiration of fresh air was being kept up the whole time by the pump.

SIR E. A. SCHÄFER: IMMEDIATE EFFECTS OF INHALATION OF CHLORINE GAS.

Fig. 1.—Heart and lungs of cat killed by three minutes' inhalation of a mixture of 20 volumes chlorine gas with 100 air. Natural size. The heart, which is still covered by pericardium, has been turned upwards so as fully to expose the ventral surface of the lungs. The lungs were of an intense dark red colour. (Under normal circumstances the cat's lungs are of a pale pink colour after death.)

Fig. 2.—Part of section of lung of cat killed by nine minutes' inhalation of air containing chlorine gas. Haematoxylin and eosin. Magnified 200 diameters.

Fig. 3.—From a section of the cat's lung shown in Fig. 1. The animal was killed by inhalation during three minutes of a 20 per cent. mixture of chlorine gas and air. Magnified 500 diameters.

Fig. 4.—From lung of rabbit killed by rapidly injecting 10 c.cm. chlorine Ringer into jugular showing great congestion of pulmonary capillaries and oedema.

Fig. 6.—Rabbit. Chlorine 1 part to 100 of air inhaled for five and a half minutes. End of tracing shown. Cessation of respiration, but spontaneous recovery on respiration of chlorine mixture by air. Very high subsequent blood pressure. *a*, Arterial pressure; *b*, respiration; *c*, time in ten seconds; *d*, signal.

Fig. 5.—Rabbit. Effects on kidney volume, blood pressure, and respiration of slowly inhaled 10 c.c. of Binger's solution saturated with chlorine into the external jugular vein. *a*, Record of kidney volume; *b*, blood pressure; *c*, respiration; *d*, time in ten seconds; *e*, signal.

Interval of 3 minutes.

Fig. 7.—Rabbit. Effect of inhalation during seven minutes of air containing 2 per cent. chlorine gas. Cessation of respiration six and a half minutes after commencement inhalation. The heart continued to beat for several minutes, but artificial respiration failed to effect recovery.

Fig. 8.—Cat. Effect on blood pressure and respiration of five minutes' inhalation of air containing 5 per cent. chlorine gas $\frac{1}{10}$ grain of atropine sulphate had been given in this case.

Fig. 9.—Cat. Effects on kidney volume, blood pressure, and respiration of three minutes' inhalation of air containing 20 per cent. chlorine gas.

Fig. 10.—Cat. Effect on blood pressure and respiration of inhalation during three and a half minutes of air containing 20 per cent. chlorine gas; $\frac{1}{10}$ grain of atropine sulphate had been given in this case.

Fig. 12 (continued).

The descriptions of Figs. 11 and 12 will be found on p. 246.

Literature.

I have not been able to find in the literature any references to the immediate physiological action of chlorine. The most exact work on the effects of respiring mixtures of chlorine and air is that of Lehmann,² who placed animals during one to six hours in atmospheres containing from 1 part per 1,000,000 to 1 part per 1,000. He found that prolonged exposure to 1 part in 100,000 is sufficient to produce pulmonary hæmorrhage and œdema—which he regards as inflammatory—whilst exposure to 1 part in 10,000 causes in addition a fibrinous ("croupous") exudation in all the air passages, even the finest, and appears ultimately to produce asphyxiation. Numerous experimental pathologists, including Welch,³ S. Mayer,⁴ Sabli,⁵ and Löwit⁶ have endeavoured to elucidate the conditions of pulmonary œdema. These conditions have also lately been studied in the "surviving" hugg in Magnus's laboratory at Utrecht by Modrakowski.⁷ In these last-mentioned papers the literature of the subject is given, but most of the work referred to has but little bearing upon the œdema produced by chlorine. Binz⁸ found in the frog that exposure to chlorine gas has no influence on the heart (as against Falk), nor on muscle and nerve, nor on the spinal cord, but believes that it is carried to the brain, in which, he states, it can be detected by the smell! I have not noticed any smell of chlorine *post mortem* in the animals I have dealt with.

TREATMENT OF GAS POISONING IN TRANSVAAL MINES.

BY

ANDREW H. WATT, M.B., F.R.C.S. EDIN.,

AND

LOUIS G. IRVINE, M.A., M.D. EDIN.,

SIMMER AND JACK HOSPITAL, GERMISTON, TRANSVAAL.

CASES of poisoning by nitrous fumes are not uncommon in the mines of the Witwatersrand, and from published descriptions of "gassing" in the trenches the symptoms appear to be very similar.

"Gassing" as it occurs here is due

(1) To the inhalation of gases formed as the result of burning blasting gelatine. These gases consist mostly of the oxides of nitrogen.

(2) To the inhalation of gases formed by the more or less complete detonation or explosion of blasting gelatine. These gases consist chiefly of carbon dioxide and sometimes carbon monoxide.

The inhalation of (1), even in small quantity, is frequently followed by delayed symptoms, and, unless treated as described below, may cause death within twenty-four hours. This form of "gassing" is apparently very similar to that caused by the inhalation of the asphyxiating gases used by the enemy. The inhalation of (2) may cause no serious symptoms beyond the immediate ones of asphyxia and unconsciousness, and if the patient is rescued in time he recovers without having developed any secondary symptoms. The symptoms are due to the inhalation of CO and CO₂.

A man who has inhaled the fumes of burning gelatine may present very few symptoms beyond a little headache, cough and tightness of the chest, which soon pass off. In from six to eight hours he begins to have difficulty in breathing and coughs up large quantities of bloody serous fluid and dies of asphyxia and heart failure (delayed nitrous fumes poisoning).

Post mortem there is marked congestion and œdema of the lungs. The mucous membrane of the trachea and larger bronchi is injected. The abdominal veins are greatly enlarged and engorged with dark tarry blood. We have had the blood examined, and have never found any nitric compounds, nor has CO been found by spectroscopic analysis. The cause of the symptoms is the inhalation of nitrous fumes.

Treatment.

Every man who has been exposed to nitrous fumes must be kept under observation, in hospital if possible, for at least twenty-four hours. An emetic of copper sulphate gr. 8, followed by a large quantity of water, is given, or a hypodermic injection of apomorphine. It is imperative that vomiting should be freely induced. If an emetic is given early, any other treatment except rest in bed for a day is not usually required. The onset of dyspnoea and cyanosis is watched, and should moist sounds develop at the bases of the lungs bloodletting is employed, and as much as a pint may be withdrawn from a vein in the arm. This is usually difficult, as the blood is tarry, and coagulates very rapidly. We have transfused with saline to replace some of the blood withdrawn. Atropine may be given hypodermically. Inhalation of oxygen is also useful.

Should symptoms of general œdema of the lungs develop, the prognosis is extremely grave. Very few recover when this stage has been reached.

To illustrate the efficacy of treatment, the following case is quoted: In one of the mines under the care of one of us a case of gelatine was accidentally set on fire. The fumes spread through the workings, and fourteen men were "gassed." Thirteen of them immediately had an emetic, and the next day were all out of danger. One man disobeyed orders, and went home without receiving an emetic. He was sent for, but he had gone out for a stroll after having partaken of a hearty luncheon. He was found four hours after the accident, and came to hospital under protest, stating that he felt quite well. In the evening he developed general œdema and congestion of his lungs, and died before morning.

These notes are written in the hope that they may be useful to those treating cases of "gassing" in the trenches

SOME RESULTS OF GERMAN GAS POISONING.

BY

WALTER BROADBENT, M.D., M.R.C.P.,

MAJOR R.A.M.C.(T.).

CASES of gas poisoning rarely arrive in this country until all the acute symptoms are over, but in the first days of the use of gas two men came under my care who had only been gassed a few days before. Their chests were full of fine moist râles, and there was great dyspnoea. Oxygen they did not like, but compound tincture of benzoin in a steam-kettle gave some relief. The thing, however, which did far and away most good was a big linseed poultice over the whole back. The men constantly asked for the poultice to be repeated.

On admission neither of these men had any albumin in the urine, but a few days later in one of them albumin appeared and rapidly increased in quantity, the urine becoming very scanty. Epithelial and granular casts were present in abundance. The legs became œdematous and the face puffy. There was no rise of temperature. All the moist sounds in the lungs had in the meantime cleared up. The man was in the hospital for two months with very little improvement in the renal condition, and the œdema was still present. He then wished to be transferred to a hospital near his home.

Since then I have seen three other cases of nephritis in men who had been gassed. One had uræmic headaches and early albuminuric retinitis. Obviously nephritis is one of the deadly sequelæ of this gas poisoning.

In my other early acute case all physical signs in the lungs cleared up, and yet, when the man began to get out of bed, he was intensely short of breath. He was kept in hospital some time, being sent out in a bath-chair every day, but he could never walk more than about two miles an hour without getting out of breath. I have at present another man in hospital with the same dyspnoea and no abnormal physical signs, who was treated in France for gas poisoning. The condition is very similar to that of a case of South African miners' phthisis, which I saw some years ago, and probably fibrosis of the lungs has been caused by the irritant gas. The outlook for these men must be very bad.

In neither of these cases suffering from dyspnoea was

there any albuminuria. In three of the cases of albuminuria there was no dyspnoea on walking, and in the other, the original very acute case, there was no way of telling, as he was in bed. It looks as if in some cases the chlorine or bromine damages the lung epithelium so severely that it does not allow absorption into the general circulation, while in others the gas passes through the lungs without affecting them permanently, but then sets up an acute nephritis.

One other case under my care, the result of gas poisoning, is difficult to explain. A well-built man of 24 was rendered unconscious by gas in April. He says that, when he came to, he was lying doubled up with his head between his knees, but he does not think that he was knocked over by shell concussion. Ever since he has suffered from severe attacks of pain in the upper chest, radiating down the left arm. These are relieved by amyl nitrite and trinitrin, and are true angina pectoris. His pulse is 80, the vessel of normal thickness and size, and tension is not high. On listening at the aortic cartilage there is a loud rough systolic murmur and a fair second sound—no diastolic murmur. The systolic murmur is loud along the course of the aorta to the left second space, and is heard in the carotids. The apex beat is in the fifth space in the vertical nipple line, the impulse is fair. There is a good first sound, a slight systolic murmur not conducted outwards, and a second sound; x rays show no enlargement of the aorta. There is no history of rheumatism or of syphilis, and the man was perfectly fit up to the day he was gassed. My impression is that he ruptured one of the cusps of the aortic valve in his struggle for breath.

THE ISOLATION OF TYPHOID AND PARATYPHOID BACILLI FROM FAECES,

WITH SPECIAL REFERENCE TO THE USE OF BRILLIANT GREEN AND TELLURIC ACID.

BY

C. H. BROWNING, M.D., D.P.H.,

AND

L. H. D. THORNTON, B.A., M.R.C.S., L.R.C.P.

(From the Bland-Sutton Institute of Pathology, the Middlesex Hospital.)

THE methods for the identification of the various organisms belonging to the typhoid-coli group which cause epidemic disease by infection proceeding from the alimentary canal have now been well established.¹ As a preliminary to identification, however, it is necessary to isolate the suspicious organisms in pure culture from the infected subject. In the case of urine this is usually simple, provided that the patient is excreting organisms at the time of examination. When dealing with faeces it may be a matter of considerable difficulty owing to various coliform bacilli being present in great excess over the specific causal organisms. Under ordinary conditions these accompanying organisms tend to overgrow the specific types in culture media. In the early stages of the acute attack of such infections the method of blood culture is, of course, the most important diagnostic procedure, but in convalescent cases, or for the detection of carriers, the faeces and urine must be examined. (The Widal reaction is obviously of extremely limited value as an indication of infection in cases which have recently been inoculated with typhoid or paratyphoid cultures, singly or in combination.)

Unfortunately the argument does not apply that if the specific organisms are so scanty as to be readily missed, then such a case is relatively of only slight importance as a source of infection; on the contrary, it is now well known that the number of specific bacilli in the faeces and urine of a carrier may suddenly undergo marked fluctuations, and a case which is liable to be overlooked at the time of examination on account of the scanty number of organisms present may later on excrete the bacilli in great abundance.

Individuals who excrete these organisms are, of course, a very serious menace to a population unprotected by prophylactic inoculation; but their danger to an inoculated

community must not be underrated. It is to be remembered that immunity is only a relative state, and although the strongest proofs of the value of antityphoid immunization have now been afforded, there can be little doubt that a considerable proportion of individuals who have received the customary two doses of vaccine will still be susceptible to a sufficiently massive infection.

For these reasons it cannot be too strongly urged that every means should be adopted to ensure as thorough an examination as possible of the faeces of possible intestinal carriers. Not merely should the faeces be repeatedly examined,² but the most precise methods available for the detection of the specific organisms should be adopted. In cases where the specific organisms are scanty in proportion to the coliform bacilli, the customary method of spreading an emulsion of the faeces on the surface of a solid medium in Petri plates is obviously a somewhat imperfect procedure. In order to obtain a sufficient number of isolated colonies so as to include one of the specific organisms a very large area of medium may require to be inoculated. The media commonly employed, Conradi and Drigalski's, Endo's, and MacConkey's, do not have any effect in reducing the proportion of *B. coli* colonies; the results of Dreyer, Ainley Walker, and Gibson³ indicate rather that MacConkey's medium tends to suppress *B. typhosus*, and they therefore recommend the use of Endo's agar in preference.

A further defect of these media is that various coliform bacilli yield "pale" colonies resembling more or less closely those of the specific organisms, so that much time may be taken up in testing "likely" colonies which are scattered among others. Of course, in cases where typhoid or paratyphoid bacilli are numerous in the faeces any of such media will yield positive results. On the other hand, where the specific organisms form a relatively scanty proportion of the total number of viable bacilli present, the most hopeful means of isolation depends on the use of some agent which, while suppressing the others, will permit the typhoid and paratyphoid bacilli to proliferate. According to the results of Dreyer, Walker, and Gibson,³ ultra-violet light produces this effect, and they have recently described a most ingenious procedure whereby, after a plate has been inoculated with the emulsion of faeces, the contaminating organisms are killed off by graduated exposure to ultra-violet rays, whereas the typhoid bacilli survive and subsequently produce colonies when the plate is incubated.

Browning, Gilmour, and Mackie,⁴ while investigating the antiseptic properties of a series of benzol dyes, found that "brilliant green" possessed a very marked differential action on organisms of the typhoid-coli group. Thus, in confirmation of Conradi, strains of *B. typhosus* were shown to be in general much more resistant to the action of this dye than were the common members of the coli group; *B. proteus* is also less resistant than *B. typhosus* as a rule; Gaertner's bacillus and paratyphoid bacilli are even more resistant than *B. typhosus* to brilliant green.⁵

The differential antiseptic power of brilliant green for the typhoid-coli group surpasses that of malachite green, and the former compound exhibits the property of permitting the growth of the specific typhoid-paratyphoid pathogenic organisms while inhibiting other coliform bacilli in a more marked degree than any other substance so far investigated. Gram-positive cocci, of course, are suppressed by it. Conradi and other workers had already employed brilliant green for the isolation of *B. typhosus*, but apparently without effecting any marked improvement on previous methods. Thus a solid medium was employed, and this is always disadvantageous if the specific organisms are scanty, since they will occur only where the plate is richly inoculated. Now rich inoculation tends to annul the antiseptic effect, and in consequence the contaminating coliform organisms are enabled to grow exactly where their presence will obscure the typhoid bacilli. In consequence, we recommended the use of brilliant green in fluid medium, a series of tubes of peptone water being employed, to which varying amounts of brilliant green were added; each was inoculated with an emulsion of the faeces, and after twenty-four hours' incubation at 37° C. subcultures were made on a solid medium

¹ For a comprehensive summary of the differential characters of these organisms see Henderson Smith, BRITISH MEDICAL JOURNAL, July 3rd, 1915.

² In regard to the general problems of typhoid and paratyphoid carriers see Ledingham and Arkwright's *The Carrier Problem in Infectious Diseases*, London, 1912.

³ Dysentery bacilli are not specially resistant to brilliant green, hence the method will not apply to the isolation of these organisms.

containing an indicator. It was found that, in cases where only scanty colonies of *B. typhosus* developed on the plate inoculated directly from the faeces, practically pure growths of *B. typhosus* resulted in the subcultures from the brilliant green peptone water tubes; in a considerable number of instances typhoid bacilli were recovered by means of the fluid brilliant green medium, where the direct plate cultures failed altogether to show their presence. Although the common types of *B. coli* are more susceptible to brilliant green than are typhoid and paratyphoid bacilli, it was found that a particular group of coliform organisms was much more resistant; so far most of those brilliant green resisting types have been found to possess another property in common—namely, that they ferment inositol (*B. lactis aërogenes* is an example of this type). The inositol fermenters when present tend to overgrow typhoid bacilli in the brilliant green peptone water tubes. The striking fact was observed, however, that of all the colityphoid group the inositol fermenting types are the most susceptible to the antiseptic action of telluric acid (Browning, Mackie, and Smith); hence by combining telluric acid with brilliant green it is possible to inhibit these organisms in addition to the ordinary forms of *B. coli*, while at the same time permitting typhoid, paratyphoid, and Gaertner bacilli to proliferate.*

We are indebted to several workers (Clarke, Smith, Stokes, Wood) who have tested the brilliant green method on an extensive scale; the original estimate of the utility of the procedure has been substantiated, and it has been shown that the employment of this method, in addition to direct plating, leads to a very material increase in the number of positive results. In the light of the experience so gained, several modifications have been suggested. As regards specimens of faeces which are to be examined for the specific typhoid-paratyphoid organisms by any method, two points are of great practical importance: (1) Cultures should be made from the motions as soon as possible after evacuation, preferably within several hours; faeces which have been allowed to stand for some time are unsuitable for the isolation of typhoid bacilli. (2) In cases where the faeces are normally solid—for example, in suspected carriers, it is advisable to administer purgatives and then examine the resulting fluid evacuations; there is a consensus of opinion that this procedure increases considerably the chances of successful isolation of the specific organisms.

Method for the Isolation of Typhoid, Paratyphoid, and Gaertner Bacilli from Faeces.

A fresh specimen of faeces, preferably fluid, is employed; pieces of solid medium containing an indicator, such as Endo's preferably, or MacConkey's, are inoculated in the usual fashion, so as to secure a large number of isolated colonies. At the same time fluid medium containing brilliant green is inoculated.

The fluid medium consists of 2 per cent. peptone and 0.5 per cent. sodium chloride in distilled water, steamed in a Koch's sterilizer (for three-quarters of an hour) and then filtered through ordinary filter paper. The reaction should be corrected if necessary till it is only very faintly alkaline to litmus paper. The medium is then sterilized by steaming or in the autoclave; when large numbers of specimens of faeces have to be examined simultaneously time is saved by sterilizing the medium in bulk, otherwise it should be distributed in amounts of 10 c.c.m. in test tubes and then sterilized. A stock 1 per cent. solution of brilliant green in distilled water is prepared; this keeps for many weeks or even months. Immediately before use a 1 in 10,000 dilution is freshly made up by adding 0.1 c.c.m. of the stock solution to 9.9 c.c.m. of distilled water, and then this dilution is added to the peptone water.

It was originally recommended that varying amounts of the dye should be added to the 10 c.c.m. peptone water tubes, for each specimen of faeces a series of five concentrations being employed—namely, 0.1, 0.2, 0.35, 0.5, 0.7 c.c.m. of 1 in 10,000 brilliant green. We believe that the employment of such a series is an important feature of the method since the conditions of growth of the specific bacilli depend on factors such as their numbers, the number and type of accompanying organisms, and the amount of organic matter present, none of which can be standardized.

* Extended observations have shown that *B. paratyphosus* B is generally more resistant to telluric acid than *B. typhosus* (Smith).

When the number of specimens to be examined is considerable, however, the carrying out of the full procedure is expensive both in time and materials, hence a simplification consists in using for each specimen of faeces a single tube of fluid medium containing 0.5 c.c.m. of brilliant green 1 in 10,000 to 10 c.c.m. of peptone water. According to the experience of Clarke and Stokes, and also of Smith, this represents the average optimum quantity for the isolation of the specific organisms. When a large number of examinations have to be carried out at one time the mixture of brilliant green and peptone water may be made up in bulk and then distributed in sterile plugged test tubes (10 c.c.m. need not then be accurately measured into each tube).

As regards the amount of faeces to be used, we originally employed a single loopful in each tube, in the case of very fluid faeces a large loop (up to $\frac{1}{2}$ in. diameter) being employed; solid faeces were emulsified by rubbing up with several volumes of sterile water. The tubes were then incubated for twenty to twenty-four hours, and subcultures were made on MacConkey's medium; but, in view of the results of Dreyer, Ainley Walker, and Gibson, Endo's medium would seem to be preferable. Three successive strokes are made from each tube; in this way one 4 in. plate will accommodate the subcultures made from three peptone water tubes. The plates are then incubated at 37° C. for eighteen to twenty-four hours, and the colonies examined, as in the case of direct plates.

Clarke and Stokes prefer the following procedure: The faeces are emulsified with several volumes of sterile water; the mixture is then allowed to sediment (half an hour), and then five or six large loopfuls of the supernatant fluid, free from grosser particles, are added to the tube of fluid medium. When such a rich inoculation is employed, subcultures are best made after nine hours' incubation at 37° C. When the specific organisms are found, they usually occur in abundance in one or more of the subcultures, thus saving much of the time which is taken up in testing a variety of "likely" colonies from the direct plates.

Tubes in which an abundant growth of organisms has occurred, as shown by marked turbidity and replacement of the original green colour of the medium by a yellowish discoloration, are not likely to yield *B. typhosus* in subculture. Where the series of doses of brilliant green is used the lower tubes may show this discoloration and the next higher ones are then the most likely to yield positive results. Should all the tubes appear clear after twenty-four hours and fail to yield growths in subculture, a positive result may yet be obtained after the fluid cultures have been incubated for a further period. When the single tube containing 0.5 c.c.m. of brilliant green 1 in 10,000 is used the occurrence of discoloration indicates the following possibilities: (1) That corresponding to the amount of faeces used for inoculation the period of incubation ought to have been shorter—experience enables the amount of inoculation and the duration of incubation to be adjusted so as to secure the best results—or (2) that green resisting varieties of *B. coli* (usually inositol fermenters) are present. When these occur they tend to overgrow *B. typhosus*. The presence of inositol fermenters is probable when the subculture on solid medium shows a very abundant broad line of growth (suggesting in appearance the half melted creamy portion of the confection known as "chocolate cream").

With a view to suppressing the inositol fermenters telluric acid should be added to the brilliant green medium. The cultures in the green telluric acid mixture may be made along with the others, or, in order to save time, this may be omitted on the first examination. The examination of the first specimen of faeces from a case will probably show whether brilliant green resisting organisms are a disturbing factor; if they occur, then a subsequent examination of a fresh specimen of faeces should be made, using in addition medium containing 0.4 c.c.m. of 1 in 1,000 telluric acid, along with varying amounts of brilliant green per 10 c.c.m. of medium. Since the action of telluric acid when mixed with green is not precisely of the nature of a summation, it is advisable, in order to secure the optimum proportions in any given case, always to use a series of doses of brilliant green (not fewer than two amounts—namely, 0.25 and 0.5 c.c.m. brilliant green 1 in 10,000), each along with 0.4 c.c.m. telluric acid 1 in 1,000, or 10 c.c.m. peptone

water. It was found by Browning, Mackie and Smith, in a case of cuteric fever which they examined, that *B. typhosus* could be recovered from the faeces by means of telluric acid and brilliant green in combination, whereas direct plates as well as brilliant green by itself gave negative results.

The passage of typhoid and paratyphoid bacilli through media containing brilliant green or telluric acid has not been found to affect their fermentation or serological reactions. So far only incomplete series of results are available, but it appears that the employment of these procedures, in addition to direct plating, will increase the number of positive results by more than 25 per cent.

SUMMARY.

1. Specimens of faeces should be cultured within several hours after evacuation. In cases where faeces are normally solid it is advisable to give purgatives and examine the resulting fluid motions.

2. Make the usual smear cultures on plates of solid medium containing an indicator—for example, Endo's or MacConkey's. At the same time inoculate peptone water containing brilliant green; employ preferably a series of tubes for each specimen, but when time prevents this, use a concentration of 0.5 c.c.m. of 1 in 10,000 brilliant green in 10 c.c.m. of medium.

3. The direct plates and the brilliant green peptone water cultures are then incubated; if typical colonies are not found on the direct plates, or if "likely" colonies are scanty, make subcultures (successive strokes) from the green tubes on Endo's or MacConkey's medium. These are then incubated for twenty-four hours and examined in the usual way; should typhoid or paratyphoid bacilli be present in the subcultures from brilliant green medium they usually occur as an abundant growth of typical colonies, and it is possible to proceed at once to identify them by the usual fermentation and serum reactions.

4. In certain cases (where green resisting organisms are present) positive results may be obtained only when telluric acid is employed, in addition to green, in the medium. The cultures in the green telluric acid mixture may be made simultaneously with the others, or this medium may be reserved until the other procedures have failed. Thus, should direct plates fail to yield positive results, and the green medium be overgrown (inosite fermenters), then, in further examinations of the case, employ, in addition, peptone water medium containing a mixture of brilliant green with telluric acid.

HISTORICAL NOTE ON FARR'S THEORY OF THE EPIDEMIC.

By JOHN BROWNEE, M.D., D.Sc.,
STATISTICIAN TO THE MEDICAL RESEARCH COMMITTEE.

WHEN modern statistical methods are being applied with more or less success to the study of epidemics, it is, I think, interesting to recall the chief early work on this subject, especially since it has fallen into complete oblivion. The first attempt to describe epidemics quantitatively is due to Dr. Farr. No other person, so far as I can discover, had so early formed the idea that an epidemic was subject to definite laws, but his ideas were greatly in advance of his time, and his treatment of the subject was so episodic, but his discovery—I think that is the true description—has suffered almost complete neglect. His first publication was in the year 1840.¹ In that year he included in his report to the Registrar-General a short note on the course of epidemics, with special reference to

¹ Telluric acid can be obtained from W. Craven Ball, 45, Hop Exchange, Southwark Street, S.E. It should be kept as a 1 per cent. solution and sterilized by heat, otherwise it may become contaminated by moulds. The free acid keeps indefinitely in watery solution; it is therefore preferable to potassium tellurate, which was originally employed, but which is extremely unstable. Brilliant green may be obtained from various chemical dealers, or from Synthetic Chemicals, Ltd., Derwent Street, Derby. Graduated pipettes for measuring 1 c.c.m. and fractions of a c.c.m. can be obtained from most dealers in chemical glass apparatus, or from Messrs. Thomson, Skinner and Hamilton, 38, Sanchiel Street, Glasgow.

the recent prevalence of small-pox. The numbers on which he based his conclusions were moderately large, more than 30,000 persons having died during the outbreak. He specially considered the decline of the epidemic, and fitted the figures to a curve calculated by a method described. Though he gives no equation of the form of the curve, it is quite obviously the normal curve of error. He finishes the article with a few remarks upon measles, typhus, etc., and then adds: "These exhibit the same regularity, but the laws which govern their course will be more conveniently discussed when the abstract of the observations has been extended over another year." He does not, however, in spite of frequent promises,² seem to have discussed the subject again for twenty-six years.

The hypothesis suggested, however, did not pass out of his mind. In fact, it seems rather to have become a part of his belief, for in 1866 he wrote a letter to the *Daily News*,³ a vivid and characteristic utterance in which he challenged the prevailing views regarding the progress of the cattle plague. This cattle plague had invaded England in the end of the year 1865, and caused very considerable damage. With the growth of the new year, week by week the number of cases steadily increased, till in the end of February Mr. Lowe,⁴ in a speech in the House of Commons, anticipated, in the absence of very determined measures, an epizootic of tremendous size. This statement Farr takes as the text of his letter. He definitely states his views regarding the progress of epidemics. In place, however, of assuming that the second difference of the logarithms is constant—a form which gives the normal curve—he calculates, in addition, the third difference from the observations, and uses this as well in his prediction. The curve obtained by this means is the same as that given in Case 2 of my note in the *BRITISH MEDICAL JOURNAL* of May 8th, 1915, though in his case the coefficient of the third power of the time is negative. Using this method, he prophesies an early maximum of the epidemic, with a subsequent decline—a prophecy which approximated with remarkable closeness to the actual facts.

The reception of this letter was not encouraging. The *Daily News* discussed the matter in a complimentary leader next day, yet no member of Parliament—though the cattle plague was being discussed nightly—seems to have thought it worthy of mention. The *Lancet* ignored the communication entirely. The *BRITISH MEDICAL JOURNAL*'s reception was distinctly unkind.⁵ It remarked:

Dr. Farr will not find a single historical fact to back his conclusion that in nine or ten months the disease may quietly die out may run through its natural curve. Dr. Farr says again that the returns show that the weekly relative increase in the number of cattle which now fall with the disease is less than it was at first, and he attributes this to the view that the disease is running the usual course of epidemics. He quite forgets to take into account the fact that at the present time every one is satisfied as to the virulently contagious nature of the disease, and consequently takes measures to prevent it. When the plague first appeared, thanks to the stupid and puffed-up ignorance of the *Times*, the disease was generally set down as a local London cowshed nuisance, got as "S. G. O." slyly suggested, by "Moonbeam" out of "Dungheap."

The letter was reprinted in the *Journal of Social Science* later in the same year (March 20th, 1866), as follows:

DR. FARR ON THE CATTLE PLAGUE,
March 20th, 1866.

My dear Sir,

I send you my letter to the *Daily News*. The epizootic has apparently attained its maximum, and is now going down, as the "law" led me to believe.

The thing was going up, and looked most alarming, when I wrote. I do not like to alter what I then wrote, lest it should be thought that the alteration is made to suit the facts.

I took the series containing the "back cases," as it was published in the second report of the Commissioners.

Before that, I had calculated a series from the weekly returns of cases reported in each week.

This series follows nearly the same course, but the numbers are about one-fourth less.

The Privy Council returns are all exceedingly imperfect; but in assuming that they are almost equally imperfect throughout, I do not think that I am very wrong.

Ever yours,
(Signed) W. FARR.

To the Editor of the "Daily News."

Sir, The following passage occurs in the report of Mr. Lowe's last speech in the House of Commons:

If we do not get the disease under by the middle of April, prepare yourself for a calamity beyond all calculation. You have seen the thing in its infancy. Wait, and you will see the averages, which have been thousands, grow to tens of thousands, for there is no reason why the terrible law of increase which has prevailed hitherto should not prevail henceforth.

No one can express a proposition more clearly than Mr. Lowe; but the clearness of a proposition is no evidence of its truth. And in the present instance I hope to be able to convince Mr. Lowe himself that the proposition which he has propounded is founded on a misconception.

It admits of mathematical demonstration that the law of increase which has hitherto prevailed, instead of implying "that the averages which have been thousands will grow to tens of thousands" implies the reverse; and leads us to expect that the subsidence will begin in the month of March.

I take the following figures from the second report of the able Commissioners on the Cattle Plague, of whom Mr. Lowe was one of the most efficient.

The number of reported cases from the commencement was:

1865.	Total.	New Cases occurring in Four Weeks.
October 7 ...	11,300	...
November 4 ...	20,837	9,597
December 2 ...	39,714	18,817
December 30 ...	73,549	33,835
1866.		
January 27 ...	120,740	47,191

NOTE.—The numbers include what are called "back cases."

It will be observed that, although the attacks in the second period of four weeks were nearly double those in the first period, that rate of increase did not continue; otherwise, on the principle of doubling, the numbers would have run up from 9,597 to 19,194 to 38,388 and 76,776. But the attacks in the last four weeks were only 47,191; and the real law implies that the ratio of increase goes on rapidly decreasing until the ratio itself is decreasing.

Thus the increase in the first interval was at the rate of 96.07 per cent.; in the second interval it was 79.81 per cent.; and in the third or last interval under observation it was only 39.47 per cent. Now here is a complicated law of decrease in these rates; and the "terrible law" is such that—if it is any law at all—the attacks in the four weeks ending February 24th will be 43,182, and the attacks in the next four weeks ending March 24th will be 21,927, and so on. The attacks in the four weeks ending February 24th will probably exceed 43,182, but the number will certainly not amount to twice—to say nothing of ten times—47,191.

Periods of Four Weeks ending	Reported Attacks.	Calculated Series by "Law."	Actual Figures.*
1865—			
November 4 ...	9,597	9,597	9,597
December 2 ...	18,817	18,817	18,817
December 30 ...	33,835	33,835	33,835
1866—			
January 27... ..	47,191	47,191	47,287
February 24	43,182	57,004
March 24	21,927	27,968
April 21	5,226	15,856
May 19	491	14,734
June 16	16	5,000 (about)

* The actual figures of the course of the epidemic have been printed alongside of Dr. Farr's calculations. The epidemic culminated about a fortnight later than he prophesied. As the actual form of the epidemic is not accurately expressible by the formula he has chosen, the degree of accuracy is certainly all that can be expected.

NOTE.—To obtain the series, multiply the first number (9,597) by 1.967, the product by 1.7981, and the second product by 1.5977. It will be observed that these rates decrease; the second is obtained from the first by multiplying by .9171, and the third from the second by multiplying by .7757. Again, .7757 is obtained by multiplying .9171 by .8458. The process is simplified by employing logarithms, and the series is continued by taking log. .5977, which equals 3.9821355; and the three orders of differences of the logarithms of the numbers derived from direct observation.

If Mr. Lowe will take his compasses and draw ordinates representing these figures, he will immediately perceive the nature of the curve: it ascends first rapidly, and then slowly, until at last it attains a maximum, makes a turn, and falls down more rapidly than it mounted. The nature of the curve is obvious.

Mr. Lowe prophesies. I will not be so presumptuous, and will admit that the law which has hitherto prevailed" may be modified by the introduction of unknown elements. But as it would be fair to infer that a projectile thrown up in the air, losing some of its velocity every second, will stop at last, so it is not unreasonable to infer that the cattle plague ere long will come to an end. The course which it has hitherto taken justifies us in assuming that the attacks will soon be at their maximum.

I will now assign reasons for believing that this indication will be realized; and that, although indigestible will remain in the country as a sporadic disease, liable to other eruptions, it will subside spontaneously as an epizootic. The holocausts about to be offered up will, we may hope, not retard the consummation.

All the epidemic poisons are reproduced in every individual that they attack; and if they lose part of the force of infection in every body through which they pass, the epidemic has a tendency to subside from this cause, which is strengthened in its operation by the fact that the individuals left are less susceptible of attack, either by constitution or by hygienic conditions, than those destroyed. This is as true of epizootics attacking animals as it is of epidemics attacking men. Now, the Russian physicians have shown that the matter—say *bovine*—which causes the *Bovilla pestis*, diminishes in strength at every transmission by inoculation, so that after it has passed through seven oxen in succession, matter which at first killed 50 per cent. of the inoculated ended by killing only six; while at a further stage of transmission few cattle sickened and none died. This was in cattle of the steppe race. "Before mitigation of the virus appears in other races," says Professor Playfair, "it must pass through from 13 to 15 cattle in succession." (See *The Cattle Plague*, by Lyon Playfair, C.B., F.R.S., one of the Cattle Plague Commissioners.) Allowing ten days of interval, the matter in England will have passed in the natural way through 24 cattle at the end of February.

Diminished activity of the zymotic matter and augmented powers of resistance in the survivors are the factors to which the subsidence of epidemics of small-pox, cholera, measles, scarlatina, and typhus are in themselves referable. The matter (cholera) inducing epidemic cholera was apparently diffused all over England in 1849; and there were two or three deaths by cholera or diarrhoea in nearly every district; everybody more or less felt its power; but the mortality was only great in the low parts of the kingdom, and where the stuff entered the system through water as well as through air and other media.

When an epidemic disease of foreign origin enters a country it encounters difficulties of diffusion, and it is undoubtedly very slow in its way, so that it may pass through its phases within the narrowest possible circle. These precautions as regards all common zymotic diseases are never pushed so far as to interfere with nursing, medical attendance, travelling, or social intercourse in England; yet all these epidemics subside within limited terms as certainly as they spring up.

I have stated that subsidence is a property of all zymotic diseases. I may cite the cholera epidemics in England as examples. In June, 1849, the deaths by cholera were 2,046; they rose in July to 7,570, and in August to 15,872. Here was a rapid and alarming increase of deaths; but the rate of increase was decreasing. The calculated deaths for September and October were 19,488 and 12,698; the actual deaths were 20,379 and 4,654. It fell headlong, and became, as an epidemic, virtually extinct.

Diphtheria is the last epidemic of England. It goes through its course more slowly than cholera. The deaths in the years 1857-8-9 by diphtheria were 1,583, 6,606, and 10,184. Here the rate of increase was itself in a decreasing ratio, and the deaths by diphtheria in the year 1860 were 5,588, which is very near the calculated number. Rinderpest, or *bovillia*, has many points of analogy with small-pox, scarlatina, diphtheria, typhus, and influenza, which all follow the law of increase and decline; the increase admitting of retardation, and the decline of acceleration, by judicious measures.

These diseases decline because their matter, generated in unhealthy varieties of race, loses some of its virulence by transmission, because all are not susceptible, and because, in their progress, they destroy the lives of animals living under such unnatural conditions as the cows of London.

The cattle plague in Rome, which Lancisi has so well described, lasted less time than our calculation gives. It began about August 10, 1713, and left no vestiges of its existence in May, 1714. It killed 26,252 cattle, according to the returns; how many it left alive Lancisi does not state; but, as he is often referred to, let me cite one cheerful passage, in which he asserts that no one felt the scarcity of meat; that lambs and wethers were unusually abundant, that multitudes of cattle fed on the fields and meadows in 1715 as of yore, and that provisions were cheaper in the Ager Romanus than in Picenus, where he was writing, which had suffered nothing from the calamity.

It is but justice to our veterinary surgeons to say that their poleaxe practice is sanctioned by Lancisi; and that, after laying down the strictest rules for the isolation, for the stopping of the movements of rustics and dogs, as well as other measures equally easy of execution, he concludes with the subjoined well-known passage: "Quae cum omnia necum reputo, eorumque simul difficultatem, expensas, pericula, laboresque confero, nihil aut facilius, aut certius, expeditiusque illatae jam pestis esse remedium video, quam si statim ab initio infirmac animantes explosis globulis interficiantur, atisque extemplo scrobibus inferantur."—*Op.*, vol. ii, p. 17.

It has been assumed by Professor Playfair that this advice was accepted by Clement XI. But Lancisi distinctly states that he humbly proposed the policy in the Sacred College; that it was supported by some eminent cardinals; but that it was rejected for a milder course (*Verm potior Patrum pars in mitiore sententiam discessit, et custodituros boves*). The most minute instructions of the Pope and the College are given by Lancisi; but no authority to slaughter, and apparently not a single head of cattle was slaughtered by authority in the Papal dominions. Yet the cattle plague subsided in nine months.

(Signed) W. FARR.

February 16th.

By the time the letter was published in the *Journal of Social Science* the accuracy of Farr's prophecies was quite obvious, and the editor, Dr. Edwin Lankester, enthusiastically received the hypothesis as on the footing of a natural law, stating that "the prediction of Dr. Farr with regard to the cattle plague has been all but literally fulfilled." These encomiums, however, do not seem to be much more scientific than the derogatory remarks with which the *BRITISH MEDICAL JOURNAL* received the communication. In the same issue (April, 1866, p. 306), reviewing works on cattle plague, "J. J. R." writes:

Dr. Farr has been working at the subject, and he has given it to the world that the cattle plague does diminish in virulence as it increases in amount of animals attacked; and it has been stated that in the natural course of events the disease would die out; in fact, that nature has adopted that which Mr. Gamgee recommends as the only cure, a "stamping out." Of course, to such declivities we cannot expect Mr. Gamgee to agree after his decided antagonism to the idea of spontaneous decline, but there is strong ground for supposing that such is really the existing state of affairs.

The *BRITISH MEDICAL JOURNAL* remained unconvinced of its error, commenting impenitently on the subject in a few lines in the issue of June, 1866.*

There was a further letter in a subsequent number of the *Journal of Social Science*† by Dr. Markham,‡ which takes a view hostile to Farr, but as the discussion is confined to the accuracy of Farr's treatment of Lancisi's statistics (vide Farr's letter), and his treatment of these statistics is wholly inadequate, further reference is unnecessary. It contains nothing of the least importance at the present day.

From this point no direct reference to Farr's letter occurs in literature. Published in a daily paper it was naturally difficult of access unless the date was known, and the republication of the letter in the *Journal of Social Science* occurred at a time when that journal, never of great vitality, was moribund. Difficulty of reference

accounts in all probability in some measure for its future neglect, but the fact that Farr never returned to the subject, and does not seem to have taken much further interest in it himself, certainly had its share.

Humphreys,‡ editing the memorial volume entitled *Farr's Vital Statistics*, reprints the earlier paper of 1840, but takes no notice of the letter, nor is any mention made of it in the short biography given in the commencement of the volume, nor in the biography of Farr given in the *Dictionary of National Biography*. Two subsequent writers have considered the paper. Dr. Ransome,§ who accepted the hypothesis to a certain extent, discussed it in a paper published in the *BRITISH MEDICAL JOURNAL* for October 10th, 1868, but he appears to be speaking without direct knowledge, and the reference he gives to Farr's paper (*Social Science Review*) is wrong. Dr. Evans,¶ who discussed and approved the method in a paper in the *Epidemiological Society's Transactions* in 1872, states that he received his knowledge secondhand from a member of the society who had obtained it from Dr. Farr. His description of the method is very obscure, but on careful examination it amounts to considering the second difference of the logarithms as constant. The third difference is not mentioned. He has, however, a curious statement in connexion with the decline of the cattle plague. He says:

Now the largest number of reported cases appeared in the sixth week of 1856, and the real decline of the epidemic was more rapid than the calculated decline, a result very reasonably attributed by Dr. Farr to the effects of slaughtering in the later weeks of the epidemic.

What his authority for this statement is I do not know. It is not true on Farr's own calculations, but only on those of Dr. Evans. It may be that he received the information verbally with the description of Dr. Farr's method, or it may be that Dr. Farr wrote some additional note on the subject, which I have not been able to trace. As Dr. Evans has been dead for many years, this point must remain unsettled.

Dr. Ransome,|| rediscussing the periodicity of epidemic disease in the *Transactions* of the same society for the year 1881, states quite definitely that he had never seen the original. Neither of these writers refers to the earlier paper of 1840, which was later reprinted in the volume of *Farr's Vital Statistics*, nor does either appear to have discussed the subject again.

The letter, I think, is one of the epidemiological classics. At the time Farr produced it, though he quotes experiments in its favour, the ideas lay outside the main stream of knowledge. There are now a number of analogous facts, and I am quite convinced that a large part of the theory of epidemics is to be explained by the means first clearly expressed in the letter now reprinted.

DR. BERTRAM HERBERT LYNNE STIVENS, who was for many years engaged in general practice at Park Street, Grosvenor Square, left estate valued at £225,799 gross, with net personality £199,113. He died on May 9th last, aged 59.

The German Society of Apothecaries (pharmacists) has combined with the "War Chemical Company" to control the sale of glycerine and nitrates for pharmaceutical purposes. The rules fix the maximum quantity of glycerine obtainable by any pharmacist at three kilograms a month, and the pharmacist must undertake to use it only in dispensing prescriptions and to make preparations which are official in the German pharmacopoeia; he must not use it for cosmetics, toilette preparations, or in soap. The regulations have been made owing to the great demands of the factories for explosives, and the falling off in the importation of fats.

* Farr, i, cap. 3, p. 5. Geneva edition of his works.

† The editor adds a footnote to this, saying he does not intend to comment on it, as Dr. Farr is quite able to take care of himself, but I have found no further note by Dr. Farr.

TUBO-OVARIAN ABSCESS, INTESTINAL OBSTRUCTION, AND URETERIC OBSTRUCTION:

SIX ABDOMINAL SECTIONS: RECOVERY.

By JOHN D. MALCOLM, F.R.C.S. EDIN.,
SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL.

A case in which three operations—the first, second, and fifth—were urgently needed to save life within two years seems worthy of record, and it is also of interest that, apparently, the first operation was not the cause of the peritoneal adhesions which brought about the intestinal obstruction.

First Operation.

Double Salpingectomy and Oöphorectomy by Another Surgeon. September 16th, 1912.—After seventeen days' illness the patient, who had in a marked degree the delicate appearance frequently associated with tuberculous disease, was operated upon by an experienced gynaecologist, who has kindly informed me that he removed a tubo-ovarian abscess from each side, that the vermiform appendix was normal, and that an uninterrupted recovery followed. Except for an attack of abdominal pain in May, 1913, the patient continued in good health for nearly seventeen months. On February 7th, 1914, at the age of 23, she consulted Dr. P. A. Storey on account of severe colicky pain of three days' duration, accompanied by vomiting. A dose of morphine was given, and the patient was sent to the Samaritan Free Hospital. On admission all symptoms except a slight fullness of the abdomen were in abeyance, but next morning an intense gripping pain recurred every few minutes accompanied by visible peristalsis. The patient stated that for fifteen years she had suffered off and on from a pain in the right loin; its significance became clear at a later date.

Second Operation.

Fistula Formation in the Small Intestine. February 5th, 1914.—The lower two to three feet of the small intestine were empty and closely matted together over the brim of the pelvis on the right side. The vermiform appendix and caecum were involved in the bowel adhesions, but lay altogether to the right of them, and otherwise appeared healthy. The anterior abdominal wall was not adherent, and where the ovaries had been removed the broad ligaments were smooth and rounded, there being only a few filmy adhesions in the pelvis. The conditions of the former operation did not explain the new trouble. Neither did an appendicitis appear to be the centre of mischief, but, in the absence of a better, this was accepted as the cause of the adhesions. The ureter was not thought of at that time as a source of infection.

The adherent coils were separated and many surfaces had to be seen over, the mucous membrane being exposed at several places. The manipulation made these coils so limp and inactive that an obstruction from paralysis seemed certain to follow if this part of the bowel was required to carry on its functions. An excision or a short-circuiting operation was indicated, but the small intestine generally showed a tendency to dilate and the patient became so feeble that a rapid termination of the operation was deemed necessary. A Paul's tube was therefore introduced into the lowest coil of healthy small intestine and the abdomen was closed around this tube, provision being made for drainage of the raw surfaces left in the peritoneal cavity. Removal of the vermiform appendix was postponed in the hope that the patient would be stronger at a later date. After this operation marked depression of the circulation persisted for several hours. The bowel above the fistula acted well from the first.

Considerable haemorrhage from the abdominal wall began on the third day, and did not stop until a vessel was ligatured under an anaesthetic on the sixth day. The loss of blood and the disturbance of the parts were unfavourable to a gain of strength, and when the Paul's tube separated the irritation of the discharges threw a further burden upon the patient.

Third Operation.

Ileo-colotomy, Caecostomy. February 27th, 1914.—On the nineteenth day, as no further progress seemed likely,

the intestine was divided above the fistula, its lower end was closed and its upper part was joined to the ascending colon by an end-to-side anastomosis. Adhesions made this operation difficult, and again the circulation became very weak. It was decided, therefore, to open the caecum and put a Paul's tube in it, to ensure an absence of backward pressure at the seat of the anastomosis. The removal of the vermiform appendix was again postponed. After this operation the bowels acted on the third day, and there was never much discharge from the caecal fistula. The patient quickly recovered and increased considerably in strength.

Fourth Operation.

Closure of Caecal Fistula and Appendicectomy. March 24th, 1914.—After twenty-five days the caecal fistula was closed and the vermiform appendix was removed. The separation of firm adhesions of the inactive part of the intestine prolonged this operation and the depression following it was alarming, but, after two days, progress was good until the patient was allowed out of bed three weeks later. She then immediately suffered from severe pain in the right loin and vomiting, with a rise of temperature to 105° F. and of pulse to 120. These symptoms abated after a few days, but returned at intervals. Later the temperature fell to normal and the vomiting ceased, but the loin pain became so severe and continuous that restful sleep was impossible. The patient stated that this pain was the same as that she had suffered from time to time for fifteen years, only more intense. A well-defined very tender immovable swelling gradually developed below the right costal margin, the rest of the abdomen being free from distension or tenderness. The bowels gave no trouble, and the only abnormal constituent of the urine was the *Proteus vulgaris*. The swelling was diagnosed as a distended kidney and the conditions became so serious that surgical interference was considered absolutely necessary to prevent death from exhaustion.

Fifth Operation.

Right Nephrectomy. May 12th, 1914.—On again opening the abdomen a slightly enlarged kidney, fixed in an unusually low position, was exposed. It was misshapen, the pelvis being on its anterior flat aspect instead of at the inner edge, but there was no obstruction in the pelvis. The ureter, where it lay on the pelvic brim, was thickened and fixed, and it appeared that some obstruction at this point was the cause of the kidney pain. It was deemed essential that complete relief should be given at once, and that if possible no further strain should be made on the patient's mental and physical endurance such as a renal fistula would involve. I therefore rapidly excised the right kidney after ascertaining that the left was normal to palpation. This was the shortest operation of those performed by me on this patient, and although the pulse became quick and feeble, she soon rallied. The cut end of the ureter was fixed to the skin between the lips of the incision, and seemed to be a source of infection, union being delayed until some sutures came away. The patient never had any of the old pain in her loin after this operation, and her whole condition at once improved.

Sixth Operation.

Closure of Fistula in Small Intestine. January 1st, 1915.—The fistula made at the second operation, February 8th, 1914, with the blind piece of small intestine above it, was excised, and the bowel below was closed, the abdominal wall being carefully repaired. The wound healed by first intention, and at this time there was no bulging of any of the incisions. The latest report (June 27th, 1915) is that, except for an occasional pain in the back, the patient's health is good, and her bowels give little or no trouble.

It seems to me that in this case there was a very old difficulty in the passage of urine through the right ureter, near the pelvic brim. The abnormal shape and fixation of the kidney could not be a cause of the symptoms, but they suggest the possibility that a congenital abnormality might exist also in the ureter. Otherwise some infection within the ureter, or in a gland close to it, was probably the cause of obstruction. The tubo-ovarian abscesses were certainly due to infection, possibly from the kidney, and their removal had no direct bearing on the history, unless

the mere opening and manipulation of the peritonæum could induce an extension of inflammation from the ureter to the serous membrane. There seems to be no doubt that such an extension took place and caused the intestinal adhesions, the vermiform appendix being involved secondarily.

It is obvious that at the second operation a short-circuiting of the bowel would have rendered the third, fourth, and sixth operations unnecessary, and possibly the need for the nephrectomy would not have arisen, but if the adherent coils had not been separated a pus focus might have been left, and when the absence of any such condition was ascertained the patient, never strong, had become so feeble that the course adopted seemed the safest. Removal of the kidney was essential for health and comfort, so the development of the renal symptoms was not regretted after they had been successfully dealt with.

INVERSION OF THE UTERUS IN A NULLIPARA DUE TO A SUBMUCOUS FIBROMYOMA.

BY

ROBERT B. JOHNSTON, F.R.C.S., M.R.C.P.E.,

PENRITH.

THE following case being of a somewhat unusual nature, I have thought that a short statement of it might be of interest.

On February 5th I was called at midnight to see a farmer's daughter, a nullipara aged 45. All the appearances of a recent severe hæmorrhage were present. A mass about 5 in. long, somewhat conical in shape, with a blunt apex and base towards the vagina, protruded from the vulva. Its lower part was quite smooth and pale red in colour, and its surface was shiny except in one or two places where there were linear excoriations up to about half an inch outside the vulva, where it abruptly became rough and shaggy, and almost black in colour. It was here covered with dark blood which slowly oozed from its surface, and was tightly constricted at the vaginal orifice. The bed and the patient's clothes were saturated with blood, as in an abortion. The pulse was 120, rather small, but steady; temperature 97°; respirations normal. The patient sweated, and was evidently suffering from shock. Thinking at first that it might be a cervical polypus protruding from the vagina and commencing to slough, I was, however, assured that nothing had projected externally until about one hour before I was summoned. On closer examination I discovered that the protruding mass was a sessile polypus attached to and occupying the whole fundus uteri, and that it had caused a complete inversion of the uterus. The dark, rough, shaggy mass was the fundus in a state of strangulation caused by the narrow vulval orifice, and I could distinguish the dimples indicating the uterine openings of the Fallopian tubes on each side, just inside the vagina. I had received no information as to the nature of the case I was called to see, so that I had no chloroform at hand; but as, fortunately, I had taken my surgical accident bag, I was provided with antiseptics. The patient's condition was very serious, so I decided to try to reduce the mass without an anaesthetic. I carefully cleansed the surrounding parts and the tumour, and grasped the fundus, which was hard and firm, close up to the vagina with my right hand, and then kept up a steady pressure, as in the reduction of a hernia, for about ten minutes, when I became sensible of a softening in its consistency. Maintaining this pressure, I now began to push the mass steadily inwards and slightly upwards until the whole fundus passed inside the vagina. The vulval orifice being so small, I could no longer keep up the pressure on the uterus, so I pressed the fibroid. When the apex of the tumour had reached the orifice, the whole mass suddenly reduced itself, and nothing could be felt in the vagina but the cervix uteri, with an external os which would just admit the tip of the index finger, and with nothing protruding. The whole process of reduction took only twenty minutes. The uterus could now be defined enlarged, as in the third month of pregnancy, and retracted. The fundus, normal in its rounded contour, showed no signs of dimpling. I cleansed the vagina as well as I could under the circumstances, and gave the

patient one-sixth of a grain of heroin hypodermically. As no hæmorrhage or pain ensued I was able to leave her one hour later. The subsequent history was uneventful; the temperature rose to 99° next day, and then fell gradually to normal; the pulse also by the second day fell to 80. On the third day an enema was given with a good result and no untoward symptoms. There has since only been a slight show daily, with no pain.

The history of the case is as follows: Until Christmas, 1914, the patient, who is a strong, healthy single woman, inclined to stoutness, and engaged in farm work, had noticed nothing unusual. After Christmas, however, she suddenly began to have occasional rather severe losses at the periods, with more or less metrorrhagia, but no pain. These symptoms were ascribed to the coming of the menopause. At 4 p.m. on February 5th, after a particularly heavy day's work, pains in the back, with some bleeding, set in, which gradually became more severe, and extended all round, somewhat as in labour. At about 7 p.m. the patient first felt that something occupied the vagina. She did not like to say anything, however, but went to bed, and fell asleep for nearly two hours, when the pains became most intense, and the mass suddenly issued from the vagina, and then I was sent for, four miles from her home.

The unusual feature of this case is the inversion of the uterus in a nulliparous woman—a condition which is rarely mentioned in textbooks, and was no doubt produced by the efforts of the uterus to expel the polypus as a foreign body. Owing to its close attachment to the fundus, the tumour gradually produced a dimpling, this process extending *propter hoc et post hoc* until the uterus was completely inverted. I may add that I was rather surprised at the fairly easy way in which it was reduced, and at the quick and steady recovery from what must have been a severe shock, not to speak of the risk of uterine infection. I would also say that the patient, who dreads operation, so far cannot make up her mind to submit to the necessary surgical treatment for her cure.

ACUTE SEPTIC MENINGITIS DUE TO B. COLI FOLLOWING SKULL WOUND.

By C. E. H. MILNER, M.R.C.S., L.R.C.P.,

LIEUTENANT R.A.M.C.(T.).

THE following case has recently come under my care at the 4th London General Hospital, and in view of one or two unusual features in its etiology and progress I have thought it worth while to place it on record.

Lieutenant R. W. was wounded in the head on May 5th by splinters of a high explosive shell, and sustained a compound fracture of the right parietal bone. Three days later he was trephined in France. Fragments of broken bone were elevated and removed, the original skull wound was enlarged, and the dura opened and drained. He was placed on the danger list and his friends telegraphed for, and it is largely thanks to the accurate observations made by his brother, who went at once to Boulogne, that I have been able to piece together a continuous history.

With a single relapse on May 21st, when he was very drowsy all day and his temperature rose to 100° F., he recovered gradually, until on June 1st he was well enough to be brought to England. On admission to the 4th London General Hospital on June 2nd he had a narrow, horizontal, nearly healed wound 3 in. long, situated 1 in. above the right ear, and overlying a larger trephine wound measuring 3 in. by 1½ in., from which a slight amount of cerebrospinal fluid was escaping. He complained of some headache, which was attributed to the journey by sea and by train. Except for slight weakness of the muscles of the left side of the face (a symptom which had been present from the outset) all the motor functions were normal; the deep reflexes normal to brisk, and both plantar flexion. The optic discs were normal and the temperature 99.8° F. It fell at night to 98.6° F.

At 4 next morning he complained of violent headache, and the temperature had risen to 103° F. There was no rigidity of neck or back muscles; Kernig's sign was absent, and there was still a complete absence of localizing neurological symptoms. Lumbar puncture was performed,

and the cerebro-spinal fluid found to be under slightly increased pressure. Cytological and bacteriological examinations were carried out, with the following results:

There were 3,760 cells per cubic millimetre, of which 70 per cent. were polymorphonuclear leucocytes; colonies of pure *B. coli* were isolated, from which a vaccine was prepared. Urotropine, which had been administered from the outset in doses of 10 grains three times a day, was now increased to 20 grains every four hours.

For three days the temperature remained high, ranging from 101.2 to 103.2 F. But clinically the symptoms—more particularly the headaches—were greatly relieved by the lumbar puncture. The patient was never unconscious, though cerebration was markedly slow; beyond some venous engorgement there was no abnormality in the optic discs.

Autogenous vaccine was given on June 5th and June 7th, in doses of 12½ and 25 million. On June 8th the temperature fell in the morning to 98.2 F. for the first time. Since that date the improvement has been maintained without interruption, and the patient is now in every respect normal.

CONGENITAL HEREDITARY ABSENCE OF SOME OF THE DIGITAL PHALANXES.

BY

D. S. CLARKE, B.A., M.B., Ch.B., R.U.I.,

RESIDENT HOUSE-SURGEON, BAGTHORPE MILITARY HOSPITAL; LATE SENIOR RESIDENT MEDICAL OFFICER, BAGTHORPE INFIRMARY, NOTTINGHAM.

The following observations are taken from a patient who was confined some weeks ago with her third child at the Bagthorpe Infirmary.

The abnormality affects both hands. There is an absence of the proximal and distal interphalangeal joints of the little and ring fingers, and of the distal interphalangeal joints of the index and middle fingers, as shown by the photograph taken of both hands. The tips of the affected fingers are rounded off, without any indication of a nail, excepting a minute vestige on the left index finger. The thumb of each hand is quite normal in appearance. The patient has no difficulty in performing the ordinary movements of the hands, but complains of inability to knit. The accompanying drawings from radiograms taken by myself illustrate the condition described below. The larger represents the mother's hands, the smaller those of her third child. As is seen, the middle and terminal phalanges are absent in both the little and ring fingers.

Fig. 1.—Drawing from radiogram of mother's hands.

In the index and middle fingers, the middle phalanx is seen to be absent, and not the terminal phalanx, as might be expected from the appearance of the hand. The patient states that her grandmother was similarly affected, as were also her mother, brother, uncle, and two cousins.

The geneological table is as follows:

The abnormality seems to affect the first two born in each family, irrespective of the sex, and is present at birth.

Fig. 2.—Sketch of mother's hands.

In the case of the above patient her third child (boy), although not by the same father, was similarly affected,

as is shown in the accompanying drawing (Fig. 3). In addition to the deformity of the hands there is a peculiar malformation of the child's penis. I cannot ascertain whether any deformity of the penis was present in any of the other male children. The prepuce is unusually long, but the frenum is imperfectly developed. The glans is quite normal, but the terminal opening of the urethra is not quite central, lying nearer the corona glandis than usual. On efforts of the child at micturition the prepuce in its lower part becomes distended, almost exceeding in size a grape, and by compressing this distended portion the urine could be expelled in a fine stream, the ballooned portion thus acting as a reservoir.

A fine catheter, if directed forwards, could be made to enter the urethra, whilst if directed downwards and forwards it would be passed into the cul-de-sac above described, thus indicating that the floor of the urethra was incomplete in its terminal portion (partial hypospadias), although to all external appearances it looked quite normal.

A fine catheter, if directed forwards, could be made to enter the urethra, whilst if directed downwards and forwards it would be passed into the cul-de-sac above described, thus indicating that the floor of the urethra was incomplete in its terminal portion (partial hypospadias), although to all external appearances it looked quite normal.

In order to stimulate the invention of methods for using alcohol for commercial purposes the Russian Government has resolved to offer for international competition a series of prizes amounting altogether to £67,500. The highest prizes (four ranging from £7,500 to £2,000) will be given for devices to utilize alcohol for internal combustion engines. Other prizes, ranging from £6,000 to £500, will be given for methods of using alcohol for lighting, heating, and in the preparation of various materials useful in industry.

At the annual meeting of the American Medical Association, held in June at Rochester, Minnesota, it was decided that the next session should be held in Washington in 1916. Dr. Robert G. Leconte, of Philadelphia, was elected president.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF LYMPHO-SARCOMA BY SALVARSAN AND GALYL.

I SHOULD like to point out that, besides their undoubted value in the treatment of syphilis, I have found these drugs to be at least efficacious, if not wholly curative, in two cases of lympho-sarcoma. Both were of speedy recurrence after a second excision of glands.

The first case, a young Norwegian sailor, after weekly intravenous injections of neo-salvarsan, refused to submit to further treatment, and left the hospital apparently cured. He worked on board ships for at least eight months afterwards, and was then lost sight of.

The second case is still under treatment with galyl.* He shows no sign of further recurrence, and is very markedly improved in general health.

These are the only cases of lympho-sarcoma I have met with during my tenancy of the post of medical superintendent of this hospital, but their temporary, if not permanently, successful treatment with salvarsan products justifies me, I hope, in appealing to the members of the profession to give these drugs a trial in similar cases.

JOHN HARTIGAN,

Medical Superintendent, Royal Hemarad Seamen's Hospital, Cardiff.

HERPES ZOSTER OPHTHALMICUS AFTER SNAKE BITE.

On April 1st at 7.30 p.m. I was called to see a woman, aged 54, suffering from violent pains in the right eye. On March 15th she had been bitten in the left hand by a snake, here called *uruth*, and half an hour afterwards she became giddy, though only for a short time, and within three hours a hypodermic injection of antiophioidic serum was administered. It was prepared in the Butantan Institute of this country—S. Paulo State, Brazil. Probably in consequence of this injection, there was no other manifestation of the poisoning besides the giddiness already referred to and some inflammation of the whole left arm. She appeared to be convalescent until she began to feel, on March 29th, a very strong pain in the right eye, which spread to the forehead, the head, and the upper gum of the same side. An eruption accompanied by fever developed all over the parts just mentioned. She could not sleep on account of the pain, and as the right eye became greatly swollen she came up to this town for advice from an oculist. This necessitated a ride from her farm lasting three hours before she reached the nearest railway station.

I found her lying down on her back, crying out and complaining of violent pain in the right side of the head and face. The right eye was very much swollen. I saw that there was intense chemosis of the conjunctiva, but no corneal lesion. Numerous vesicles, varying in size and more or less confluent, covered the right side of the head, the forehead, the temple, the integuments around the eye and the cheek down to the corner of the mouth. I detected a few vesicles on the upper gum, which was toothless, and the right half of the palate. The preauricular gland was swollen and painful, and all over the head, specially on its right half, there was an almost continuous and profuse perspiration. Temperature 38° C. As the pain was the most conspicuous and troublesome symptom, I prescribed:

Phenacetin) ʒā gr. iv
Salophen)
Caffeine gr. ʒ

Make into a capsule; one to be taken every two hours.

As an external application I ordered:

Lassar's paste ʒj
Icthyol gr. xxv

On the following day the pains were less severe. The patient had been able to sleep for some hours, but complained of general weakness. Appearances were unaltered; temperature 37°. I prescribed calomel with rhubarb, and instead of the capsules of phenacetin, salophen, and

* Galyl can be obtained in this country from Messrs. Roberts, 76, New Bond Street, London.

caffeine, I directed her to take the following mixture as a cholagogue and diuretic:

Sodium salicylate gr. xxxij
Sodium bicarbonate gr. lxxj
Potassium acetate gr. lxxj
Potassium nitrate gr. xxxiij
Syrupus maydis stigm. ʒi
Aq. dest. ʒiv

One tablespoonful every two hours.

In the afternoon her temperature again reached 38° C., but the pains abated so much that she slept well during the day. The disease then ran the ordinary course of herpes zoster. The temperature fell to normal, the vesicles burst and dried up, the perspiration on the head gradually ceased, the chemosis of the conjunctiva subsided and the pains did not return.

This case is interesting:

1. On account of the intensity of the eruption and its extension over the right side of the face and head, as above described.

2. On account of the intense pain inside the mouth, which, I must add, was accompanied by profuse salivation. This pain prevented the patient from taking anything but liquids.

3. On account of the abundant, yet quite local, perspiration, so profuse that it kept the pillows constantly wet, specially at night.

4. On account of the fact that this attack of herpes appeared fourteen days after the bite of a snake, treated by an injection of antiophioidic serum. This circumstance is noteworthy, because the etiology of herpes zoster ophthalmicus is not yet well established, and the case favours the theory that this disease depends on some toxic agent. Physicians who practise in countries where snake bites are common may be able to inform us if they have observed the complication here reported.

The good effect of the combined anodynes in this case is worthy of note, as is also the fact that the pains subsided much sooner over the external parts where Lassar's paste with ichthyol could be applied than in the mouth.

CASSIO DE REZENDE, M.D.

Guareatinguá, S. Paulo, Brazil.

COMPLETE INVERSION OF THE UTERUS.

WHEN in a large general practice in the country I had one case of complete inversion. I found the woman on her side completely exsanguinated, the uterus wholly outside on the bed, and the placenta closely and wholly attached. The nurse said she had pulled it "like that." I peeled off the placenta, which was more adherent than usual, and slowly pushed the uterus back into position, but its substance was so very flaccid that the dome of the fundus kept falling on the supporting fingers. I now poured cold water from jugs on the abdomen; the uterine tone returned, the uterus contracted, and the patient made a slow but uncomplicated recovery.

London, N.W.

EDMUND HOLLAND, M.D., F.R.C.S.

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

B.D. PETIT PARSİ GENERAL HOSPITAL, BOMBAY.

SARCOMA OF THE PROSTATE.

(By B. P. SABAWALA, F.R.C.S. Edin., Surgeon to the Hospital.)

SARCOMA of the prostate is rare. Bland-Sutton has seen only one such case, and says that only thirty-four more are on record.¹

P. N. M., a Parsi lad, aged 17, was admitted on July 24th, 1914, complaining of pain in the back and painful and frequent micturition. The flow at times stopped suddenly, and pressure on the hypogastrum caused a little more to be passed. The day before I saw him the passage of a catheter had been followed by hæmorrhage

¹ *Tumours, Innocent and Malignant*. By Sir John Bland-Sutton. Fifth edition.

lasting for twenty-four hours. He said he had occasional rises of temperature.

The hypogastrium was filled with a tumour, firm, tender, and dull on percussion. It extended to within an inch of the umbilicus, projecting more in the left iliac fossa than in the right (Fig. 1). A lump was felt in the left inguinal canal, but it could not be separated from the main tumour.

On rectal examination a rounded mass was felt in the region of the prostate about the size of a cricket ball, firm, and extending towards the left iliac fossa. On the right side it could be separated from the pelvic bones. Its upper boundary could not be reached by the examining finger. The kidneys could not be palpated. There was tenderness on deep pressure in the left kidney region. On July 25th it was noted that 40 oz. of urine were passed during twenty-four hours. The maximum quantity passed at one time was 5 oz. Usually about 2 oz. came away.

My diagnosis was sarcoma either of the bladder or the prostate. Various suggestions were made by my colleagues who saw the case. The von Pirquet reaction was negative. The blood examination was as follows:

Red blood cells	...	3,100,000
White blood cells	...	15,000
Polymorphonuclears	...	50 per cent.
Large mononuclears	...	1
Small mononuclears	...	19 "
Parasites	...	None

No organisms were found in the urine, which was acid in reaction, and no albumin or sugar was detected. Examination by x rays showed no shadow. The pelvic bones were normal.

On July 31st an exploratory laparotomy was done. An incision was made to the right of the mid-line and was finally extended to about 8 in. In the subcutaneous tissue we came upon a bluish mass, about the size of a shilling, which turned out to be an angioma. On opening the peritoneum a tumour was seen arising from the pelvis, which had pushed up the reflection of that membrane from the bladder to the anterior abdominal wall (Fig. 2). The omentum was adherent to the top of the mass, which extended to a little above the umbilicus. On the left side the tumour completely filled the pelvic cavity. Posteriorly there was some space between it and the sacrum. On the right the fingers could be pushed to some distance down the pelvis. The intestines were adherent everywhere, except anteriorly. The bladder was found flattened and stretched on the anterior surface of the tumour (Fig. 2). The other abdominal viscera were palpated, but no secondary deposits were found. An attempt to pass a gum-elastic catheter into the bladder failed. Urine, however, came away on pressing upon the anterior surface of the tumour, which felt soft and fluctuating. The abdominal wall was stitched up with silk in layers.

On August 3rd the left parotid was greatly inflamed and the temperature was 101.2°. On August 7th most of the stitches were removed, the wound was healed, and the parotitis much better. The patient complained of tingling and numbness in the left foot and leg. He passed a round worm. Calomel and santalin were given, but no more worms came away. On August 10th the temperature was 101.6°, the parotitis had quite subsided; lungs, heart, liver, spleen were normal, and all stitches were removed. The

wound was soundly healed. The tumour had enlarged towards the left iliac fossa, and was firmer.

On August 21st puffiness of the eyelids and the cheeks were noticed. The parotid regions were normal. There was no pitting on pressure. On August 23rd the patient vomited after food, the puffiness of the face had increased, but was still limited as before. There was oedema of the left foot and ankle. About 10 oz. of urine had been passed in the last twenty-four hours; it contained albumin. The voice was husky. The temperature was 98.4°.

The patient was removed from the hospital by his parents on August 24th. The tumour had much enlarged since his admission so that it filled both iliac regions and reached up to midway between the umbilicus and the ensiform cartilage.

The subsequent history I gathered as follows: He was taken to another hospital, and the surgeon in charge also diagnosed rapidly-growing sarcoma of prostate. The patient died three or four days later. Among Parsis *post-mortem* examination is not allowed.

In conclusion, I must thank my colleagues, especially Dr. Baria, for the consultations and his valuable help at the operation, as also my house-surgeon, Dr. Engineer, for his unremitting care of the patient and the detailed notes he kept of the case.

Reviews.

SPRUЕ.

SPRUЕ is a very interesting though obscure disease, and the London School of Tropical Medicine, recognizing this, sent out one of its pupils to Ceylon to investigate the subject in detail. A report on these studies is now published by Dr. BAHR.¹ With its bibliography and appendices, it contains much useful and carefully collected information about the disease as it occurs in Ceylon. Anything that will throw light upon the etiology of this disease is valuable. Of the many different theories that have been advanced from time to time one is that of Kohlbrugge, which suggests that the disease may be in some way connected with certain yeasts; of these *Monilia albicans* is the most widely known, and the author of the present report seems to lean towards the view that it is important in the etiology of the disease. Other observers point out that yeasts are very common in stools generally, even in temperate climates, and that it is very possible that their superabundance in sprue only means that they have found a suitable site in which to multiply and grow in profusion. However that may be, more work based upon this suggestion will not be out of place.

The morbid anatomy of the disease is well dealt with in the report; the belief that the changes in sprue are due to a destruction of the villi and a loss of surface epithelium has lately been questioned by Faber and Justi, and the author agrees with them that some of the changes are due to *post-mortem* degeneration and decomposition, which is specially rapid in a tropical climate. It is right to point out, however, that *post-mortem* examinations made of persons dying of sprue in England in cold weather have shown an atrophic condition of the bowel with patches of denudation of the epithelium and mucosa. In other cases examined in the same manner the intestines have not shown such changes as was to be expected if they are really due to *post-mortem* decomposition. In Dr. Bahr's own diagram facing page 70 the atrophy and disappearance of the villi is very well seen, as is also the small-celled infiltration. The surface epithelium looks as if it were denuded in places, and one can readily appreciate that if the degeneration and inflammation of the mucous membrane went further this layer would disappear. The most important conclusions of the report are that sprue is a specific disease of tropical and subtropical countries, and that it is prevalent in Ceylon and also occurs amongst the natives; this fact, together with the occurrence of the disease in people closely associated with one another, suggests a communication of the specific cause from man to man. The pathological findings suggest an alimentary toxæmia, and rather point to an

Fig. 2.—A, bladder; B, symphysis; C, urethra; D, ansæ; E, rectum; F, tumour; G, omentum; H, peritoneum.

¹ A Report on Researches on Sprue in Ceylon, 1912-1914. By P. H. Bahr, M.A., M.D., D.T.M. and H. Cantab., and M.R.C.P. Lond., M.R.C.S. Cambridge: The University Press. 121s. (Sup. royal 8vo, pp. 163, 7s. 6d. net.)

infection with the thrush fungus. Apart from the presence of yeasts no parasites, protozoal or other, were discovered. Though such have not been found at the present moment some new germ may eventually be discovered to be the cause of the disease. Castellani, it will be remembered, has described a chlamydozoon-like body from the tongue epithelium of a case of spruce, and this interesting observation should be followed up. According to Dr. Balz these bodies had disappeared from the case some time later, but this only points to the importance of examining the cases at the beginning of the disease. Castellani has also described a dysentery bacillus associated with spruce, and here again careful and extended observations into the realm of bacteriology might help.

The report is well illustrated and has some coloured plates, one, showing the different spruce tongues, being specially worthy of notice. As already stated, the report contains much useful information, and certainly shows evidence of very careful and hard work. It should prove useful, especially to those who in the future attempt to unravel the mysteries of the etiology of the disease. The London School of Tropical Medicine is to be congratulated on the energy shown in having this important research carried out.

RECTUM AND COLON.

It must be assumed that the author of *Diseases of the Rectum and Pelvic Colon*,² Dr. MARTIN L. BODKIN, of New York, desired either to place his views on the subject before his professional brethren or to write a textbook for the guidance of practitioners and students. He has succeeded, however, only in producing a book which is a puzzle to the reader and an embarrassment to the reviewer. It is not only that many stylistic errors occur in its pages, but the author's meaning is often obscure and sometimes unintelligible, his statements inaccurate, and his accounts of treatment usually catalogues of alternatives. After a chapter on anatomy the author writes on "general examination." He refers to mistakes in rectal therapeutics, and remarks, "this criticism is more severe when the surgeon premeditatedly presumes to treat these cases in an ignorant manner." He states that he not infrequently receives a patient from some professional friend who has "carelessly summarized a rectal condition," and proceeds, "this criticism does not apply to cases presenting themselves for the treatment of a complicated fistula, . . . but it should include the knowledge that the patient is suffering from a rectal disease." The meaning is just intelligible, but obviously a criticism of the author's can hardly include knowledge on the part of some one else. Another example of the same kind of diction occurs later in the same chapter. The writer is speaking on anaesthesia, and says: "When we consider that laboratory investigations have shown conclusively that chloroform and ether impair phagocytosis and produce anaemia, rectal operations, which certainly are more liable to infection, require the best effort in this direction." The chapter following is on the examination of the faeces. The second paragraph is as follows: "Microscopic examination of the faeces ordinarily reveals the digestive residue germs and other elements gathered as the mass travels through the intestinal tract, or there may be present foreign bodies which have been swallowed in the form of fruit pits (*sic*), coins, buttons, etc." The microscopic button is unknown to us. A little further on we read: "Parasites are easily recognized in the stool by the naked eye, as they are common constituents of the intestinal canal," and later we are told that on microscopic examination "fatty acids and soaps may be seen in large amounts." As to the diagnostic value of faecal examination, we are told "intussusception of the sigmoid or complete prolapse of the rectum are diagnosed by local examination independently of the discharges, which are due to traumatism rather than any bacterial factor." Here we fail entirely to penetrate the meaning, and also when we are informed, in regard to typhoid fever, that "the danger of infection to the examiner is unwarranted because of the simple methods now in vogue." Further examples of the author's style are as follows: "Pruritus ani may be confused with marginal eczema (ringworm), and when suspected a microscopic examination will affirm the diagnosis by

finding the fungus (trichophyton)." In dynamic (*sic*) nervous conditions "the relaxed and inactive sphincters may allow the escape of the bowel contents, but by its inactivity, associated with the loss of sensation in the rectum, permit the faeces to mass themselves, causing an impaction." In the practical chapters the writer shows evidence of having read diffusely on the subject of rectal disease, but the want of arrangement and classification and his ineffectual methods of expression make it impossible to recommend the volume.

PHYSICAL CHEMISTRY.

THE unadorned title, *Molecular Association*, will, in all probability, frighten away the unscientific public from Dr. TURNER'S monograph;³ but if the work should by any chance fall into their hands, one can imagine what a crucible of gentle mockery will be prepared for such a term as amidobenzophenoneoxime, or methoxybenzene-azophenol; or, most fearsome of all, a certain bromide which runs almost twice through the alphabet before reaching a conclusion. We own to the feeling that this fretful terminology and its associated symbolism are mere disguises or elaborate pieces of bluff, assumed to hinder us from finding out how very much akin to the romantic poets these physical chemists are. The alarming syllables are only the barbed wire around an Aladdin's palace. Indeed, as we study this work with something of the strenuous patience which is its due, the simile of architecture constantly recurs to us. The molecules are the stones in the temple of matter, and this fundamental investigation concerns the building and unbuilding which proceeds among them according to the nature of their constituent atoms, and to the forces acting upon them from without. This is one of the places where chemistry and physics, so sharply distinguished twenty years ago, now become convergent, and chemical action has something to teach the physicist who is concerned with molecular association. The formation of molecules of so many substances into aggregates is very similar in some respects to chemical combination; intramolecular attraction takes place in both phenomena, but in the one case the attraction is between like molecules, and in the other between unlike. The author suggests, without carrying the idea any further, that the forces which cause molecules to associate may be electrical as distinct from chemical in origin. That is the speculative vista which he opens out in his concluding sentence. Perhaps it is inevitable that such a work as this should leave a ragged edge, and it begins equally abruptly, taking for granted in the reader more than a moderate degree of chemical knowledge. The author discusses molecular association in gases and liquids, and touches briefly upon solids, although very little is yet known about the behaviour of the molecules in this third state of aggregation. Another hiatus is the absence of any adequate means of making quantitative determinations of molecular sizes in the liquid state. It is easy enough to detect the association of molecules, but, so far as methods of measurement are concerned, some great reconciling principle seems to be needed. A most valuable feature of the book is a table containing a summary up to date of the molecular complexity of over twenty groups of dissolved substances, with their concentrations in various solvents. According to this table, the class of organic compounds in which the highest degree of molecular aggregation is reached is the alcohols; then follow amides, carboxylic acids, oximes, and anilides. Strong association has also been found in the case of all true salts. The advanced student of chemistry, whether reading for a degree or proposing to undertake research, should find this summarized account of recent progress most useful.

THERAPEUTICS.

THE second edition of HOLT'S *Practical Therapeutics*⁴ gives a clear picture of current American practice in the administration of drugs. It is concisely written; the first half consists of thirty chapters, in which the various classes of drugs are considered in accordance with their main or reputed actions. In the second half of the book

² *Molecular Association*. By W. F. S. Turner. D.Sc. Lond., M.Sc. Birm. Monographs on Inorganic and Physical Chemistry. Edited by Alexander Findlay, M.A., D.Sc. London: Longmans, Green and Co. 1915. (Post 8vo, pp. 178; 5 diagrams. 5s. net.)

⁴ *Practical Therapeutics*. By D. M. Hoyt, M.D. Second edition, revised and rewritten. London: H. Kimpton. Glasgow: A. Stevenson. 1914. (Med. 8vo, pp. 426; 16 figures. 21s. net.)

³ *Diseases of the Rectum and Pelvic Colon*. By M. L. Bodkin, M.D., of New York. New York: E. B. Treat and Co. 1913. (Demy 8vo, pp. 416; 90 figures. 3.60 dollars.)

is a long and useful list of the chief new and non-official remedies, an index of drugs presenting the matter of the first half of the book in a concentrated form, and a general index. The work offers a brief summary of the physiological actions of drugs, with particular emphasis on their clinical applications and on the limitations of their employment. It lays no claim to encyclopedic completeness, and it should appeal to the practitioner rather than the student of medicine.

The issue of a new edition of the *British Pharmacopœia* has rendered necessary the adaptation of RAHMALDAS GHOSH's well known *Treatise on Materia Medica and Therapeutics*⁵ to the alterations ordained by the official publication. The new edition—the sixth—has been prepared by Lieutenant-Colonel B. H. DEARE, of the Indian Medical Service, with the assistance of the author's son, B. N. GHOSH, F.R.F.P.S. Glasg. The book has undergone a thorough revision. By judicious omissions, mostly of non-official preparations, its size has been reduced by forty-four pages. Necessary additions have been made, and portions have been rewritten in order to bring the volume up to date. The chapters on serum and vaccine therapy have been revised by Major E. Greig, C.I.E., of the Indian Medical Service. The chapter on organo-therapy has been amplified, and useful appendices have been added, indicating "alternative preparations sanctioned for use in tropical, subtropical, and other parts of the British Empire," and "additions and omissions in the present edition of the *British Pharmacopœia*" as compared with its predecessor. While the scheme and contents of the volume, which have met with such warm acceptance, have been preserved, an important change has been made by arranging the articles of the materia medica under classes founded on chemical, physiological, and therapeutical characters. This is an important step towards a more scientific classification than a mere alphabetical arrangement. Difficulties arising from the same drug entering into different classes as fulfilling various indications are met by cross-references and a copious, carefully prepared index. Another useful change consists in adding the doses of drugs according to the metric system. In addition to information regarding the physiological and therapeutic action of medicines, the poisonous effects of overdoses, their symptoms and treatment, are clearly displayed. Synonyms in the Indian vernaculars are given, and the more useful Indian and Colonial drugs included. This edition fully maintains the high position which the work has attained in professional estimation, and is admirably suited for use as a textbook by students and a book of reference by practitioners. It is a marvel of orderly arrangement, condensation, and scientific accuracy.

NOTES ON BOOKS.

BOOKS on flies have lately been much before the public eye. A little work by Mr. HURLSTONE HARDY, named *The Book of the Fly*,⁶ gives a considerable amount of useful information. Perhaps the most interesting chapters are those dealing with the extirpation or destruction of flies. It is said that chloride of lime is now chiefly replaced by a solution of iron sulphate—2lb. in one gallon of water—as a general fly insecticide. The advantage of this substance is that it does not deteriorate the hoar, the cultural value of stable manure. Perhaps, however, the simplest method of all is to spread out the manure in a thin layer in fine weather, thus killing off the fly maggots very quickly. All manure pits and other similar collections in towns should certainly be made fly-proof, and if this were done the breeding grounds of the insects, as far as towns themselves are concerned, would be diminished. In the country, of course, it is not so easy, and unless measures of this sort are universally adopted they are of little use. A greater cremation of refuse is certainly a desirable thing, and this could be adopted with very little trouble. Something, perhaps, might also be done with regard to the natural enemies of the flies, and Mr. Hardy has devoted a

chapter to this subject. In an appendix Wingate's Fly Chart is given, an alphabetical list of sixty families, and an analytical table of families, etc.; these will be found to be of much use. The book can be thoroughly recommended to laymen, and it should prove useful also to sanitary inspectors and others called upon to deal with the fly pest. Though so much has recently been written about flies, it is well to remember that the medical officers of health have been dealing with this subject for many years past, and much useful work has already been achieved.

In *Typical Flies: a Photographic Atlas of Diptera, including Aphaniptera*,⁷ Mr. E. K. PEARCE approaches the subject from a new point of view. As he says in his preface, his work is chiefly a picture book—pictures, he believes, appealing more to the eye than many pages of letterpress. After his preface, then, he gives Brauer's classification of the diptera, marking the species that are illustrated in his work by an asterisk, and passes direct to the photographic representations of the different flies. Some of these are excellent, while others are indifferent, lacking clearness in definition. A short description is printed below each figure, so that the reader is able to appreciate the habits and breeding places of the insect. The work should prove useful to naturalists and others interested in British diptera.

The House-fly, a Slayer of Men,⁸ by F. W. FITZSIMONS, Director of the Port Elizabeth Museum, gives a very good description of the life-history and habits of *Musca domestica*, the common house-fly. The dangers of flies have been insisted upon for some years, and the time has come when something should be attempted to diminish their numbers. A perusal of Mr. Fitzsimons's book, especially chapters viii and ix, will indicate to those not conversant with the subject how this can be accomplished. Many methods are dealt with and some ingenious traps are also described. The little manual is very clearly written, and it should do much to educate the public in this elementary branch of sanitation.

Another book, *Fighting the Fly Pest*,⁹ is well described as a popular and practical handbook. It is written by Mr. C. F. PLOWMAN and Dr. W. F. DEARDEN, and has an introduction by Dr. A. E. SHIPLEY. After chapters on the public health aspects, on the habits of the fly, and the dangers it entails, preventive and remedial measures are described. In the last chapter is related a British experiment which seems to promise well. There are some excellent practical illustrations.

An interesting series of lectures for young men, by well known members of the medical profession, has been published in a small book entitled *How to Keep Fit*.¹⁰ Taken as a whole the book is so good that it is strongly to be recommended to the attention of young men of all classes. As might be expected, considerable stress is laid on the ethical and religious aspect of matters, but this does not impair the vigour and instructiveness of the lectures. Mr. Eccles leads off with a lecture on alcohol. The arguments against it are sufficiently good (we should have thought) to make unnecessary an appeal to its action on plants, whose anabolic and catabolic processes differ so materially from those of animals. Dr. Burnet deals well with the subject of diet; Sir Dyce Duckworth with cleanliness; Sir Douglas Powell with the value of discipline. Perhaps the two best lectures are those of Sir George Savage, "A sound mind in a sound body," wherein he exhibits a penetrative philosophy of life, as well as of medicine; and that of Mr. James Cantlie, wherein he breezily criticizes our common habits of dress and instructs us how to clothe children and boys. The book ends with a lecture on "Chastity"—always difficult to treat—by Sir F. Champeys. It is well done and the facts are soundly presented, though the lecture has a more highly religious flavour than would suit some readers. It must, however, be admitted that it is unlikely that a sound sexual ethic can prevail in communities where religion is at a discount.

British Medical Journal.

SATURDAY, AUGUST 14TH, 1915.

THE INSURANCE ACTS COMMITTEE AND ITS WORK.

THE publication in the SUPPLEMENT of the report of the first meeting of the new Standing Insurance Acts Committee affords an opportunity for reviewing the evolution of what is probably the hardest working Committee that even the British Medical Association has ever possessed. The Committee began as the Poor Law Reform Committee, appointed in 1909 to consider the report of the Royal Commission on the Poor Law. It developed into the State Sickness Insurance Committee in 1911, when it commenced the discussion of the principles underlying all systems of insurance against sickness. It collected the views of the profession as to the essentials which any system must embody if a prima facie case was to be made out for its acceptance by the medical profession. When the Insurance Act was under consideration it became the Insurance Act Committee, and to it was entrusted the arduous and thankless task of ascertaining the minimum requirements of the profession. It went through a period, in 1913, of laborious, continuous, and anxious toil under a heavy fire of criticism, which would have broken the spirit of any body less inured to that kind of thing. It got into its stride in 1914 and settled down to steady work for the protection of the interests of that very large section of the profession which, for good or ill, is now an essential part of the machinery of the State Insurance system. Towards the end of that year and at the beginning of this, it grappled with the problem how to co-ordinate the efforts of the Association centrally with the work of the statutory committees set up for the local medical administrative work of the Act, and established itself as the central body to which these local committees might properly look for that unifying influence which is essential. All this time it had been a special Committee elected by the Representative Body from year to year and undergoing from time to time changes in its constitution. Now it emerges as a Standing Committee established definitely under the By-laws of the Association and with a constitution which differs from other committees of the Association, inasmuch as it consists, to quite a considerable extent, of members nominated by bodies other than the Council and the Representative Body. This constitution has been reached by a series of experiments, and is worth a little study. The Committee comprises representatives of three bodies all having a strong natural interest in the working of National Sickness Insurance—the Societies of Registered Medical Women, the Society of Medical Officers of Health, and the Poor Law Medical Officers' Association. It also includes six representatives nominated by the Local Medical and Panel Committees of the kingdom, and thus brings into official and close touch with the Association those committees on whose efforts and vigilance panel practitioners must locally so much depend.

The personnel of the Committee is equally worthy of attention. Some of its members have been on the

Committee since its inception, and their experience is of the greatest assistance to their colleagues, as a proper understanding of some of the newer developments can be attained only through a knowledge of their evolution. In addition to these veteran members there are those with special experience of certain aspects of the Acts and those who have won their spurs by devoted work on local committees. It must be admitted by any candid inquirer that the Committee as now constituted is a very strong body indeed.

Its attention in the immediate future will probably be mainly devoted to strengthening the ties between itself and the local committees and to consolidating its position with the Commissioners as a body of reasonable but, if necessary, determined and pugnacious persons. No body of this kind ever built up a really useful position on pugnacity alone, but composed as it is of persons of experience and judgement and given the support of the Local Medical and Panel Committees and generally of panel practitioners, there is no doubt that its position must be exceedingly strong. Already the Commissioners have recognized it as the central medium of exchange, so to speak, between them and the local committees. It is obviously convenient for all persons concerned that there should be such a body. It remains to be seen whether the local committees are prepared to trust it to act as their central agent in such a way as to save trouble all round, and at the same time build up a strong central and peripheral organization, or whether the committees will insist—as is undoubtedly within their right if they so choose—on having all negotiations, both great and small, conducted between themselves and the Commissioners direct instead of through the Insurance Acts Committee. We believe that convenience as well as wisdom will dictate the latter course. The Committee will naturally be for some time on its trial. Its composition, however, is a guarantee that the interests of panel practitioners, as well as of the profession in general, will be well safeguarded. Its practical experience with the subject of its reference is guaranteed by the fact that of its 25 members no fewer than 17 are actually insurance practitioners themselves, 20 are secretaries, chairmen, or members of Local Medical and Panel Committees, while of the 8 who are not themselves engaged in insurance practice, all but 2 have experience of the administrative work of the Act either as members of Advisory Committees, or Local Medical, Panel, or Insurance Committees.

The profession may at any rate be assured that such a Committee is not likely to be guilty of the ignorance or malice which has instigated a circular recently sent out by a body professing specially to appeal to panel practitioners. The circular repeatedly plays on the fears of practitioners by suggesting that the Commissioners intend to spring on them at short notice fundamental alterations of the Regulations, and that the Treasury grant of 2s. 6d. per insured person has "well nigh run its appointed course." It need hardly be said that the Insurance Act Committee has already satisfied itself on these points. In a letter addressed by Sir Robert Morant to the Medical Secretary of the British Medical Association in March last the statement is specifically made that there is no intention during the war of using the power taken to alter the Regulations at eight weeks' notice, except "in order to meet any entirely unforeseen contingency that might arise. . . . Nothing of the kind has arisen, and consequently no changes of any kind have been under consideration here for adoption during

the currency of the present year." As regards the 2s. 6d. having "run its appointed course," it need only be pointed out that the 2s. 6d. was voted in the Estimates for 1915-16, and no alteration of the terms of remuneration can take effect before March of next year at the earliest. Whether or not any attempt be made at that time to revise the terms, it is quite certain that the medical profession will have ample warning through the British Medical Association. As to this the Commissioners have pledged themselves. Panel practitioners have many anxieties of an extraordinary kind at the present time, and it is nothing less than cruel that a body purporting to be founded in their special interests should set afoot this false alarm, in the hope, as it would seem, that a certain number may be frightened into its ranks. We hope that panel practitioners generally will treat this ill-timed and mischievous effusion with the contempt it deserves.

Meantime the first great task of the Standing Insurance Acts Committee of the British Medical Association will be the consideration of the entirely new conditions that will arise when the Departmental Committee on the drug tariff produces, as is shortly expected, a commercial tariff fundamentally different from that now in operation. But Local Medical and Panel Committees may rest assured that they will be kept fully informed of the position, and will be consulted in good time on this as on all other points which affect them and their constituents.

FARR'S THEORY OF EPIDEMIC FORMS.

We think that all epidemiologists will endorse Dr. Brownlee's conclusion that the letter by Dr. Farr, reproduced by him in the article which appears at p. 250 of this issue of the JOURNAL, is one of the classics of epidemiological science. The thanks of students are due to Dr. Brownlee for the labour he has undergone in tracking down the original publication.

Like so many conclusions of great importance, Farr's law seems simple enough when enunciated in general terms, for it amounts to no more than the assertion that in an epidemic there will always be a period of rise, decline, and fall. So far as the secular aspect of epidemic disease is concerned, the application of this principle was made long enough ago. The precept of ancient philosophy so well phrased by Lucretius:

Sic igitur mundi naturam totius aetas
Mtat, et ex alio terram status excipit alter,
Quod potuit, nequeat: possit, quod non tulit ante,

finds its epidemiological application in Sydenham's famous doctrine:

Quocirca opinari mihi fas sit, morbos certas habere periodos pro occultis illis atque adhuc incomperitis alterationibus quae ipsis terrae accidunt visceribus, pro varia scilicet ejusdem aetate ac duratione; quodque, sicuti alii morbi jam olim extitere qui vel jam ceciderunt penitus, vel aetate saltem pene confecti exolevere, et rarissime comparant (ejusmodi sunt lepra atque alii fortasse nonnulli), ita qui nunc regnant morbi aliquando denum intercedunt, novis cedentes speciebus, de quibus nos ne minimum quidem hariolari valeamus.

We do not, however, recall any passages in the classical writings of epidemiology which apply the same reasoning to the immediate course of an epidemic, although it must have been evident that the vast majority of epidemics did in fact come to an end before all the susceptible persons exposed to risk had been attacked. Perhaps the natural tendency of man to attribute importance to the results of his own

activities may have something to do with this, but of more influence has undoubtedly been the recognition of seasonal factors. In other words, those who did not attribute the termination of an epidemic to their own efforts were generally inclined to lay stress on meteorological conditions, and consequently did not think of applying the principle of secular change to account for possible inherent modifications of the *materies morbi* during the limited period of time which forms the life-history of a single epidemic.

Had Farr merely taken this step, he would have deserved credit, but it would only have been the credit attaching to an ingenious and plausible speculation. He was, however, endowed not merely with scientific imagination but with the hardly less important gift of realizing the necessity of proofs as well as analogies, and of discerning the lines along which such proofs might be profitably sought. There have been statisticians before and since Farr's time whose mathematical knowledge was much greater than his, there have been few or none with greater ability to apply mathematical methods to the elucidation and testing of biological hypotheses.

Some few medical men have objected that Farr's law, either in its original form or as modified by Dr. Brownlee and others, amounts to a fatalistic confession of impotence in the face of zymotic disease. This objection is based upon a very superficial understanding of the law. To state, as Farr does, that "subsidence is a property of all zymotic diseases," is not to say that sanitary measures are useless; even if we went further than Farr actually did and asserted that the form of the epidemic curve was invariable, it would not follow that the scale of its ordinates could not be reduced. To argue, as perhaps we might, that the relative successes of the enemy in August, 1915, being less than those of August, 1914, therefore the Teutonic epidemic curve must shortly descend, would not be to dissuade any one from straining every nerve in the combat. The only form of sanitary enthusiasm which the work of Farr and his successors is calculated to depress is that which we are accustomed to associate with the writings of Mr. Bernard Shaw and his friends in the antivaccination and antivivisection societies, which, unhampered by any real knowledge of epidemiology, attributes all improvements in the public health to the action of some half-comprehended ritual termed "sanitation."

RESEARCH IN ANTISEPTICS.

At a very early stage of the war it was realized by all surgeons who had to attend wounded abroad or at home that a very large proportion of the wounds, including almost all extensive wounds of the extremities, were infected from a very early stage, and in many instances from the moment of their infliction. The aseptic methods by which surgery had been dominated during the previous decade were, therefore, no longer applicable save in exceptional instances, and the study of antiseptic drugs consequently assumed a new importance. Recognizing this, the Medical Research Committee established under the National Insurance Act decided, in accordance with its policy of assisting the military authorities, to subsidize such investigations, and the results are now beginning to be published.

It is an interesting fact that two distinct researches, conducted by two teams of researchers working independently, have both arrived at the conclusion that one of the most effective and innocuous antiseptics is hypochlorous acid, which, in contact with the tissues

or discharges, is decomposed, its antiseptic effect being, there is little doubt, due to the chlorine liberated in the nascent state.

Chloride of lime or chlorinated lime (bleaching powder)—a very old antiseptic and deodorizer familiar for half a century at least—is a mixture of variable composition but consists chiefly of calcium hypochlorite. It occurs in a pure solution in the *British Pharmacopœia* as liquor calcis chlorinatae. There is also a solution of sodium hypochlorite (liquor sodae chlorinatae) in the *British Pharmacopœia*; it is practically identical with eau de Labarraque, which is a common French preparation.

Eau de Javelle, which has long been a favourite preparation in France, and has been largely used by French surgeons during the present war, is made by treating chlorinated lime with excess of sodium carbonate solution. It therefore contains sodium hypochlorite and calcium carbonate. Its reaction is strongly alkaline, and, owing to its high alkalinity, it cannot be applied to the tissues unless greatly diluted.

Under the auspices of the Medical Research Committee, Professor Lorrain Smith, with the assistance of Professor Drcman of the University of Otago, Dr. Rettie, a chemical expert, and Lieutenant W. Campbell, R.A.M.C., undertook, in the pathological department of the University of Edinburgh, a research to ascertain what antiseptic preparation would best meet the special conditions which military surgeons require to be fulfilled in the present war. In a paper published in this JOURNAL three weeks ago (July 24th, p. 129) they stated that comparative tests had in their hands confirmed the conclusion previously reached by other investigators that hypochlorous acid was a most powerful antiseptic, that its action was purely local, its decomposition products being devoid of toxicity, and that it met a condition insisted upon by Sir Almoth Wright in that it induced a flow of lymph from the tissues. The ideal antiseptic for the field, they were advised, should be a dry powder which can be applied direct, not only because such a powder is more portable, but because water is often not procurable. The substance they prepared was made by rubbing up chloride of lime (commercial bleaching powder) to a fine powder, and mixing it with an equal weight of boric acid in powder. When dissolved in water, this yielded a solution containing hypochlorous acid and calcium borate and chloride. Clinical tests in over 100 cases had, it was stated, yielded very satisfactory results.

Last autumn Professor Cohen of the University of Leeds, recognizing the importance of studying antiseptics for surgical use, sketched out a plan of research, and entered into communication with a former pupil, Dr. Henry D. Dakin, Director of the Herter Laboratory, New York, who is acting as bacteriologist to the hospital and laboratory established at Compiègne—with the approval of the French War Office—by the Rockefeller Institute. The arrangement was that the substances produced by Professor Cohen in Leeds should be tested bacteriologically by Dr. Dakin in his laboratory at Compiègne, and that the most promising should be tried clinically by Dr. A. Carrel of the Rockefeller Institute, who is acting as a surgeon to the hospital. The firstfruit of this combined work was reported to the Académie des Sciences in Paris by Dr. Dakin on August 2nd.¹ In this paper he describes an antiseptic preparation, found effective in practical application at Compiègne, which seems to be practically the same as that devised and tested, both bacteriologically and

clinically, by Professor Lorrain Smith and his coadjutors in Edinburgh. The solution used at Compiègne is made by adding 200 grams of chloride of lime to 10 litres of water in which 140 grams of carbonate of soda have been dissolved. The mixture is well shaken and after half an hour the liquid is siphoned off from the precipitate of carbonate of lime and filtered through cotton. To the clear liquid thus obtained boric acid is added in quantity sufficient to render the liquid acid or neutral. The titration is made with an aqueous solution of phenolphthalein; the amount of boric acid required is generally 25 to 40 grams. A solution thus prepared having a hypochlorite concentration of less than 1 in 500,000 was found to kill staphylococci in two hours. The concentration of hypochlorite required to produce the same result in the presence of blood serum was from 1 in 1,000 to 1 in 2,500. Carrel reports that he has found this solution very efficacious in the treatment of infected wounds. They could be irrigated continuously for several days without marked irritation of the skin being produced. Bacteriological examination of the discharges from the wound showed that the solution possessed an energetic antiseptic action, and that it had also the property of dissolving necrosed tissues, and some haemostatic power.

Meanwhile Professor Cohen at Leeds, according to a scheme he had set before himself, had gone on to study a large number of other substances which might be expected to have antiseptic properties, and was sending them to Compiègne to be tested by Dakin and Carrel in the manner above explained. The Medical Research Committee gave its assistance to Professor Cohen, whose researches have recently been concerned with the examination of a long series of toluene derivatives. He has, we believe, already studied between one and two hundred, and one of these has given results in the laboratory and wards at Compiègne as to which Dakin gave some interesting details in his paper before the Académie des Sciences. He expressed the view that the antiseptic action of hypochlorites was probably due to the chlorine they contain replacing atoms of hydrogen in the protein molecules to form substances of the chloramine group; this, he pointed out, suggests the desirability of a careful study of the action of this group of substances. Most encouraging results, he says, have been obtained with sodium salts of the aromatic sulphochloramides, and in particular with derivatives of benzene and toluol.

These substances, he says, are active antiseptics of low toxicity and they can be employed in the treatment of wounds in stronger aqueous solutions than the hypochlorites. They do not dissolve necrosed tissue owing to the fact that their chlorine is already combined with nitrogen. Para-toluen-sodium-sulphochloramide in concentration below 1 in 10,000,000 kills *B. pyocyaneus* suspended in water in two hours. In the presence of horse serum the concentration must be raised to from 1 in 2,500 to 1 in 5,000 to bring about the same result. Staphylococci suspended in water are killed by solutions of the strength of 1 in 1,000,000 and in the presence of horse serum of 1 in 2,000. *B. pyocyaneus* suspended in water is killed by a solution of 1 in 100,000, and in the presence of horse serum of 1 in 1,500. Sterilization is complete in two hours. Experience has shown that a watery solution of para-toluen-sodium-sulphochloramide of the strength of 4 per cent. does not produce appreciable irritation in a wound. It is added that as these substances possess a marked haemolytic power they are not suitable for intravenous injection.

A COMBINED ATTACK AGAINST TUBERCULOSIS IN WALES.

The independent action taken by the founders and supporters of the Welsh National Memorial to King Edward VII, to provide for the treatment and prevention of tuberculosis within the Principality, has been steadily maintained during the past three years, and the president, who is also the founder, Lieutenant-Colonel David Davies, M.P., was able to give a most encouraging account to the recent annual meeting at Llandudno, a report of which appeared in our last issue, p. 235. The third annual report, which embodies the medical report of the Medical Director, Dr. Marcus Paterson, and contributions from other medical officers of the association, contains, apart from statistics, many interesting features which call for more than passing attention.

Foremost among these must be noted the very harmonious combination of the various county, sanitary, and insurance authorities who have worked together to establish an organization which may well claim to give the lead to other antituberculosis bodies throughout the kingdom. With the single exception of Pembrokeshire, all the counties, including Monmouth, have loyally co-operated. The Pembrokeshire County Council would apparently prefer to set up a scheme of its own, but it does not seem to have materialized. Large sums of money have been contributed to the National Memorial, and various plots of land have been given by local landowners for the erection of buildings in suitable districts. Four tuberculosis hospitals have been opened up to the present time and others are projected, but existing and prospective difficulty in the matter of funds and the letting of contracts has suspended any further building ventures. In these, as in almost all hospitals, the withdrawal of so many of the medical and nursing staffs for military service has thrown an additional burden upon those who have been able to remain, but it does not appear that any curtailment of the work has been thereby involved.

In order to cope with the widely-scattered population in the mountainous districts a system of district sanatorium areas has been established; these areas are served by a central institute in each, with several visiting stations affiliated to it. The staff in each case consists of a tuberculosis physician, assisted by a specially trained sister, and the institute is provided with the necessary consulting and waiting rooms. The visiting stations are established in outlying places where they are most likely to be needed, and consist of two rooms only. The cases are there investigated in the first instance, and home conditions ascertained, the more detailed examination of suspected cases being carried out in the institute. By these means it has been found that about 1 per cent. of the total population of Wales has been examined, and of these about 25 per cent. have been found to stand in need of treatment or supervision.

Apart from the purely medical aspect of the campaign, a great deal of attention has been paid to the educational side of the question. The council of the association has determined that "the men and women of the future shall be freer from the scourge of tuberculosis than their predecessors," and vigorous action is being taken to instil the cardinal rules of hygiene into the minds of the rising generation in Wales. Much has been achieved, but it is obvious that much more remains to be done if the comparatively high percentage of tuberculosis, especially in the less accessible parts of the country, is to be dealt with adequately. A pleasant feature of the whole

scheme is the cordial support given to it by the general practitioners, both in town and country districts. While aiding in the discovery and treatment of tuberculous patients they have themselves derived no little assistance from the special skill and knowledge of the tuberculosis physicians.

The need for more appropriate accommodation for dealing with surgical tuberculosis is fully recognized, and is being provided at Glan Ely, near Cardiff, for the southern part of Wales, and at Llangywyfan, near Denbigh, for the northern. The former is a separate institution, while in the latter the surgical hospital will form a separate block of a sanatorium now in course of erection. The general plan in view is to utilize these two hospitals for surgical cases at a stage which calls for active intervention or special treatment of any kind. For instance, at Glan Ely the value of exposing the patient with proper precautions to sunlight has been recognized, and it is intended to install a quartz lamp for treatment by ultraviolet rays during the winter. When the patients have so far advanced that they no longer require active or special treatment, it is intended that they should be drafted into surgical annexes at the various sanatoriums for their convalescence.

Popular errors with regard to tuberculosis are very hard to combat, and in spite of the fact that the sputum is universally recognized as the infective element, still the free spitter in public places is tolerated without remonstrance, while the user of a pocket sputum flask is looked upon, and shunned, as a leper. Hence the difficulty of enforcing the obvious precaution, except within the walls of a home or hospital. The public are learning that promiscuous spitting is generally objectionable, but they have yet to be taught that the use of the sputum flask is a safeguard and not a danger to the community.

WAR EMERGENCY COMMITTEE.

THE second meeting of the War Emergency Committee was, as will be seen from the report in the SUPPLEMENT, mainly occupied in receiving and considering the report of a deputation of its members which had had an interview at the War Office with the Director-General Army Medical Services. The Committee, it will be remembered, contains representatives, not only of the British Medical Association, but also of other medical bodies, including the Universities of Oxford, Cambridge, and Edinburgh, and the Royal Colleges of Physicians and Surgeons in London; it has the power also to co-opt other representatives of universities, colleges, and medical bodies. Sir Alfred Keogh expressed the pleasure with which he had learnt that the Association had set up a special committee to deal with the great and pressing medical emergency produced by the war and the satisfaction he felt that the Committee included members of bodies outside the Association itself. He explained very fully to the deputation the military exigencies determining the number of practitioners who during the next six months will be required by the War Office for the medical service of the new armies, and to replace casualties and invaliding. It is not considered advisable in the national interest to publish figures, but the members of the Committee were fully convinced that the need was still great and urgent. In this connexion it may not be out of place to refer to a matter dealt with more fully elsewhere—that is to say, the serious addition to the total number of casualties attributable to the operations in the Dardanelles. Roughly speaking, it appears, from the figures given to the House of Commons by the Prime Minister on July 28th, that the casualties in the Dardanelles, where operations were only begun last March, had constituted down to the middle of July about one-

seventh of the total of all the casualties in both the army and the navy since the war began a year ago. Without professing to have any special knowledge of the strategy to be developed in Gallipoli, it is safe to say that if the task before the Allies in the Gallipoli peninsula is to be successfully achieved the number of casualties must be expected very largely to increase. This expectation makes it absolutely essential that the War Office should provide a large medical personnel in the eastern Mediterranean. The deputation from the War Emergency Committee having asked that the Committee, in calling upon medical practitioners to join the R.A.M.C., should have the authority of the War Office, Sir Alfred Keogh on August 9th addressed a letter to the secretaries of the Committee stating that he recognized in it an excellent medium for dealing with the great problem which now faced the profession, namely, how to supply medical officers for the forces and at the same time to protect the needs of the civil population. He has authorized the Committee to make appeals to the profession to secure these ends; in doing so he emphasized the importance of ensuring prompt and increasing supplies of medical officers by saying that the claims of the medical department of the army could not be put too strongly before the profession. The War Emergency Committee sitting in London is concerned with making the appeal to the medical profession in England and Wales and Ireland. A similar appeal in Scotland is made by the Scottish Medical Emergency Committee, which has already done most valuable work in organizing the profession in that country to meet the demands of the military medical services by setting free men of fitting age and physique, and making arrangements to provide as far as possible against loss to them and inconvenience to the public.

THE NEUROLOGY OF WAR.

STRUCK by the splendour of a sudden thought, the Neurological Society of Paris has made a special study of the lesions and affections of the nervous system that have been so numerous and varied in the present war, and has published the results of its labours in a special double number of its monthly review.¹ This contains a number of original articles, abstracts of which are published elsewhere in this issue of the JOURNAL. Besides these, the review contains a hundred and sixty-four abstracts of the most important communications on the subject recently made to learned societies in France, and, in a few instances, in other countries. Members of the society have naturally had a very extensive experience of the nervous lesions caused by the war. As a result of this experience, they presented a petition to the French Minister of War last March, praying, first, that all patients suffering, or apparently suffering, from organic or inorganic nervous troubles should be referred as soon as possible to special neurological services; and, secondly, that services organized particularly from the point of view of medical supervision and discipline, should be created to look after patients in whom an abnormal condition persisted in spite of treatment, and those suspected of exaggeration or simulation. The society laid great stress on the importance of an early diagnosis and correct treatment in the military cases of hysteria, hysterotraumatism, traumatic neurosis, and nervous troubles due to suggestion. In their early stages these are all readily amenable to treatment by psychotherapy and counter-suggestion. Late in the day they are difficult to cure, for suggestion gets to work and the patient's moral is sapped by the sympathy, solicitude, and commiseration that have been showered upon him by his *entourage*, medical and otherwise; in addition, obstinate contractures and partial ankyloses may have developed in the affected limbs, and these conditions may even become incurable. The society estimated that, without exaggera-

tion, there actually were, in the French military hospitals and ambulances, thousands of patients such as these, who could have returned to their posts had they been properly treated as the functional cases they were at the outset. Perusal of the papers in this double number of the *Revue Neurologique* makes it apparent that the nervous lesions of all sorts due to the war are protean in their manifestations, and may demand the most thorough and methodical examination before a correct diagnosis can be reached. Disturbances of sensation, disturbances of motility, the electrical reactions of the different muscles apparently involved, vasomotor and secretory troubles, and the distribution of the apparent lesions, must all be mapped out by careful investigation, demanding much time and the use of proper apparatus. Cases in which hysteria or, worse, simulation, is suspected may require careful control and watching by trained observers before the diagnosis can be established; it is satisfactory to note that a clinician of Dejerine's experience was able to say, after six months of war, that no single military case of simulation had yet come under his observation. The need for medical men specially trained in the diagnosis and treatment of the nervous disorders of all sorts due to the bodily and mental injuries of war is undeniable; the French army is fortunate in having the services of the Parisian Société de Neurologie so freely at its disposal.

THE PATHOLOGY OF SHELL CONCUSSION.

THE present war has considerably added to our knowledge of injuries caused, directly and indirectly, by high explosives, but there are some mysterious occurrences of which no satisfactory explanation is as yet forthcoming. Instances have been recorded on apparently good authority in which, without any outward and visible sign of injury, death has occurred so suddenly that the victims retain the attitude, and even the gesture, of the fatal moment. It is said that the French have sometimes met with instances in which such deaths have occurred in groups, the men still lifelike, in the act of eating or drinking or smoking—so much so that the assailants hesitate to approach until the unnatural immobility shows what has happened. One spectator compared such a group to figures in a waxwork exhibition. In other instances death has not taken place at once; a big shell explodes, and the men near by are rolled over by the concussion without being struck by any of the fragments. They get up, feeling rather stunned, but in the course of a few hours, or a day or two, they collapse and die without presenting any obvious injury. These are the sort of cases that used to be attributed to the wind of the cannon ball, which Larrey declared to be a bogey not only hypothetical but absurd. Larrey's denial may apply to instances of laceration of viscera and damage to hard parts beneath an uninjured integument because the lesions can be explained on the assumption of the injury having been inflicted by a projectile at the end of its trajectory, depressing the yielding skin and exerting its momentum on the more resisting parts within. But in cases of delayed death after concussion, not associated with obvious injury, *post-mortem* examination reveals extensive damage to internal organs, especially the hollow viscera, amply accounting for the fatal result. A plausible hypothesis to account for such cases is that the sudden and tremendous disturbance of atmospheric pressure produced by the explosion of the bigger shells acts in one of two ways: either the enormous momentary pressure forces air into the cavities of the body, or the temporary vacuum that follows violently disturbs atmospheric conditions within the body, inflicting extensive lesions. If this be so, it would be the strict equivalent of the wind of the cannon ball which performed such extraordinary feats in the annals of ancient military lore. There are hundreds of instances of acute neurosthenia suddenly induced by the shock of explosion in previously normal men, and in some there have been auditory

¹Revue Neurologique, Paris, 1915, xxii, Nos. 17-18.

or visual disturbances in the absence of demonstrable local injury. Dr. Ravaut has stated that lumbar puncture in some of these cases yielded a blood-stained fluid or one containing an unduly high proportion of albumin, so that it is difficult to exclude the existence of actual physical, though histological, injury to the nerve centres. The suddenness of onset and protracted nature of the psychical disturbances, indeed, compel the idea of structural damage, and pathological evidence, as far as it goes, confirms that assumption.

MESS PRACTICES.

THERE are dozens of Territorial battalions still in England and hundreds of units of the new armies still under training for a task which will test their physical strength to the full and strain their mental and moral fibre to the utmost. In the circumstances it might be expected that they were being prepared for the future that lies before them in every way, but we have an unpleasant doubt whether proper influence is being exerted by the seniors in respect of the young officers. It has been alleged that the messing expenses—in certain regiments, at any rate—are unduly high, and there is no reason to suppose that this statement is ill founded. For some part of its height bad management may account in some cases, but in others the real explanation is that the living standard is far more extravagant than it need be, and more luxurious than it should be, considering the very special circumstances in which these units have been raised. The men who form them are not the ordinary recruits of peace, but soldiers already on the threshold of an enterprise which can successfully be undertaken only by men who are initially well suited to the task, and who, in addition, have left no means neglected of developing their moral and physical capacities to the utmost. In short, in the mess huts of officers who have to set an example to their men, who are daily expecting to enter into a prolonged and trying campaign either in Flanders or the Dardanelles, and who have still to prove their mettle, the tendency should be towards the simple life, even towards a certain degree of asceticism in matters of food and drink. In certain battalions no doubt this tendency does exist, but there are others in which the reverse is the case. If the only result were that messing expenses became unduly high for the pockets of many of the young men who have entered the army the matter might be considered to be of relatively small importance, but this is not the case. We have too good reason to believe that in very many battalions the consumption of alcoholic liquors is a great deal higher than it should be, and that in a certain number, at any rate, the general atmosphere after the morning work and until midnight may be described as being one of drinks all round on any and every excuse. The bad habit of treating, which is a legal offence in the proclaimed districts, ought to be discouraged. In this matter officers should set an example not only to their men but to the country. Some of the evil may be due to the failure of commanding officers of some of the new units fully to realize their responsibility towards their subalterns, many of whom are no more than lads who until the other day were under the discipline of school or the restraining influence of home. We are disposed to think that General Officers Commanding ought without delay to call the attention of officers commanding units in their commands to the risks which are being run, and the serious obligation which rests on them to guide the steps of their juniors through the pitfalls that beset them.

THE ATTITUDE OF DUTCH SCIENTISTS TO GERMAN KULTUR.

THE *Deutsche medizinische Wochenschrift* for June 17th devotes a good deal of space to a plaintive discussion of the unsympathetic attitude adopted by Dutch medical men

to their German colleagues. Dr. Seydel writes that Dr. G. van Rijnberk, editor of the leading Dutch medical journal, *Tijdschrift*, has drawn unkind comparisons between the scientific achievements of many poorly equipped Italian laboratories and the princely establishments of many German "Bier-universities." This contemptuous reference to the convivial tastes of the German scientist is not, in the opinion of Dr. Seydel, worthy of the serious attention of his countrymen, but he deduces from other remarks by the Dutch editor the existence of a widespread movement in the ranks of the Dutch medical profession against Germany. It appears that in the past much of the work of Dutch scientists has been published in German, where it has been submerged in the flood of gigantic tomes and series which for several decades have poured from the German press, so that its educative value has been lost. Foreign professors in Holland are usually Germans, and these imported teachers are in the habit of lecturing in their own tongue. Dutch textbooks are scarce, having been to a great extent supplanted by German works. The Dutchman seeking post-graduate teaching generally goes to Germany, which is also the chief foreign source of instruments and medical appliances. There is a powerful movement afoot in Holland to counteract these Germanic influences, to nationalize Dutch science, and to cultivate greater self-reliance and independence. Holland does not mean to rob herself of the fruits of scientific research elsewhere, but it is her ambition, in addition to fostering science at home, to exchange the one-sided yoke of German *kultur* for a wider and more international scientific intercourse with all her neighbours. Referring to the value of Germany's scientific achievements as compared with those of her neighbours, Dr. van Rijnberk is said by Dr. Seydel to have written: "Still to-day, the great ideas in science germinate repeatedly in France and England, and even in Italy and the Netherlands, whence they are transported to German soil, where they bloom into the perfect plant ready for export." Dr. J. Schwalbe, editor of the *Deutsche medizinische Wochenschrift*, deprecates this attitude of Dutch scientists to Germany, and he interprets the Dutch propaganda not only as a nationalist movement, but also as a movement prompted by actual hostility to Germany. Dr. H. Treub, professor of gynaecology in Amsterdam, who has protested against the appointment of Germans to Dutch professorships, comes in for severe censure for poking fun at Prussianism. It is, in the German editor's opinion, deplorable that Professor Treub should symbolize Prussia in 1813, 1870, 1914, 1915, and 1920 by a series of casts of deformed fetal heads, the Prussia of 1920 being represented as an anencephalic monster!

DEMAND FOR A MIDWIVES BILL FOR SCOTLAND.

A MOVEMENT, which is receiving influential backing, is being made in Edinburgh to memorialize the Secretary of State for Scotland (the Right Hon. T. McKinnon Wood) for the introduction, as a Government measure, of a Midwives Bill for Scotland. But for the war and a small amount of opposition the private bills of 1914 would doubtless by this time have been an Act in full operation, for all the questions of any real difficulty had been overcome both in the House of Lords and in the Commons. The reasons which call for this piece of legislation, even in war time, have already been stated at the various conferences which have recently been held in Scotland in connexion with the Maternity Hospitals and the Approved Societies under the Insurance Act (see pp. 81 and 82 of the SUPPLEMENT for August 7th); but another reason has come to the front during the past few months to reinforce those which have been named. Scotland has sent her full share of medical men into active military service, and when they have been drawn from country districts the

pressure of work upon those left behind has been increased to a degree which is likely in the winter to threaten a complete breakdown; if, however, the remaining practitioners can be helped in their midwifery work by the employment of trained maternity nurses, certified as midwives and on the Roll of a Midwives Act for Scotland, not a little of the congestion in country places may be relieved. These nurses will, it is true, be in large measure the same persons as the ones now practising in Scotland or being trained in her institutions; but, through the passing of such a bill as has been indicated, they will be no longer acting without control and supervision. As an instance of the pressing necessity for some such legislation may be named the application received a week or two ago by the Edinburgh Royal Maternity Hospital to supply a trained midwifery nurse for one of the Shetland Islands, in which several confinements were pending and in which no medical practitioner was available. We understand that the memorial to Mr. McKinnon Wood has the support of the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh, of Sir Halliday Croom, Dr. Haig Ferguson, and others.

ASSISTANCE FOR PREGNANCY CASES IN FRANCE.

In a recent communication to the Académie de Médecine, Professor G. Lepage,¹ Obstetrician to the Boucicaut Hospital, Paris, argued that the beneficial action of the French law of June 17th, 1913, may be facilitated and increased by the earlier examination of women who believe themselves to be pregnant. He would add a footnote to the regulations already published as a guide to women for whom the financial benefit both during the four weeks which precede and the four weeks which follow confinement is intended; and he would make the note read: "Every woman who on account of the non-appearance of her period believes herself to be pregnant and who desires to profit by the advantages of the said law is advised, in order that she may know the probable date of her confinement, to consult a doctor during the fortnight which follows the date of the disappearance of the period." It may, however, be asked whether this early medical examination can be expected to yield information of any real value, and to this question Dr. Lepage replies strongly in the affirmative, always supposing that the right method of examination be employed. He admits that the woman's statements with regard to the last date of menstruation, even when fortified by a careful physical examination of her person, does not enable a categorical answer to be given regarding the probable date of confinement, and he also allows that some women have forgotten entirely when they last menstruated; but he expects great advantage from a bimanual examination of the pelvic organs carried out in the first weeks of pregnancy. He instructs the medical man to employ Puzos's method of bimanual examination, which is done as follows: The medical man should introduce his index finger, in the case of a primipara, and both his index and middle fingers, in a multipara, into the vagina; he should push the whole uterus from behind forwards and from below upwards, so as to bring it as near as he can to the upper border of the symphysis pubis. Having accomplished this he should next transfer his finger (or fingers) from the posterior to the anterior vaginal fornix, and, fixing the uterus between the finger or fingers of this internal hand and the fingers of his other hand placed over the abdomen, he should recognize not only the somewhat soft consistence of the uterine walls, but also the changed form and size of the organ, and should be able better to judge the exact age of the pregnancy, and so more accurately foretell the date of confinement. He cannot of course be absolutely certain about the date, but his opinion is more likely to be correct than when the examination is made at a later

time in gestation; and thus his patient is more likely to receive the pecuniary assistance which is hers by right in the four weeks which precede parturition. This assistance will enable her to take the rest from her work which she then needs so much both for her own sake and for that of her child. Every obstetrician may not agree with Dr. Lepage as to the ease with which such a bimanual examination can be carried out or as to the prognostic value of the information to be derived from it, save by such an expert as Professor Lepage himself, but every one will welcome the result which is likely to follow the bringing of such a notice as he advises before the attention of pregnant women. That result will almost certainly be the earlier application of expectant mothers to medical practitioners for advice, and the advice, needless to say, may extend to other matters than the prediction of the day of delivery. In Great Britain, as well as in France, the earlier coming of pregnant women to doctors would have great advantages both as to the health of the women and their expected infants and as to the prevention of the many causes which lead to miscarriages and premature labours. In this country the law in its relation to pregnancy is not so far advanced as in France, but the Insurance Act has opened up a vista along which the expectant mother may look with real hopefulness to the time when she will be watched over medically during the whole of her pregnancy, and be relieved from financial embarrassment during, at any rate, the later weeks of it.

THE SOCIETY OF APOTHECARIES.

ALEXANDER POPE said he would not have the stump of an old tree pulled up which he remembered as a boy, and there are many who share the feeling. Persons of this temper of mind will therefore hear with regret that it has been decided to pull down the old Mill House of the Apothecaries' Hall in order to widen the thoroughfare in Water Lane. To members of the medical profession that corner of London, though not exactly picturesque, is full of historical associations. The Company of Apothecaries was first incorporated by a charter granted by James I in 1606; by this charter the Apothecaries were united with the Grocers. According to Mr. C. R. B. Barrett, they remained united till the end of 1617, when a new charter was obtained which formed the Apothecaries into a separate company under the designation of the Master, Wardens, and Society of the Art and Mystery of the Apothecaries of the City of London. There was a good deal of opposition to the separation on the part of many of the apothecaries, chiefly, it would seem, on financial grounds. The new society, in its early years, had a hard struggle for existence, and it was not till 1632 that it was able to purchase a house and ground in Blackfriars to serve the purpose of a Hall. The Hall was burnt in the Great Fire of London, though, strangely enough, no record of its destruction is to be found in the Minutes of the Society.¹ It was rebuilt some years later, and, as Mr. Barrett says, "the strenuous efforts required to build their home had the effect of spurring the Court of Assistants on to make greater exertions than hitherto to extend the scope of the Society. It became larger and more powerful in numbers, and during the next half-century increased in wealth." Although a committee was formed in 1667 "to treat about the building of the Hall and consider for raising the money and to compute the charge," the Society was too poor to carry out the project in full at the time, and it was not till ten years after the fire that the buildings were completed. Among these was the Mill House, where drugs were ground, weighed, and preserved. The Court of Assistants of the Society decided

¹ *Bull.*, s. 3, t. lxxiii, p. 18, July 6th, 1915.

¹ *The History of the Society of Apothecaries of London.* London, 1905.

some time before the outbreak of the war that it would be desirable to increase the facilities for the wholesale manufacture of drugs which is carried on at the Apothecaries' Hall, by the construction of a new Mill House with modern and improved machinery in order to cope more efficiently with the large and increasing business done by the Society. This "trade," as it is familiarly called in the Society, has now been carried on for nearly 300 years. As the result of the erection of the new Mill House, the old Mill House is to be demolished, and new buildings erected upon the site. It is a pity, but we suppose that this removal of an ancient memorial of the past must be regarded as a sacrifice to progress.

MILITARY LIFE AND PHYSICAL HEALTH.

The extraordinary improvement in the physical fitness of men who joined the new armies in this country is a commonplace observation, and most of us have had the opportunity of watching the improvement from month to month in personal friends or relations. Similar observations have been made in France, where hundreds of thousands of men accustomed to sedentary lives were mobilized at the beginning of the war, and have since led the strenuous outdoor life which falls to the soldier actually engaged in warlike operations. A correspondent writing from that country tells us that of the French territorials who have been at the front since the outbreak of hostilities, many are being allowed home on short furlough, and that their aspect on arrival is often, nay usually, destructive of many illusions on the part of the pining wife or anxious mother. People at home thought sadly of the absent one, passing nights in half-drained trenches, a prey to numberless scares and anxieties, frightened half out of his wits by exploding bombshells, fed erratically, and exposed to drenching rain or the paroling rays of an implacable sun; he would naturally return with haggard and weebegone looks, the shadow of his former self. But lo! on the contrary, his face beams with smiles and good health. The podgy shopkeeper has lost his *embonpoint* and pasty complexion. He is smart, his eyes are bright, his skin tanned, and his movements alert and manly. The fond wife is on the verge of disappointment, for she was expecting to play the nurse to a worn-out, debilitated husband, instead of which he has regained the jollity of his early married days and, far from complaining, he boisterously describes his strenuous days and disturbed nights. Given a fair standard of physical stamina, it cannot be questioned that the active adventurous life of the soldier in the field makes for health and strength. Confirmed alcoholics, now that their consumption is necessarily kept within moderate limits, recover the power of self-control and appreciate the gain in dignity and self-esteem. Neurasthenics, under the influence of war work, forget to worry about their inside, and, living as they do from hand to mouth, look out instead of looking in. Hard work and frugal living in the open air raise the standard of vitality, and effect cures which had defied the pharmacologist. The moral being undergoes a salutary change *pari passu* with the physical. The implacable pursuit of a common object, the sharing of a common danger, and the perpetual emulation render selfishness despicable and make the man conscious of his individual insignificance; his personality is sunk in the common weal. The weaklings, of course, go to the wall, the strain is more than they can bear, the feeble nervous system breaks down, the damaged heart yields to the strain. Given, however, an adequate margin of resilience, the fact seems to be that, apart from the casualties of actual fighting, the conditions of a soldier's life in war afford a special case of the operation of the law of the survival of the fittest. Those who possess the necessary resilience survive, and are all the better for the experience.

DREAD OF INFECTION FROM PULMONARY TUBERCULOSIS.

The ever-increasing amount of attention devoted to the study and prevention of pulmonary tuberculosis, more particularly the endeavour to familiarize the public with its dangers and its prevention, has, as our columns have more than once borne witness, had one undesirable effect, inasmuch as it has given some of the less instructed an exaggerated idea of the risk involved in attendance on persons suffering from "consumption." A letter published elsewhere in this issue shows that such fears may make it a difficult problem to carry out the home treatment of the disease owing to the dislike which servants manifest to being brought into contact with sufferers. What medical teaching really aimed at was to impress upon those in attendance on phthisical patients the desirability of observing certain elementary precautions in order to prevent the spread of the disease, but the proposals advocated in various countries to make pulmonary tuberculosis a notifiable disease have had the effect of making the public jump to the conclusion that pulmonary tuberculosis is a highly contagious affection. This unwarrantable scare may indirectly be of some advantage by rendering people circumspect, but it entails extremely distressing consequences for the victims, who find it difficult to obtain housing accommodation, and find themselves treated as pariahs. Inasmuch as it is impossible to provide sanatorium facilities for all cases of phthisis, and as there are numerous patients who neither desire nor require to be segregated, it behoves us to complete the education of the public by teaching them that the risk of contracting the disease is almost non-existent when certain simple precautions are observed.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

The outstanding feature of the week's subscriptions is the fine contribution from the Canadian Committee. The generosity of the Dominions, which has been so marked a feature in the growth of the Fund, is further shown in subscriptions from Newfoundland and Cape Colony.

Thirty-sixth List.

	£ s. d.		£ s. d.
Canadian Committee (per Dr. J. Gibb Wishart, Hon. Treas.) (6th donation, total £2,227 3s. 11d.)	800 0 0	H. A. Giovannetti, Pritchard, Scully, Burden, Jones, A. K. Anderson, O'Connell, Breslin, Freebairn, Hogan, Mackay, Cowperthwaite, Mitchell, Stafford, Parsons, J. J. Smith, Cron, Chisholm, Carnell, Donahue, A. MacDonaid, W. Roberts, M. C. Roberts, Jamieson, S. S. Smith, Fitzgerald, LeVisconte, Parker, McLeod, G. N. Murphy, Mr. J. McFarlan	36 7 8
Dr. F. de Havilland Hall (5th donation, total £10)	1 17 0	Mr. Allan Gray	1 0 0
Col. Charles Ross Pearce, I.M.S.	1 1 0	Dr. A. D. Clark	1 1 0
Cape Colony District Surgeons' Association (per Dr. W. Darley Hartley)	20 9 0		
Dr. Bill Alden	0 7 5		
Newfoundland Medical Men (per Dr. H. Rendell, Registrar, Newfoundland Medical Board) - Drs. McKendrick, Macpherson, Duncan, Rendell, Fraser, R. Forbes, C. Forbes,			

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and would be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments, etc., contributed by the following donors since the publication of the last list:

Dr. Frosser White, Wigan.	Miss H. C. Boulman, Leeds.
Anonymous, Merthyr.	Dr. F. W. Collinson, Preston.

SPECIAL courses of toxicology have been organized at the Military Medical School of Val-de-Grâce, near Paris. They are intended for pharmacists who will be employed in the new laboratories recently established at the front. Detachments of analytical chemists have been organized in this country as units of the Royal Engineers.

THE WAR.

MEDICAL ARRANGEMENTS FOR THE DARDANELLES.

THE increase in the magnitude and scope of the operations in the Dardanelles has entailed a corresponding increase in the medical provision for the forces engaged. The Prime Minister stated in the House of Commons on July 28th that the total number of killed and wounded among the naval and military forces engaged in the Dardanelles down to July 18th was 37,962; of these, 8,099 were killed (officers, 562; men, 7,537), while the wounded numbered 29,883 (officers, 1,375; men, 28,508).

Owing to the topographical peculiarities of the Gallipoli peninsula and military exigencies, the problem presented to the Army Medical Service has been one of extraordinary difficulty, and one for which no parallel is to be found in any previous experiences of the military services of any country. The foothold obtained at the southern end of the peninsula and a little further north-east at the point now, we believe, called Anzac, where the Australian and New Zealand Army Corps effected a landing, concerned only a very limited extent of ground, almost everywhere exposed to the fire of the enemy. It was, in fact, not found possible to find a site for a hospital ashore. One casualty clearing station was established near Sedd-el-Bahr, which is at the eastern end of the promontory, five miles in width, which forms Cape Helles. The situation was so exposed that the clearing station was on several occasions shelled out. The wounded brought down from the field ambulances were put as quickly as possible on board barges, which were towed out to the hospital ships afloat. These hospital ships may almost be said to have acted as the casualty clearing stations, as well as the first line hospitals of the force ashore, the base hospitals being at Lemnos, Alexandria, and Malta. The number of hospital ships has been largely increased since the landing at the end of April, as has also the hospital accommodation for sick and wounded both in Malta and Egypt. Malta has been found a particularly suitable place for base hospitals, and a large number of beds are now provided there; but, as is well known, a number of wounded have been brought home to England direct in hospital ships.

The great increase in the accommodation for sick and wounded in Egypt and Malta has called for a corresponding increase in the medical and nursing personnel. As has already been announced, the army has the advantage of the services of a number of consulting physicians and surgeons of distinction who are for the most part stationed at the base hospitals at Malta or in Egypt. The situation, as far as the medical service is concerned, is now well in hand, and steps have been taken to keep up the personnel to full strength, and to increase it as may be required.

The full magnitude of the operations in the Dardanelles has, perhaps, as yet hardly been appreciated in this country, but, after what has been said, it will be easy to understand that the number of medical officers required to serve there in various capacities has contributed very materially to increase the demand which the army is making on the medical profession in this country and in Australasia.

THE BRITISH RED CROSS IN THE DARDANELLES.

The Joint Committee of the British Red Cross Society and the St. John Ambulance Brigade recently received a report from its Chief Commissioner in the Mediterranean, Sir Courtauld Thomson, describing the work which had been done down to the middle of July to assist in the treatment of the wounded from the operations in the Dardanelles. A Red Cross store has been established adjoining the casualty clearing station under Cape Helles, the southern extremity of the Gallipoli peninsula; both are open to shell fire, though it is not believed that they are intentionally shelled. In spite of this, some motor ambulances are working on the peninsula and arrangements are being made to send out others. The wounded, when removed from the casualty stations, are placed on barges and towed out to hospital ships or other vessels, in which they are carried to base

hospitals at Mudros on the island of Lemnos, Alexandria, or Malta. The removal of the wounded to the hospital ships or transports is facilitated by motor boats, but a larger number could be utilized. A Red Cross store has been established also at Mudros, and has been able to supply the ships carrying the wounded from there with additional comforts for the wounded, including shirts, pyjamas, and pillows. A buffet for light refreshments has been established on the beach. More motor boats are also required at Mudros for the conveyance of wounded and stores. These are being supplied by the Joint Committee. From Alexandria the wounded are taken direct to hospitals in the city in motor ambulances, or in ambulance trains to Cairo. At Alexandria two additional convalescent hospitals for officers have been opened. At Cairo the Red Cross hospital has been extended; it is under the charge of Major and Mrs. Phillips, who act as medical officer and matron respectively. There is a hospital and Indian convalescent camp at Suez, where the Red Cross representative (Dr. Arthur Hayes) is able also to supply comforts to the hospital ships proceeding to India and Australia. Red Cross stores have also been established in connexion with provincial hospitals and convalescent homes in various parts of Egypt where local committees are at work. In all the work in Egypt great assistance has been given by Dr. Ruffer, President of the Sanitary, Maritime, and Quarantine Council of Egypt, and by Sir John Rogers of Cairo.

TRANSPORT OF THE WOUNDED.

In the August number of the *St. Bartholomew's Hospital Journal* Captain L. B. Cane, R.A.M.C., gives an account of the difficulties of transporting the wounded to the ships and from them to the base hospital. Within three weeks, he says, nearly twenty thousand wounded men were taken to Alexandria and hundreds continued to arrive daily. "Many of these were shot long before they reached the Turkish shore; some of the boats were sunk and others turned back full of wounded, with scarcely an uninjured man left on board to land. From the beginning the hospital ships have been quite insufficient to deal with such thousands of wounded, and have had to be supplemented by many of the transports in which the troops went out. In some instances these refilled so soon with urgent cases that they returned to the base even before the last of their men and stores had been disembarked. Several medical officers from the field ambulances or other units were put on board each transport, with what orderlies could be spared. These worked night and day during the return voyage, but, in spite of all exertions, found it often quite impossible to render more than the most urgent first aid treatment. Several transports returned with over 800 wounded, one with nearly 1,100 and one with 1,618, and in each only three overworked medical officers, a few orderlies, and no nurses, to do the entire work of an improvised floating hospital, full of surgical cases, during its two and a half days' voyage back to Alexandria."

By the middle of June more complete arrangements had been made, and a number of transports were fitted out for use as hospital ships, with staffs of four medical officers, six nurses, and twenty orderlies on each. The transference of the wounded from the shore had frequently to be carried out under fire. Often the men had dragged themselves or been helped by less severely wounded comrades for about two miles to a dressing station, from which they were carried some distance to the shore. Then they had to be conveyed through shallow water to landing boats or lighters, which were rowed or towed out to the transport or hospital ship. Those who could not walk were slung over the ship's side by ropes; fortunately the sea was smooth. Hundreds of wounded had to be hurriedly dressed on board and then disposed about the docks and in every available space in the ship. At Alexandria notice of the probable date of arrival of each ship and the approximate number carried was in most cases received a short time before she was due, and hospital trains and motor ambulances were waiting on the quay. Four Red Cross trains were in use, each capable of taking about 200, though generally not more than three were got off in a day. A fleet of about forty motor ambulances disposed of the rest, and the work was carried out for the most part smoothly and expeditiously. Disembarkation,

however, was not always free from danger. Captain Cane gives a picture of an officer with seven wounds and a fracture being lowered over the side who, owing to the slipping of the ropes, narrowly escaped being tilted out of the stretcher. The worst cases were usually removed first to the hospital in Alexandria, the others being sent to Cairo or elsewhere by motor ambulances and trains. On one day five ships full of wounded were alongside at once. At one time, when there was an exceptional rush, and after the worst cases had been taken off the ships and retained in Egypt, some 3,000 were sent on to Malta. During the early operations the hospital ships lay sometimes for days close in to the shore between great battle-ships firing broadsides at the Turkish positions and in full view of the fighting. Occasionally aeroplanes dropped shells on the Red Cross ships, sometimes killing a few of the wounded.

THE NEUROLOGY OF WAR.

The Neurological Society of Paris has devoted a special double number of its Review¹ to the organic and functional cases of nervous disorders caused by the war. The original papers on these subjects may be analysed in the following five groups.

Lesions of the Nerves.

J. Babinski discusses the diagnosis of traumatic lesions of the nerves, pointing out how the paralyzes here met with may be simulated by divisions of tendons or muscles, or complicated by hysterical paralyzes. He notes that when a nerve has been divided or injured, the patient has often felt an extremely violent or fulgurating pain at the moment of injury; possibly this symptom is diagnostic of an organic lesion of a nerve. Injuries of the brachial plexus produce lesions of two main types: (1) Paralysis of the circumflex, musculo-cutaneous, and radial nerves, and (2) paralysis of the ulnar and median nerves. Lesions of the nerves commonly produce vasomotor and secretory disturbances, and very often result in fibro-tendinous contractures, especially when the lesion is painful. Surgical interference in lesions of the nerves is often called for, particularly in cases where much pain is felt; the cut nerve should be sutured, the injured nerve freed from adhesions. Sensation often returns early after operation, and before movement. P. Marie and Mme. Athanassio-Benisty have observed that much pain and vasomotor disturbances (cold, cyanosis, sweating) are common in lesions of the median nerve, rare in those of the radial or ulnar. Injuries of the sciatic and internal popliteal nerve, as of the median, give rise to intense burning pain aggravated by pressure. The claw-hand, appearing at once, is characteristic of ulnar lesions, if the median nerve escapes injury. The special phenomena observed in injuries of the radial, median, ulnar, and sciatic nerves are tabulated very fully; the subject gave rise to a general discussion. J. Dejerine and E. Schwartz give a full description of the case of a soldier with an irritative shell wound of the left median nerve which caused articular deformations similar to those of chronic rheumatism, trophic troubles, and hyperhidrosis, in the area supplied by the nerve. Operation four and a half months later showed no visible lesion of any of the nerve trunks in the forearm; treatment effected but little improvement. M. and Mme. Long describe three somewhat similar cases with marked trophic and neuralgic signs and symptoms. M. and Mme. Dejerine and J. Mouzon give a summary of the clinical symptoms of injuries of the large nerve trunks, their complete interruption, their recovery, and the indications for operation in these common cases. The authors remark that the nerves are very fragile structures and should be manipulated or exposed as little as possible by the surgeon. A. Léri records his experience of 400 patients with wounds of peripheral nerves, treated by operation in seventy-five instances. In only one case was the crural nerve injured, as compared with forty-three lesions of the sciatic trunk. Operative interference is advised after two months in cases with complete paralysis, and is to be considered in cases where spontaneous improvement is doubtful or slow after three months. Léri recommends oiling of the nerves exposed at operation, to prevent the further formation of adhesions; and in ten

cases has joined up the cut ends of shortened nerves by enclosing them in the hardened excised arteries or veins of calves, as Foramiti advised, with good results. J. Tinel records a case of ischaemic paralysis of the right leg following ligation of the popliteal artery for aneurysm, with pain, cyanosis, and sweating, greatly improved by treatment. The return of faradic excitability before the power of movement, after lesions of the peripheral nerves, is described as a sign of good prognostic import by P. Marie and Mme. Athanassio-Benisty.

Lesions of the Spinal Cord.

De Lapersonne and Wiard offered for diagnosis the case of a soldier wounded in the neck by the explosion of a shell. A skiagram showed that a fragment of bone was pressing on the cord at the level of the seventh cervical vertebra. The man had paresis of the right leg and arm, some ptosis and enophthalmos, small pupils preserving their reflexes, and marked oedema of the right optic disc, more than two discs in diameter. There was no history of syphilis; the cerebro-spinal fluid was normal. The authors contemplated operation. J. Mouzon and D. E. Paulian give an account of a case of Brown-Séquard paralysis due to a shrapnel bullet entering at the root of the nose and lodging in the right-hand side of the body of the third cervical vertebra. Four months later the right side of the body was weak, and showed associated movements when voluntary motions were made on the left side; there was marked loss of sensation in the areas supplied by the third and fourth cervical nerves on the right, of the sacral and fifth lumbar nerves on the left, and diminished sensibility to heat up to the second thoracic nerve on the left. A. Léri describes functional cases of commotion of the medulla or cord, with partial or complete paraplegia and sometimes disturbances of micturition. The symptoms may not come on until long after the shock that produced them; yet they may last for months unless they receive the proper psychotherapeutic treatment. E. Dupré, Le Fur, and Raimbault communicate notes of a case of traumatic haemorrhachis, with spasmodic paralysis of the four limbs and sphincter troubles, due to the passage of a bullet through the upper part of the neck. The patient made a fairly good recovery in five months. A. Souques relates a case in which a bullet wound of the left leg, leaving a condition of talipes equinus behind it, gave rise to definite ankle-clonus (spinal epilepsy) on examination. This he referred to the state of muscular contraction of the sural triceps. J. Tinel gives details of a case of continual functional nystagmus, transverse and very rapid, capable of arrest for a few seconds on fixing an object, and replaced by a slower and more normal nystagmus on application of the methods of producing artificial nystagmus. It came on gradually in a young soldier awakened by a shell explosion; the patient was nervous and had a pulse of 120 to 140. H. Meige, commenting on the case, remarked that the patient was a cinematograph employee, and was inclined to believe the nystagmus to be a tic, voluntary, used more or less consciously by the patient. G. Roussy and Ichlonski describe the case of a soldier with a bullet wound through the parietal region of the head, who recovered with a left hemiplegia, left astereognosis, and marked syncinetical movements of the left arm and (less so) leg when the right limbs were moved.

Lesions of the Brain.

A. Polosson and F. J. Collet describe the case of a young soldier who received a glancing bullet wound on the right parietal region. Consciousness was not lost, but rapid small movements of extension and flexion appeared at once in the left wrist, four or five a second, with paralysis of the thumb, inability to separate or flex the fingers, and inability to move the wrist; the fingers were semiflexed, the thumb adducted, the form of objects was not recognized by the left hand. The movements persisted during sleep. Eight days later the patient was trephined over the wound, and a small extradural haematoma was found; the dura was not opened. Three days later there was a left-sided fit of Jacksonian epilepsy lasting five minutes; a few more fits occurred during the next days. Three months after the injury the patient returned to the front. The authors describe this as a case

¹ *Revue Neurologique*, Paris, 1915, xxii, May-June.

of "partial continuous epilepsy," or Kojewnikow's syndrome (1894), comparable to pre- or post-hemiplegic tremors, and due in this case to local irritation of a small area of the cortex of the ascending frontal convolution. J. Dejerine and J. Monzon relate two cases of Dejerine's "syndrome of cortical sensibility." The patients had bullet wounds in the left and right parietal regions respectively; their right and left hands respectively preserved sensibility to touch, pain, and heat almost unaltered, but had lost tactile discrimination, sense of position, and deep or bony sensibility; so that astereognosis was present, and the hands were clumsy and ataxic. The authors contrast with this picture thalamic lesions, in which all modes of sensation are altered. G. Roussy and J. Bertrand give details and a discussion of a somewhat similar case. E. Dupré and Le Fur recount the case of a soldier struck by a bullet on the vertex, with fracture of the external table of the skull. This produced an incomplete spastic paraplegia, which made walking, even with crutches, still difficult five months later; two months afterwards lumbar puncture showed that the cerebro-spinal fluid was increased in amount, though free from leucocytosis. The authors concluded that the two ascending parietal convolutions had been injured, with meningeal haemorrhage and inflammation.

Hysteria.

G. Roussy describes how three Zouaves were knocked out by the violent explosion of a shell in their trench, which killed two men outright and buried a dozen more or less completely in earth. Two of the three died from the noise and ears; all three found they were deaf, and became dumb also. Three days later they reached Roussy's clinic in Paris, deaf, dumb, communicating by signs only; one of them, nervous and excited, feverishly wrote long accounts of the accident. The three, presenting such uniform symptoms, were placed apart in separation rooms, and Roussy described in the presence of each how they would recover completely in a day or two. Two recovered hearing partially and speech very completely next day, the third the day after. Each had perforation of the tympanum and otitis media, one bilaterally. Each had been for several months at the front and each had been wounded already, one twice. Roussy has seen a fourth similar case, and gives a careful analysis of 50 cases of hysteria, and 4 of simulation he has had under his care as a result of the war. Nine of the 50 had hysterical fits and required severity of treatment; 4 were temporarily deaf-mutes; 4 resembled cerebral commotion; 7 had functional hemiplegia or paraplegia; 8 resembled cases of neuritis; 16 had painful monoplegia of the arm or leg after shock, injury, or operation, the paralysis being either logical in type or paradoxical. A. Souques described 2 cases of hystero-traumatic crural monoplegia in soldiers, pointing out how difficult it may be to prove that such cases are not cases of simulation. He also illustrated the hystero-traumatic contractures or pseudo-contractures in the limbs of wounded soldiers, which, he said, again might be indistinguishable from simulated contractures. J. Dejerine narrated fully 2 cases of functional paraplegia in emotional young soldiers, due to bullet or shell wounds. In each of these neuropaths there was a past history of similar attacks in years gone by brought on by excessive emotions.

Simulation.

Naturally, the border line between cases of hysterical loss of function and cases of simulation or fraud is very ill defined. J. Babinski points out that there may be no objective distinction between the two, and quotes a case showing that an organic paralysis from disuse may follow a hysterical paresis of the leg. He had had four cases of hemiplegia or paraplegia due to the explosion of a shell at a distance, in which no evidence of organic disease could be found; recovery followed rapidly when military penalties were threatened. P. Marie notes the difficulty of distinguishing fraud from hysteria, quoting three cases of simulation; one patient, a hemiplegic, received as punishment twenty-five days in prison, twelve in the cells. He says the best punishment in these cases would be to state on their papers that their disease is imaginary; and he would divide the apparently hysterical patients into two classes—

namely, (1) unconscious simulators, including neuropaths, cases of hysteria, and traumatic hysteria, requiring strict treatment in military hospitals; and (2) exaggerators, who have actually been wounded, but have added physiological solacisms to their real troubles, and require treatment by suggestion or reasoning, as well as treatment for their surgical lesions. J. Dejerine states that he has not yet seen a case of simulation or fraud among the many patients with functional nervous disorders due to the war who had passed through his hands. He quotes three functional cases in which the plantar reflex had been lost, and expresses the opinion that excessive emotion rather than mechanical shock to the nervous system is the cause producing functional cases. Among other speakers at a discussion on this subject was J. Babinski, who dwelt on the difficulty of detecting adroit simulators of nervous lesions, and on the difficulty of being sure that an apparent fraud, such as a dumbness cured by faradizing the larynx, was not really due to auto-suggestion rather than fraud. He concluded that the object of examining and treating these patients should be to cure them rather than to make a differential diagnosis between hysteria and fraud. Energetic and authoritative treatment would often work marvels, even in the obstinate cases of old standing. As a record or diagnosis to be written on the papers of these patients, he suggested some such formula as the following: "Neuropathic troubles due to suggestion, not grave, and curable by psychotherapy and counter-suggestion." H. Meigs emphasized the importance of discriminating between these cases and those of real trauma of the nervous system. H. Roussy, commenting on his four cases of simulation, was inclined to write the diagnosis on the papers of the patient, and let him suffer the consequent military penalties.

DISPATCHES.

DARDANELLES.

A SPECIAL supplement to the *London Gazette*, published on August 5th, gives a dispatch dated June 12th from General Sir Ian Hamilton, commanding the Mediterranean Expeditionary Force, in which a large number of officers and men are specially mentioned for good service, including the following members of the Medical Services:

R. A. M. C.—Colonel M. T. Yarr.
Field Ambulances.—Major C. H. Lindsay, M.D., 1st West Lancashire Field Ambulance (T.F.), 89th Field Ambulance; Lieutenant G. Davidson, M.D., 1st Highland Field Ambulance (T.F.), 89th Field Ambulance; Corporal J. W. Jones, 89th Field Ambulance; Private A. Cook, 87th Field Ambulance.
Royal Naval Division, Howe Battalion.—Surgeon E. G. Schlesinger, R.N.

AUSTRALIAN AND NEW ZEALAND FORCES.

Australian Army Medical Corps.—Captain A. G. Buller, D.S.O., 9th Queensland Battalion; Captain E. T. Brennan, 11th West Australia Battalion; Captain H. L. StV. Welch; Sergeant H. Jackson; Private L. W. Burnett.
1st Field Ambulance.—Captain C. E. Wassell; Private G. Macgregor.
2nd Field Ambulance.—Lance-Corporal V. Cayley.
3rd Field Ambulance.—Captain D. MacWhae, Lance-Corporal G. C. Faruham, Private C. H. G. Ross.
1st Australian Casualty Clearing Station.—Lieutenant-Colonel W. W. Giblin, Major J. Corbin, Private M. D. Cowan.
New Zealand Army Medical Corps.—Lieutenant-Colonel W. W. Fearless, V.D., Captain G. Craig, Lance-Corporal G. Steedman.
New Zealand Field Ambulance.—Major E. J. O'Neill, Lance-Corporal W. Singleton, Private J. Comrie, Private J. Crawford-Watson, Private W. Heaver, Private W. J. Henry.

FRANCE.

Some additional names recommended for gallant and distinguished service in the field in continuation of those mentioned in the dispatch from the Field Marshal Commanding-in-Chief dated May 31st, and published in the *London Gazette* of June 22nd, were printed in a supplement to the *London Gazette* issued on August 7th. The following names of members of the medical profession appear in the lists:

Staff: Colonel E. G. Browne, A.M.S.
Munro Ambulance Corps: Henry Jellitt, M.D., F.R.C.P.I. late Master of the Rotunda Hospital, Dublin.

CASUALTIES IN THE MEDICAL SERVICES.

NAVY.

Wounded.

Surgeon H. K. Shaw, R.N., Dardanelles.

ARMY.

Killed in Action.

Lieutenant George McCallum, R.A.M.C., was reported in the casualty list of August 8th as killed in Flanders. He was educated at Glasgow, where he took the M.B. and Ch.B. in 1914, and took a temporary commission as Lieutenant, R.A.M.C., on January 25th, 1915. He was attached to the 6th Duke of Cornwall's Light Infantry.

Lieutenant John Cornock Hawkes, R.A.M.C., attached to the 8th Battalion, King's Royal Rifle Corps, was also reported in the casualty list published on August 8th as killed in Flanders. He took the Scottish triple qualification in 1910, and received a temporary commission as Lieutenant on December 16th, 1914. *The Medical Directory* gives his address as Castletown, Berehaven, co. Cork.

Died of Wounds.

Major S. J. Richards, 1st Australian Clearing Hospital, Dardanelles.

Lieutenant John Cattanauch, R.A.M.C., who was reported as wounded in the Dardanelles in the casualty list published on July 29th, has since died of his wounds. He was the son of Mr. William Cattanauch, merchant, Newtownmore, and was educated at Newtownmore and Kingussie schools, and at Edinburgh University, where he took the M.B. and B.Ch. in 1912. He took a temporary commission as lieutenant in the R.A.M.C. on October 10th, 1914. During his university career he was a noted athlete; he was considered the finest shinty player in Scotland. He represented Edinburgh in the inter-university sports of 1909, 1910, and 1911, and received international caps for Scotland both for athletics and for hockey.

Wounded.

Major T. Holt, R.A.M.C.(T.F.), Dardanelles.

Captain J. Lithgow, R.A.M.C.(T.F.), Dardanelles.

Lieutenant (temporary) H. J. Burke, R.A.M.C., Flanders.

Lieutenant (temporary) J. N. Clark, R.A.M.C., Dardanelles.

Both Major Holt and Captain Lithgow have been reported as wounded before, the former on June 15th and the latter on July 24th.

DEATHS AMONG SONS OF MEDICAL MEN.

Andrews, Alan Charles Findlay, 2nd Lieutenant 2nd Royal Fusiliers, elder son of Mr. C. H. Andrews, St. Giles, Norwich, killed in the Dardanelles on June 28th. He was born on November 2nd, 1894, and educated at Norwich Grammar School and at Sedbergh, where he was in the O.T.C., gained his shooting colours, and represented his school at Bisleigh. He held a commission for two years in the 4th Norfolk Territorial Battalion, and after the war broke out joined the 16th Battalion of the Royal Fusiliers. Early in May he was transferred to the 2nd Battalion, with which he went to the Dardanelles, where he fell in the attack on Krithia on June 28th.

Carter, Gerald Francis, 2nd Lieutenant 7th Battalion King's Royal Rifle Corps, son of Alfred H. Carter, F.R.C.P., of Abingdon, late of Birmingham, killed in Flanders on July 31st, aged 18. He was educated at St. Nims, Moffat, and at Winchester, where he twice gained the job of medal for gymnastics. When the war began he was on the point of going to St. John's College, Oxford. He enlisted in the Public Schools Battalion of the Middlesex Regiment, got his commission in the K.R.R.C. on April 6th, and went to the front on May 18th.

Colston, Harold Kelway, Major 1st York and Lancaster Regiment, only son of the late Deputy Surgeon-General C. K. Colston, I.M.S., killed at Ypres on April 23rd. He was educated at Clifton, joined the army in November, 1891, became Captain in September, 1901, and Major in January, 1910. He served in the South African war, in the operations in the Orange River Colony, gaining the Queen's medal with two clasps. He was reported missing on April 23rd, and has since been reported as then killed.

McClellan, Lewis Alexander, Lieutenant 8th Battalion Rifle Brigade, son of William McClellan, M.D., J.P., of Coolen, West Kirby, killed recently in Flanders. He was educated at Merchiston, where he was in the Rugby fifteen, and as a medical student at Pembroke College, Cambridge, and at the London Hospital. He was a noted Rugby football player, gaining his blue against Oxford in 1910 and representing his hospital for three years. He got a commission as Second Lieutenant on September 9th, 1914, and as Lieutenant on December 7th.

MEDICAL STUDENTS.

Dewes, Bryan Osmond, Second Lieutenant 1st Battalion Middlesex Regiment, killed in Flanders on July 30th. He was

the elder son of Hugh Dewes, Esq., was educated at St. Andrews and at Kepton, and had just entered St. Thomas's Hospital as a medical student with a First Arts Scholarship. He was a member of the London Rowing Club, which he represented at Henley in 1914. He enlisted in the Artists Rifles in August, 1914, got a commission as Second Lieutenant on February 2nd, 1915, and was serving as machine gun officer when he was killed.

NOTES.

DISTINGUISHED CONDUCT MEDAL.

On August 5th the War Office issued a list of warrant officers, non-commissioned officers, and privates to whom the Distinguished Conduct Medal had been awarded for acts of gallantry and devotion to duty. The list contained 405 names, besides six by whom the D.C.M. had already been earned, who now gained clasps. Among them were the following members of the medical services:

Lance-Corporal V. Cawley, No. 2 Field Ambulance, 1st Australian Division; Private M. D. Cowtan, 1st Australian Casualty Clearing Station; Private W. R. Fitch, R.A.M.C., attached 1st Hampshire Regiment; Corporal J. E. McNeill, R.A.M.C., attached 2nd Royal Inniskilling Fusiliers; Sergeant J. Percy, R.A.M.C.; Private W. Steedman, R.A.M.C., attached 9th Lancers; Sergeant H. W. Stoner, R.A.M.C., attached 1st Royal Irish Fusiliers; Acting Sergeant R. M. Watchorn, 3rd Welsh Field Ambulance, R.A.M.C.(T.F.).

BRITISH HOSPITAL UNIT FOR RUSSIA.

A special committee has been formed, under the auspices of the Anglo-Russian Committee in London, for the equipment of a complete hospital unit for service on the Russian front. The President of the Committee is the Earl of Cromer, and the members are Lord Chelyesmore, Lord Weardale, Sir Starr Jameson, and Sir William Mather. The details of the proposal will be published shortly. The committee has issued an appeal asking the British people to give practical proof of their sympathy with the Russian people, whose soldiers are at present bearing so heavy a part in the burden of the Allies. Subscriptions should be sent to the Anglo-Russian Hospital Fund, Messrs. Baring Brothers, 8, Bishopsgate, London. All information can be obtained from the Honorary Secretary, Anglo-Russian Hospital, 116, Victoria Street, Westminster, S.W.

THE YOUNGEST RECRUIT.

We are informed that the youngest recruit in the present campaign is Thomas Warwick Newbigging, the son of Dr. T. Duncan Newbigging of Abington, Lanarkshire. At the age of 13 he was engaged at the recruiting office at Leith, and when 14 years old was permitted to join the Lanarkshire Yeomanry. Before this he had been the youngest King's Scout, having joined at 11 years of age.

MEDICAL OFFICERS WANTED.

1st Wesser (S) Casualty Clearing Station, R.A.M.C.(T).

Medical officers are required to complete the establishment of this unit. Two should be operating surgeons, preferably holding F.R.C.S. All must be prepared for both home and foreign service. Those recently qualified acceptable. Ambulance workers specially welcome. Applications to Lieutenant-Colonel C. I. Ellis, Officer Commanding, 71, Holloway Street, Exeter.

We have received a circular containing an appeal from the Presidents of King Albert's Civilian Hospital Fund, the Duchess of Buckingham and Chandos, and the Earl of Halsbury. The aim of the fund is twofold: there is not only an overwhelming need to succour the distressed people still on Belgian soil, but it is also essential that the country through which the allied troops may eventually have to pass shall be free from disease or danger from infection. The condition of the civil population of that portion of Belgium still held by its heroic people is pitiful; invaluable help has already been given by the hospitals at Poperinghe, Ypres, Hazebrunck, Montreuil and St. Idesbald, supported partly by voluntary contributions and partly by the Belgian Government. An appeal is now made for subscriptions to the fund, which may be sent to the London County and Westminster Bank, 62, Victoria Street, S.W. The work of administering the relief will be in charge of the Executive Committee, and a direct representative of the fund in Flanders will attend to the distribution of articles and cash. Contributions of medical stores, articles of clothing, foodstuffs, etc., and all books and cases containing such gifts will be gratefully received and acknowledged by the Hon. Mrs. Oliphant Murray or the Hon. Sybil Amherst at the hospital depot, care of Harrod's Stores, 116, Brompton Road, S.W.

Ireland.

THE UNIONS AND THE DUBLIN HOSPITALS.

The guardians of the North Dublin Union at their last meeting discussed the resolution of the Corporation of June 7th, addressed to the Local Government Board, pointing out the congested state of the city hospitals, and suggesting that the amalgamation inquiry should take into consideration the question of converting the hospital buildings of the North and South Unions into a district hospital. The following resolution was proposed:

We consider that no such inquiry would be just to the citizens that did not take into account the enormous number of provincial patients receiving preferential treatment in the city hospitals, and whilst not asking for the return to the state of affairs that existed up to 1877 when citizens had the exclusive right to the city hospitals, we ask, through the City Council, that their representatives on the City Hospital Boards, be requested to produce for the information of the Corporation, and any such inquiry, evidence as to whether the objects for which they were founded are complied with, or that the wishes of all who endowed them with large sums are carried out.

It was objected that such a resolution would do no good, but rather infinite harm to the object they had in view in the establishment of a district hospital for the people of the city. It was pointed out also that no resolution of the guardians would have any effect in interfering in any way with bequests or grants made to any of the city hospitals. After some discussion the motion was put to the meeting and defeated.

INFANTILE MORTALITY IN DUBLIN.

Sir Charles Cameron, Medical Superintendent Officer of Health for Dublin, has written to the press on the subject of infantile mortality, which for some time past has been a subject of much discussion; the mortality, he admits, is high, but he denies the statement, so frequently made, that it is the highest in the towns of the United Kingdom. In the decade ended 1913 the mean death-rate of children under 1 year of age, per 1,000 births, was 149 in Dublin and 136 in the large English towns, an excess in Dublin of 13. But in Dublin, and indeed in all the Irish towns, the death-rate at all ages is much above that of the large English towns. In the five years ended 1913 the average death-rate in the Irish towns was 18.9 per 1,000 persons living, whilst in the English towns it was 15.3, or 3.6 less than in the Irish towns. In the English towns the deaths of children under 1 year formed, on the average of ten years, 23 per cent. of the total deaths, whilst in Dublin they formed 29.3 of the total deaths. It is contended, therefore, that the higher death-rate of Dublin, and indeed of other Irish towns, as compared with English towns, is due in the main to the greater mortality of persons above the age of 1 year. In 1914 the proportion of total deaths ascribed to infants under 1 year exceeded that in the English towns; this was, perhaps, chiefly due to unfavourable economic conditions arising out of the great and continued strike.

SOUTH DUBLIN UNION AND UNSATISFACTORY VACCINATION.

At the last meeting of the South Dublin Union a letter was read from a man stating that his child had been vaccinated three times and that the vaccine did not take effect. The doctor now required the child to be vaccinated a fourth time. The father said he did not object to the law, but he objected to have his child suffer unnecessary pain. The doctor wrote that the lymph supplied by the Institute had been unsatisfactory; it caused much annoyance to parents, who had to take their children to the dispensary so often; he had lodged a complaint about the matter. A guardian said that the case was only one of hundreds. The Chairman said that the Board could not adjudicate in a matter that was purely medical. An order was made that no prosecution be undertaken in regard to it. The following notice of motion was handed in:

That the guardians of the South Dublin Union, having on this date (August 9th) had ocular demonstration of the most convincing and painful character of the evil results of vaccination in the case of the child O'Kelly, 39, Pimlico, which was brought before the Board, hereby decide that no further action be taken in this union in the direction of enforcing the vaccinations.

THE WAR AND INSANITY.

Dr. Graham, Resident Superintendent of the Belfast Asylum, in his annual report states that there was a remarkable decrease in the number of admissions this year as compared with the twelve months preceding—220 as against 276. "This contrast," he says, "would be worthy of notice at any time, but it becomes almost an enigmatic paradox when we recall that the nation since August, 1914, has been plunged, in common with nearly all the great civilized Powers, in a struggle more terrible in nature and more momentous in consequences than any of which our earth has been the scene since the fall of the Roman Empire. The very foundations—moral, social, intellectual, and economic—of European society are being shaken, and in such a period of upheaval it is natural to suppose that mental suffering, ending in collapse of the brain, should be the order of the day, yet up to the present this has not been the case. So far as figures throw light on the matter, there has been a decrease, not an increase, of insanity. And this fact raises an interesting and important question as to the relations of mental disease to the miseries and horrors of war. Why is it that the shock of the world conflict has not worked the mental disaster to be expected, either in the case of the heroes who have survived or in that of the relations of those who have died so magnificently? It is here that attention must be called to a profound psychological law. It is not the great tragedies of life that sap the forces of the brain and wreck the psychic organism. On the contrary, it is the small worries, the deadly monotony of a narrow and circumscribed existence, the dull drab of a life without joy and barren of an achievement, the self-contained anaemic consciousness—it is these experiences that weaken and diminish personality, and so leave it a prey to inherited predispositions or to the 'slings and arrows of outrageous fortune.' It is often said that war brutalizes the soldier and so opens the door for the ingress of all sorts of mental disorders. To this it suffices to reply, not all war degrades, and whether a given war degrades or not depends on the motives which sustain the soldier."

VACCINATION IN ENNISCORTHY UNION.

At the last meeting of the Enniscorthy Board of Guardians a report was read from Dr. T. J. Browne, Medical Inspector of the Local Government Board, calling attention to the fact that there were 5,340 defaulters under the Vaccination Acts in the union area, and pointing out that it was the duty of the guardians to enforce the law. The clerk said that Dr. Browne wanted the guardians to get the doctors in the several dispensary districts to submit a list of the defaulters in their districts with a view to the guardians instituting legal proceedings.

DECLINING FIGURES FOR IRISH EMIGRANTS.

The Registrar-General's return of the number of natives of Ireland who emigrated during June, 1915, showed that 770 males and 353 females left Irish ports, as compared with 769 males and 691 females in June, 1914. For the first six months of the present year the total number of Irish emigrants was 4,061 (2,590 males and 1,471 females), compared with 12,907 (6,757 males and 6,150 females) in the same period last year, a falling off of 8,848. The returns from each of the provinces showed that during the six months 1,168 persons left Leinster, a decrease of 461 as compared with the first half of 1914; Munster 607, compared with 3,548—a decrease of 2,941; Ulster 1,216, compared with 4,281—a decrease of 3,065; and Connaught 1,070, compared with 3,451—a decrease of 2,381.

Scotland.

HEALTH OF EDINBURGH IN 1914.

DR. MAXWELL WILLIAMSON, the medical officer of health for the city of Edinburgh, has just issued his annual report of the Public Health Department for the year 1914. The public has become accustomed to expect more from Dr. Williamson than dry details, and certainly the present document contains much that is of real interest, whilst even the statistics are made if not actually

attractive, at least not repellent, by the skilfully employed device of charts with many colours.

Population.

The population of the city (registration area) at the last census was 320,769, and the present population, calculated to the middle of 1914, and including the inmates of the City Fever Hospital and of Craiglockhart Poorhouse (which are outside the city boundary), was 325,780; the natural increase (excess of births over deaths) was 1,441; and so Dr. Williamson calculated that it would take 173 years before the population (at the present rate) would double itself. The city covered an area of 11,416 acres, but if the public parks and principal open spaces were excluded, the ground covered was approximately 6,267 acres. The density of the population was 28.5 persons per acre over the total area. There were 72,523 inhabited houses and 3,838 unoccupied habitable houses; the number of inhabited houses showed an increase of 902 as compared with the previous year (1913). What was of more importance, and formed the source of some gratification, was the decrease in the number of lower-rented houses and tendency of the citizens to remove from the central congested districts to the less thickly peopled portions of the city.

Marriages.

The marriages registered in Edinburgh in 1914 were 3,165, as compared with 2,947 in 1913 and 2,857 in 1912; this represented a marriage-rate of 9.7 per 1,000 persons living. Glasgow, with 9.8 per 1,000, was the only large town in Scotland with a higher rate. The medical officer of health is careful to qualify his satisfaction with these figures by the following remark: "An increased marriage-rate may generally be taken as an indication of industrial prosperity, but in view of the large number of 'irregular' marriages which take place in Edinburgh in the course of the year, it is impossible to make any accurate deductions from these figures." The third quarter of the year was the favourite one for marriages, 964 taking place then as against 793 in the second, 776 in the fourth, and 632 in the first quarter.

Births.

The birth-rate for the year, whilst it showed a slight improvement as compared with that of 1913 (20.2 per 1,000 as against 20.0), yielded no real cause for satisfaction, for there had been a steady decline year after year for the past thirty-four years. In 1871 it was 34.8 per 1,000, in 1881 it was 32.2, in 1891 it was 28.2, in 1901 it was 24.9, and in 1911 it was 21.2. The drop each decade had been not much below 4 per 1,000. The striking fact emerged that in 1881, with a population of 226,346, Edinburgh had a total of 7,360 births, in 1914, with a population of 325,780, she had only 6,706 births; in other words, whilst the population had actually increased by nearly 100,000 the number of births was actually less. Even these numbers placed the births in a better position than was really theirs, for when the country births (taking place in Edinburgh) were deducted the city was left with 4,666, or a rate of only 19.8 per 1,000. Again, there was cause for discontent in the fact that when the various wards of the city were examined the higher birth-rates were found (as had been the case in previous years) in the poorer districts, where also the infantile mortality was high. Speaking generally, it would seem that more children were born where the chances of their receiving care sufficient to keep them in life were lower. Dr. Williamson, however, was of opinion that to some extent the higher birth-rates in the parts of the town referred to could be explained by early marriages among the working class population. Leaving out of account (for special reasons) Brighton with its birth-rate of 17.6, there were only three other large towns in Great Britain and Ireland which had lower rates than Edinburgh, namely, Huddersfield with 18.2, Perth with 19.7, and Bradford with 19.6; of these Bradford, in point of population, came nearest to Edinburgh. The only cities having birth-rates above 30 per 1,000 were Greenock, Sunderland, and Liverpool; Glasgow had 28 and London 24.2.

Deaths.

The deaths in Edinburgh for 1914 numbered 5,319, but after correction for country deaths, etc., the number was

reduced to 5,025, giving a death-rate of 15.4 per 1,000 of the population, or 1.1 per 1,000 higher than the rate for 1913. Nevertheless, the city still occupied a good place among the large towns in Scotland; Perth had a rate of 13.8, and Leith one of 15.3. The death-rate for Scotland was 15.5. Among English large towns London, Birmingham, Leeds, Bristol, Hull, Nottingham, Leicester, Portsmouth, Cardiff, Brighton, Derby, Southampton, and Huddersfield had all smaller rates than Edinburgh. Curiously enough, Bradford and Edinburgh, whose birth-rates were 19.6 and 19.8, had death-rates of 15.5 and 15.4. The wards in the city, where the density of population was greatest, and where the housing and general sanitary conditions left much to be desired, had also the highest death-rates, a fact which allows Dr. Williamson to reiterate his condemnation of inferior housing conditions. He supports his contention with the striking case of St. Giles Ward, which, with a much greater number of one-roomed houses than any other ward, had a death-rate of 21.4 per 1,000, a phthisis death-rate of 1.9 per 1,000, and an infantile mortality-rate of 151 per 1,000 births (or 40 per cent. greater than that recorded for the whole city). Statistics are given of the mortality in connexion with various trades and occupations, both for men and women; but the medical officer of health rightly advises that too much reliance should not be placed upon such figures. In dealing with the causes of death, Dr. Williamson refers to the small number of deaths from influenza—9 as against 18 in the previous year; he notes a very slight increase in the mortality from infectious diseases, and he points out that there were 569 deaths from tuberculous diseases in the year (a rate of 1.7 per 1,000). The death-rate from cancer was the highest ever recorded for the city—namely, 1.37 per 1,000 persons living; it was only 0.95 in 1900, but it rose to 1.07 in 1905 and to 1.20 in 1910. An interesting and striking table shows the great and almost continuous fall in the mortality from pulmonary phthisis since 1864 and the steady and alarming rise in that from cancer during the same period. The occurrence of cancer cases in various streets is set forth in the tables; but the key to the understanding of these local variations in frequency has not been found. Whilst most streets did not record more than one or two deaths from malignant disease, Montgomery Street with 6 and Panmure Place with 5 were exceptions for which it would be difficult to assign a cause.

Infantile Mortality.

There were 709 deaths under the age of 1 year, giving a rate of 9 per 1,000 births higher than in the preceding year; still this was a vast improvement on the alarming rates which prevailed before the systematic supervision now carried out was made possible by the passing of the Notification of Births Act in 1907. It is a striking fact that 128 infantile deaths, of which 110 occurred in the first month, were ascribed to premature birth, whilst 107 (of which 64 were in the first month) were put down to atrophy, debility, and marasmus. These figures inspire the hope that there is still a large section of infantile deaths which it may fairly be expected can be prevented. With its infantile mortality-rate of 110 per 1,000 births, Edinburgh came after Perth with 80, Leith with 99, and Greenock with 108; Dundee had 135, Glasgow and Paisley 133, and Aberdeen 121. During the year the number of births intimated was 6,415; but from this figure 276 stillborn infants had to be deducted, leaving 6,139 living births intimated out of 6,706 registered. The number of cases attended in institutions, or by students and nurses from one or other of the various organizations in the city, was 2,020, while 130 were attended by midwives (who therefore did no very large share of the obstetric work in Edinburgh). As in previous years, the systematic visitation of infants belonging to the poorer districts of the city had been assiduously carried out by the voluntary health visitors organized in connexion with the public health department. Further, over 300 homes had been visited, and whilst few of them suggested the presence of poverty, whilst open windows were frequently found, and whilst the babies were almost invariably clean, yet there were defects, particularly in the matter of food and of beds. During the year 118 cradles (22 more than in the previous year) had been sold by the visitors. Interesting health

lectures had been given to the workers during the year. Altogether, this branch of the preventive work in Edinburgh can be regarded as in a flourishing state.

Infectious Diseases.

The infectious diseases which were notifiable were pulmonary phthisis, small-pox, typhus, enteric, relapsing and continued fever, puerperal fever, diphtheria and membranous croup, scarlet fever, erysipelas, cerebro-spinal fever, ophthalmia neonatorum, and "other forms of tuberculous disease," which was added to the list in the month of July. Those which were not notifiable were measles, whooping-cough, and chicken-pox. The notifications numbered 4,450 cases, or an increase of 1,008 as compared with 1913; but to obtain a fair comparison one had to deduct the 105 cases of "other tuberculous diseases" and of ophthalmia neonatorum, leaving 4,345, as against 3,422 in 1913. The increase was due to the increase in scarlet fever and diphtheria in the last four months of the year. A gratifying feature was the increase in the number of cases treated at Colinton Mains in the City Hospital; a table supplied by Dr. Williamson showed that whilst in 1890 only 40 per cent. of the cases of scarlet fever and 29 per cent. of those of diphtheria were sent into the hospital, in 1914 the percentages of cases sent in were 97 and 95 respectively. The number of cases in the City Hospital was further increased by the admission of military patients stationed in close proximity to the city boundary, the army authorities having found it most convenient to have their patients treated there; but, of course, these cases were notified to the public health authorities of the district in which they were discovered. The hospital accommodation had been severely taxed, and, through the absence of Dr. Ker, Dr. MacLeod, two residents, and three ward sisters, by reason of the war, the strain on the staff had been heavy but had been partly met by making use of senior students. The sudden enlistment of the laboratory assistant at an exceptionally busy time had made matters still more difficult. One effect of the strain upon the nursing staff had been the greater number who had contracted infectious diseases. Dr. W. S. I. Robertson reported on the hospital in place of Dr. C. B. Ker.

Phthisis, Typhoid Fever, Diphtheria, etc.

The deaths from phthisis numbered 379, equivalent to an annual death-rate of 1.1 per 1,000 of the population. In Dundee the rate was 1.4, in Glasgow 1.3, in Aberdeen, Greenock, and Perth it was 1.0, and in Leith it was the same as in Edinburgh—namely, 1.1. When the different wards of the city were considered it was found that fully 52 per cent. of the notifications of this disease occurred in five wards (out of the sixteen), that these five were all in older parts of the city, and that they contained only 36 per cent. of the total population. The incidence-rate for these five wards was 3.3 per 1,000, while for the remaining eleven wards it was only 1.7 per 1,000. Enteric fever had 63 notifications, as compared with 45 in 1913; the number of deaths was 11. The decrease in typhoid was very marked when decades were looked at; thus, in the years 1884-1893 the average number of notifications was 375, in 1894-1903 it was 273, and in 1904-1913 only 90 per annum. There had been a marked prevalence of diphtheria during the last quarter of 1914, regarded by Dr. Williamson as an illustration of school influence and as in part due to the congregating of considerable bodies of troops in the city following upon the outbreak of war, and in buildings where the sanitary arrangements were of an improvised character. The number of cases of diphtheria notified during the war was 902, and the number of deaths 97, figures which represented an attack-rate of 2.76 per 1,000 of the population and a death-rate of 0.29 per 1,000. To the hospital, however, no fewer than 1,283 suspected cases were admitted, of which only 857 were true diphtheria; the non-diphtheritic cases were mostly influenzas of the throat type (which were very common in the autumn). The increased prevalence of scarlet fever was brought out by the number of notifications, 2,270 cases, as against 1,675 in 1913 and 893 in 1912; the maximum for the year was reached in October, when 332 cases were reported. The deaths were 45, equal to 0.13 per 1,000 of the population. The cases of erysipelas notified numbered 278, as against 223 in 1913 and 239 in

1912; and there were 12 deaths. In the hospital 151 cases were treated, of which 116 were facial in origin. Previous attacks had occurred in 30 cases, and one patient had had the disease no fewer than nine times. Measles was very common in the early part of the year, how common the absence of notification tended to conceal; but 109 deaths were due to this malady, and of these 104 were in children under the age of 5 years; 316 cases were admitted to the hospital, of which 13 were found to be suffering from German measles. The city was practically free from whooping-cough and chicken-pox was very rare, only 27 patients suffering from it being admitted to the hospital.

Ice-cream Shops, Hairdressing Saloons, etc.

Ice-cream shops, which had been doing a steadily declining business for some years, increased in number during 1914, when seventy-eight new shops were opened. The increase was probably due to the reintroduction of the so-called "gaubling machines," which for some years had been banished. The cleanliness of these shops was rigidly insisted on, 505 visits were paid during the year, and four offenders were summoned, and in each case a conviction was secured. It was reported that in all the hairdressing saloons (174) on the register antiseptics of some kind were in use. The Shop Acts (1912 and 1913) worked smoothly, only one prosecution being necessary.

England and Wales.

SALFORD HEALTH REPORT.

FROM the annual report of the medical officer of health for Salford for 1914 it appears that there has been a slight decrease in the birth-rate from 27.0 to 26.9 per 1,000 and a slight increase in the death-rate from 16.3 to 17.1 per 1,000. The infant death-rate has markedly decreased from 139 per 1,000 births, which was the average of the previous five years, to 126, which is the lowest recorded for the borough. The death-rates from cancer and heart disease continue to increase, but the medical officer of health considers this is due to the larger number of persons that live to the ages where these diseases become more common. The borough has suffered from an extremely severe epidemic of scarlatina, 2,336 cases having been notified in the year, of whom 84 per cent. were removed to the Ladywell Sanatorium. The previous highest record was in 1896, when 1,579 cases were notified. Fortunately the mortality-rate has been low, being only 3.3 per cent. of the cases. At the tuberculosis dispensary 2,256 new cases of tuberculosis came under treatment, the total attendances at the dispensary being 17,300. The treatment of selected cases by tuberculin has been continued with very satisfactory results, as after this treatment 69 per cent. of the cases were enabled to resume their ordinary employment. It is stated that the treatment has seemed to be of more benefit in cases of chronic disease, however extensive, than in cases presenting acute symptoms. There has been a marked reduction in the percentage of samples of milk which showed the presence of tubercle bacilli. In 1913, 16.2 per cent. of the samples contained tubercle, while in the past year the percentage dropped to 6.6, the lowest on record.

The medical officer of health is also the medical adviser to the Salford Insurance Committee, and in the section of the report dealing with the work of the borough analyst it is stated that in addition to regular examination of foods, thirty-nine samples of drugs have been examined, including nineteen mixtures dispensed according to prescriptions under the Insurance Act, and eleven samples, or 28 per cent., were found to be adulterated. This large percentage of adulteration is almost entirely due to the carelessness shown in dealing with the solution of ferric acetate. Of seven mixtures containing potassium iodide, six were correctly dispensed, while the other one contained an excess of 18 per cent. over the correct amount. Samples of atropine sulphate, syrup of orange, ground rambur, morphine lozenges, and bismuth lozenges were found to be genuine. But of twelve mixtures containing ferric acetate, seven were adulterated. Some of these

contained a large excess of iron, and had probably been dispensed from the stronger solution of ferric acetate official in the 1885 *British Pharmacopœia*. Others had evidently been dispensed from old solutions, as they contained no iron in solution and also a deficiency of total iron, the iron present existing as a precipitate of ferric hydroxide. All the vendors were cautioned, and the local Pharmaceutical Society warned each member as to the care necessary in the dispensing of prescriptions.

Canada.

THE ONTARIO MEDICAL ASSOCIATION.

THE thirty-fifth meeting of the Ontario Medical Association was held at Peterborough on May 25th to 28th in conjunction with the fourth annual meeting of the Medical Officers of Health of the Province of Ontario. The session on May 25th, and part of that of the following day, were devoted to a meeting of the medical officers of health, of whom 280 were in attendance. The presidential address was given by Dr. W. R. Hall of Chatham. The question of salaries paid to medical officers of health was discussed, and a schedule of rates adopted as follows: Townships, 300 dols. per annum; incorporated villages up to 1,000 population, 150 dols. per annum, with addition of 50 dols. for each additional 1,000 population or majority thereof; towns, 100 dols. for first 1,000 population, with addition of 50 dols. for each subsequent 1,000 population; cities under 20,000 population, 1,000 dols. per annum; cities over 20,000, 1,200 dols. per annum. Dr. A. W. McPherson of Peterborough, who is on active service, was elected president for the year 1915-1916. At the evening session on May 26th Dr. D. J. Gibb Wishart delivered the presidential address, and a paper on the clinical manifestations of syphilis was read by Dr. J. G. Phillips of Cleveland. The sections in medicine, surgery, obstetrics, and gynaecology, and eye, ear, nose and throat met on May 27th, and in the afternoon Dr. F. J. Shepherd, former dean of the faculty of medicine at McGill University, delivered the address in surgery. Dr. Shepherd's address was followed by a paper on medical education and fee splitting by Dr. A. H. Wright of Toronto, and one on the local medical society by Dr. A. F. McKenzie. A report of the Committee on the affiliation of the county medical societies was then read by the Secretary, and Dr. H. J. Hamilton of Toronto presented the report of the Committee on the relations of the Ontario Medical Association and the Canadian Medical Association, reporting progress. These reports were adopted. A resolution was then adopted expressing the opinion that active steps should be taken immediately for the prevention of insanity by the establishment of separate neurological wards in general hospitals, especially in those hospitals where clinical teaching is given. It was resolved to express deep appreciation of the loyalty and self-sacrifice of fellow-members of the profession who had offered themselves and were serving the empire and its allies at the front in the various services. In thus serving the cause of freedom, many would come back under conditions which would practically mean beginning their professional life over again, and the members of the association as fellow-practitioners formally assured them that, as far as lay in their power, they would see that their old *clientèle* awaited them on their return to civil practice, and that their relations to former patients were as far as possible restored.

A resolution was passed deploring the fact that such inadequate provision has been made in the Workman's Compensation Act for the payment of medical and hospital fees incurred by workmen injured in industrial pursuits. The hope was expressed that the Act would be so amended that workmen who receive only half pay while incapacitated would not be under the necessity, as at present, of paying such charges out of their already too scanty receipts. At the suggestion of the Section of Obstetrics and Gynaecology it was decided to appoint a committee to consider and enforce adequate measures for a campaign amongst the members of the medical profession and the public to guard against the ravages of cancer by early diagnosis and treatment, and to report to the next meeting of the Association. Next year the Association will meet at Toronto under the presidency of Dr. H. B. Anderson.

The forty-eighth annual meeting of the Canadian Medical Association, which was to have taken place in Vancouver on July 6th, 7th, 8th, and 9th, has been postponed on account of the war. The annual meeting of the Saskatchewan Medical Association has also been postponed for the same reason.

India.

MADRAS PRESIDENCY WATER SUPPLIES.

THE Government of Madras has under investigation an hydro-electric scheme in connexion with what is known as the Siruvani project in the Coimbatore District. Coimbatore town is badly in need of an improved water supply, and it is hoped to get the supply at a reasonable cost from the Siruvani River by combining the hydro-electric power scheme with the water supply scheme. If the power scheme now under investigation is proved to be practicable, it is believed that the South Indian Railway Company will build a new workshop at Podanur, obtaining its power and water supply from the Siruvani project. There is also considerable demand for power for mills in Coimbatore. Another hydro electric project is under investigation in connexion with Pykara Falls. There are minor schemes for the lighting of Ootacamund, one for getting its water power from Lovedale Lake and the other from Kalbatty Falls, yet another power scheme is based on Coonoor River, either alone, or in conjunction with the Karteri Stream.

BENGAL CHEMICAL EXAMINER'S REPORT.

There is a pathetically tragic record of poison cases in the report of the Chemical Examiner of Bengal, narratives of mean crimes that have taken their toll of human life. There is, for instance, an example of a phase of crime not infrequently met with in this country, in which innocent children are sacrificed to satisfy the grudge entertained against their parents. A man had long had an enmity with his cousin over some landed property. The cousin threatened to exterminate his enemy's family. One day he called the son, aged 12, to his house and gave him sugar; he also gave another quantity of sugar to a nephew of his who was standing there to avert suspicion. The deceased, not liking the taste of the sugar, wanted to throw it away, but the accused made him swallow it by giving him a draught of water; the nephew showed no signs of poisoning, but the boy died within a few hours. Arsenic was detected. Then there was the tragedy of a love philtre in which it appeared that a Mohammedan made several unsuccessful attempts to take home his wife from his father-in-law's house. Another Mohammedan who was believed to be in criminal intrigue with his wife, gave the deceased some "charmed" sugar to eat stating that it would make his wife more loving and cause her return to him. The man died within a few hours. White arsenic was found in his case. There are also several cases of death through using quack medicines, and on this is based the opinion that more qualified medical practitioners are needed. Serological laboratory which materially helps the police in the analysing of blood-stains on garments, weapons, etc., is to be retained in Calcutta experimentally until February next.

Hong Kong.

THE annual report on the health of the colony of Hong Kong for the year 1914 issued recently shows that the estimated population exceeds half a million, of whom some 444,000 are Chinese.

Birth-rate.

The birth-rate for the year among the Chinese population was 9.3 per 1,000, and among the non-Chinese 16.8 per 1,000. The low Chinese birth-rate is attributable to the fact that a large proportion of the native working-class population are young male adults whose wives are domiciled in China. The means of transport to and from the mainland are varied and inexpensive, and as the cost of living in the native villages of South China is far less than

in Hong Kong, many of the "coolie" class live, while at work in the colony, in common lodging-houses, or in sheds upon the works, and pay frequent visits to their homes in the intervals of their labour. This explains, to a large extent, the fact that almost 4,000 Chinese passengers leave Hong Kong daily for the mainland of China, and about the same number return. Incidentally, it may be noted that this interchange of passengers must greatly increase the difficulties of dealing with the importation of infection.

Death-rate.

The death-rate for the year among the Chinese population was 23.88 per 1,000 and among the non-Chinese population 12.99 per 1,000; among the resident civil community (non-Chinese)—excluding, that is to say, the army, navy, and mercantile marine—it was 17.85 per 1,000. The death-rate among the Chinese population was high owing to the inclusion of nearly 2,000 deaths from plague. Tuberculosis is very prevalent among the Chinese, for the death-rates show that 11.3 per cent. of the total Chinese deaths are attributable to this cause; this is, however, a considerable reduction on the percentage for the previous three years. The pulmonary form of the disease alone accounts for 7.9 per cent. of the total Chinese deaths. The sanitary department has for years past made considerable efforts to reduce the heavy mortality from this disease by means of antispitting notices, literature, and lectures, both in English and in Chinese, and it is hoped that the spread of education among the masses will tend still further to reduce the death-rate under this head. The deaths from malaria, especially in the city, continue to show a reduction, while the military figures for hospital admissions indicate a steady fall in the amount of malaria infection in the colony. One rural district shows a fairly large increase in deaths from this cause, owing to the fact that several thousand workmen have been employed there during the year on an extension of the city reservoirs.

Plague.

The most important occurrence of the year was a heavy outbreak of plague which was attributed by the medical officer of health (Dr. Francis Clark) to the serious overcrowding resulting from the influx of many thousands of Chinese during 1913, occasioned by political disturbances in Southern China. This overcrowding leads to a great increase in the amount of waste food and refuse generally, which is believed to result in an increase in the rat population, while the crowding of the native houses with the beds and baggage of the refugees is believed to afford greater facilities for the access of rats to these dwellings. On the outbreak of the European war some 60,000 Chinese left the colony hurriedly, and thus the overcrowding was to some extent abated, but too late to stay the epidemic which runs usually from March to July. The recorded mortality from this disease among the Chinese was 95 per cent., while among the non-Chinese (chiefly Indian, Malays, and Japanese) it was 70.8 per cent. Ten British cases were reported, and of these two died. Considerably over 100,000 rats were caught or found dead during the year, and 652 of these proved to be plague-infected. The rat figures for the past few years appear to suggest that a rat infection exceeding 5 per cent. coincides with a severe human epidemic.

Typhoid Fever.

One hundred and forty cases of typhoid fever were reported during the year, of which 38 were Europeans, 92 Chinese, and 10 other Asiatics, and it is recorded that twenty-two of the Chinese cases and one British case occurred in children under 5 years of age. Paratyphoid was made noticeable during the year and 4 British cases, 3 Chinese cases, and 1 Indian case were reported; one of the Chinese cases died.

Other Infectious Diseases.

There were no locally acquired cases of cholera; the incidence of small-pox was light, only 110 cases being reported, while there were 78 cases of diphtheria, most of which occurred in the cool and dry season of the year—December to February.

Rabies was introduced into the colony after many years of freedom, and three human deaths were recorded—one British, one Japanese, and one Chinese. Stringent muzzling orders were at once enforced, and the importation

of dogs from infected countries prohibited. Seven infected dogs were found as the result of the segregation and examination of all suspects, and it is hoped that the disease will be promptly stamped out by a continuance of these measures.

Correspondence.

NOTIFICATION OF BIRTHS.

SIR,—My attention has been drawn to an error in my statement at the Representative Meeting (SUPPLEMENT, July 31st, p. 63) which is contained in my use of the word *or* where the Act says *and*, and the consequences of the correction are interesting and peculiar.

By Sect. 1 (2) notification must be made "within thirty-six hours after the birth."

By Sect. 1 (1) it must be made by the father (if actually resident) *and* by "any person in attendance upon the mother at the time of, or within six hours after, the birth. . . ."

According to this, it might easily happen to be the "duty" of several persons to notify the same birth, but fortunately Sect. 1 (3), which imposes a penalty of 20s. for default, adds the following words: ". . . a person shall not be liable . . . if he satisfies the court that he had reasonable grounds to believe that notice had been duly given by some other person."

Which, after all, is what I said.—I am, etc.,
T. W. H. GARSTANG,
Aldridge, Aug. 9th. Chairman, Medico-Political Committee.

MISSIONARIES AND WAR SERVICE.

SIR,—In a recent number of the JOURNAL (July 17th, p. 124) a correspondent asks why missionaries have not come home to serve their country.

The fact has possibly not been made public that the members of the Medical Missionary Association of India, some 200, of all denominations, on the outbreak of war at once offered their services to the Government of India. Some were accepted for civil duties, thus setting free many I.M.S. men, many more of whom could in this way be replaced by missionary and other civil practitioners if necessary.

Other medical missionaries came home, and at the present time, from the Church Missionary Society alone, no fewer than sixteen doctors are serving in the R.A.M.C.

This leaves many very important mission hospitals very shorthanded. In some of these hospitals 150 beds are kept occupied, and from ten to twenty operations daily performed. Is this work to be stopped? We are told that in many military hospitals there is a large staff with very little work.

As regards clerical missionaries, these also were willing, but they were told that their presence among the natives, fostering loyalty and maintaining confidence, is more valuable than any work they could do at home.—I am, etc.,

Brighton, Aug. 4th. A. NEVE, Major R.A.M.C.

CAPTAINS I.M.S.

SIR,—Might I draw attention to a concession that might be made to those of the I.M.S. whom it affects?

Accelerated promotion to major of six months is given to those who are considered to have deserved it by passing an examination on completing certain courses of study. Now to do this leave is necessary, and this has been notoriously difficult for men in civil employ to obtain. Personally, I have had one year's furlough, and that on medical certificate, in nearly twelve years' service. I think that this concession might be granted automatically during the war to those who are affected, because otherwise the man who went into civil employ early will be very unfairly handicapped compared to his contemporary who remained in military employ where leave is much easier to obtain.

One cannot grumble at the fact that many of us have lost by being reverted to military duty, or that the proposed increase in our pay has been indefinitely postponed. Every one must expect to make sacrifices at such a time,

but I think we may fairly ask that a few of us shall not be unjustly handicapped by the fact that we have been unable to obtain the furlough necessary to qualify, and shall be unable to do so for a long time to come.—I am, etc.,

July 28th.

CAPT. I.M.S.

COMPULSORY MEDICAL SERVICE IN THE PAST.

SIR.—At the present time, when there is likely to be a scarcity of surgeons for military service, it is interesting to note what has been done in the past to meet military and naval exigencies.

I think there can be no doubt that, from time immemorial in this country, the State has exercised the right of enforcing service on any of its subjects, when the voluntary supply was insufficient for national needs. Old records give fairly numerous instances of compulsory medical service in ancient times. We find that in 1560 the following Order under the Great Seal was served on the Company of Barber Surgeons by Queen Elizabeth:

We lett you wete that for certeyne considerations us movinge we have by these presents authorised & lycensed our Trustie and Wellbelovyd Servaunte Thomas Vicary Serjeant of our Surgions & the Wardens of the Fellowship of the said Surgions within our Cytie of London that now be or hereafter shalbe, that they by themselves or their assigne bearer hereof shal & may from henceforth take & retyene at our wages as well within the Cytie of London as elsewhere within any other Cytie Towne Bouroughe or other place within this our Realme as well franchised and privileged as not franchised nor privileged suche and as many Surgions as they shall thinke mete and able from time to time to doe unto us servyce in the scyence of Surgerie at any season hereafter as well by sea as lande and further that the Sergeant and Wardens aforesaid shal or maye take of such as be not able to serve such instruments and other stuff of Surgerie as they thinke mete to serve ageynce and payntie therefor to all suche of whom any suche instruments or stuff shall be taken. Wherefore we will and commaunde you & every of you that unto our saide Sergeant and the Wardens aforesaid and their assigne bearer hereof in the due execution of this our autoritie and lycence ye within helpeinge and assistinge as onf as the case shall require without any your denyall lett or contraryoyn as ye and every of you shall please and will avoide the contrary at your peril. In witness whereof We have caused this our Lettres of Comission to be sealed with our Great Seal. Witness ourself at Westmynstre the day of Decembre the seconde yere of our Reign.

It is to be noted that in this year there was no particular national crisis. War was threatened with Spain, but the period of the Armada was thirty years later. Again the Order for imprisonment was general, and might have been enforced at any time.

Passing on to December 7th, 1598, we read in the Annals of the Barber Surgeons of London:

This day commaundment came from the lordes of her majestys most honourable privy counsell for to press a Surgion for her majestys service in Ireland under the conduct of Captayne Winsor.

On December 12th John Cumberland was pressed, and four or five other surgeons were also pressed and handed over *noletis volentis*.

As might be expected, abuses arose under summary methods of this character. One of these surgeons, Dominick Lomaline, is recorded on January 16th following, as having voluntarily confessed before the Masters, "that to be discharged of his presse for Ireland, it stood him in Twenty Nobles, of which the Captayne (Winsor) had in moneye three pounds."

The provision of deputies was not always good for the patient, for under date February 6th, 1599, it is recorded that:

One Richard Hallydaie, mariner, made his complainte of Raphe Rowley for settinge forth an insufficient man not approved to serve as a surgeon at sea in the Sheepe called the Costely of London by whose unskiffulness hee was dismembered of his arme and is in greate dainger of life.

Ralph Rowley had been pressed for a surgeon and had sent an unqualified deputy.

Again, in the time of Charles I, when the war broke out with Scotland (1633-39), a large army being collected in the north, the Barber Surgeons of London were directed to "press and forward 23 surgeons to Newcastle." In the Annals of the Company appears the following minute:

20th April, 1639.—Upon reading the warrant sent to this house from Yorke signed by the Lord Generall concerninge the want

of Surgians in the Armye it is concluded by the Governour and Assistants here presented that Mr. Warden Dunn and Mr. Collins shall go on, & goe aboarde some Newcastle shipp and agree with a shipper for ye conveyance of ye Surgians & their Chests & provisions & their mates, & likewise give them conduct money, & that for the present that charge to be borne out of the stock of this house until it can be reboytyned from Throsurer of ye Armye.

The cost to the Company was £44 14s., but of this only £23 were subsequently repaid by the Government; so that the profession, as represented by the Barber Surgeons, not only found the men, but also paid a portion of the cost.

In the receipt given for the expenses, the name of Mr. Sergeant Clowes appears. He received £17 10s., but probably had to share some of it with the other surgeons. This was Wm. Clowes, jun., the son of Wm. Clowes, Surgeon to Queen Elizabeth and James I, who accompanied Sir Philip Sidney in the English expedition to Flanders. He was Sergeant Surgeon to Charles I, and did military service during the parliamentary wars.

The above extracts from the Annals of the Barber Surgeons of London will, I think, throw sidelights on the way in which our services were once requisitioned by the State, and history may repeat itself. In the present war the Government has approached the British Medical Association to assist it in getting a voluntary medical service. This is more in accordance with the present principles of democracy, and if voluntary methods suffice, there may be no necessity to follow the example of our forefathers. If, however, a voluntary system prove inadequate, some form of compulsion will become necessary. In that case, it should be clearly understood that compulsion, if unpleasant, is by no means a novelty; that we are only repeating a procedure that has been frequently adopted in the past history of our country.—I am, etc.,

London, N.E., Aug. 11th.

MAJOR GREENWOOD.

IS URINARY CALCULUS RARE IN IRELAND?

SIR.—There seems to be a general opinion that urinary calculus is rare in Ireland. This opinion would seem to be borne out by statistics given in a paper recently read before the Royal Academy of Medicine in Ireland by its President, Dr. Walter Smith, physician to Sir Patrick Dun's Hospital, a reprint of which has been sent to me by the author. Dr. Smith quotes the following physicians and surgeons:

Sir Thomas Myles (Dublin), who states that his experience confirms the view of the late Robert McDonnell, that calculus is rare in Ireland compared to England; Mr. Gunn (Dublin), who, having looked over his cases for some years, finds 19 patients suffering from urinary calculus; Mr. William Taylor (Dublin), who supplies an elaborate table of the results of his practice since 1900 (his total number of cases is 25); Sir William Whitla (Belfast), who sees only a very odd case of calculus; Mr. Mitchell (Belfast), who has met with about 15 cases in the last fifteen years; Professor Sinclair (Belfast), who has not during the last twenty years operated more than thirty-six times for stone; Professor Pearson (Cork), who finds that urinary calculus is very rare in the South of Ireland (he has had 15 cases in fifteen years); and Dr. MacDowel (Sligo), who reports 3 cases in twenty years. Dr. Smith applied to me for statistics from my practice, and I sent him a list of 82 cases, 41 of which were vesical and 41 renal. Unfortunately, Dr. Smith mislaid my memorandum, and the cases were consequently not referred to in his paper. The comparatively large number of 82, to which I have added several since, would indicate that, at any rate in the North of Ireland, calculus is not so rare as Dr. Smith's paper would lead one to suppose. I hope at a future date to publish a short article on my cases, giving, so far as I know, the district in which the patient has been domiciled, and the chemical composition of the stone. These cases have been collected for a period of about ten years, and form about 8 per cent. of something approaching 1,100 cystoscopies in hospital and private practice.—I am, etc.,

ANDREW FULLERTON, M.Ch., F.R.C.S.Irel.
Belfast, July 10th.

DREAD OF INFECTION FROM PULMONARY TUBERCULOSIS.

SIR.—My daughter has the misfortune to be suffering from pulmonary tuberculosis, and is being treated at

home, but I find it increasingly difficult to keep my servants, such as their unreasoning dread of this disease. It is not as if they were asked to nurse her, or, indeed, do more than convey her meals to her, but, thanks to the campaign against tuberculosis and the proposal to make it a notifiable disease, they have become imbued with a belief in its infectiousness. It is high time we went astern a bit lest the outcome of our efforts to educate the public should be to convert the unhappy victims of consumption into pariahs, and to deprive them of the care and sympathy to which they are entitled, which, moreover, they received until we recklessly disseminated what I am fain to regard as exaggerated views of the risks entailed by the presence of a consumptive person in the family circle.

It is generally agreed that by the adoption of a few simple, common-sense precautions all danger of infection virtually disappears, and this is a point—an all-important point—which the public do not grasp.—I am, etc.,

A MEDICAL FATHER.

THE CAUSE OF HARE-LIP, CLEFT PALATE, CRETINISM, Etc.

SIR,—At the annual meeting of the British Medical Association in Carlisle in July, 1896, I gave a lantern demonstration of cretinism, in which I suggested that the sporadic form, due to lack of development of the thyroid body, was analogous to any other embryological stunting, such as abscence or dwarfing of uterus, ovaries, or testicles, acardia, acphalia, anencephalia, hare-lip, cleft palate, spina bifida, etc.

In Battlett's *Wild Animals in Captivity* it is stated that lions, fed on the flesh only of large animals, instead of on a larger proportion of the body of smaller animals (with small bones, skin, intestine, blood, and all), rarely have completely developed offspring, the most frequent and almost constant imperfection showing itself in the form of defective palate, and that the certainty of this has been fully established by observations made on animals bred in captivity.

It might be worth while in the case of any infant showing any of the above or other signs of incomplete development, to make inquiries as to any nutritive defects of its parents.—I am, etc.,

Kendal, Aug. 11th.

WM. R. PARKER, M.D.

DIAGNOSIS OF GOUT.

SIR,—Dr. W. J. Midleton's reply to Dr. Berkart is interesting in two respects—first, in his remark that gout is due to a specific micro-organism, and, secondly, in his apparent opposition to Dr. Berkart's denial of counter irritation in the treatment of this supposed trouble. It seems remarkable that anyone believing in the micro-organism theory should suggest treatment by counter irritation in a disease where there would be reasons to believe that such procedure would be as futile and harmful as in phthisis or any other disease of micro-organic origin. The only rational treatment would be the injection of a specific antitoxin when the particular organism has been discovered. But since sufferers from gout have been for ages past bringing on their own trouble by errors in diet and getting better by their correction, the discovery of such organism seems neither likely nor necessary.

A patient of mine, usually in vigorous and robust health, can bring on an attack of gout by drinking a few glasses of champagne; and the effects of rich foods, strong ale, porter, and port wine are too well known to need comment. But I have never yet heard of any inducing an attack by drinking gin. Gin contains juniper, and juniper clears the kidneys, and hence there is little possibility of an accumulation or deposit of urates, which Dr. Midleton seems to think Dr. Berkart relies upon for a correct diagnosis.

I am of opinion that if any medical man who is a sufferer from gout will go to the trouble to study the specific gravities of his urine he will find that for a day or two before an attack, or in some cases for a week or two, his urine will fall in specific gravity—that is, a urine which, in the ordinary health of one who is a free eater, varies between a specific gravity of 1030 to 1015, will fall much below the latter figure, reaching specific gravities sometimes so low as 1003 or 1002, and for some hours may even equal that of pure water. But metabolism is going on and the uneliminated products of katabolism or tissue waste are

steadily accumulating in the blood. The patient sooner or later is ripe for his attack and is struck down in the agonies of gout. But at the same time, or before long, the kidneys, in spite of their previous sluggishness, now take on activity as unaccountable as it is vigorous, the result being a copious deposit of uric acid, uric acid, and its associates. This clears the system and in a typical case the patient usually recovers. But in the pathological picture which Dr. Berkart draws such recovery would be impossible. That the theory of "perforative synovitis" is inadequate to explain the symptoms of many cases which have hitherto been attributed to the deposition of uric acid or sodium bicurate is plainly shown by Dr. Berkart's own statement, in which he points out that "this cystoid degeneration" . . . "may, however, become gouty if from a concomitant disease of the kidneys uric acid is retained and accumulates in the blood," which is no more than to say that gout after all is due to a deposition of uric acid; and yet in the opening lines of his article he repudiates the supposition of such deposition in the majority of cases as misleading and mischievous, and states that uric acid could act neither as a mechanical irritant nor as a toxic agent without leaving invariably indelible changes in the articular cartilage; concluding the paragraph with the statement that in "numerous instances"—diagnosed as gout—"the articular cartilage appears on *post-mortem* examination to be perfectly normal"—showing plainly that whatever the nature of the trouble, it could not have been due to cystoid degeneration which must necessarily be a permanent pathological change. It is, however, difficult to understand why uric acid, especially when merely acting as a toxic agent, should not undergo absorption leaving as little evidence of its injury upon the articular cartilage when there has been no actual degeneration as that certain skin troubles will frequently disappear, without leaving the slightest evidence of their ever having been present.

Dr. Berkart therefore adequately explains an articular disease due to cystoid degeneration with a superadded gout, but leaves us completely in the dark as to the nature of those "numerous cases diagnosed as gout," but showing no structural alteration in the joints.—I am, etc.,

Liverpool, Aug. 8th.

WILLIAM BRAMWELL.

ON THE CURVE OF THE EPIDEMIC.

SIR,—I thank Mr. Trachtenberg for his letter of July 22nd. The separation of the two parts of the logarithmic expression was of course a slip, and he is quite right in pointing out that the substitution that I made was illegitimate and does not lead to an identical solution. I hastily overlooked the fact that we were not provided with the functional relation between y and t . On May 8th Dr. Brownlee gave us three suggestions, but no indication of what kind of function he intended this y to be. Under the circumstance it does not appear to be possible to integrate the equation, or to form any but the vaguest idea of its meaning.—I am, etc.,

Newcastle-on-Tyne, Aug. 10th.

A. S. PERCIVAL.

THE STERILIZATION OF THE SKIN WITH TINCTURE OF IODINE.

SIR,—If Surgeon-Major Porter will read my original paper, which appeared in the *BRITISH MEDICAL JOURNAL* of August 14th, 1909, he will find that I referred to the work of Professor Grossich. I also referred to his paper which was published in the *JOURNAL* of February 6th, 1909, and to a contribution by Mr. Goodwin the following week.

They had all used a 10 per cent. solution of iodine, which is known in this country as liq. iod. fort. or lin. iod. Prior to my communication no one had ever suggested using tinct. iodi, B.P.

If Surgeon-Major Porter "quickly discovered that the 10 per cent. solution was not necessary and was sometimes injurious," he did not impart this knowledge to us, nor did he suggest an alternative method. I have never claimed to be the originator of the liq. iod. fort. method. I was the first to use and to advocate the tinct. iodi, B.P., and this is the solution which is now universally used.—I am, etc.,

J. LIONEL STRETTON.

Kidderminster,
Aug. 9th.

Senior Surgeon, Kidderminster Infirmary and
Children's Hospital.

THE LATE MR. EDMUND OWEN.

SIR,—I have read with much interest the obituary notice of Mr. Edmund Owen which you published in your issue of July 31st.

I should be glad, however, if you would kindly supplement it in your next issue by mentioning the eminent services which our lamented friend rendered to the French Hospital, and for which he received the Cross of the Legion of Honour from the hand of M. Emile Loubet when, as President of the French Republic, he visited the hospital in 1903.

Mr. Edmund Owen succeeded Sir William MacCormac as surgeon of the French Hospital in December, 1901, and up to his death always manifested the liveliest interest in the hospital; many are the patients who have benefited by his talent and devotion. On several occasions at our annual banquets he has given expression to the sympathy which he had for the French Hospital and the patients whom he had under his care.

But if he loved the hospital, everybody here loved him; his death leaves a great void, and we shall ever regret the loss of a man who combined with the highest professional capacity a character of lofty personality, straightforwardness, and affectionate devotion.—I am, etc.,

ARTHUR BAUME,
President of the Committee of the
French Hospital.

Shaftesbury Avenue, Londres,
Aug. 10th.

Obituary.

HENRY MACDONALD CHURCH, B.Sc., M.D.,

F.R.C.P. EDIN.,
EDINBURGH.

On the evening of Tuesday, August 3rd, Dr. Henry Macdonald Church, after forty years of devoted, sympathetic, and conscientious ministrations to the sick and suffering in Edinburgh, passed peacefully to his reward, and to that life of higher service toward which he had been constantly pressing forward. On the afternoon of Thursday, July 29th, on his return from a visit to a professional friend, while stooping to take off his boots, he was suddenly seized with right hemiplegia and aphasia. He never recovered consciousness. Dr. Church was born in Dalhousie, near Edinburgh, sixty-six years ago.

He studied at Edinburgh University. During his medical course he took the degree of B.Sc., and graduated M.B., C.M. in 1872. He assisted Dr. Shand of Kirkcudbright till November of that year, when he became junior demonstrator of anatomy to Professor Turner. Six months later he entered the Royal Infirmary as resident to Professor Amundale and later to Sir Thomas Grainger Stewart. Having completed these periods of valuable experience, he continued his medical education in Vienna, Berlin, and London, and on his return to Scotland he acted as assistant to Dr. Brotherton of Alloa. In 1875 he began practice in George Square, Edinburgh, where his kindly, skilful treatment drew to him a large amount of general practice. Four years later he was elected a Fellow of the Royal College of Physicians.

During his undergraduate course Church became a member of the Royal Medical Society, and he was afterwards elected one of the presidents of that oldest of all medical societies. He took an active part in the work of the Medico-Chirurgical and of the Obstetrical Societies of Edinburgh and made occasional communications to them. Two of these deserve special mention. One of these was the paper he read in 1903 before the Obstetrical Society on "Overlapping of pregnancy and lactation," founded on facts observed by himself in a series of 7 cases. He pointed out the dangers to the mother, the suckling, and the embryo. The other communication was on rheumatoid arthritis, and in it he discussed the etiology and also advocated on chemico-physiological grounds a liberal diet in treatment. On two different occasions the Obstetrical Society asked him to occupy the presidential chair, a position which he would have adorned, but on each occasion he declined the honour on the ground of health, but he retaliated (in a kindly fashion) by presenting to the society a very handsome chair for the use of future presidents.

Dr. Church was most highly appreciated by those who knew him most intimately. He was a warm-hearted, staunch friend. Although he had a high standard of morals, he was always ready to find an excuse for the failings of others. He had a fine imagination, a poetic mind, and was a great lover of nature, especially of botany. When in 1907 the Royal College of Physicians was invited to send two delegates to Upsala to take part in the bicentenary celebrations of the great Swedish botanist, Linnaeus, Dr. Church was one of the two who were chosen by the College. Linnaeus and Boerhaave were two of his heroes; he loved to study their lives and work.

The anxieties of medical practice press somewhat seriously on those of highly sensitive and sympathetic nature. Dr. Church found it advisable some years ago to take a prolonged holiday, and later to limit the number of his engagements. During his holiday he revelled in his much-loved books. Although he had so great a love of nature, science, literature, and golf, he never allowed any of these to interfere with duty. He always gave his patients of his best. A large circle of friends and patients will greatly miss his kindly presence and his wise counsel.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. F. T. Bicknell, one of the organizers of the medical department of the University of California, and for many years professor of gynaecology in that institution, aged 73; Dr. R. H. M. Dawbarn, clinical professor of surgery in Fordham University School of Medicine, New York, and emeritus professor of surgery in the New York Polyclinic Medical School, aged 55; Dr. Francis Delafield, emeritus professor of medicine in the New York College of Physicians and Surgeons, president of the Association of American Physicians in 1886, author of well-known textbooks on morbid anatomy and physical diagnosis, aged 73; and Dr. W. B. Dorsett, professor of pelvic surgery and gynaecology in the St. Louis University School of Medicine, aged 65.

The Services.

ROYAL ARMY MEDICAL CORPS.

PROMOTION OF LIEUTENANTS, SPECIAL RESERVE, AND TERRITORIAL FORCE.

The following Army Order has been issued:

1.—Promotion of Lieutenants of Royal Army Medical Corps, Special Reserve, and Territorial Force.

1. With reference to paragraph 102, Territorial Force Regulations, it is notified that, during the present period of embodiment, Lieutenants of the Royal Army Medical Corps, Territorial Force, will be eligible for promotion to the rank of Captain on the completion of six months' embodied service.

2. No promotion under this decision will, however, bear a date prior to the 1st April, 1915, even though the officer may have completed the qualifying minimum period of six months' embodied service sometime prior to that date. Subject to this proviso, embodied service rendered before the 1st April, 1915, will be allowed to count as qualifying service for the purpose of these promotions.

3. Recommendations for promotion should be put forward immediately in accordance with the above decision.

4. The promotion of Lieutenants of the Royal Army Medical Corps, Special Reserve, will be made on similar lines. The necessary action in their case will be taken by the Army Council direct.

By Command of the Army Council,
R. H. BRADY.

War Office,
5th August, 1915.

TERRITORIAL FORCE.

EXCHANGE DESIRED.

LIEUTENANT A. G. S. LOGIE, R.A.M.C.(T.), 21st South-Eastern Mounted Brigade Field Ambulance, Maresfield Park, Sussex, wishes to find a substitute so as to enable him to transfer to a unit going on foreign service. He would exchange with an officer in a unit going abroad or already abroad.

Medical News.

The library of the Royal College of Surgeons of England, which, though the museum is closed, remains open, will be closed as usual during the month of September, to be reopened, according to custom, in October.

AN international committee is being formed to assist the University of Louvain to reform its library. Many of the rarer works it will probably be impossible to replace, but already in response to an appeal made recently in the *Bulletin of the John Rylands Library*, Manchester, upwards of three thousand volumes have been received or promised.

A COURSE of lectures for school teachers and others entering for the examinations in school hygiene has been arranged by the Royal Sanitary Institute, Buckingham Palace Road. The first lecture will be given on Monday, October 4th, at 7 p.m., and the course will conclude on Friday, November 26th. The fee for the course is £1 1s. The sixtieth course of lectures and demonstrations for sanitary officers will be held at the Institute from September to November. Further particulars can be obtained on application to the Secretary.

We are informed by the Secretary of the Board of Education that, some eighteen months ago, Madame Bergman Osterberg, the principal and founder of the well-known Swedish Physical Training College at Dartford, desired to relinquish the active direction of the work of her college. In so doing, she wished in the national interest to secure the continuation of the work which had been so successfully established and developed. With this purpose in view, she generously offered, with the full approval and sympathy of her husband, Dr. Edwin Osterberg of Stockholm, to transfer her college to the Government. For reasons in no way connected with the college, it was found impracticable to accept the offer, and Madame Osterberg was advised to create a trust. Almost her last act before her death was to sign the trust deed, vesting her property in a trust with the object of carrying on the college in the national interest on its existing lines, and maintaining the traditions already established. The trustees appointed are: Dr. Christopher Addison, M.P., Mr. Valdorf Astor, M.P., Sir George Newnes, M.P., the Marchioness of Salisbury, and the Right Hon. Lord Shaw of Dunfermline. While the ultimate control of the institution rests with the trustees, the general management and working of the institution will be placed in the hands of an executive committee of ten persons representative of various official and other bodies concerned with the physical education of women.

The report on the public health of Adelaide for 1914 shows that the population has remained about stationary, an increase of 305 only being recorded. The birth-rate—28.23—was considerably lower than that of 1913, which was 31.03; the death rate was lower also—13.63 in 1914, as against 14.42 in 1913. The infantile mortality rate was considerably higher than 1913, being 87 per 1,000 births; it was 63 per 1,000 in the previous year. The medical officer of health, Dr. Borthwick, however, states that these rates, which are based on the data supplied by the Registrar-General's monthly returns, do not afford a correct view of the position. This is partly owing to many persons who are resident outside the city coming for treatment and dying in the various institutions. The deaths from phthisis represent the lowest mortality-rate on record; the number of deaths from cancer was above the average of the preceding six years. From the tables of prevalence of various diseases we find that the only material increases were in respect of typhoid fever and whooping-cough. There was a satisfactory decrease in the number of cases of diphtheria, scarlet fever, and measles. Some progress was made during the year in the crusade against consumption. The metropolitan boards of health contributed £350 a year towards the funds of the James Brown Trust, which in return provided at least seven beds for the treatment of poor patients in the early stage of the disease. In addition, there are sanatoriums for patients who are able to pay; and the Government has provided for the isolation and treatment of poor patients in the advanced stages of the disease. So far as the city is concerned, the education and supervision of consumptive patients are being carried on by the city-trained nurse, and every house is disinfected after removal or death of a patient. The general sanitation of the city has improved, and the staff of sanitary inspectors, under the medical officer of health, made no fewer than 14,253 visits to various premises in order to abate nuisances.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Hillog, Westrand, London*; telephone, 2633, Gerard. (2) SPECIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Arviculate, Westrand, London*; telephone, 2630, Gerard. (3) MEDICAL SECRETARY, *Medisera, Westrand, London*; telephone, 2634, Gerard. The address of the office of the British Medical Association is 15, South Frederick Street, Dublin.

ES—Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

RECURRENT ERYSIPELAS OF LEG.

C. D. asks for advice in the preventive treatment of recurrent erysipelas of the leg. The attacks have occurred about twice a year for the last ten years. He asks whether any serum is available.

INCOME TAX.

H. B. has been asked by the surveyor of taxes to supply statements of accounts for three years, and inquires as to what expenses he can deduct.

Speaking generally, the cost of maintaining, but not of improving, the professional equipment is deductible. Thus, to take the items mentioned by H. B., the cost of upkeep of a car, including petrol, tyres, driver's wages, etc., but not depreciation, can be deducted, nor the cost of the original car, or the amount by which the cost of a new car exceeds the net cost of the car displaced. The payments made to a locum-tenent are frequently allowed when incurred by reason of the illness of the practitioner and refused when occasioned by a holiday. The interest referred to will be allowed if paid on an ordinary bank overdraft; otherwise H. B. should deduct tax on payment of the interest, and no income-tax allowance will then be due to him under that head. Interest paid off a loan cannot be deducted, being purely capital payments. Expenses of house decorating and painting would presumably be allowed in the same ratio as rent and rates—that is, to a reasonable extent (not exceeding two-thirds), having regard to the proportion of the premises used as surgery, consulting and waiting rooms, and garage. Our correspondent may find it useful to refer to an article on the general question which appeared in our issue of April 18th, 1914.

ANSWERS.

D.—We cannot ascertain that any brown aniline colours have been used medicinally, and we have been unable to find any reference to such use in the literature. With regard to brown colours for colouring food materials, the number of these appears to be somewhat limited. The brown known as Chrysinin K is stated to be harmless, while Messrs. Read, Holtby and Sons, Ltd., Huddersfield, state that they are able to supply Bismarck browns suitable for such purposes.

LOW SPECIFIC GRAVITY OF URINE.

DR. ARTHUR GEORGE HARVEY (Wirksworth, Derbyshire) writes: A few days ago a gentleman came to me to be examined for life insurance. He was a healthy, vigorous young man, aged 23, engaged in farming. I left him alone to pass urine, and on returning to the room I was surprised to find the fluid was exactly like spring water, and had a specific gravity of 1000. He was perfectly normal in every other respect. The next morning he sent a sample of his urine passed early in the morning. This sample was normal in colour, had a specific gravity of 1024, acid, and free from albumin and sugar. I have frequently had cases of low specific gravity of urine due to nervousness, but never one approaching this case. The peculiarity of this case is that he showed no sign of nervousness during examination, and I am inclined to attribute it to his drinking large quantities of tea, as he is a total abstainer. I should like to have the experiences of other men on the subject.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 8 0
A whole column	5 10 0
A page	10 0 0

An average line contains six words

All remittances by Post Office Orders must be made payable to the British Medical Association, General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-voucher letters addressed either in initials or numbers.

THE

INFLUENCE OF INTRAVENOUS INJECTIONS OF NEO-SALVARSAN ON THE ARTERIAL BLOOD PRESSURE.

By H. D. ROLLESTON, M.D., F.R.C.P.,

SURGEON-GENERAL (TEMPORARY), R.N.,

CONSULTANT PHYSICIAN TO THE ROYAL NAVY, ROYAL NAVAL HOSPITAL, HASLAR; SENIOR PHYSICIAN, ST. GEORGE'S HOSPITAL.

The blood pressure was investigated in a hundred consecutive cases in which neo-salvarsan was given intravenously for syphilis, in almost all in the secondary stage. The patients were in the Royal Naval Hospital, Haslar, under the care of Staff Surgeon J. S. Dudding, R.N., who kindly gave me every facility for examining them. Their average age was 24 years, and except for twelve who were 30 years of age and over, and for six under 20, were all between 20 and 30 years of age. The amount of neo-salvarsan varied between 0.9 and 0.6 gram. The blood pressure (systolic and diastolic) was taken (i) on one or more days before the injection was given, (ii) about seven hours after the injection, and (iii) on three or sometimes four subsequent mornings. In 19 of these cases the blood pressure was also taken during the intravenous injection of neo-salvarsan. Included in the 100 cases were 12 cases in which the blood pressure was investigated in connexion with both first and second injections of neo-salvarsan—usually at a month's interval. Mercer's sphygmomanometer, with an arm-cuff of 14 cm., was used. The auscultatory method was employed, the maximum systolic pressure being estimated as the mean between the points where the auscultatory sound disappeared and reappeared, and the diastolic pressure at the time of the so-called fourth phase, where the intensity of the auscultatory sound suddenly diminishes. I took all the blood pressure estimations myself, so that errors from more than one personal equation were avoided.

Comparison of the Blood Pressure before and after the Intravenous Injection of Neo-salvarsan.

In every case the average of the blood pressure estimations taken before injection was compared with the average of the blood pressure estimations taken on the days subsequent to the injection. The blood pressure estimations taken seven hours after the injection were not included here, and are dealt with below. In 77 out of the 100 cases the intravenous injection was followed by a fall in both the systolic and diastolic pressures. The average fall of the systolic pressure was 16 mm. Hg, and of the diastolic pressure 13 mm. Hg. Out of the 23 remaining cases there were 8 in which both the systolic and diastolic pressures were higher after than they were before the injection, the average increase in both the pressures being 11 mm. Hg; 8 cases in which the systolic pressure was higher after than before injection (average increase 5.2 mm. Hg), while the diastolic pressure was lower after than before injection (average fall 6.5 mm. Hg); 6 cases in which the diastolic pressure after was higher than before injection (average increase 4.5 mm. Hg), while the systolic pressure after was lower than before injection (average fall 8 mm. Hg); and one case in which both the systolic and diastolic pressures were the same before and after injection. By arranging these figures rather differently it is seen that after injection there is

A fall in both the systolic and diastolic pressures in	77
A fall in the systolic alone in	6
Making a fall in the systolic pressure in 85	8
A fall in the diastolic alone in	8
Making a fall in the diastolic pressure in 85	8
A rise in both the systolic and diastolic pressures in	8
A rise in the systolic pressure alone in	8
Making a rise in the systolic pressure in 16	6
A rise in the diastolic pressure alone in	6
Making a rise in the diastolic pressure in 14	1
No change in either the systolic or diastolic pressure in	1

It is therefore clear that the average of the blood pressure estimations taken after injection is usually lower than that before injection. In the systolic blood pressure there was a fall in 85 cases, as compared with a rise in 16, or in the proportion of 5 to 1. The average fall in the

systolic pressure was 15.4 mm. Hg. In the diastolic blood pressure there was a fall in 85 cases, as compared with a rise in 14, or in the proportion of 6 to 1. The average fall in the diastolic pressure was 12.4 mm. Hg. The fall was therefore slightly less in the diastolic than in the systolic blood pressure. But before assuming that the fall in blood pressure is the direct result of the injection of neo-salvarsan, two factors must be taken into account:

1. That the patients were kept in bed from the day before the injection until some days after, and that the blood pressure estimations were nearly always taken early in the mornings of the days subsequent to the injection when the patients were in bed, even though they sometimes got up later in the day. In some cases the last blood pressure was taken when the patient was up, and in these cases the pressure was usually higher than those taken in bed. The fall of blood pressure may, therefore, have been partly due to rest in bed.

2. Mental excitement, although guarded against as far as possible, may have raised the blood pressures before injection; and hence the fall in the average of the blood pressure estimations taken after injection may have been more apparent than real.

In the light of these considerations, it does not appear that the fall in blood pressure was necessarily due to the intravenous injection of neo-salvarsan. At any rate intravenous injection of neo-salvarsan does not tend to raise the blood pressure on the following days.

Comparison between the Blood Pressure taken before and that taken Seven Hours after the Intravenous Injection of Neo-salvarsan.

In 55 out of 99 cases both the systolic and the diastolic pressures were lower seven hours after the intravenous injection of neo-salvarsan than they were before; the average fall of the systolic pressure was 16 and of the diastolic pressure 10 mm. Hg. In 16 of these 55 cases the temperature rose to 100° F. or higher, and in these the average fall in the systolic pressure was 19 and in the diastolic pressure 11 mm. Hg. Among these 16 febrile cases, 7 showed Herxheimer's reaction, and presented an average fall in the systolic pressure of 19 and in the diastolic of 13 mm. Hg. In the other 39 cases the averages of the falls in the systolic and diastolic blood pressures were 15 and 9 mm. Hg. The influence of fever caused by excessive liberation of spirochaetal toxins was not marked, as the average fall of the systolic and diastolic blood pressures was 4 mm. Hg only. In the remaining 44 cases the following results were obtained: In 19 cases both the systolic and diastolic pressures were higher after than before injection. The average rise in the systolic pressure was 8.4 and in the diastolic pressure 9 mm. Hg. In 4 of these 19 cases the temperature rose to 100° F. or above, and the average rise in the systolic pressure was 6 and in the diastolic pressure 9 mm. Hg. In the other 15 cases the average rise in the systolic pressure was 9 and in the diastolic pressure 10.6 mm. Hg. In 7 cases the systolic pressure was higher (the diastolic being on an average 7 mm. Hg lower) after than before injection. The average rise in the systolic pressure was 5 mm. Hg. In 1 of these 7 cases the temperature rose to 100° F., with a rise of 2 mm. Hg in the systolic pressure and a fall of 14 mm. Hg in the diastolic pressure. In 18 cases the diastolic pressure was higher (the systolic pressure being on an average 8 mm. Hg lower) after than before injection; the average rise in the diastolic pressure was 7 mm. Hg. In 9 of these 18 cases the temperature rose to 100° F. or above, and the average rise in the diastolic pressure was 8 mm. Hg and the average fall in the systolic pressure 11 mm. Hg. In the other 9 cases the average rise in the diastolic pressure was 6 mm. and the average fall in the systolic pressure was 5.5 mm. Hg. By arranging these figures rather differently it is seen that seven hours after injection there is

A fall in both the systolic and diastolic pressures in	55
A fall in the systolic pressure alone in	18
Making a fall in the systolic pressure in 73	7
A fall in the diastolic alone in	7
Making a fall in the diastolic pressure in 62	19
A rise in both the systolic and diastolic pressures in	19
A rise in the systolic pressure alone in	7
Making a rise in the systolic pressure in 26	7
A rise in the diastolic pressure alone in	18
Making a rise in the diastolic pressure in 37	1

The blood pressure seven hours after the intravenous injection of neo-salvarsan is therefore usually lower than the blood pressure before injection. In the systolic blood pressure there was a fall in 73 cases, as compared with a rise in 26, or, approximately, in the proportion of 3 to 1. The average fall in the systolic blood pressure was 14 mm. Hg. In the diastolic blood pressure there was a fall in 62 cases, as compared with a rise in 37, or in the proportion of 5 to 3. The average fall in the diastolic pressure was 9.6 mm. Hg. The fall in the diastolic pressure is therefore slightly less than in the systolic pressure. The fall of blood pressure seven hours after injection cannot be explained as due to fever, for a rise to 100° F. or more occurred in 30 cases only. Out of these 30 febrile cases the systolic pressure was lower in 25 and higher in 5 cases seven hours after injection than it was before injection. The average additional fall of the systolic blood pressure in the 25 cases was 4.5 mm. Hg, while the diastolic was lower in 17 and higher in 13 of the 30 febrile cases; and the average additional fall in the 17 cases was 2.6 mm. Hg. The influence of fever so far as it goes in depressing the blood pressure is even less marked on the diastolic than on the systolic blood pressure.

Comparison of the Blood Pressure taken Seven Hours after Intravenous Injection of Neo-salvarsan with the Average of the Blood Pressure Estimations on Subsequent Days.

Out of 98 cases there were 58 in which the averages of both the systolic and diastolic pressures on the days subsequent to injection were lower than those seven hours after the injection. The average fall in the systolic pressure was 7.3 mm. Hg and in the diastolic pressure 10.4 mm. Hg. Among these 58 cases there were 17 with a temperature of 100° F. or more seven hours after injection, showing an average fall of 10 mm. Hg in the systolic and 11 mm. Hg in the diastolic pressure; whereas in the other 41 cases the corresponding average falls in blood pressure were 8.7 and 10 mm. Hg. Out of the remaining 40 cases there were 13 in which the averages of both the systolic and diastolic estimations on the subsequent days were higher than the blood pressure seven hours after injection. The average difference in the systolic pressure was 9.5 mm. Hg and in the diastolic 8 mm. Hg. In 4 of these cases there was, seven hours after injection, a rise of temperature to 100° F. or more with corresponding differences of 13 mm. Hg and 16 mm. Hg, contrasting with differences of 8 mm. Hg (systolic) and 5 mm. Hg (diastolic) in the remaining 9 cases. In 21 cases the average of the systolic blood pressure estimations on the subsequent days was higher and the average of the diastolic blood pressure estimations on the subsequent days lower than seven hours after injection. The average difference in the systolic pressure was 5 mm. Hg, and in the diastolic 6 mm. Hg. In 8 of these 21 cases there was a temperature of 100° F. or more seven hours after the injection, and the corresponding differences were on an average 3.5 mm. Hg (systolic rise) and 6.5 mm. Hg (diastolic fall); whereas in the remaining 13 cases the difference was 6 mm. Hg in both cases. In 6 cases the systolic pressure was higher and the diastolic pressure lower seven hours after injection than the average of the blood pressure estimations on subsequent days, the average differences being 4.3 mm. Hg and 3 mm. Hg respectively.

By arranging these figures rather differently it is seen that, as compared with the blood pressure seven hours after intravenous injection, there is on the subsequent days:

A fall in both the systolic and diastolic pressures in	58
A fall in the systolic pressure alone in	6
Making a fall in the systolic pressure in 64	
A fall in the diastolic pressure alone in	21
Making a fall in the diastolic pressure in 79	
A rise in both the systolic and diastolic pressures in	13
A rise in the systolic pressure alone in	21
Making a rise in the systolic pressure in 34	
A rise in the diastolic pressure alone in	6
Making a rise in the diastolic pressure in 19	

This shows that the average of the blood pressure estimations taken on the subsequent days is usually lower than the blood pressure taken seven hours after the intra-

venous injection. The systolic blood pressure was lower in 64 cases and higher in 34, or roughly in the proportion of 2 to 1; while the diastolic pressure was lower in 79 and raised in 19 cases, or in the proportion of 4 to 1. The fall, therefore, is more marked in the diastolic than in the systolic pressure. The modifications in the blood pressure in the cases with fever seven hours after injection are not sufficiently constant or definite to justify any conclusions as to the influence of fever.

Blood Pressures taken during the Intravenous Injection of Neo-salvarsan.

As already mentioned, this was done in 19 cases. In 15 cases both the systolic and diastolic pressures were higher during the injection than they were on the previous days or day. The average rise in the systolic pressure was 22 mm. Hg, and the greatest 46 mm. Hg. The average rise in the diastolic pressure was 14 mm. Hg. In 2 cases the systolic pressure was higher, but the diastolic pressure lower, than on the days or day before the intravenous injection. In 1 case the systolic pressure was lower, while the diastolic pressure was higher than before injection. In 1 case both the systolic and diastolic pressures during injection were slightly lower (systolic by 1 mm. Hg, diastolic by 3 mm. Hg) than before injection. By taking the blood pressure throughout the process of injection it was shown that the systolic pressure may fluctuate considerably; the maximum variation was 28 mm. Hg, and the average 15 mm. Hg. It may be highest before the skin is punctured; thus, in 1 case the systolic blood pressure was 160 mm. Hg just before the injection was actually given and fell while it was going on to 140 mm. Hg. In most instances it was lower at the end than at the beginning of the *séance*. The diastolic pressure fluctuated less than the systolic pressure during the performance of intravenous injection; the maximum variation was 14 and the average 6.5 mm. Hg. In 18 out of the 19 cases both the systolic and diastolic pressures were higher during the injection than they were seven hours later, the average systolic difference being 23 mm. Hg, and the average diastolic difference 12.8 mm. Hg. In the remaining case the systolic pressure was higher, but the diastolic pressure was lower during injection than seven hours later. In 18 out of the 19 cases both the systolic and diastolic pressures during the injection were higher than the average of these blood pressure estimations taken on the subsequent days. In the remaining case the systolic pressure during injection was 22 mm. Hg higher than the average of the systolic estimations on subsequent days, but the diastolic was 3 mm. lower than the average of the diastolic pressures on subsequent days. It appears that the rise of blood pressure during the intravenous injection of neo-salvarsan is due to mental excitement.

Comparison between the Blood Pressure Estimations taken in Connection with (1) First and (2) Second Injections of Neo-salvarsan.

In 12 cases the blood pressure estimations were carried out in connexion with two intravenous injections of neo-salvarsan given at an interval of about one month. In 10 of these cases both the systolic and diastolic blood pressures taken before the second injections were lower than they had been before the first injection; in one case the systolic before the second injection was higher than it had been before the first injection, and in one case the diastolic pressure before the second injection was higher than it was before the first injection. The fall in 10 out of the 12 cases might be interpreted to mean that the remote effect of treatment was to lower the arterial blood pressure. But this must not be insisted upon, as the pressor effect of excitement would be much more powerful when the estimation was first done than on the occasion before the second injection. In addition 12 cases is too few to justify any far-reaching conclusion.

A comparison between (a) the average of the blood pressure estimations made on the days subsequent to the first injection, and (b) the blood pressure taken before the second injection, shows that in two-thirds of the 12 cases the blood pressure was higher in (b). But it must be remembered that in (a) the patients had been in bed for some five days, which would tend to lower the blood pressure, whereas in (b) they had been up.

CONCLUSIONS.

1. The average of both the systolic and diastolic blood pressures on the days after injection is generally lower than before injection, the fall in the systolic being slightly more marked than in the diastolic pressure. This fall, however, is very probably not a direct result of the action of neo-salvarsan, and, in part at least, may be due to rest in bed.
2. The blood pressure seven hours after the intravenous injection of neo-salvarsan is usually lower than it was before. The fall in the diastolic pressure is slightly less than that of the systolic pressure. The fall cannot be explained as due to fever.
3. As compared with the blood pressure taken seven hours after the intravenous injection of neo-salvarsan, the average of the blood pressure estimations on subsequent days is usually lower. This is more marked in the diastolic than in the systolic blood pressure.
4. During the actual intravenous injection of neo-salvarsan both the systolic and diastolic pressures are nearly always higher than on other occasions. This appears to be due to excitement. During the operation the pressures may vary considerably, the systolic blood pressure being more affected than the diastolic.
5. The blood pressure before the first injection of neo-salvarsan is nearly always higher than the blood pressure before the second injection of neo-salvarsan, but here again mental excitement may be responsible.
6. Finally, the general effect of intravenous injections of neo-salvarsan is rather to lower, certainly not to increase, the arterial blood pressure.

NOTES ON THE TYPHUS EPIDEMIC IN SERBIA, 1915.

By T. GWYNNE MITLAND, M.A., B.Sc., M.D.,
D.P.H.L.,
DIRECTOR OF THE TYPHUS COLONY, SREPLJE, SERBIA.

From March 1st to the end of April, 1915, about 1,800 cases of typhus passed through our hands. It is impossible to form anything like a correct estimate of percentages with regard to deaths and sequelae, for the hospital was seriously handicapped by reason of the dearth both of nurses and medical attendants. So far as hospitals were concerned, the epidemic was almost entirely neglected during the first three weeks. So great was the mortality among the native doctors that the few who could be induced to take charge of the General Fever Hospital had to leave the supervision and treatment of patients almost entirely in the hands of the orderlies.

HOSPITAL ORGANIZATION.

When the Sixth Reserve Hospital was taken over for the purpose of isolation and treatment of these cases it was considered unjustifiable to detach nurses from the existing units, inasmuch as most of these nurses were surgical nurses whose services were required elsewhere. It thus happened that during the earlier days at the Sixth Reserve Hospital the nursing was left in the hands of three volunteers from the surgical unit. Two only of these were fully qualified nurses; the third was a probationer. These three nurses, together with one doctor, were left to cope with the typhus outbreak.

With such a staff it was, of course, impossible to provide adequate treatment, and so it was necessary to enlist in the work some Serbian soldier orderlies and a number of Austrian prisoners, and as a necessary precaution only orderlies and prisoners who had had typhus were selected. The wards one by one were emptied, scrubbed and washed with disinfectants, and the ceilings, walls, and floors were afterwards brushed with petrol. This cleaning was done twice weekly afterwards throughout the entire hospital buildings. The Austrian and Serbian attendants were, with a few exceptions, thoroughly washed, bathed in disinfectant, and given clean clothes. They were then isolated and not allowed to come into contact with anybody, save those in authority or patients under supervision. It was hoped in this way to avoid all contamination, and we found that only one case during the first few weeks became reinfectd by vermin. A certain number of the orderlies were not disinfected, and these were given the

charge of the admission of patients to the wards. To them was left the duty of unclotting the patients, shaving their heads, and passing them through the bath of disinfectant. From the bath of disinfectant the patients passed directly to the clean orderlies, who wiped them down and gave them clean night things. They were then sent to clean beds. We invariably carried out this method of handling new arrivals. As soon as we had a sufficiency of the requisite combination garment (to which reference will be made later) to distribute throughout the hospital staff, all the orderlies were disinfected, as they were enabled to maintain their cleanliness by discarding their clothes after each admission.

In the early days the conditions under which all the foregoing was performed were extremely primitive. The patients were disrobed on the steps of the pavilion in the open air, and passed into the hall—the antechamber to the wards—where they were immersed in a disinfectant bath, after which the “disinfected orderlies” took them at once into the wards. Later on, when the colony included two excellent cadet schools, we were able to take over the outside offices—kitchens, baths, and wash-rooms—and here, in these outbuildings, the patients received the same treatment as above, but under much more favourable conditions.

It is unnecessary to dwell upon all the difficulties that we encountered in this procedure, such as shortage of water, and occasionally the inability of the Serbian authorities to give anything like proper notice of arrivals. The staff in the earlier days was driven to distraction by the difficulty of trying to uphold the ideal of scrupulous cleanliness as regards patients admitted. Realizing all these difficulties and how gravely we were understaffed, it is not surprising that during the first three weeks we could not perform any autopsies or bacteriological investigations. It was only later, when we obtained the services of Dr. Bellingham Smith and Dr. Daylell, and an efficient staff, that we were able to undertake this work. With our full staff—two doctors and Dr. Daylell, the bacteriologist, and twenty-six nurses—we were able to introduce order and provide adequate treatment.

To prevent lice getting into underwear it was necessary to improvise suitable garments—not such an easy matter, since the necessary tailoring was not to be had. At first we tried a jacket fitting high in the neck, long sleeves to button securely over the wrist, trousers fastening round the waist with string, and the legs tucked into high rubber boots. Finally I decided upon a sort of combination suit which answered admirably to all requirements, and was especially welcome in the hot weather. It was made in one piece, fastening at the neck like a bathing suit—that is, by two buttons on the shoulders, the trousers ended in feet which were slipped into sandals. To protect the hands, rubber gloves (previously boiled) came up well over the wrists. We made it a rule that all the staff should wear this outfit. Changing-rooms were provided, the combination suit being put on before going into the wards, and removed when going off duty.

SYMPTOMS AND COURSE.

As is always the case when one meets with diseases with which one is unfamiliar, one is inclined to dogmatize on the first few cases, but in reviewing to-day all the cases which passed under our notice, one finds it extremely difficult to give anything like a clear-cut picture of this fever. For instance, one hesitates now to conclude that the gravity of the case was indicated by the severity of the exanthem, or to presume that if the first fortnight passed without incident the prognosis was good. Infereuccs such as these were in course of time corrected. So far as possible one ought to abstract from the many cases, and give a typical example.

The incubation varies from five to fourteen days, but usually it is a period of twelve days—an onset of two days and a fever of sixteen days resolving in lysis. At the onset the patient shows no more discomfort than he does with an ordinary common cold. He may feel slight headache, a little pain in the back; he may lose his appetite, but for two days he does not show anything very suggestive. It is only on review that he remembers that he was somewhat out-of-sorts. On the third day these symptoms become aggravated, and he may now begin to suggest the typhus facies. He is not yet feeling sufficiently

unwell to take to his bed, but he has no inclination whatsoever for work, and by the following day, probably, definitely takes to his bed. Now the typhus facies is almost universal. If asked to distinguish it from the facies which goes with a common cold, one might say that it differs only in the respect that the secretions, instead of being excessive, are suppressed, and that as a consequence the nose and lips do not present the slightly swollen appearance they have in the common cold; otherwise the face is flushed slightly and the eyes are unquestionably congested, the vessels being decidedly injected. It is, perhaps, this absence of swelling of the nose and lips and the presence of the congestion elsewhere that makes all those who come in contact with typhus expert in distinguishing it by these features alone. The pulse is the only other feature which is at all distinctive. Its rate is slightly increased, it remains rhythmic and regular; with a large amplitude to the wave, its tension is low.

The skin looks slightly reddened all over, and frequently shows a kind of watercourse appearance, red channels running in every direction, confluent and often so diffused as (when not closely examined) to give merely an appearance of erythema. The urine is unchanged, there is no great increase in urates, and no albumin at this period. The bowels are slightly inactive and the appetite is poor. The thirst is from the first excessive. There are no physical signs to help one at this stage. The spleen is not enlarged. On the fourth or fifth day there appear for the first time some rose spots, widely separated and located variously over the abdomen, the lower part of the chest, and on the anterior surface of the shoulder. The patient is now beginning to look seriously ill. He is lethargic, his movements are sluggish, and he is almost comatose. From this time onwards his mouth is the greatest source of trouble. Sordes appear, and unless the mouth is carefully washed its foul condition is the beginning of various sequelae—parotitis, laryngitis, and otitis media. At the very best there is always a certain hoarseness and a certain amount of deafness. It is common at this stage also to find the urine suppressed for two or three days and then afterwards to find the urine displaying albumin and casts. For seven to ten days this condition goes on practically without change. The patient remains lethargic, seems dull and stupid, and almost comatose. He becomes markedly constipated, frequently wets his bed, and his mouth throughout the whole of this time requires constant attention. After this the patient begins slowly to recover, and at the end of the fourteenth day frequently shows a crisis which turns out to be a remission, the fever running up again for two or three days to decline afterwards in lysis. From this point onwards the patient again slowly recovers, and may, at the end of another week, begin to show a healthy and voracious appetite, a clear mind, and a considerable contentment. He is, however, distressingly weak; all his muscles are flaccid and his heart is readily upset.

SEVERE TYPES.

The two morbid types which we found to defeat all treatment were, first, those we called fulminating, and secondly, those exhibiting circulatory stasis.

Fulminating Cases.

Beginning in the ordinary way, the great difference between these and the normal cases took place about the second or third day after a rise of temperature had set in. It is from the observation of these cases that one is well advised to take the deposition of all patients before they lose consciousness, since these fulminating cases never recover consciousness. The patient passes into a deep coma. He displays very marked and exaggerated twitchings—subulturn tendinum. He mutters, picks at the bed-clothes, his face is markedly congested, and his eyes are frequently nystagmic with a squint. He has no control whatever over his sphincters, and usually within three days or so he dies.

Cases exhibiting Circulatory Stasis.

The next class of cases, in which the mortality is, perhaps, as great, is infinitely more disappointing. Patients in this class seem to pass through the whole fever without incident, so that one is justified in presuming that everything is well, when there begins,

about the twentieth day or so, typical circulatory stasis. The feet frequently become blue, the pulse small and thready; sometimes gangrene sets in, and the patient dies as if from asthenia.

These two types are the two morbid types. If one might venture to generalize, one might say the full plethoric individual is the more liable to the fulminating attack; the second is the type which affects and causes a great mortality among the older men, and, curiously enough, chiefly among the Austrians. It suggests inability of tissue recuperation, through senility of tissue in the older men; in the Austrian prisoner, devitalization of tissue through exposure, want, and depression. The impression that these cases leave with us is that the toxin is overwhelmingly potent, and affects all the tissues equally. There does not seem to be usually a selection or a nidus, except in the fulminating cases, where the toxin undoubtedly appears chiefly to irritate the cerebral cortex—in fact, the whole appearance of the patient makes one feel that he is of essentially low vitality, that all his tissues are depressed, particularly his musculature. As evidence of this he betrays hardly a movement. The tongue, for instance, which in health is constantly undergoing movement, lies in the mouth as if dead. It is no wonder that in such a septic cavity as the mouth, when the secretions are suppressed, there is such extensive vegetable formation to account for the sordes which is always present.

CONCURRENT DISTURBANCES.

Now, as regards the variety of coincident troubles that may develop in the course of this fever. In early days, when we were unable to provide individual treatment, we found that a large number—probably between 20 and 40 per cent.—displayed either parotitis, otitis, conjunctivitis, or laryngitis. One, some, or all together. On examining the patients the absence of spots did not permit us to exclude typhus—it was enough to find a patient unable to speak, almost deaf, or with a swollen gland or discharging ear, to make one suspicious that the disease was due to typhus. These symptoms alone were sufficient to justify us in placing the man under observation.

The Exanthem.

The spots usually described as typical of typhus were not characteristic in the majority of our cases; a minority of cases showed the typical form—that is, a rose spot about 1 mm. in diameter with indefinite edges, sometimes raised, sometimes impalpable. This rose spot occasionally became purplish, and was then definitely hæmorrhagic, no longer disappearing on pressure. A careful look-out for the first appearance of the exanthema will reveal the fact that it is first found on the upper segment of the abdomen, just as in typhoid; at a later stage only is it found extending up the chest and on to the shoulders. The majority of cases are protean. Very few of the spots become petechial; the majority vanish before that stage. This is the rule. Then, again, the time of persistence of the rash varies extraordinarily. Some spots behave in the orthodox manner, but they may be so evanescent as to elude observation altogether. It might be only that the case presented other distinctive symptoms that one was able to decide on the diagnosis at all. Again, the exanthem is by no means invariably a spotted rash; it presents occasionally a kind of watercourse appearance (already described), or a general erythema. Only in about two or three cases did we see a definite spotted rash extending over the entire body, with the exception of the face, the palms of the hands, and the soles of the feet. These cases were, it is true, unusually severe—in fact, fulminating cases; but there were fulminating cases without this extensive rash, so that one must not be led to the conclusion that the extensiveness of the rash was in proportion to the severity of the toxæmia. On the contrary, we found that the toxæmia was equally profound in evanescent rashes, so that it would be unwise to lay down rules with regard to the prognostic value of the rash.

One may say with regard to the concurrent disturbances associated with typhus that these may be removed to a great extent by careful nursing. One of the points which we insisted on was that the mouth should be most rigorously attended to. The mouth was washed out with

some solution, such as permanganate—the only disinfectant we had in any quantity in the earlier days; later, when we had supplies, hydrogen peroxide was substituted, and, as a result, parotitis, otitis, and other naso-pharyngeal disturbances disappeared. Constantly snubbing the back of the throat considerably ameliorated the condition of deafness. Patients who were able were taught to gargle periodically throughout the day, and as a result the laryngeal trouble was improved.

Circulatory Disturbances.

Another condition which caused us much anxiety, and which occurred frequently in asthenic cases, was the circulatory trouble. For a considerable time we were unable to account for this. All that we noticed to begin with was that the feet and hands became blue and cold, and the pulse small and thready, indicating a general cardiac failure. But, apart from this, we found that we had to deal with local degenerative troubles. Patches of redness usually appeared on the feet, active congestion evidently occurring there, and later this was followed by patches of gangrene. Sometimes the toes would be symmetrically affected, would disorganize and fall off. We had two cases in which the nose was affected. The fingers, though frequently showing the earlier signs, never, in cases under my observation, went on to gangrene, but, in fact, completely recovered.

The general plan adopted in these cases was that, when the feet showed coldness and blueness, hot-water bottles were at once applied, and a supporting treatment was also adopted. Strychnine and digitalis were frequently injected, brandy occasionally administered, and, when possible, massage was given. If the condition of the extremities did not improve under this treatment but proceeded to redness, then evaporating lotions were applied, and these measures met with a fair amount of success.

If one were to form a surmise one might venture to say that the extremities were the parts most likely to become morbid, in view of the fact that they were the parts exposed to the detrimental action of frost and cold in the trenches, and that in all cases it might be said there was a previous degenerative disturbance due to long exposure to cold. It is well known, for instance, that a frost-bite, once obtained, leads to a tendency to recurrence under conditions which would not otherwise produce a frost-bite, and so in this condition we have such a grave circulatory disturbance that with the acute toxæmia of the disease and the preceding history of frost-bite there was a sufficient local disturbance to bring about a further depression of the circulation and a condition of gangrene.

Temperature.

On the second or third day of the onset of malaise the temperature gradually rises, until it reaches 103° on the fourth or fifth day. This temperature is continuous, occasionally rising to 104°, until it ends in lysis. In some cases the temperature is remittent, and these, together with the fulminating cases, are the types which give the most anxiety. The cases with remittent temperatures caused the greatest anxiety after the subsidence; they were probably due to the associated cardiac disturbance—the failure of the cardiac muscle to respond to the toxins. The fulminating cases usually displayed continuous temperatures.

Pulse: Respiration.

The pulse was never very rapid and was usually associated with the temperature. The respiration was, however, frequently entirely dissociated with the temperature and pulse, and in some cases, until we gained larger experience, this dissociation with the temperature and pulse caused us grave anxiety. We felt it represented a definite local toxæmia of the medulla and to be the prelude to dissolution. Fortunately, however, with a wider experience we found that this dissociation was not a grave matter. A pulse of 98 and a temperature of 101° was occasionally combined with a respiration of 45. There never was the least sign of pulmonary stasis, and this is one of the most remarkable features of the typhus epidemic, considering the amazing depression of all the tissues together with the cardiac asthenia, that congestion and oedema of the lungs was not more frequently met with. In very few cases indeed did we know of any lung trouble at all, and these were only due, it was said, to secondary invasion. In only one case under my observation did we

get a bronchopneumonia, which is usually considered a frequent sequel, a result of the extension of the infection of the organism from the mouth down the larynx into the bronchi.

TREATMENT.

Finally with regard to treatment. A supporting diet, which usually included soups, Benger's food, Horlick's milk, and so on, was administered for the first fortnight. Occasionally brandy was given, but not often. There is a great prejudice in the Balkans against the use of brandy for typhus. One must acknowledge the right of the local opinion in this matter because of the considerable experience they have of the local form of typhus; they declare, and we think with good reason, that alcohol in any form aggravates the cerebral symptoms, which are such grave and important indications of brain toxæmia.

It must be remarked, therefore, that the next point in treatment which they always insist upon, and which is a corollary of the above, is the application of ice to the head. Ice was placed on the head from the onset, and maintained there until the subsidence of fever, and, if one can generalize at all, one may say with the greatest benefit. As has been stated, the mouth was attended to every half-hour throughout the day. In some cases sordes collected almost as quickly as it was wiped away. The patient was always moved very carefully, and turned from side to side to avoid bedsores, which occurred with amazing frequency considering the short duration of the decubitus. The extremities were kept warm. There was of course the greatest insistence on fresh air, and the window frames in the wards were removed. This appeared to the majority of patients to be, of all things, their greatest hardship when the icy winds of March were blowing through. In fact, patients of all classes in the Balkans always cover their heads when going off to sleep, and it was the duty of the nurse to see that their heads were uncovered, and that breathing was free and comfortable. At one time we thought that if we were to insist sufficiently on the principles of fresh air we should do much to diminish the virulence of the toxæmia, but we are unable to say that it had that profound effect we anticipated. The tradition of typhus is that it is associated with filth, overcrowding, and the absence of fresh air, and of course it was believed that if one could provide cleanliness, space, and fresh air, one would do much to diminish the virulence of the fever. But our experiences went to show that here fresh air was not apparently the potent factor that it is advertised to be, though naturally fresh air in all disease is a *sine quid non*.

ARTIFICIAL PNEUMOTHORAX IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

A CLINICAL STUDY OF EIGHTEEN CASES.

BY

C. H. VROOMAN, M.D., C.M.,

MEDICAL SUPERINTENDENT, KING EDWARD SANATORIUM, TRANQUILLE, KAMLOOPS, B.C.

THE object of this paper is to give a brief account of our clinical experience at Tranquille in the treatment of pulmonary tuberculosis by compression of the lung with artificial pneumothorax in a series of 18 cases. The literature on this subject during the past two years has been very extensive, and the selection of cases, results obtained, and obstacles to be overcome in the use of artificial pneumothorax are still too much in the formative stage for any one to be too dogmatic. It is through correlating the experience of many independent observers in different circumstances that we can hope to ascertain the true place of this procedure.

Artificial pneumothorax was first used by us at Tranquille in December, 1913, and since that date we have tried to give 18 patients this treatment. The apparatus used was a modification of the Floyd-Robinson.¹ We were forced to make our own apparatus as a matter of economy, and have found it to work quite satisfactorily. At first we used nitrogen gas obtained by abstracting the oxygen from the air by pyrogallic acid and potash solution. After reading the research work of Webb and others² we came to the conclusion that sterile air would be quite as good and less troublesome, and for some months past we have been using

sterile air. Our results have been quite as good and we have not found that we had to make refills any oftener. We unfortunately have no x-ray apparatus at the sanatorium, so that we were not able to check our findings by this means.

The technique has been that most commonly used—namely:

1. Sterilization of the skin with tincture of iodine.
2. Injecting 4 per cent. novocain as a local anesthetic. The important point here is to inject the novocain deeply, so that the parietal layer of pleura is anesthetized as well as subcutaneous tissues.
3. Puncturing the skin with a sharp, thin-bladed knife.
4. Inserting the blunt Floyd needle. With practice we have found that one could tell when the needle had passed through the parietal pleura by the slight popping sound heard, like sticking a needle through a tense piece of cloth. The site of injection has been by preference the fourth or fifth interspace in anterior or mid-axillary line, though sometimes it has been found necessary to go much further back.
5. After withdrawing the stylet of the needle to get a proper fluctuation in the manometer. This is the crux of the whole proceeding. Once a proper fluctuation is obtained the rest is easy. In favourable cases, at the first injection slight withdrawal of the needle, and with very little manipulation, a good fluctuation was obtained almost at once. It has averaged from negative 2 cm. to negative 4 cm. (water). Unfavourable cases—that is, cases in which there were many adhesions—often required prolonged manipulation, and then only a very slight fluctuation of 0 to 0.5 cm. was obtained. Several times we punctured the lungs during our manipulations. Beyond the spitting of a little blood-streaked sputum it did no harm. After getting a fluctuation the gas or air may be allowed to flow in at the rate of about 100 c.cm. a minute, manometric pressure being taken after every 100 c.cm.

Refills.

The average amount injected at the first operation was 734 c.cm. The highest quantity was 1,200 c.cm. and the lowest 195 c.cm. In the earlier cases as much as 1,000 c.cm. to 1,200 c.cm. were injected at the first sitting, and though the patient showed no subjective symptoms at the time, yet we found symptoms sometimes developed within an hour or two, and now I consider 500 c.cm. to 600 c.cm. quite sufficient for the first injection. At subsequent refills the sensations of the patient have been our best guide. Severe pain, shortness of breath, and sensation of tightness or coughing, are all signs showing that enough had been injected. Even in the absence of sensations we have found that when pressure in the manometer went to about 4 cm. or 6 cm. positive water pressure it was time to stop, as we were liable to have subcutaneous emphysema if more were injected. This, while not a dangerous complication, is unpleasant. During the injection a number of our patients complained of pain in the shoulder. This was due to stretching of diaphragmatic adhesions, and is an excellent example of referred pain as pointed out by James Mackenzie.³ In attempting to give this treatment to cases in which there were many adhesions and considerable fibrosis we have met with great difficulty. In some cases in which we had been able to get 500 c.cm. to 700 c.cm. of gas in the first time and which showed on examination a partial pneumothorax, we were greatly disappointed in that we had as much, if not more, difficulty with the refills.

In a number of those classified below as Group 2 we have secured a fair fluctuation, from zero to 0.5 cm. or even 1 cm., and proceeded to allow the gas to flow in. On testing it from time to time we found no change in the fluctuation, and even as when in one case we allowed 3,000 c.cm. to flow in, the patient noticed no increasing tightness or any symptoms whatever. The only explanation, of course, is that the gas escaped into the parenchyma of the lung, either through puncturing a cavity or small bronchus. I have never seen any harm result from this, in fact the patients often assert that they felt better because of the large amount of gas they were able to take.

We have given in all 202 injections, and in one case we had symptoms of pleural reflex. The patient stopped breathing and went into a state of collapse, lasting

one or two minutes; another patient vomited after each injection, but the reason in both these cases was putting in too much gas at one sitting. From my experience I would say that it is rarely advisable to give more than 700 c.cm. to 1,000 c.cm. of gas at one sitting, unless it is necessary to get a rapid collapse to stop hæmoptysis. Pleuritic effusion has been diagnosed in three of our cases. It has possibly been present in more, as in one case it was discovered by x-ray examination while the patient was away at the neighbouring town, and had been entirely overlooked in our physical examination. The quantity was small, and possibly if all our cases had been systematically screened we would have found more effusions. It developed in each case after the patient had been treated for some time.

Cases Treated.

The cases we have attempted to treat by pneumothorax may be divided into three groups.

Group 1 (3 Cases).—Far advanced febrile cases with bad prognosis, the disease being mostly confined to one side, but some involvement of the other lung. We treated three of this type. In all of them the prognosis was absolutely bad. One had only one injection, and refused to go on. He died two months afterwards. Of the other two, in one a partial, and the other a good pneumothorax was obtained. One died in two months, the other in eight months. Both claimed that their symptoms were better after treatment, but I do not think the treatment hastened or delayed the inevitable result.

Group 2 (8 Cases).—These were far advanced long-standing chronic cases, mostly non-febrile. In this group the cases were those in which there was extensive involvement of most of one lung with long-standing cavity. The other was involved, but had undergone considerable fibrosis. They had all been under sanatorium treatment for a long time, some of them for years. Their condition had in each case been stationary for a long time under ordinary sanatorium life. The pneumothorax treatment was given with the hope that the outlook of a life of chronic invalidism might be changed into one of at least partial usefulness. That this hope was not realized in these cases is one of our great disappointments in this treatment. The average time from onset of the disease to the time of doing pneumothorax on these cases was forty-two months. They were all difficult to treat on account of adhesions and the general fibroid condition of the lung. In 3 a good pneumothorax was obtained, in 5 a partial one, and in 1 we could not find the pleural space. In 3 there was partial benefit, symptoms of cough and sputum being lessened, but no marked improvement in their general condition. Of the 5 in whom a partial pneumothorax was obtained after six months' treatment, in none could signs of a pneumothorax be found. Their condition was practically the same as when the treatment had been started. The air had escaped into the parenchyma of the lung either through rupture of adhesions or punctures made at refills. I could not see that the treatment had done them any harm, and they were all rather disappointed when the treatment was discontinued. These old-standing cases are not likely, unfortunately, to be benefited by this treatment. Adhesions and general fibrosis hinder collapse of the part of the lung we want collapsed, and should one obtain a partial pneumothorax it is the remaining healthy lung tissue which is collapsed rather than the diseased area. However, I still think it is worth trying to get a collapse in those cases in which the disease is unilateral, as occasionally a case in which a good collapse is obtained will improve considerably, and a bad prognosis modified if not absolutely changed. If, though, after two or three refills, it is still difficult to find the pleural cavity and signs of collapse are not marked, it is hardly worth while persisting.

Group 3 (6 Cases).—This is the most encouraging group of the series. They were all, except one, far advanced cases, but the onset had been recent. The average time since onset of the disease to the time of doing a pneumothorax was 7.8 months. The disease was more active than in Group 2, as indicated by moist rales, rapid pulse, and slight rise of temperature. It was not so extensive, and, as far as I could tell, very little fibroid change. In all this group a good pneumothorax was easily obtained, and refills were made without any trouble whatever. Every

one of this group showed marked symptomatic improvement, and all but one improved in their general condition, as denoted by gain in weight and ability to take exercise without rise of temperature. One has been under treatment sixteen months, two eleven months, and they have shown such marked improvement that a bad prognosis has been changed to a good one, and we can be hopeful in each case of a permanent arrest of the disease. The others have only been under treatment from four to six months, but they are all showing marked improvement. Their improvement has been more rapid with pneumothorax than it was under exactly the same conditions without it.

Our experience in this group may be illustrated by one typical case:

A. R. G., male, aged 25, physician, had always had good health until onset of present illness. Onset of illness, December 1st, 1913, with rather severe haemoptysis. Admitted to the sanatorium January 14th, 1914. Weight, 120 lb. Average afternoon temperature, 99.4°; pulse, 90. Examination of chest showed: Right, consolidation of upper lobe, and infiltration of upper part of mid-lobe; left, thickened pleura at the apex and some fibrosis, probably due to an old lesion. There was also a suspicion of some laryngeal involvement. The patient did well for a time under sanatorium treatment, but then had another haemoptysis in April, developed an afternoon temperature of 100°, and examination of chest showed extension of the disease. In June, after five months' sanatorium treatment, practically a bed patient all the time, the patient showed upper two-thirds of right lung involved, with signs of cavity in upper lobe. There were a few fine crepitations at left base. He also developed a fistula in ano, which was discharging quite freely. June 26th, 1915, artificial pneumothorax was done on the right side, and examination of chest showed extension of the disease, a fluctuation of negative 2 cm. to negative 4 cm. (water) was obtained at once; 850 c.cm. of gas was injected the first time. Six days later he was given 1,100 c.cm., twelve days later 1,250 c.cm., and in two weeks 1,500 c.cm. There was evidence of a good collapse, and since then he has received refills of from 600 c.cm. to 900 c.cm. at four to six weeks' intervals. He showed marked improvement from the beginning; temperature became normal; he had no more haemoptysis, except on two occasions slightly streaked sputum. In January last his condition was so far improved that he was operated on for the cure of the fistula in ano. He took the anaesthetic well, and stood a rather extensive operation well. Since then his improvement has been rapid. At present date his general condition is good; temperature normal, pulse 90°, weight, 150 lb. (normal weight for him). There is a good collapse of the right lung; x-ray examination showed a slight amount of fluid present. His throat condition has cleared up, and the fistula in ano was healed.

I have given a rather lengthy account of this patient as I consider this the type of case in which we are likely to get good results from pneumothorax treatment. My regret in this case is that we did not compress the lung at the beginning.

Conclusion.

To draw conclusions from so limited a number of cases is somewhat dangerous, and it would be absolutely unfair to judge the merits of the treatment from the results obtained from these 18 cases. Of the first 12 of the series 9 were failures and only 3 showed partial benefit. This was because they were long-standing cases, in which there was an absolutely bad prognosis anyway. To obtain good results we must, I am convinced, use this treatment in those of recent origin.

The moderately advanced case of recent onset, with the disease confined almost altogether to one side, is the type of case in which we should produce a pneumothorax at once. Many of these progress rapidly, and at the end of six months must be classified as far advanced, so that by the use of artificial pneumothorax we have a most valuable adjunct to our treatment. Incipient cases, with severe haemoptysis, should also be treated by pneumothorax at once. In so many of these there is such a rapid extension of the disease after haemoptysis that it is better to give them the benefit of this treatment. I cannot go as far as some and advocate that all incipient unilateral cases be treated, as our results with ordinary sanatorium treatment are good. My great complaint is, like that of all men in sanatorium work, that so few of these cases are sent for treatment. On the other hand, my experience does not encourage me to hope for much benefit from pneumothorax in the far-advanced, long-standing cases. I would distinguish here the far-advanced case which has recently become so, and that in which the disease has been of some years' standing.

A case of recent onset, which from physical signs we must classify as far advanced, but which from general condition is still moderately advanced, is eminently suited for pneumothorax, provided, of course, the disease is mostly unilateral.

Artificial pneumothorax is, then, a valuable addition to our methods of treating tuberculosis, but unfortunately its application is restricted to not more than 5 per cent. of cases which have come under my observation.

OUR PRESENT POSITION WITH REGARD TO THE PRESCRIPTION OF PROPRIETARY FOODS IN INFANT FEEDING.*

BY

HECTOR CHARLES CAMERON, M.D., F.R.C.P.

ASSISTANT PHYSICIAN, AND PHYSICIAN IN CHARGE OF THE CHILDREN'S DEPARTMENT, GUY'S HOSPITAL.

In the artificial feeding of infants we must recognize two types of diet, and if we keep the distinction clearly in mind we shall be saved from a good deal of the confusion which at present hangs around the subject. In the first place we must recognize that for the normal healthy infant, who is unfortunate enough to be deprived of his mother's milk, there exists what we may call a standard substitute diet.

I. Cow's Milk as the Standard Substitute Diet.

It is the experience of all those who are best qualified to judge that in cow's milk we have the most suitable standard diet available in a form that is cheap and easy to procure. It does not matter whether we use the cow's milk undiluted with the addition of a little sodium citrate, and we shall then obtain both the good effects and the bad effects of a diet of cow's milk in the purest and most pronounced form, or whether we dilute the milk by the admixture of water or barley water and add very small amounts of sugar. It does not even matter very much, broadly speaking, whether we use fresh milk or substitute for it a preparation of condensed milk—so long as we choose an unsweetened variety with all the cream retained—or one of the many preparations of dried milk which have now been placed upon the market. In every case the result which we shall attain will be very much the same.

The infant fed upon cow's milk in one form or another will show in his growth and development the marks of the character of his diet. If he does not rival the child at the breast in agility, in rapidity of growth and in resistance to infective catarrhs, at least there is much in his condition with which we may be well satisfied. A critical eye may note at times a laxity and flabbiness of the muscles; the skin may be a little pale, although this is often masked by a fixed colour in the cheeks due to a slight eczematous infiltration over the malar bones and at the point of the chin; the abdomen is sometimes too distended, and the umbilical cicatrix may be unduly stretched; constipation is common and the putrefactive changes in the bowel are apt to be more prominent than the fermentative changes, and to make themselves evident by the characteristic smell of the evacuations; sweating is often excessive and micturition profuse; there may be some tendency to the appearance of transitory urticarial and erythematous skin eruptions. But these are small drawbacks to a diet which gives in general good results, and which can claim that it possesses one all-important advantage. Upon a diet of cow's milk the digestive processes of the infant are comparatively stable, and the infant runs little risk of such violent, dangerous, and even fatal attacks of diarrhoea and vomiting as are common enough in children whose food contains a high percentage of starches and sugars. I am not here speaking of the possibility that the contamination of the

* An address delivered at the Child Welfare and Mothercraft Exhibition at the Passmore Edwards Settlement, Tavistock Place.

milk with virulent organisms of disease may produce in the child a severe or even a fatal infection of the bowel. That is a possibility which must always be borne in mind, although I would protest against the view, which appears to be widely held at the present time, that the origin of most severe cases of diarrhoea in infancy is to be found in accidental infection of the bowel wall by organisms conveyed in the food. To me it seems proved without doubt that the truth lies with those who contend that the origin of the majority of alimentary disturbances in infancy is to be found in a bacterial fermentation of the food, both within and without the alimentary canal, by which not the bacteria themselves but the decomposition products of the food constitute the dangerous factor.

Nevertheless, it is to be conceded that the chief drawback to the use of cow's milk as the standard substitute diet in infancy lies in the readiness with which it is infected in its passage from the udder of the cow to the child's mouth, and that although the vast majority of contaminating organisms are harmless to the child, there exists always the possibility of an accidental infection with virulent organisms capable of producing enteritis. It is clearly the part of those who would attempt to reduce the high infant mortality from diarrhoeal diseases in this country to do all they can to safeguard the purity of the standard diet. Such a society as the National Association for the Prevention of Infant Mortality and the Welfare of Infants rightly does all in its power to raise the standard of the milk supply of this country, and it busies itself in framing directions for the preservation of milk in the homes of the people, and for its administration to infants. In such an effort the assistance of the lay public and of all those who are interested in the care of the health of the nation is of the first importance.

2. *Carbohydrate Foods as Therapeutic Diets.*

The practising physician, however, must carry the matter a stage further. He must not only be familiar with the standard substitute diet and the effects produced by it, he must be prepared to recognize certain diets which, for want of a better term, I may perhaps call therapeutic diets. The physician must be prepared to deal with that minority among children in which the ill effects of a cow's milk diet are unusually prominent and call for correction, and he must be prepared to deal with infants who are suffering from intercurrent infective disorders and illnesses of all sorts during which cow's milk may not be well borne. To achieve good results in such cases it is necessary to know how to change the character of the diet in order to modify and control certain unfavourable symptoms. Half a century ago and more it was clearly recognized by the physicians of the day that there were certain infants who, for the time being, refused to thrive except when their diet contained a much larger carbohydrate component than is contained in cow's milk. They therefore devised certain foods with a generous admixture of malted or dextrinized flour, and they gave to the world certain simple recipes for making these preparations in the kitchen. Our grandmothers were taught to prepare, and no doubt often did prepare, for our fathers and mothers a preparation of dextrinized flour, known as "Baked Flour." Dr. Cheadle constantly recommended a preparation of dextrinized flour which is known by the name of "Cheadle's mixture." Liebig showed the success which can often be obtained in the treatment of wasted infants by the use of his celebrated *Maltsuppe*—a mixture of milk, malt, and flour. I might multiply these examples, but these three must suffice to make my point clear. Those who first recommended them understood clearly that their use was only temporary; they had recourse to them to produce certain effects and to control certain unfavourable symptoms in the child, and recognized that they were remedies potent for good in suitable cases but capable of disastrous results if used ignorantly or carelessly—in other words, they did not set them forth as substitutes for the standard diet, but as therapeutic diets to be used in certain contingencies.

3. *The Objections to the Use of Carbohydrate Proprietary Foods.*

In more recent times these recipes have been utilized by the manufacturers of innumerable proprietary foods. A recent investigation by Dr. Coutts and Mr. Julian Baker

for the Local Government Board goes to show that, of 106 foods examined, over 70 per cent. consisted of "baked flour." Liebig's malt soup has become the progenitor of a number of preparations described as malted milk or malted food. At least one largely advertised food seems to be practically identical with Dr. Cheadle's mixture. The price of these foods is very high, owing no doubt to the large sums spent upon advertisement and the large profit to the proprietor. A packet of baked flour which contains twopence worth of baked flour may be sold at a shilling or even more. The malted foods are still more expensive.

It is not only because of their high price that exception is taken to the extensive use of these infant's foods at the present time, but even more because of the misleading character of the advertisements which extol their merits. These advertisements commonly claim that the particular food concerned excels and should supersede the standard milk diet. Their net must be spread as widely as possible and the praise of their own merits must be coupled with an attempt to bring the use of cow's milk into discredit. In this attempt they are assisted to some extent by the steadfastness with which medical opinion has adhered to the view, of which Biedert was the foremost champion, that the protein of cow's milk presents unusual difficulties to the digestion of the infant. Although Biedert's views were based upon faulty observations—as, for instance, when he confused the common soap curds in infants' stools with casein curds—and although his theories are not supported either by the careful researches, from the chemical side, of his successors in the German school, or by the clinical observations of Budin and many others both in France and in this country, nevertheless the belief that the difficulties of infantile digestion revolve around the question of the coagulability of the casein clot and around this alone remains imprinted upon much of the writing and teaching upon the subject in this country. The extreme emphasis which has thus been laid upon a peculiarity of the protein element of cow's milk has been utilized by the vendors of proprietary foods to encourage the popular distrust of the use of cow's milk.

As the permanent diet of the child the majority of these foods are quite unsuitable. An exception may possibly be made in the case of the foods composed of dried milk and malted flour. As compared with Liebig's original recipe, the amount of added carbohydrate which they contain is in most cases small. Speaking in terms of pharmacology they contain relatively little of the active principle—namely, the malted flour. They are thus, relatively speaking, much better adapted for use as a permanent diet, although their therapeutic effects are correspondingly less marked. Nevertheless, the practitioner who understands the use of a malted flour in controlling the occasional ill effects of a diet of cow's milk will probably prefer himself to add the prescribed amount of malted flour to the milk, and to keep the control of the dosage in his own hands.

4. *The Reasons for the Occasional Success of their Use.*

No doubt even when the proprietary food is adopted by the mother haphazard and in complete ignorance of its nature and composition, good results follow in not a few cases. The foods achieve success by reason of the contrast which their composition presents to that of cow's milk, to their low content of fat, and to their richness in carbohydrate of one form or another. For this reason they do not infrequently succeed when the use of cow's milk has been something of a failure. Moreover, they are often better digested during the course of some intercurrent infective disorder. Upon such lucky chances their reputation depends, and the grateful mother henceforth attributes to them powers which she would never claim for an identical mixture made in her own kitchen, and is not slow to recommend her favourite preparation as a panacea for all infantile disturbances of digestion however produced. In practice one has often occasion to observe how faulty is the reasoning which attributes recovery to the fortunate prescription of a patent food. A mother brought her baby to me with the story that some five weeks before the breast had suddenly begun to disagree. The child had therefore been weaned, and two different kinds of

food had been tried only to be discarded. Of these the mother professed the poorest opinion. When, however, a third largely advertised food was begun improvement had been immediate, and of this her praises were loud. An examination of the baby showed that its illness had been due to anterior poliomyelitis, which had paralysed the extensor muscles of the right leg. Because of the obvious paralysis in this case it was easy to prove the point that the alimentary disturbance had been secondary to the infective disorder and had disappeared when the infection declined, and that, as many diets had been tried, the last was bound to bear off the credit. In most cases, however, the infection which underlies the symptoms of digestive disturbance will subside leaving no trace by which we may confuse such claims.

In observing the course of an alimentary disturbance which is secondary to infection of parts remote from the bowel—which is secondary, for example, to influenza, naso-pharyngitis, bronchitis, otitis media, pyelitis, and so forth—it is obviously a matter of great difficulty to estimate the part played in improvement by changes in diet, and the inherent tendency of the infant to recover from the infection must not be taken as evidence of the success of any dietetic modifications which may have been introduced. The frequency of these obscure and often undetected infections in infants, and especially in artificially fed infants, accounts for the apparently discordant results obtained in the treatment of infantile diarrhoea and vomiting by dietetic measures, and while it explains many of the successes which have followed a haphazard change to a proprietary food, it teaches us at the same time how little importance is to be attached to the deductions of nurses and mothers which appear in the testimonials and advertisements.

5. The Dangers of their Prolonged Administration.

The child which is permanently deprived of the standard substitute diet, that is to say, cow's milk, and receives only one or other of the proprietary foods which contain a high percentage of starch and sugar, is in a condition of unstable equilibrium. For a time the greater intake of carbohydrate may appear to have achieved nothing but good. The rate of growth may become more rapid, and the agility and vigour of the child may increase. When the tolerance for carbohydrate is exceptionally good these benefits may even be permanent. For the majority of infants, however, the risk of fermentative dyspepsia is too great to be lightly disregarded. Especially in times of great heat, when both the need for carbohydrates and the tolerance of them rapidly diminish, a very large proportion of infants fed in this way will develop severe diarrhoea.

The dyspepsia of infants fed upon cow's milk to which no large proportion of carbohydrate has been added resembles that of the breast-fed infant in its relatively mild type. In the infant whose diet contains a relatively high percentage of starch or sugar dyspepsia may become a formidable disorder with intense diarrhoea, severe prostration, and a great and rapid loss of weight. Although the risk is not equally great with all proprietary foods, nevertheless it remains true that their permanent use is fraught with dangers which are too considerable to be neglected. With the biser kinds of foods, which consist chiefly of unaltered starch, their tendency to cause diarrhoea becomes an important factor in the production of our present high rate of infant mortality.

But the danger of a too high percentage of sugar or of starch is not confined to the risk of severe and even dangerous fermentative diarrhoea. It is, perhaps, of even greater significance that the use of such a diet is often accompanied by a profound lowering of the child's resistance to infective processes of all sorts, and that the infant fed in this way is not only more prone to nasal, respiratory, or intestinal catarrhs, but during the attack suffers more severely, and shows more constitutional disturbance than the child whose diet is better adjusted.

6. Conclusions.

The danger to the nation of the unrestricted sale of carbohydrate foods or of foods containing a very high percentage of carbohydrate is not lightly to be disregarded. The great movement which is now afoot, and which has as its object the lowering of our high infant mortality, is checked on all sides, not only by the ignorance and apathy

of the poor and by the difficulty of securing a reasonably pure milk supply, but also by the blind, unquestioning belief of the public in the misleading claims of the vendors of proprietary foods. Although in appropriate cases their temporary use under strict supervision may achieve excellent results, nevertheless, if it were possible wholly to do away with them, only good would result, because they contain nothing which cannot be adequately replaced by a simple combination of milk, malt, and flour, and because their advertisements deliberately encourage in the public mind distrust of the standard substitute diet, cow's milk.

In France—a country forced by the stern necessity of a fast declining birth-rate to interest herself in the welfare of infancy—the Roussel law prohibits the administration of any solid food to infants under the age of 12 months without the express direction of a medical man. In Australia a regulation is general which demands that starch-containing foods shall bear upon a label the words, "Not suitable for infants under the age of 6 months." In this country no such safeguards exist, and no attempt is made to curb the vast sale of foods unsuitable for young infants, nor is it likely that legislation will shortly supply the deficiency.

There is but one suggestion which it seems worth while to make. The undoubted therapeutic effect of the use of carbohydrate foods can be achieved equally well by preparations of baked flour or malted flour made in the home; and if among the poor the want of facilities for cooking prove an obstacle to this, then I do not see why it should not be possible to have something in the nature of a pharmacopoeial preparation of dextrinized flour and a pharmacopoeial preparation of malted flour, which, dispensed in a plain wrapper, could be prescribed without fear of the effects of misleading advertisements.

CALCULI OF THE PROSTATE.

BY

R. L. SPITTEL, F.R.C.S. ENG.,

SURGEON, GENERAL HOSPITAL, COLOMBO; LECTURER ON OPERATIVE SURGERY, Ceylon Medical College.

IN THE BRITISH MEDICAL JOURNAL of January 6th, 1912, I reported a case in which two calculi of the prostatic urethra were removed by the suprapubic route from a youth of 20. I there called attention to their faceted arrangement and the resemblance they bore to the scaphoid and semilunar bones of the wrist.

I now report two other cases of calculi of the prostate, from one of which twelve faceted calculi were removed, and from the other forty-six seedling calculi.

Prostatic calculi usually occur in middle life and old age. In the three cases that have so far come under my notice, the largest stones occurred in youths of 19 and 20, and small seed calculi in a man of 35.

As to the origin of prostatic calculi we know that, though lodged in the region of the prostate, they may have three modes of origin and formation:

1. They may be formed in the substance of the prostatic gland itself. They have then as their basis the corpora amyacea with varying amounts of calcium phosphate and carbonate deposited round them, giving rise to stones varying in size from grains of sand to large calculi.

2. They may be formed in pouches, congenital or acquired, that communicate with the prostatic urethra, catching up deposits from the urine, and eventually forming stones that are more or less the moulds of the pockets that lodge them.

3. They may have their origin in the kidney or bladder, and become lodged in the prostatic urethra secondarily, where successive phosphatic deposits cause an increase in their size and mould them to the shape of the passage or diverticulum that gives them lodgement.

CASE I.—One Vesical Calculus and Twelve Prostatic Calculi Removed by Suprapubic Cystotomy; Subsequent Perineal Drainage; Recovery.

W., 19, Cingalese, agricultural labourer, was admitted into the General Hospital, Colombo, on September 5th, 1912, complaining of great difficulty in micturition, accompanied by a burning sensation in the urethra during the act, and of pain in the hypogastrium and penis at all times, but worse at night. He was in a highly nervous state, and was continually trembling.

The symptoms began with a white urethral discharge and burning pain which he noticed for the first time about a year ago. He denied ever having had sexual intercourse. The symptoms continued in greater or less degree until the present time. When he came under observation micturition was very scanty and accompanied by a severe burning sensation all the way down the urethra. By dint of much straining he was able to squeeze out a few drops of urine at frequent intervals, about ten times during the day and ten to twelve times during the night. A purulent urethral discharge was present, which on microscopic examination proved to be free from gonococci.

On digital examination per rectum the prostate felt stony hard, was slightly crepitant, and very painful; this at once settled the diagnosis. Further, on exerting pressure on the prostate, a drop of sero-purulent discharge appeared at the meatus. The urine (specific gravity 1015) was alkaline; slight traces of albumin were present; there was no evidence of blood; phosphates, pus, and epithelial cells were present in abundance; no gonococci in centrifugized deposit.

Operation.

On September 10th, 1912, a sound was introduced into the bladder without much difficulty, and a grating sensation was communicated to the hand from the region of the prostate; this confirmed the diagnosis already made; also a characteristic tug was felt in the bladder. Through a supra-pubic incision a calculus free in the bladder, of the size of a hen's egg was removed from the bladder; and by means of a finger passed through the bladder meatus, aided by a finger in the rectum, no less than twelve faceted stones of various shapes and sizes (see fig.) were extracted from the prostate, which was found to be

Case 1.—Twelve prostatic calculi, showing facets. Natural size.

tightly packed with them. Removal of the first was a somewhat difficult matter, but after that there was not very much difficulty with the rest; they were all removed by the index finger without the aid of scoop or forceps. A large rubber drainage tube was passed into the bladder, and a gauze strip to the fossa of Retzius. The patient's condition after operation was grave, and showed signs of profound shock, from which he rallied under saline proctoclysis, warmth, etc.

Progress.

The temperature varied from 97° to 103° for the next twenty-two days, during which time he was given urotropin and acid tung state phosphate. There was a tendency for pus to accumulate in the prostatic cavity left by the removal of the stones; this was overcome by massage per rectum combined with the urethro-vesical irrigations by means of a short nozzle, the irrigating fluid finding an exit in the supra-pubic wound. These measures, however, proved insufficient, and the temperature kept up. On October 2nd the urethra was dilated with bougies, and a quantity of encysted pus was liberated from the prostatic region. On October 12th, the temperature still keeping high, a catheter was again passed under an anaesthetic and a large quantity of pus was again liberated from the same area. As the temperature still kept up, and as the patient was now in a rather low condition, he was anaesthetized for the third time and perineal drainage of the prostatic pouch was established. After this his condition improved, but his temperature still continued high. On November 14th, under anaesthesia by reopening the supra-pubic wound, which had quite healed by this time. From then on recovery was uneventful but slow, and, except for urethral dilatations on four subsequent occasions, nothing more was done. The patient left hospital, quite recovered from his prolonged illness and without sequelae. I have lost touch with him since then.

Description of Calculi.

The vesical stone measured 5.3 cm. by 2.5 cm. It was rough and spiculated on its surface, as rapidly growing phosphatic calculi often are. It was laminated, the outer laminae fracturing easily in flakes.

The prostatic calculi were twelve in number. Two of the largest measured 2.2 cm. by 1 cm. and 2 cm. by 1.8 cm. respectively. The smallest was 0.7 cm. One was almost as round and smooth as a small marble, but it, too, like the others, bore the

facet but distinct marks of two facets. The rest were of various shapes and sizes; they fractured easily, and carried different shaped facets, many as four facets; several contained three or four facets; even the smallest had at least one facet. They were somewhat rough on their non-articular surfaces. Some fractured fairly easily; others were harder and more compact. When dry they presented a mottled appearance, and were stained a patchy light yellow.

Chemical Composition of the Calculi.

The vesical calculus and one of the prostatic calculi were sent to Mr. C. T. Symons, to whom I am indebted for the following analysis:

The vesical calculus consisted of a dense inner core, which contained mostly urates, with some calcium phosphate. The next layer, which was looser, contained the same mixture, but not so much urate. The outer loose layer contained calcium phosphate, with a trace of calcium carbonate, but no urates. The prostatic calculus was composed in its central part largely of urates; the outer portion contained, in addition, a considerable proportion of calcium phosphate.

Judging from the history of this case, I am inclined to think that the large stones shown in the figure were formed primarily in pouches communicating with the prostatic urethra. This form usually occurs in young men. The case previously reported by me also comes under this category. What the origin is of the pocket under this category, which the origin is of the pocket that predisposes to this stone formation it is difficult to say; perhaps in this case it was congenital in the first instance, and then, as the stones gradually formed, they excavated for themselves roomier recesses by irritation round stagnating deposits, thus preparing the way for further deposits and faceted calculi. Chronic abscesses of the prostate may, it is true, open into the urethra and create a pocket in which a calculus may lodge or form; but there is no reason to suspect such an origin in this case, as there was no antecedent history of prostatic trouble, his earliest symptoms were urethral discharge and a burning sensation on micturition, which were no doubt the result of calculus irritation and not the cause of its formation. The composition of the core of the prostatic stone—urates—may suggest the view that a renal calculus formed the nucleus of the stone, but there is no evidence to support this in the absence of preceding symptoms of renal colic or discomfort. There is surely no reason why calculi having other composition than phosphates or carbonates should not be formed lower down the urinary tract than the kidney; a recess opening into any part of the urinary channel, or the part immediately behind a stricture, is quite capable of catching up or filtering off any urinary sediment, whether organic or mineral. The view that obtains with some that only phosphatic stones are formed *in situ*, and that urate, uric acid, and calcium oxalate stones found in diverticula must necessarily come from above, does not seem at all feasible.

If we look at the symptoms in this case we find that the main ones were great frequency and pain on micturition and a purulent urethral discharge. The highly nervous state of the patient was also a striking symptom which I noticed in my previous case; it is due as much to pain and loss of sleep and rest as to the peculiarly unnerve nature of prostatic stimuli. The evidence of this case seems to point to the conclusion that stones may form in the prostate and give rise to no great symptoms until secondary infection or projection of the calculi into the urethra or against the vesical neck cause symptoms of urgency.

The diagnosis of these cases would not be difficult if one kept in mind the possibility of their occurrence and made routine rectal prostatic palpation a rule in the examination of all genito-urinary cases. It is on the rectal feel that the diagnosis is made, and this may be confirmed by sound only when the stone projects into the urethra. It is, of course, of course, invaluable.

As regards the operation performed in this case I would not doubt it advised in the choice of my route. The tardy convalescence and the need for operative interference on four separate occasions proves conclusively that the perineal route should have been the route of choice in this instance, as it would have afforded the best means of draining the prostatic pouch and diverticula left after removal of the stones, in which fetid urine and pus collected and caused infection to spread along cellular planes, giving rise to para-rectal and para-vesical abscesses.

CASE II.—*Forty-six Scedling Calculi of the Prostate, Combined with Urethro-Rectal and other Fistulae, and Strictures of the Penile and Bulbous Urethra.*

S. A., 35, Cingales, cultivator, came into hospital on January 31st, 1914, complaining of great difficulty in micturition; he had also two urinary fistulae, one scrotal and one perineal, and a urethro-rectal fistula. There was frequency of micturition to the extent of about eight times during the day, and five to six times at night. Whenever he urinated there was also an inclination to defaecate; he sometimes felt that urine dribbled through the anus. Micturition was most easily accomplished by resting on one or other buttock, especially the left, and coxing the urine out by stroking the skin at the peno-scrotal junction. Even at the end of micturition he never felt that he had completely emptied his bladder. Whenever the inclination to micturate was strong there was some incontinence, the urine flowing out in drops at the fistulae and meatus. He states that for the last three years he has not had seminal emissions during coitus, an act which he is, however, capable of performing. He is the father of a child aged 4 years, but has had no children since.

His present illness dates from twelve years ago, when he had an attack of gonorrhoea, which lasted for about eighteen months, and was complicated by a left epididymitis, which terminated in a small focus of suppuration; this attack left him with disordered micturition, there being great frequency—at one time almost hourly—and considerable difficulty in passing water; he states there were times when each act lasted about half an hour. Some months ago there was a profuse discharge of pus through the rectum.

Operation.

On February 13th, 1914, Wheelhouse's operation was done, as the bulbous stricture was an impassable one; there was also a penile stricture and a prostatic urethro-rectal fistula. The scrotal and perineal fistulous tracts were dissected down to the urethra and removed. On inserting a Wheelhouse's probe into the bladder a sensation of gritiness was communicated to the hand; this led to the discovery of a large number of minute stones—forty-six stones were removed with a scoop; the largest were about the size of grape seeds, the majority about the size of cardamom seeds. A rubber catheter was passed from the external meatus into the bladder and tied in; the urethra was partially mobilized and the deficiencies left in it by the dissection of the fistulae were repaired with catgut. No attempt was made to dissect up and suture the recto-urethral fistula, as manipulation was difficult in the position it occupied, namely, in the prostatic region. The patient left hospital six weeks later relieved of his symptoms, but with the urethro-rectal fistula still persisting.

Description of the Calculi.

Forty-six were removed in all, a few being probably left behind. Four or five of the biggest were about the size of grape seeds; the others averaged about half the size. They were smooth and of various shapes; some were rounded, most flattened; the majority were more or less faceted. They came away in clusters, cemented together by a glutinous material. It was difficult to say whether they occupied separate pockets or were agglomerated together in a single one.

Mr. C. T. Symons's report on one of the largest of these was as follows: It consisted mostly of calcium phosphate, with trace of another compound, probably oxalate. It contained no urates.

This was a case in which antecedent gonorrhoea seemed to play an important part. There were strictures and fistulae; there was undoubted evidence of persistent infection of the prostate, as shown by epididymitis with suppuration, and the fact that a prostatic abscess burst years later into the rectum establishing a recto-urethral fistula. In the infected prostate and the recesses left by foci of suppuration in it scedling calculi, the so-called true prostatic calculi, formed.

As to the mode of formation of these calculi and their relation to the corpora amylacea, it may not be out of place to summarize some views. Corpora amylacea are found in various organs of the body. Thompson says they are always present in the prostate after the twentieth year of life throughout the gland, chiefly in the ducts about the verumontanum; in one prostate several thousands are present. They are microscopic as a rule. Their colour is a light yellow growing darker with age. Although the small uric acid calculi, they are not of urinary origin. Siegler says they are due to degeneration of epithelial and connective tissue cells, others say to stagnation of gland fluid, calcified glandular epithelium, etc. Posner classes them as calculi, and English shares Posner's view, and says that a final cause of their formation is possibly a microbic invasion of the gland. The small bodies are mostly organic and the larger chiefly inorganic. According to Thompson the corpora amylacea, having attained the size of their enclosing follicle, act as foreign bodies, and in consequence of the general law that all mucous membranes

when sufficiently irritated throw out a deposit of calcium phosphate and carbonate, ultimately form calculi; the earthy matter they contain being from 45 to 85 per cent. They are associated with glandular hypertrophy and periacinous round cell infiltration; pressure atrophy may cause entire disappearance of the gland with the exception of the capsule. English points out that the paucity of symptoms is in striking contrast to the wide extent of disease in the gland, hence the great importance of physical examination. The complications apt to arise are abscess, fistula, incontinence or retention, and sexual disorders.

To return to the present case. On surveying the condition of things, we see that in addition to the prostatic calculi there were two strictures and several fistulae present; the symptoms, therefore, should be warily interpreted, as those caused by the calculi are almost hopelessly obscured by the other conditions. Most of the symptoms recorded were no doubt due to the strictures and fistulae rather than to the prostatic stones.

The absence of seminal emissions may have been due to:

1. Occlusion of the common ejaculatory ducts by the prostatic abscess, and stenosis of the vas and ducts of the epididymis on one side at least—the left—where an abscess is said to have formed. It is significant that there was no atonic impotence so often associated with chronic prostatitis.

2. The presence of urethral strictures and fistulae; these are of themselves sufficient to prevent any seminal fluid present from appearing at the meatus. The fact that a son was born to him about eight years after his initial attack of gonorrhoea and epididymitis is proof that the ducts from the testicle were not completely destroyed or occluded before that time. The events that occurred after this were (a) the prostatic abscess which burst into the rectum, and (b) the gradual tightening of the urethral strictures. It is therefore probable that the prostatic abscess was responsible for the absence of seminal emissions by destroying and occluding the openings of the ejaculatory ducts or by directing what little seminal fluid there was down the fistula into the rectum, the impassable bulbous stricture helping in this.

THE CAUSES AND TREATMENT OF SEVERE PRURITUS ANI.

By P. LOCKHART-MUMMERY, F.R.C.S.,

SENIOR SURGEON, ST. MARK'S HOSPITAL FOR CANCER, PISTOIA, AND OTHER DISEASES OF THE RECTUM, AND TO THE QUEEN'S HOSPITAL FOR CHILDREN; HONORARY SURGEON, KING EDWARD VII'S HOSPITAL FOR OFFICERS; AND SPECIAL SURGEON TO FULHAM AND HORNERTON MILITARY HOSPITALS.

PRURITUS ANI is a peculiar complaint in that, with the exception of pruritus vulvae, to which it is closely related, it differs from all other forms of irritation of the skin. Other forms of skin irritation, though common enough, are never so localized nor so persistent; moreover, they are generally due to some constitutional condition. Pruritus ani is seldom due to a constitutional condition, and the worst forms never are. Diabetes is always given a prominent position in the textbooks as a cause of pruritus ani, but I have never yet seen a case of bad pruritus ani due to this cause.

In this paper I do not propose to deal with these cases of pruritus ani in which the irritation is only of an intermittent character and is relieved fairly easily, although perhaps only temporarily, by some simple application, but with the really bad cases in which the irritation is almost continuous and sufficiently severe to cause insomnia and serious interference with the patient's general health. In this category one must include all the cases of "paroxysmal pruritus ani" in which itching of an intense character comes on suddenly in violent paroxysms. It falls to my lot to see a large number of such cases, and the first thing that strikes one is that they are very difficult to treat successfully. This is shown by the fact that a very large proportion of such cases have been previously treated by many other practitioners, and often for years without any permanent success.

The causation of pruritus ani is a very difficult subject, and one has only to read a few of the textbooks on rectal

surgery to realize that we do not yet know very much about the pathology of the condition. A great number of different causes are given by different authors, and there is little agreement. Thus one writer states that he believes the cause to be a small internal fistula beneath the mucous membrane. Another is equally convinced that the cause is hypertrophy of the anal papillae. Others put the cause down as constitutional, and so on. I have always believed that pruritus ani is a condition set up by a local cause, and increased experience has only tended to confirm me in this view. The obvious deduction from this is that the pruritus can be cured if the local cause is discovered and removed. Unfortunately, however, this is not the case, and any one who has had a large experience in the treatment of these cases must have been struck by the fact that in quite a large number the removal of an obvious local cause entirely fails permanently to relieve the irritation. What one finds is that in cases in which the pruritus has been in existence only a short time, say a matter of months, the removal of the local cause, such as, for instance, a fissure, polypus pile, or submucous fistula, will, if accompanied by suitable local treatment, lead to a complete and permanent cure of the irritation. On the other hand, where the pruritus has been severe and continuous for a long time, and is, in fact, a matter of years, the removal of even a quite obvious local cause usually fails to give any permanent relief. In the typical paroxysmal type, in which frequently no local cause can be discovered, treatment generally fails to give any permanent relief.

Many patients have in the course of time discovered some local application, often an ointment, which if applied frequently gives temporary relief, but they are hopeless without this application, and there are times when it fails, with the result that they have sleepless nights and get bad attacks of eczema from the constant scratching. I have often seen patients who had become so desperate from constant irritation that they had seriously contemplated suicide, and one often finds that they have applied such things as pure carbolic, or almost boiling water, to the parts in order to try and get some temporary cessation of the itching. It is obvious, then, that we have to deal in these cases of old-standing pruritus with a different condition from that which is present in slighter and more recent cases, and that some change has taken place in the skin as the result of prolonged irritation, which is interfering with recovery. I believe that this change is of the nature of a fibrosis in the terminations of the nerves, or possibly the end plates supplying the affected area of skin. It seems probable that this has been set up by the constant scratching, but in any case it certainly takes a long time to occur, and is not present until the irritation has persisted over a long period. It is obvious that such a condition ought to be capable of proof by pathological evidence. There are, however, practical difficulties in the way of obtaining such evidence, and it is not at present forthcoming. It has for a long time been recognized that some definite pathological lesion of the affected skin is present in old-standing cases of pruritus ani, and various theories have been propounded as to the nature of this change. Thus, Unna suggested that it was due to a difference in the osmotic pressures of the different layers of the skin. It seems much more probable, however, that it is in the nerve extremities themselves that we have to look for the lesion.

The earliest treatment which was based on this assumption was cauterization or excision of the skin in the affected area, as sometimes carried out by the Allingham's. The operation originally described by Sir Charles Ball in the BRITISH MEDICAL JOURNAL (January 21st, 1905) was designed on this assumption. I shall not go into the details of the operation here, as a full description will be found in my book on *Diseases of the Rectum and Anus*, and also in Sir Charles Ball's original paper. The object of the operation is to divide all the nerves passing to the affected area of skin just before they reach the skin. I have for the last ten years frequently performed this operation, or some modification of it, and the results obtained have convinced me that the lesion lies in the nerve endings; and I have become so convinced from my own experience of the value of this operation that I always advise its performance in cases where I have reason to believe that this change in the nerve endings has already occurred, and careful non-

operative treatment has been given a good and sufficient trial.

There are several modifications of the original operation, but all have the same object—namely, division of the nerves before they reach the skin. One modification consists in making radiating incisions from the anus, through which the nerves can be cut. Other surgeons, again, advise the subcutaneous division with a tenotome. Personally I prefer the original incision described by Sir Charles Ball, or a modification of it which I have recently adopted, in which a narrow bridge of skin is left on each side to prevent retraction of the flaps. Several surgeons have, I know, discarded this operation owing to frequent failures to cure the patient. I believe, however, that the cause of the failure has been that the nerves have not been completely divided. It is obvious that if the operation is to be a success all the nerves to the irritable area must be cut. As an immediate result there will be complete anaesthesia of the whole of the affected area. The operation has not been successfully performed unless it is found on examining the patient the day after that there is absolute anaesthesia over the whole of this area. I am convinced that the cause of non-success with this operation is the failure to divide the nerves sufficiently. It is essential for success that the anaesthesia should be total. Many of the sensory nerves passing to the edge of the anus come down from between the sphincters and pass parallel to the bowel wall and just beneath the mucous membrane. These nerves are easily missed unless the operation is performed very carefully. The operation looks very easy and simple on paper, but in practice it is far more difficult than it appears, for one has to be certain to divide all the nerves, and at the same time to avoid buttonholing the skin or seriously damaging the blood supply. In a large experience with this operation I have never seen any serious sloughing of the flaps, or any stricture or other serious inconvenience result from it. The anaesthesia prevents pain after the operation, and the relief from the irritation is immediate. The anaesthesia is total for about ten to fourteen days. After this slight sensation begins rapidly to reappear in the skin, and sensation is generally normal in the affected area of skin within three or four weeks.

The only failures I have had with this operation have been cases in which the division of the nerves has not been sufficient, or in which the irritation has occurred in some area the nerves to which were not cut. The skin around the anus returns to a perfectly normal condition in a very short time, even though it may have been thickened and horny for years.

The explanation of this operation seems to be that new nerve endings grow into the skin to take the place of the original ones which have degenerated as the result of the division. It is inconceivable that the nerves should be able to find their original nerve endings, and one must assume that new nerve endings are formed.

I have never seen a case in which sensation was not normal at the end of a month or five weeks. This operation is the only method of treatment upon which one can at all rely to give complete and permanent relief in old-standing cases of pruritus ani and in severe cases of paroxysmal pruritus. I feel convinced that failure to achieve success by this operation is to be attributed to incomplete division of the nerves to the affected area. If, on the day after the operation, the affected area is found to be completely anaesthetic I do not think failure will result.

This method of treatment may easily be adapted to treatment of pruritus vulvae, and I have frequently used it in such cases with success. As already stated, the operation is by no means as easy as it looks, and requires to be carried out with great care. The after-treatment, too, must be carefully supervised in order to prevent sepsis beneath the flaps.

If properly performed, however, the operation gives wonderful results. The pruritus is immediately cured, and does not return. I have operated upon patients whose lives for ten or fifteen years have been rendered miserable by irritation, and they have never had any return of the trouble. One such patient went directly after the operation to reside in a tropical climate for two years, and never had the slightest reminder of the pruritus which had previously been a constant torture to her. I am convinced that division of the cutaneous nerves to the affected area

is the only treatment which affords any real chance of a permanent cure to sufferers from this condition when it has been in existence for more than a short time.

A cure has sometimes been effected by x-ray applications in large doses, but I have been very much disappointed with x-ray treatment in pruritus, most of my cases in which it has been tried having been complete failures. I have several times operated with success after x rays had entirely failed.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

FOREIGN BODY IN THE STOMACH.

An idiot, M. E. J., was admitted on September 13th, 1906, at the age of 6 years. It was expressly stated by his parents that he had never suffered from epilepsy or convulsions of any kind.

In August, 1907, however, he was sent to the institution infirmary suffering from a succession of convulsions with severe collapse. The ordinary treatment for collapse was resorted to, and in addition the patient was ordered an enema, which resulted in the evacuation of a large quantity of such rubbish as hair, bits of bootlace, string, etc. He continued to pass this stuff for some days, but eventually recovered completely.

He was never a strong boy, and constantly suffered from lung trouble, colds, and diarrhoea, but there is no further

note of his having had another fit until May 6th, 1915, while in the infirmary with general debility and persistent diarrhoea. On this date he was very much collapsed, everything having failed to relieve the very persistent and offensive diarrhoea. Just before death he had an epileptic seizure, from which he never rallied.

On post-mortem examination, the stomach and beginning of the duodenum were distended and very hard. I removed the lower part of the oesophagus, the whole of the stomach, and the duodenum.

On opening these I found a hard, solid, and compact mass of hair, tapc, bootlace, etc., as shown in the illustration, forming a complete cast of the stomach, and weighing 14½ oz. The stomach was slightly dilated, but showed no sign of ulceration; the remainder of the intestines were normal.

This case is of interest in two ways:

First, was the gastric irritation set up by the presence of this foreign body the cause of the boy's epilepsy?

Secondly, so much controversy has been raised lately regarding the shape of the stomach that I think the accompanying photograph is interesting as showing the shape, at least, of the contracted stomach.

The Royal Earlewood Institution,
Eedhill, Surrey.

J. M. GAGE,

It is reported that in Hungary several doctors have been arrested on the charge of improperly giving medical certificates to persons who sought to avoid military duties.

Rebivus.

ARTERIAL DISEASE AND ANGINA PECTORIS.

The unstinted admiration of the profession will be accorded to Sir THOMAS CLIFFORD ALLBUTT for the untiring energy which he has displayed in the devotion of the later years of his busy life to the advancement of medical knowledge and to the promulgation of new lines of thought on many of the obscure phases of medical science.

Many as have been the subjects to which he has devoted his remarkable powers of clinical investigation, there are few to which he has given more earnest thought than to the problems associated with arterial pressure and the conditions under which it may be modified.

The depth and wide range of his study of this subject may be judged by the two weighty volumes on *Arterial Disease and Angina Pectoris*,¹ which have recently been made public. Nearly a quarter of a century has passed since he made his own views on these points known to the profession, and on several occasions in recent years he has pressed some of them home in addresses and lectures, but the difficulties and intricacies of the research have been made increasingly manifest as time has gone on, and the literature of the subject has reached huge proportions. In order to deal fairly with the observations and conclusions of others, Professor Allbutt has expended a vast amount of energy in the attempt to bring them into some sort of line and order. His readers will readily concede the claim, laid down in the introductory chapter, that such labour has been honest labour, undertaken with the sole desire to unravel a very tangled skein. Although described as the winter fruitage of an old tree, they will also find it to possess the soundness of maturity, delightfully blended with the mellowness of age. The perusal of a work such as this is indeed a delight to the clinical reader.

Careful observation, checked by critical acumen; reasonable deduction tempered by common sense and well-balanced conclusions enunciated after judicial summary, are the distinguishing features of the methods adopted throughout this important work. No one, and least of all the author himself, would claim that finality has been reached. There is far more yet to learn than has hitherto been achieved, but a definite classification is possible which, if accepted, may go far towards a better understanding of the disease and its treatment in time to come.

Arterio-Sclerosis and "Hyperpiesia."

Degeneration of arteries, localized or diffuse, producing visible lesions, has been recognized since the earliest days of medicine, but it was not until the middle period of the last century that the microscopic changes in vascular walls began to be noted and described. The condition known as arterio-capillary fibrosis was gradually demonstrated and its close association with renal disease was generally accepted. With it also was associated the condition of increased tension within the pulsating vessels, and this high tension was directly attributed to the altered condition, with loss of elasticity in the vascular wall, coupled with the hypertrophy of the left ventricle of the heart, which was, in itself, the consequence of the obstructed circulation. About the year 1875 the late Dr. Mahomed of Guy's Hospital brought forward some striking evidence to prove that the condition of high tension was not always the consequence but might be the forerunner of the renal and vascular changes of a later stage. Although it was afterwards abundantly proved that such cases of high vascular tension might continue for long periods without producing the more obvious lesions either in the renal or other organs, still the work done by Mahomed definitely established the fact that high tension might be present without any recognizable cause for it.

It is to this form of high arterial tension unassociated with renal disease that Sir Clifford Allbutt has devoted his best powers of study and investigation during the last twenty years; the outcome is embodied in the work under review. While others have been content to follow their leaders in maintaining that high tension is produced by

¹ *Diseases of the Arteries, including Angina Pectoris*. By Sir T. Clifford Allbutt, F.R.C.B., M.A., F.R.C.P., F.R.S., Hon. M.D. Dub., LL.D., D.Sc. In two volumes. London, Macmillan and Co. 1915. (Med. Soc. pp. 576 and 565. 3s. net for the two volumes.)

vascular fibrosis or other forms of obstructive degeneration, he has steadfastly maintained that the increased tension is generally the cause, and not the consequence, of arterio-sclerosis. In this he has been supported by a few but by no means a majority of clinical observers.

To this condition of high tension of indeterminate origin he has given the name of "hyperpiesis," and the disease itself he describes as "hyperpiesia." It may be defined as persistent high blood pressure with cardiac hypertrophy, but without clinical evidence of renal disease.

Arterio-sclerosis, when recognizably established, may be regarded as due to mechanical and toxic influences of innumerable variety; but a definite form of the disease, to which he has given the name of "decreescent arterio-sclerosis," is insisted upon by the author. This form is characterized by an assumed frailty or toxic susceptibility of the arterial structure, and has been found to run in families. It is not of necessity associated with high arterial tension. A long series of conditions which might conduce to such arterial degeneration are passed in review. The influence of a toxic poison is very difficult to demonstrate; a vast field of recorded observation has been closely investigated, and has been found to present much conflicting evidence. The results of his researches in these and other stores of clinical and pathological archives are set forth in the breezy argumentative tone of the critical physician, which renders the whole work attractive to the reader, even where a good deal of superfluous energy appears to be expended in disposing of self-condemning assertions.

Although the main purpose of the book is to inquire into the whole question of arterio-sclerosis as it occurs in practice, the phenomena of high tension, before and after the occurrence of the obvious vascular changes, is constantly kept in view, and, as a consequence, a good deal of repetition is unavoidable. Professor Allbutt has convinced himself of the soundness of his opinions, and he is well alive to the fact that new ideas must be rammed home if they are to find an abiding place in the average brain.

Among the many important considerations involved in acceptance of his hyperpiesia as a definite morbid condition is the evidence that he quotes to prove that cerebral haemorrhage is more often the result of high tension than of arterial disease, of hyperpiesia than of decreescent arterio-sclerosis. But the causes of the hyperpiesia have still to be assumed rather than demonstrated. At best it can only be said to be a proclivity to some ill-understood poisoning, making for high pressures.

That it may occur at all periods of life and that it is susceptible of modification or even cure by means of moderation and mercury is clearly manifested. But the intricate relation which it bears to renal, cardiac, and other organic diseases is manifold, and its extent may be to some degree gauged by the countless investigations made by observers in many lands, aided by the most ingenious mechanical means of record, to which reference is made in this comprehensive work. The end is yet to seek, but Sir Clifford Allbutt's work has established a platform upon which others may build, and has indicated the lines for future research, while clearly demonstrating the present position of a most difficult subject.

Angina Pectoris.

In the second volume the author has set forth his views as to the causes, diagnosis, and treatment of angina pectoris. They have been submitted to the judgement of the profession on more than one occasion, but are here revised and brought into relation with the latest observations by the most modern investigators, due acknowledgement being accorded to the work of the younger generation of experimental pathologists.

For many years he has maintained, against a good deal of important adverse criticism, that the group of symptoms rightly comprised under the heading of angina pectoris is a direct outcome of disease of the aorta, more especially of that part of it immediately above the sigmoid valves, and that the disease and occlusion of the coronary arteries so often found after death, although they may be the cause of the final stoppage of the heart, are not the true cause of the angina.

The whole subject of aortitis is first considered, and it is made manifest that inflammatory affections of the vessel are much more common than is usually taught, and

that they not infrequently follow some of the commoner forms of infectious disease, especially in young persons. The many clinical controversies that have raged in past times over the exact part played by syphilis in the production of arteritis and aneurysm is recalled in a most interesting section, wherein every aspect of the subject is presented in the light of personal experience or published records.

Confusion has too often arisen from lack of precision in nomenclature, and many thoracic pains have been called angina which do not present the concomitant features of the recognized disease. The position of the pain itself is variously stated by different writers. Although its sub-sternal position is almost universal, it has been described as precordial or intercostal by many, and its area of distribution has been very loosely defined. Upon these points the author lays down very definite instructions, especially with respect to the lines of radiation which the pain of true angina has been observed to follow. Incidentally, the occurrence of herpetic eruptions along such lines is noted.

The theories that have been put forward to account for the pain by changes in the coronary arteries or by overaction of the muscular walls of the heart itself are somewhat severely handled, but not without fair and full examination. Equally severe is the dissection of the theory of intermittent claudication. The seat of the pain is in the aorta, and the immediate cause of it is held to be tension of the fibrous outer coat of the vessel, of which the nerve supply is traced.

That pain may be of cardiac origin he does not deny, but he maintains that it is of recognizably different character and course from that of true angina. The sudden stoppage of the heart which may attend an attack and which cannot be accounted for by obvious cardiac lesion is held to be due to the shock of the sudden pain exercising inhibitory influence through the vagus. The interpretation of symptoms which are found to be due to varying pathological conditions must always be the subject of controversy, and Professor Allbutt admits that in many of his contentions he is in a minority. The arguments by which he upholds his views, his cogent criticism of opposing theories, and his apt illustrations by means of recorded cases cannot fail to carry weight with those who are open to conviction and are equally bound to give pleasure to others who are not to be shaken from former beliefs.

Thus the profession is the richer by a comprehensive clinical treatise which will doubtless take its place among the medical classics of its day as the *magnum opus* of a great clinical philosopher.

THE EMERGENCIES OF PRACTICE.

In the preface to his *Urgent Medical Symptoms*² the distinguished author, Professor SAUNDY of Birmingham, tells us that it "is intended to be a handy work of reference for the busy practitioner or student who desires to learn quickly, without the delay and labour of consulting several volumes, the significance of a particular symptom, the indications it affords, and the means whereby it may be relieved, due regard being had to the importance of attacking the true cause, and not merely the superficial phenomena of disease." To those who may be disposed to object that the treatment of symptoms is in all cases undesirable, the author justly replies that "there are many symptoms which are sources of distress, or at least of discomfort," and that "attention to them need in no way interfere with the measures required to control or cure the main disorder." All experienced practitioners will assuredly agree that it is (in the bad sense) a "counsel of perfection" to teach that symptoms as such are in all cases unworthy of direct therapeutic attention. One of the paradox-mongers of the late nineteenth century asserted that "the only golden rule is that there are no golden rules," and the saying is not without its application to medical practice. Assuredly the house-physician or young practitioner who wants to have ready to hand a book to serve as guide, philosopher and friend in medical emergencies, may safely be recommended to acquire Professor Saundby's well-stored volume. The author's clinical and scientific repute

² *Urgent Symptoms in Medical Practice*. By R. Saundby, M.D. Edin., Lect.-Col. R.A.M.C.(T.). London: E. Arnold, 1915. (Post 8vo, pp. 437, 7s. 6d. net.)

is ample guarantee that he will not be led astray, even if we had not satisfied ourselves that the guidance offered in respect of the numerous conditions touched upon is always sound and physicianly. The book is arranged in alphabetical form, and is obviously designed purely as a work of reference. As such it bears on every page evidence of wide experience, keen observation and familiarity with all the latest developments of diagnostic and therapeutic method. It abounds in valuable hints as to the management (hygienic, dietetic, and medicinal) of everyday ailments such as asthina, quinsy, constipation, and epilepsy. Not less useful are the clear and concise definitions of many rare and obscure symptoms and symptom-complexes, for example, paramyoclonus multiplex, paragonimiasis, Korsakoff's psychosis, Gordon's reflex, Magnan's sign. Under the heading "Flanders foot" the two conditions erroneously termed "frost-bite," which have been observed as results of standing for many hours or even days in the half-frozen mud of the trenches, are briefly described, the one attended by desquamation, haemorrhages, or oedema, the other only by pain or other perversions of sensation. From what we have said it will be evident that Dr. Saundby has produced a book which, inasmuch as it renders easily accessible a great deal of valuable information, some of it not readily obtained elsewhere, deserves and is likely to enjoy wide popularity.

The German original of *Emergencies in General Practice*,² written early in 1913, was reviewed in the BRITISH MEDICAL JOURNAL of that date (BRITISH MEDICAL JOURNAL, 1913, i, 1116), and we welcome Dr. KRONN's excellent translation which now puts it within the reach of medical practitioners in this country. The book is divided into seven sections, dealing with sudden dangers to life that may arise in connexion with diseases of the brain, the lungs, the heart, the digestive tract, the urino-genital apparatus, pregnancy, and poisoning. At the end there is an excellent chapter on serum sickness, or the anaphylactic troubles to which the use of antitoxic serums may give rise, and there is a good general index. It is clear that the work is from the pen of an able general practitioner with actual experience of most of the acute morbid conditions with which he deals, and with a sound judgement in the matter of the lines of treatment he advocates or condemns. The pathology and diagnosis of the conditions described are well expounded, and this is one of the most valuable features of the book. The book is well printed; it may be noted that the German original is published at two-thirds the price of its English translation.

² *Emergencies in Medical Practice. The Pathology and Treatment of Morbid Conditions that may Suddenly Endanger Life.* By Dr. R. Kronn, M.D. Translated from the third German edition by R. E. S. Krohn, M.D. London: John Bale, Sons and Danielsson, Ltd. 1915. (Roy. 8vo, pp. 52. 2s. net.)

SIR FELIX SEMON.

The Internationales Centralblatt für Laryngologie, Rhinologie, etc., which was founded by Sir Felix Semon, contained in its issue for June (Jahrgang XXXI, Berlin, Juni, 1915, No. 6) a declaration, of which the following is an accurate translation:

Declaration.

In the *Times* of July 12th there is an open letter from Sir Felix Semon as follows:

To the Editor of the "Times."

Sir,—For many years I believed in the possibility of a better understanding between this country and Germany, and it was a most bitter disappointment to me when the great crash came last year. Even then I hoped that it would suffice for a naturalized British citizen of German extraction loyally to do his duty by his adopted country without making any public expression of his faith. The inhuman methods of German warfare, however, have often and of late with ever increasing force, induced me to think that it would be right for a German by birth to publicly express his detestation of that policy. What has hitherto deterred me from doing so has been the fear that such a statement might be misconstrued as a desire to personally court favour. But now that Sir Arthur Pinero in the letter published in *The Times* of to-day has pointed out that an attitude of continued silence might be interpreted as "sitting on the gate," I beg to say that I emphatically abhor the barbarous methods, one and all, employed by Germany.—Yours obediently,

FELIX SEMON.

Rignalls, Great Missenden, May 11th.

When Sir Felix Semon, surely misled by the lying reports of the Press inimical to Germany, wrote this letter in which he publicly takes a stand against the land of his birth, he must have known that he thereby caused sincere pain and bitter disappointment to his German friends and colleagues. Sensible and farseeing as he is, he surely could not be in doubt for a moment as to the effects which were bound to result for his further relations with everything which connected him with the old Fatherland. Nor could he doubt that the same conditions would apply with regard to his relation with this *Centralblatt*, which he has founded, edited for a quarter of a century and made successful, and which in memory thereof still bears his name. For, although this journal is an international one, intended to transmit the results of scientific work in the whole domain of our speciality to the specialists of all countries, and although it has always most carefully kept this international character, yet the fact remains, that it is being published in the German language and in the capital of the German Empire.

The Editor and Publisher, who are proud to be Germans, consider it to be further irreconcilable with this fact, that at the head of this journal the name of a man should appear who in a public declaration has sided against their fatherland, and hence they feel compelled to declare, to their keen regret, and whilst still gratefully acknowledging Semon's achievements with regard to this journal, that the name of Semon in the title of the "Centralblatt" will henceforth be omitted.

The Editor and Publisher of the *Internationales Centralblatt für Laryngologie,*

Professor DR. G. FINDER,
AUGUST HIRSCHWALD.

Sir Felix Semon, who has resided and practised in this country for some forty years, is, even in the retirement which he imposed upon himself a few years ago, still, we think, looked upon by British laryngologists as their leader. His declaration of loyalty to his adopted country has already led to his name being expunged from the list of honorary members of the laryngological societies of Vienna and Berlin. This, in the present state of the mind of even scientific men in Germany, was perhaps to be expected, but the action of the editor and publisher of the international journal which Sir Felix Semon founded must be looked at in a different light. Sir Felix Semon is a man of world-wide reputation and the *Centralblatt* is international; the action taken by the editor and publisher has been deeply resented by laryngologists in this country. All the British editorial contributors to the *Centralblatt* who have hitherto had an opportunity of seeing the declaration printed above have withdrawn their names and have resigned their editorial connexion with it. Among these are Dr. Peter McBride, Dr. H. J. Davis, Dr. Logan Turner, and Dr. Watson-Williams. They have taken this course as the only effective protest open to them against the affront to a British colleague for whom they entertain the highest respect involved in the removal of his name from an international journal founded by him. We have no doubt that similar resentment will be felt by his colleagues in France, Italy, and Russia, and in neutral countries also. Already, we understand, the American collaborator, Dr. Emil Mayer, has withdrawn his name and resigned his editorial connexion with the *Centralblatt* as a protest against the high-handed action of the editor and publisher.

We desire to add the expression of our own sympathy with Sir Felix Semon, who has shown himself a loyal citizen of this country not only by his own declaration but also in the fact that all his three sons are now serving the country in military capacities.

The Times states that the official reports give 629 cases of Asiatic cholera in Austria on August 1st. The deaths include the Austrian Army Corps commander, General von Ziegler, who was the only officer on the staff who refused to be inoculated against the disease, and the only soldier in the whole district who died of cholera.

The Hon. John Mildred Creed, M.D., member of the Legislative Council of New South Wales, has been a prominent figure in Australian politics for the last forty years. It is announced that Mr. Herbert Jenkins will issue next month a book by him entitled *My Recollections of Australia and Elsewhere*. Dr. Creed's reminiscences include numerous anecdotes of many distinguished personalities who have visited Australia during that period.

DESIGN FOR THE WELSH NATIONAL SCHOOL OF MEDICINE.

The part to the spectator's right will form the Physiological Department. The building of this part and the central tower will be proceeded with at once.

From a sketch by the architect, Colonel E. M. Bruce Vaughan, F.R.I.B.A.

THE WELSH NATIONAL SCHOOL OF MEDICINE.

THE foundation stone of the physiological department of the buildings for the Welsh National School of Medicine at Cardiff was laid by Lord Pontypridd on August 12th.

The School of Medicine of the University of South Wales and Monmouthshire was established in 1893, when a story was added to the main buildings of the college in Newport Road. Dr. W. T. Edwards, physician to the Cardiff Infirmary, had long cherished the desire for the formation of a medical school for Wales, and when President of the British Medical Association, at its annual meeting in Cardiff in 1885, he offered £1,000 for the foundation of such a school. Dr. Edwards continued to show his interest in the project, and when he died on April 11th last, he left in his will the sum of £7,000 to the University College. For the purpose of the alterations and extensions made in 1893 the sum altogether of £7,000 was raised.

The extended buildings were opened in 1894 by Sir Richard Quain, then President of the General Medical Council, and for the last twenty-two years teaching has been provided in the subjects of the first three years of medical study, including physiology, and since 1899 post-graduate instruction for the diploma in public health. The first professor of anatomy was Dr. Alfred Hughes, who died during the Boer war after serving in South Africa. His memory is perpetuated in the school by a medal and by a fine anatomical museum. He was succeeded by Professor Dixon, now of Dublin, and the present occupant of the chair is Dr. Hepburn, now in command of the 3rd Western General Hospital at Cardiff. During this time Dr. Berry Haycraft has been continuously professor of physiology. During the twenty-two years 224 former students have obtained medical qualifications and have won 32 gold medals and distinctions at the University of London. They have also won 45 entrance scholarships into London hospitals.

The council of the college has worked in cordial relation with the authorities of King Edward VII Hospital. The professor of pathology and bacteriology of the college is one of the honorary pathologists of the hospital, and is now officer commanding of mobile bacteriological laboratory of the Welsh Army Corps, and all the work of the school in pathology and bacteriology, which has hitherto necessarily been of a post-graduate character, is done at the hospital, where the necessary rooms and laboratories have been provided by the foresight of the hospital authorities for that purpose. The department was opened by Sir William James Thomas on June 1st, 1912.

Since 1903 the college has received a grant from the Treasury for the purposes of the medical school. In 1906 the University of Wales obtained a supplemental charter

authorizing it to confer degrees in medicine and surgery, but, owing to the want of a complete medical school at Cardiff, students have hitherto had to go to other schools for the later subjects of the medical curriculum. In 1908 Professor Haycraft drew attention to the need for new physiological laboratories, both for teaching and research, and three years later, at the instance of Colonel Bruce Vaughan, Chairman of the House Committee of the Cardiff Infirmary, a committee of the council of the college was appointed to consider the needs of the department of physiology and the comparative claims of other departments. This committee recommended that greatly improved accommodation for the medical school was required. Eventually, in February, 1913, Sir William James Thomas offered a sum of over £10,000 towards the cost of building the new department of physiology, and in the end undertook to erect the whole of the buildings required for physiology and to increase his donation to £30,000 so that the great hall and staircase for the use of the complete school of medicine should be provided at the same time. In January, 1914, Sir William James Thomas announced that he was prepared to promise a further sum of £60,000 to provide a public health department and school of preventive medicine, together with the necessary buildings for a complete school. One of the conditions attached to the offer was that the Treasury, in addition to its present annual grant of £1,500, should make a grant adequate for the administration and maintenance of a school worthy of Wales. In February, 1914, a deputation consisting of members of the University of Wales and its constituent colleges and of other bodies interested in medical education in Wales, appealed to the then Chancellor of the Exchequer, Mr. Lloyd George, for Government assistance towards the maintenance of a complete medical school for Wales at Cardiff. Mr. Lloyd George promised a substantial contribution from the Government, and a scheme has recently been submitted to the Treasury by the Welsh Educational Conference for the formation of a University of Wales Council of Medicine. The school will thus become a national institution controlled by a national body, while its administration will, subject to certain conditions, remain in the hands of the Council of the University College of South Wales and Monmouthshire.

THE NEW PHYSIOLOGICAL BUILDINGS.

The new physiological buildings, with the great hall and staircase now to be erected, form the first part of the larger scheme for the complete school of medicine. The new building will face on to the Newport Road, one of the principal thoroughfares of the city, and will be within five minutes' walk of the hospital. When completed it will measure 368 ft. from east to west. The physiological

department will occupy 116 ft. of its frontage, and the hall, which will be common to all departments of the new school, 42 ft. The design by Colonel E. M. Bruce Vaughan, F.R.I.B.A., provides a basement, a ground floor, four upper floors, and a mezzanine between the first and second floors. It will have a depth of 47 ft.

The eastern part of the basement and ground floor will be occupied by a large lecture theatre to seat 140 students; adjacent to it will be preparation rooms and a museum. The first floor, to be devoted to experimental physiology, will contain large laboratories for forty-eight students, a smaller laboratory for advanced students, the professor's private room and private laboratory, a dark room, a departmental library, and a workshop. The second floor for chemical physiology will contain a students' laboratory with eight benches for five students each, a lecture room for small classes, a research laboratory, a private room and a research laboratory for the lecturer in chemical physiology, and store and preparation rooms. The third floor will be entirely devoted to histology and embryology. The laboratory with both top and side light will provide accommodation for eighty students, and there will also be a lecture room, a demonstration theatre, a room for the lecturer, a laboratory for advanced students, a museum for embryological and histological specimens, and preparation and store rooms. Above the third floor there will be a photographic dark room and an optical room.

In the design of the front the need for abundance of light has been fully recognized, and the façade shows many windows. The centre and end blocks and the wide bays between are stone. The main walls will be faced with narrow red bricks joined with light mortar. The general design is English Gothic of the fourteenth century, modified by the influence of the French Renaissance architecture of the following century. The central block rises to a height of 100 ft. with side turrets, between which will be a pointed arch deeply recessed. The lower portion of the central feature, forming the portico, will be divided into three bays by columns surmounted by canopied niches to contain the statues of Hippocrates and Esculapins. The flanking panels will contain busts of Pasteur, Lister, Hunter, and Jenner. Over the central block will be a lantern with a vane rising to a height of 150 ft. above the ground. The entrance hall will measure 65 ft. by 30 ft., and the ceilings will be panelled, showing the arms of each county in the Principality with the arms of Wales in the centre.

THE FOUNDATION CEREMONY.

In opening the proceedings at the ceremony of laying the foundation stone Lord ABERDARE, who presided as president of the University College of South Wales and Monmouthshire, said that the Welsh National School of Medicine would be a memorial to many great men who had worked in or been born in Wales and had attained eminence in medicine. He was glad, particularly, that Dr. W. T. Edwards had lived long enough to know that the generous gift of Sir William James Thomas had ensured the beginning of the erection of buildings suitable for a national school. He paid a tribute to the work of Colonel Bruce Vaughan, expressing his belief that no one had done so much for the medical school and for the King Edward VII Hospital as he.

The stone was then laid with proper ceremonial by Lord PONTYPRIDD, who in the course of a short address spoke of the pioneer work of Daniel Jones of Beaupre, who would have rejoiced that they had returned to the site chosen by him when he built the hospital, and were now commencing the erection of an institution of loftier ideals than could have been conceived in his time. Having traced the development of the King Edward VII Hospital from the days when, twenty-five years ago, it was a "glorified cottage hospital," with Mr. Lynn Thomas as the only house surgeon, Lord Pontypridd said that the great extension of the institution to its present magnitude was largely due to the influence wielded by the architect of the new buildings of the National School of Medicine about to be erected. Colonel Bruce Vaughan and Mr. Lynn Thomas from their first association with the hospital had bent all their energies to the attainment of the loftiest ideal of a complete medical school. The institution that was being set up would not only be of the first order, but would be the pioneer in

Great Britain in adopting the methods and system of the most advanced schools on the Continent and America. It was gratifying to be assured that the project had the cordial approval of such high medical authorities as Sir Donald MacAlister and Sir William Osler. Those distinguished gentlemen, by their warm encouragement, had inspired all concerned to make a supreme effort for the consummation of the object all had at heart. There were many absent faces they might recall, especially that of the late Dr. W. T. Edwards, the father of the present medical school. The success of the school was immediate, under the able direction of Professor Berry Haycraft and Professor Alfred Hughes, and had continued unabated up to the present time. Professor Haycraft was still with them, and they trusted it might be his good fortune long to enjoy the great facilities that his valued suggestions had done so much to crystallize. The name of the late Professor Alfred Hughes was so well known throughout Wales and his Cardiff friends so valued his work and personality that they had perpetuated his name by calling the Museum of Anatomy the "Alfred Hughes Museum." As a Welshman, Lord Pontypridd continued, he wished to point out that the nationality of the candidates for positions on the professorial staff of the school did not count, but their efficiency. As an instance of this he recalled that although the first holder of the chair of anatomy was a brilliant Welshman, Dr. Alfred Hughes, the second, Professor Dixon, was a distinguished Irishman, and the third was Professor Hepburn, an eminent Scotsman. The number of gold medals won by the students was one of the proudest achievements of the University College. But however high their attainments might have been in Cardiff, they were compelled to go elsewhere to complete their medical course. Very shortly Welsh medical students would have the opportunity of completing their studies in Wales under auspicious conditions. A beginning was that day being made in the building of a complete medical school, thanks to the means placed at their disposal by the princely munificence of Sir William James Thomas. It would be a national institution; and, as such, the Welsh nation, through its accredited representatives, would be associated in its management. It would be an institution that would fulfil Wales's highest aspirations, and be a source of pride and gratification when ranked with the great medical schools of the world. He had once said that the great captains of industry in Wales had not done themselves justice in connexion with their national institutions. That could be no longer said of two of them, Sir William James Thomas and Colonel David Davies, M.P. The inspiring work of those two young sons of Wales was a landmark in the history of their country, the one being the complement of the other, and thus making a grand unification of design in the endeavour to solve the problem of health.

THE LUNCHEON.

The company present were afterwards entertained at luncheon at the City Hall by Sir William James Thomas. After the usual loyal and patriotic toasts the Lord Mayor gave the health of Sir W. J. THOMAS, who, in reply, said that it was a great and peculiar pleasure to him that Lord Aberdare was able to preside at the ceremony, for it was to his distinguished father, as much as to any other man, that the establishment of the University College of South Wales and Monmouthshire was due. Moreover, it was also to his great work as Chairman of a Departmental Committee of Inquiry, appointed thirty-five years ago, that Wales was indebted for what might be called, without exaggeration, the most important document ever published in connexion with education in Wales; it was, indeed, the Charter of Education of Modern Wales. To Lord Pontypridd, also, warm thanks were due for his valuable services in connexion with the college and for laying the foundation stone of the first of the new buildings of the Welsh National School of Medicine. He thanked those representatives of physiology and of medicine who were present, and expressed regret at the absence of Sir Isambard Owen, who had done so much for the University of Wales not only by speech, but by action, and whose ideals had inspired it on more than one occasion to real purpose. He went on to bear testimony to the great work which Colonel Vaughan had accomplished at the hospital and in the college; to his efforts, more

than to those of any other single individual, it was due that the ceremony of the day had taken place, marking a stage in progress towards the establishment of a complete school of medicine for Wales. No one who had seen the great work of healing the sick and suffering carried on within hospital walls, and had realized the part hospitals took in the still greater work of research, could fail to be touched with a desire to have the privilege of taking some share in it. For himself, he had willingly promised to perform a humble share in setting up this school by providing the necessary buildings, for he had been convinced that unless the several departments of a modern school were well housed and equipped, men sufficiently highly qualified to make the school one of the leading schools in the world could not be attracted. There was much left for further private munificence to do and for adequate co-operation by the State. There was a great opportunity to retain the services and future distinctions of Welsh students for Wales by endowing research, thus enabling the greatest brains Wales produced to spend all their days in research which did not bring immediate results, but whose reward would come in the improved health and happiness of future generations. Another argument that had appealed to him as a reason for the establishment in Wales of a full school of medicine was that parents not in good circumstances, and who were therefore not in a position to send their sons to London or elsewhere for the latter half of their training, should be able in the immediate future to send them to Cardiff for their medical education. Mr. Lloyd George had expressed the same desire when replying to the deputation on February 18th, 1914. He said: "The cost of medical education was almost prohibitive, except for people who could spend large sums upon the education of their children, and he hoped that the establishment of the school at Cardiff would make it easier for children of parents of small incomes to enter that noble profession." Sir W. J. Thomas concluded by saying that he hoped that what had been able to do would be an inducement to others not only to assist in the completion of the medical school but in the many other activities for which the college required money, such as the proper housing of the applied sciences, and new laboratories for chemistry, physics, and other departments. It would, he hoped, also induce the wise and generous co-operation by the State.

Sir WILLIAM OSLER, in proposing the toast of the Welsh National School of Medicine, paid a tribute to the excellent work done in the departments of physiology and anatomy by Professors Hayeraft and Hepburn. During the past twenty-five years or so the first and most essential element in a great medical school—namely, a great hospital—had been established, and in connexion with it a good pathological department in charge of a whole-time professor. When the building, the foundation stone of which had been laid that day, was completed, the medical school would have as good a physiological department as there was anywhere in the kingdom or anywhere in the world. The school would have also an anatomical laboratory, a splendid public health and pharmacological laboratory, and a central library. Touching upon the relation between the medical school and the hospital, he said that the authorities would have to face the problem of organizing the departments in the hospital on university lines. It had to be recognized that the departments of medicine, surgery, pathology, and obstetrics and gynaecology, as well as the minor departments, must be units in the university scheme. The university and the hospital must work in co-operation, and all the departments in connexion with the hospital must be equipped on exactly the same scientific lines as the physiological department. He was aware that there were difficulties in adjusting the relations of the medical school with the University of Wales, but with goodwill they could be overcome. It would be unwise to attempt to have three universities, and equally unwise to attempt more than one medical school. Turning to the question of the selection and appointment of professors, Sir William Osler expressed an emphatic opinion that all appointments should be made by a small board of electors, and the best men appointed irrespective of nationality. He knew that a grant was expected from the Treasury, but he might say without fear of contradiction that the Government only helped those who helped themselves. Wales was helping itself nobly, but it must not

expect too much from the Government, although it was known to be willing to help.

Dr. E. H. GRIFFITHS, Principal of the University College of South Wales and Monmouthshire, said that the object in view was that the school should be national in the true sense. While all the higher educational interests in Wales should have some voice in its management, it must remain a collegiate institution in the sense that Cardiff could not spare its medical students.

The toast of the Visitors, given by Sir GARRON THOMAS and Professor BERRY HAYCLAFF, was acknowledged by Mr. H. E. DAVIES, the secretary of the Welsh department of the Board of Education, by Professor LANGLEY (Cambridge), and Professor STARLING (University College, London).

Sir E. VINCENT EVANS, in proposing the toast of the Lord Mayor and Corporation of Cardiff, said that Wales owed a great debt of gratitude to Cardiff for what it had done.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE CENTRAL COMMITTEE.

At the last meeting of the Central Committee, which was held on August 12th, it was announced that the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés had acknowledged the receipt of the cheque sent to the Committee on June 12th. The minutes of the meetings of the Belgian society showed that its financial position during June and up to July 8th was satisfactory. The last report received, bringing the accounts up to the beginning of June, showed the Belgian society to have £750 in hand. By June 10th this had dropped to under £500, but by June 24th the total in its hands had risen to over £900, at about which figure it was maintained till July 8th, the date of the last minutes received. The minutes showed that the receipts and expenditure seemed to balance very well, as the sum on July 8th was a little larger than the sum in hand in the beginning of May, although credit had not been taken for the last sum sent in June by the British Central Committee. Subscriptions in Belgium, though small, appeared to be regular, and the sums spent in relief were only granted after close investigation. The chairman said that, acting on the authority given by the Committee on July 15th to himself, the secretary, and the treasurer, a further sum had been dispatched to Belgium, Mr. Hoover advising this course.

A letter was read from Dr. Des Voeux, the treasurer, who is absent on a short holiday, reporting that places had been secured now for most of the Belgian refugee doctors, and that there was much less demand for relief in money or kind. He brought before the Committee the question of refunding to its donor, a Belgian pharmacist, a sum of money which that gentleman had expended out of his own pocket on one of the refugees who had already been helped by the Fund. This was an exceptional case, as the lady in question is alone in England. Her father is much respected by both Belgian doctors and pharmacists, and she has worked gratuitously amongst the Belgian refugees for a long time. She now, however, has obtained work in the Censor's office. In the meantime her benefactor has become penniless. The Committee decided to pay a portion of the debt. Dr. Des Voeux's financial statement showed that up to August 11th, 1915, £17,892 had been received. From July 15th to August 12th £2,417 2s. 3d. had come in, including £22 6s. 6d. bank interest.

THE WEEK'S SUBSCRIPTIONS.

The following subscriptions to the Fund have been received by Dr. Des Voeux:

Thirty-seventh List.

£ s. d.		£ s. d.	
South Australian Belgian	...	Dr. John Stewart (2nd	2 2 0
Doctors' Relief Fund	...	donation) ...	1 0 0
(per the Agent-General)	...	Dr. G. D. H. Carpenter ...	1 1 0
(3rd. donation—total.	...	Dr. C. G. MacLagan ...	1 1 0
£500	100 0 0		

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

British Medical Journal.

SATURDAY, AUGUST 21st, 1915.

THE SALE OF SPIRITS IN FRANCE.

The Académie de Médecine of Paris has been discussing alcoholism and alcoholic beverages on and off since last autumn. The Académie has a way of its own of discussing a subject of general interest. It often happens that when a paper is read remarks by one or two other members show that the question raised is ripe for debate, if not for decision. The custom then is to refer it to a commission which may take several weeks or months to prepare its report. This, however, does not prevent other members or correspondents from reading papers on the subject in which they express their individual opinions. When the report of the commission is presented it may lead to a full dress debate, extending over portions of three or four sessions, and contemporaneously a whole series of independent papers may be read dealing with various parts of the original subject, or opening up new considerations by which the grounds of debate are enlarged. In this way no doubt the subject comes to be looked at from many points of view, but the Académie sometimes finds it a little difficult to reach finality and the foreign reader may be not a little embarrassed to make certain what the opinion of the Académie really is, if indeed he can be sure that it has gone so far as to express any collective opinion.

The discussions of the last six months, however, have gone a long way to define the attitude of the Académie towards alcoholic beverages, or at least towards spirituous liquors. On February 12th, during the debate on the bill to regulate the sale of alcoholic beverages, the French Chamber of Deputies passed a clause prohibiting the manufacture and sale, wholesale or retail, of absinthe and "similar beverages"; in the measure, as it eventually became law, this term was retained. Meanwhile, a report of a committee on the measures to be taken against alcoholism had been presented to the Académie on February 23rd by M. Gilbert Ballet, Professor of Neuro-pathology in the Faculty of Medicine, Paris. This report was discussed at a meeting of the Académie in the following week, when a series of resolutions were adopted recommending (1) that a surtax should be imposed and regulations made in respect of the manufacture and sale of all *apéritifs* containing essences and of those made from wines of alcoholic strength greater than 23 degrees, (2) the diminution of the number of wine and spirit shops and the prohibition of the sale in such shops to women and to children less than 18 years of age, (3) that the right of private distillers should be abolished, and (4) that debts incurred for the purchase on credit of alcohol by retail should be rendered insusceptible of recovery by judicial process. Later on the regulations proposed to be made by the fiscal authorities under the Act were reported to the Académie, and it appeared that the authorities had difficulty in defining the term "similar beverages." The Académie accordingly turned its attention to this subject, and on June 29th Professor Ballet presented a further report by the committee. At its meeting

on July 13th the Académie unanimously adopted a series of resolutions for the guidance of the fiscal department and parliament. These resolutions recommend: (1) The prohibition of the sale of spirits exceeding 50 degrees in strength,² (2) The prohibition of the manufacture, distribution, and sale of all liqueurs and all aromatic wines of strength above 23 degrees, neither category of these beverages being permitted to contain more than $\frac{1}{2}$ gram of essence to the litre. Sweet liqueurs, containing 300 grams of sugar to the litre, may be permitted of the strength of 30 degrees. (3) The prohibition of the use for flavouring alcoholic beverages of chemical products, plants, or essences containing among their normal constituents thujone, benzoic aldehyde, aldehyde, or salicylic ethers; and (4) the imposition of a high supertax on all beverages, of whatever nature, in which the amount of alcohol exceeds 15 degrees. The Académie also adopted two supplementary resolutions. In the first it expressed the hope that the public authorities will without delay, and pending the adoption of legislation to diminish the number of spirit shops, institute the necessary measures of supervision and police to close the very numerous clandestine spirit shops which exist; in the other it recorded the pleasure with which it had noted that the high command of the army had forbidden the sale and distribution of alcohol in the zone of the armies, and expressed the desire that this protective measure should be maintained and extended.

In order to understand the action of the Académie, it should be noted that wine is not among the alcoholic beverages it condemns—that is to say, the ordinary light wine, chiefly red, which is made in nearly all districts in and south of the Loire Valley. In the greater part of France it is the usual beverage of all classes; it is of low alcoholic strength, and is taken very commonly diluted with water (*eau rouge*). The wine is not only light but acid, and does not make any strong appeal to the untrained British palate. Nor does the Académie's condemnation extend to beer—for the most part very light—nor to the elder drunk in many parts of Northern France. The recommendations no doubt in theory include certain strong wines, but practically they affect almost solely spirituous liquors, or strong wines in which aromatic substances are dissolved—brandy, *apéritifs*, and liqueurs. It must have struck many travellers in France that the drinking of neat brandy—or shall we say *eau de vie*, for it is often a very artificial product—is a rather common habit at odd times of the day among porters and labourers, and that it does not always follow a cup of coffee even early in the morning. A similar habit, with whisky instead of brandy, is not unknown in Scotland, but in England it is rare to see a man drink neat spirit, though the total quantity of spirit consumed by the English toper may not be less than that taken by his Scottish or French counterpart.

The third of the Académie's resolutions is directed against absinthe, the typical *apéritif*. Thujone, an isomer of camphor, occurs in the essential oils of absinthe (*Artemisia absinthium*) and of sage (*Salvia officinalis*); it has also been found in several other plants of less common occurrence. Benzoic aldehyde (C₆H₅CHO), or benzaldehyde, is a colourless liquid having physical properties identical with those of oil of bitter almonds which has been deprived of hydrocyanic acid; in fact, the oil so treated consists

² The word "degree" of alcoholic strength when used in this connexion is equivalent to per cent. of real alcohol by volume. A spirit of 50 degrees therefore contains 50 per cent. by volume of absolute alcohol.

almost wholly of benzaldehyde; a minute trace of this substance also occurs in cherry-laurel water. It is made synthetically on a large scale from benzyl chloride. Aldehyde, by which is no doubt meant acetaldehyde (CH_3CHO), is a colourless liquid with a characteristic odour, formed in the oxidation of ethyl alcohol. A number of salicylic ethers are known, the only one of interest in this connexion, however, is methyl salicylate, which is the chief constituent of oil of wintergreen and oil of sweet birch. It is prepared synthetically on a very large scale from methyl alcohol and salicylic acid. It may be pointed out that the liqueur known as *noyau* or *crème de noyau* sometimes contains oil of bitter almonds, while *crème de menthe* is stated to be prepared from ingredients which include sage. Such liqueurs might be prohibited by a strict interpretation of the third resolution, but they are probably intended to come under the head of "sweet liqueurs," on the ground that, like other pungent aromatic liqueurs, they are generally taken after meals.

The Académie, as has been said, raised no objection to the use of wine. In fact, what may be called another discussion has already been raised by a series of papers by Vidal, Armand Gautier, and Landouzy, who urge that the wine ration should not only be maintained but even increased. The suggestion has been referred to the committee on alcoholism for report.

THE TYPHUS EPIDEMIC IN SERBIA.

The great armies which are engaged in this tremendous struggle have so far been remarkably free from serious disease, at least when we recall the experiences of other campaigns; but the small kingdom of Serbia, which has fought so splendidly for the cause of the Allies, is an unfortunate exception, for she has in very truth been stricken by pestilence.

We publish to-day the first detailed account, from the clinical standpoint, of the epidemic of typhus which has been raging in Serbia since the beginning of January, but which has now, thanks to the exertions of various British and foreign doctors and the devoted labours of many nurses, been brought to an end.

Though there were some sporadic cases of typhus in Serbia prior to the great Austrian defeat last December, there is good ground for supposing that the epidemic originated among the Austrian prisoners, of whom, early in the year, the Serbians had taken as many as 67,000. The starting point seems to have been Valjevo, a small town in the north-west of Serbia, not far from the frontier of Bosnia. When evacuated by the Serbians it had been free from disease, but on their return they found 3,000 wounded and sick Austrians, many of them suffering from typhus fever. In one building 150 dead Austrians were found in the cellars; men and cattle were buried indiscriminately.

From there the disease spread in a south-easterly direction to Kragujevatz, and then to Nish, the temporary capital of Serbia, where a very large number of troops were encamped, and after that further south to Skoplje in new Serbia, and Monastir, close to the borders of Greece, and, in fact, to wherever the army might be quartered. There were, of course, plenty of cases among the civil population, but the soldiers were the main victims of the disease. The infection was carried largely by soldiers returning home from the army, by peasants wandering about at large, or travelling in the crowded trains, clad in filthy clothes, rags, and goatskins, there being at first no restrictions placed on railway travelling or any attempt made to

disinfect the carriages. Later on, when, early in March, a detachment of the Royal Army Medical Corps arrived, Colonel Hunter and Lieutenant-Colonel Stammers, in conjunction with the parliamentary sanitary commission at Nish, caused quarantine stations to be established behind the various camp lines, notification of disease was enforced, infectious patients were removed from their homes to hospitals; all railway communication was stopped for a time, all soldiers on leave were immediately recalled so that there might be no danger of re-infecting the railway carriages after the disinfection, which was carried out during the stoppage.

It will be advisable to wait a little before attempting to frame an estimate of the total number who suffered in the epidemic. We know that early in March there were 8,000 cases at Nish. At Kragujevatz, out of a civil population of 20,000 inhabitants, there were 1,400 cases of typhus. Dr. Maitland mentions 1,800 cases as having passed through his hands in two months at the typhus hospital at Skoplje, and there were doubtless as many cases in the two months before the hospital was in full working order. Probably in the six months during which the disease was active, when the returns from all the villages have come in, the number of cases will be found to amount to something like 80,000.

Dr. Maitland describes in some detail the methods of disinfection which he adopted for the wards and the orderlies, hampered as he often was by shortage of water and the inability of the Serbian authorities to give adequate notice of the arrival of new patients. Certainly his policy seems to have been eminently successful, and the disease was got under control at Skoplje sooner than elsewhere. Colonel Soubotitch, Vice-President of the Serbian Red Cross Society, and one of the leading medical authorities in Serbia, inspected this hospital and was deeply impressed by it, saying that the isolation scheme there adopted was the only effective plan, and that it would be copied all over the country.

In the interesting account which Dr. Maitland gives of the symptoms, stress is rightly laid on the importance of the hygiene of the mouth, the neglect of which so readily leads to such complications as parotitis, laryngitis, and otitis media, which at first could hardly be avoided when the number of the patients and the smallness of the staff prevented adequate attention being given to individual cases. In most instances the onset of the disease was rather slow, which is contrary to what has been generally observed in previous epidemics, but to some extent each epidemic is a law to itself. The great infrequency of pulmonary stasis, where there was often much cardiac asthenia, is certainly a striking feature.

Tender toes, which are often described as a sequel of enteric fever, are in reality extremely rare after that disease, whereas after typhus fever they are very common; the condition lasts for ten days or a fortnight, without any discoloration or swelling, but perhaps giving the patient more pain and discomfort than any other symptom of the disease; it is probably due to a local peripheral neuritis. In spite of careful nursing, bedsores occurred with astonishing frequency, thus showing the devitalizing effect of the toxin on the tissues. Patients who survive typhus usually regain their former vigour, but for a considerable time there may be much neuro-muscular weakness, which often retards convalescence; the usual view that recovery from typhus is rapid, requires, therefore, some modification. In many cases this neuro-muscular weakness recalls post-influenzal conditions, but typhus, unlike influenza, does not

permanently damage the myocardium. The prejudice in the Balkans against the use of brandy in cases of typhus, to which Dr. Maitland alludes, is undoubtedly well founded. The heroic doses of alcohol given by our ancestors, such as the two bottles of Madeira daily for several days ordered by Dr. Carmichael Smyth to a Spanish prisoner in the Winchester gaol, or the two bottles of port in twelve hours to another who recovered, were probably due to an excessive reaction against the treatment by venesection.

It was generally expected in Serbia that cholera would break out there in the early months of the summer; happily, so far this expectation has been falsified, and, in any case, preparations by inoculation and attention to the water supply have been made to meet this unwelcome guest.

With the knowledge gained from this epidemic of typhus fever it seems highly probable that there will not be another outbreak this winter, or that, if it comes, it will assume much less serious proportions. The Serbians have already learnt much about sanitation and ventilation, and will doubtless daily learn more from the large number of foreign doctors and nurses still present in the country. In the month of March there were as many as 300 foreign doctors, nurses, and orderlies in Serbia. The whole administration of the country will also have improved, and there will not be the same deficiency of food, which is so important a factor in the production of typhus that at one time it was known as "famine fever."

To many of our readers Skoplje, the scene of Dr. Maitland's labours at the typhus colony, may be better known as Usküb, as which it appears in most maps. The town is beautifully situated on the river Vardar, surrounded by snow-clad mountains; it is of considerable antiquity, and by some authorities considered to be the birthplace of the Emperor Justinian. It was the ancient capital of Serbia in the fourteenth century, when their empire, in the famous reign of Stephen Dusan, included the greater part of the Balkan peninsula. But on the fatal field of Kossovo (1389), when the Serbians, owing to treachery, were defeated by the Turks, Usküb was lost to Serbia for more than 500 years, and has been a Turkish town until 1912, when the Balkan Alliance won its signal victory over the Turkish Empire, and Usküb, or Skoplje, passed once again under Serbian rule.

THE SHORTAGE OF GLASS.

It is unfortunately a fact that for many years Great Britain and other countries have largely depended upon Germany and Austria for their supplies of several varieties of glass used in the manufacture of lenses and optical apparatus. Thus, the Jena glass—a product with a high "antidispersion" coefficient—was, before the war, imported from Germany. Not only was it not produced commercially in England, but even now it is difficult to obtain the pure barium compounds which are necessary for its manufacture. The history of the Jena glass is interesting. We believe that we are correct in saying that it was only discovered after years devoted to costly experiments, and that success was not attained until the Government stepped in and subsidized the firm engaged in the work when its financial resources were exhausted. The amount of this glass required in the optical trade of the world being comparatively limited, it is not commercially possible for an English firm to undertake its manufacture unless it receive adequate guarantees, for any attempt to compete with Jena would be successfully met by price cutting. The absence of the necessary technical education, the want of protection, and, it is said, the vexatious

interference of trade union officials, have made it impossible for British firms to compete with Germany, and the manufacture of high-class glass has been driven out of this country. The same circumstances killed the home production of chemical glass apparatus, which, before the war, was imported from Bohemia. Soon after the outbreak of hostilities the British Science Guild appointed strong committees to investigate the questions of the manufacture of optical instruments and scientific glass apparatus respectively. The reports published in the spring of this year show that the Guild is satisfied that the supply of optical glass for the manufacture of telescopes, binoculars, range finders, and other service instruments is sufficient for the purpose. Messrs. Chance Bros., of Birmingham, have quadrupled their plant for the production of optical glass, and are fully prepared to increase its capacity still further. With regard to the special grades of glass used in the manufacture of photographic and microscopic lenses the outlook is not so promising. The Guild is of opinion that serious inconvenience is to be expected, more especially because, as has been stated above, it is very difficult to obtain in England the necessary barium salts in a pure state. The variety of English glasses offered is insufficient for the most recently designed optical systems. Thus, while the leading English firm listed only thirty types of glass, the chief German firm offered and actually stocked seventy types. The Guild pointed out the lack of facilities for research upon the manufacture of optical glass, and suggested as immediately necessary an investigation to discover a refractory lining for the melting "pot" which would resist at fusion temperatures the action of the materials used in the glass mixtures, and would leave the contents of the pot uncontaminated at the end of the operation. It suggested that this research might be undertaken by the National Physical Laboratory. The Guild regards the provision of adequate facilities for education in technical optics as a national want, and states that at present they are quite inadequate. The second committee—that which investigated the provision of glass apparatus for educational purposes—reported that the efforts made since the outbreak of hostilities have been attended with satisfactory results as regards the quality of the products. But, in the absence of any promise of protection after peace has been signed, British manufacturers are disinclined to expend the capital necessary to establish a new industry, inasmuch as there is every likelihood that they will be undersold by dumped goods in the British market when normal trade conditions are re-established. The Guild has been informed that this fear has acted as a strong deterrent to British glass manufacturers contemplating the production of scientific glass apparatus. The Guild has written to 860 educational authorities, and about 70 per cent. have promised, as far as possible, to buy only British-made glass apparatus during the war and for a period of three years after its conclusion. Finally, the Joint Committee expresses its strong conviction that every effort should be made to encourage the manufacture of glass and porcelain apparatus in the United Kingdom.

DEFECTIVE ADMINISTRATION OF THE SERVICE FOR THE FRENCH WOUNDED.

ALLEGATIONS against the military medical administration have brought about, or have been used as an excuse for bringing about, something approaching a political crisis in France. A debate was raised on August 15th during which the arrangements for treating the wounded were very severely criticized. M. Peyroux, who led the attack, said that the arrangements for the evacuation of the wounded after the battle of the Marne were of the most casual kind, and as an instance of mismanagement said that over 1,300 men had been sent to a place where there was not a single bed. At that time there were no hospital trains, and though an order had been given on November 10th for the equipment of such trains, cattle trucks were

still being used within the last three weeks. He alleged also that there had been great waste of money in requisitioning hotels quite unsuitable for use as hospitals. He also alleged that men had been employed as hospital orderlies who had undergone no sort of training, while mobilized medical students might have been employed in this capacity. Finally, he alleged that the organization of the medical service at the Dardanelles was extremely bad, and that at Mudros there were no beds, no bedding, no drinking water, and hardly any drugs, M. Navarre, who followed, condemned the spirit of routine which prevailed in the Medical Department of the War Ministry and the opposition it showed to all voluntary effort, a statement which was received with loud applause. Every difficulty, he said, had been put in the way of the National Committee of Public Hygiene over which Dr. Rous, Director of the Pasteur Institutes, presides, and he made a strong attack upon M. Troussaint, Director of the Army Medical Service, on the ground among others that he had failed to appoint surgical specialists to places where their services could have been of the greatest use. The Chamber became very excited, but on the appeal of the President the discussion was adjourned until August 20th, so that the reply of the Ministry has not yet been heard. M. Andre Maginot, formerly Under Secretary of State for War, has since published in *Le Journal* a long article in which he analyses the defects he has observed in the French medical service, but states that certain improvements have been introduced, among others a system under which surgeons at the front and at the base exchange places from time to time. He asserts, however, that many temporary military hospitals are insufficiently equipped with linen and clothing, and that the deficiency in instruments and surgical appliances leads to men being detained in hospital awaiting operation for weeks or even months. He alleges that no steps are being taken to heat the temporary buildings during the coming autumn and winter. He traces all the defects of the service to the fact that the authority of medical officers is insufficient; they have to get anything they want for their hospitals through a circumspection office where laymen sit in judgement on medical demands. He quotes one instance in which a lay official replied to the medical officer in charge of a hospital, "Your demands are justified in principle, but they are too numerous and will end by tiring out the patience of the Minister." The remedy, he asserts, is to give a greater degree of autonomy to medical officers in charge of hospitals.

DIETETIC TREATMENT OF SICK INFANTS.

LAST January some account was given in an editorial article of two valuable reports issued last year by the Local Government Board on the use of proprietary foods for infant feeding, by Dr. F. J. H. Coutts, and on the analysis and composition of some proprietary foods for infants, by Mr. Julian Baker, F.I.C. Mr. Baker undertook a systematic and comprehensive analysis of a large number of proprietary foods, which showed that by far the greater number consisted of cereal flours, the starch of which was not appreciably altered. Dr. Coutts discussed the whole question in some detail, and brought forward a mass of evidence to show how misleading were the claims of the advertisements of many of the proprietary foods, and how unquestioning was the belief which they inspired in the mind of some sections of the public. He described at length the regulations which had been adopted in other countries to control or abate the evil, and devoted a chapter to a discussion of the general question of the suitability of foods containing starch and high percentages of sugar for young infants. The opinion of many authorities can be quoted both for and against their use. Dr. Cameron returns to this question in our present issue. He emphasizes the distinction between the standard substitute diet of cow's milk and

certain special diets, which, however unsuitable as the permanent food of the child, are, nevertheless, useful in the treatment of certain disorders, and in the control of certain unfavourable symptoms in artificial feeding. To the latter class by far the greater number of proprietary foods belong, and he urges that under no circumstances should we allow their claim that they may serve as permanent substitutes for the standard diet of cow's milk. The subject is of importance in view of the keen interest which has always been shown in the subject of artificial infant feeding by persons who have not undergone any medical training, and of the use which is now being made of the services of lay workers and nurses in schools for mothers and centres for infant welfare. Dr. Cameron is no doubt right in saying that the artificial feeding of infants, so long as it is concerned only with the use of cow's milk, is to a great extent a matter of routine, rightly falling within the province of an intelligent district worker or nurse. It ought not to be difficult to frame general rules which would be almost universally applicable, as to methods of cleanliness, dosage, and dilution, in such terms as could be understood by the general public. To recognize this is not, however, to shut our eyes to the harm and needless suffering and loss of life which results from the failure of the medical profession to keep completely in its own hands the control of the diet of sick infants. At the present time foods containing very high percentages of carbohydrate, whether in the form of cane sugar, unaltered starch, or flour partially or completely malted, are freely administered by self-constituted and ignorant advisers. The sick baby, without medical examination and without any attempt at diagnosis of the cause or nature of the disorder, is too often condemned to suffer a series of rapid and radical changes of its diet in the hope that some one of many much lauded foods will make good its claims and save life. That the majority of infants survive the indigestion so produced and ultimately begin to improve only brings conviction to the mother that matters have after all been managed for the best, and the sufferings of each infant in turn achieve only the unfortunate effect of establishing in one family circle at least the reputation of some one proprietary food. It is to be hoped that the work of such societies as the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy will succeed where we fear the medical profession has somewhat failed, and, while encouraging among mothers and lay persons the study of a sound technique of artificial feeding with cow's milk, will at the same time be successful in putting a stop to all ignorant and rash assumption of knowledge and experience in that most difficult of subjects, the dietetic treatment of the sick child.

THE DEATH-RATE IN BERLIN DURING THE FIRST SIX MONTHS OF THE WAR.

A PAPER by Stadtrat Dr. Gottstein¹ on the death-rate in Berlin and Charlottenburg brings out some curious facts. He has drawn up a table showing the mortality from various diseases and suicides in Berlin in the period August to January, from the year 1910 to 1914 inclusive. Putting the mortality from various causes during these years of peace at 100, he shows that the corresponding mortality in the period August, 1914, to January, 1915, was in some cases considerably affected by the war. This was particularly the case with regard to suicides, which for men have fallen since the war to 76.2 and for women to 80.9. He admits that there may be sources of error in his calculations, and he points out that as the mortality from malignant growths can scarcely be affected by the war, the fall in the mortality from this cause to 96.5 is the measure of the margin of error. The mortality from pulmonary tuberculosis among men was raised to 102, and among women was lowered to 97.6. Curiously enough the

infantile mortality for children born out of wedlock has fallen to 94.7, and for children born in wedlock to 97.8. Most striking of all was the increased mortality from diseases of the heart and blood vessels, which rose to 107 among men and to 110.9 among women. A closer scrutiny of these two figures showed that there was no increase in the mortality from these causes among patients under 50 years of age, whereas there was a rapid rise among patients over 60. It would therefore appear that the war has taken a heavy toll among elderly patients suffering from heart disease.

CAPTIVE MILITARY SURGEONS.

THERE have on all sides been complaints of the high-handed action taken with military surgeons who have fallen into the hands of the Germans. The French medical papers have published from time to time lists of military surgeons who have been illegally kept back in Germany. The French protests have drawn from Dr. J. Schwalbe,¹ editor of the *Deutsche medizinische Wochenschrift*, the following defence of Germany's action. In the Geneva Convention of July 5th, 1906, there are, he says, two important clauses, dealing with the retention by the enemy of members of the Army Medical Service. In Article I it is agreed that the belligerent who is forced to leave the sick and wounded in the hands of the enemy must also leave a certain proportion of medical attendants and equipment. In Article 12 it is agreed that members of the Army Medical Service who have fallen into the hands of the enemy must continue their duties, but that as soon as their services can be dispensed with, they must be sent back. Dr. Schwalbe argues from these articles that it is lawful for the enemy to retain the services of captive military surgeons as long as their services are required, and that the decision whether their services are indispensable or not must be made by the captor, not the captive. Dr. Schwalbe goes on to enumerate the arguments for retaining the services of captured military surgeons for attendance on their fellow captives. It is, he says, of great advantage for the Russian prisoner, who does not speak German, to be attended by a Russian surgeon, in whom he would naturally have greater confidence than in a German. This arrangement also sets free German surgeons to attend to their wounded countrymen. It is further admitted that this arrangement diminishes the risk of infection for German surgeons. Infectious diseases, such as typhus, are prevalent among the Russian prisoners, and are, according to Dr. Schwalbe, more dangerous to the German than to the Russian surgeon, whose immunity is greater. Dr. Schwalbe admits that his arguments cut both ways, and that captive German military surgeons are probably kept back for the above reasons. According to the official lists, and these, he says, probably do not include all the losses, the majority of the 166 missing German surgeons are kept back by the enemy. He says that Russia has not hitherto sent back a single German surgeon, and that the majority of the missing German surgeons have been captured by the Russians. He is convinced that the supply of military surgeons captured by the Germans is at present inadequate for attendance on the more than 800,000 prisoners requiring treatment, and that these prisoners still constitute a drain on the supply of German military surgeons.

INFLUENCE OF REMOVAL OF THE ADRENALS.

DR. G. A. FRIEDMAN publishes in the (Boston) *Journal of Medical Research*, May, 1915, a series of experiments throwing light on the influence of removal of the adrenals and one-sided thyroidectomy upon the gastric and duodenal mucosa, and demonstrating the experimental production of lesions, erosions, and acute ulcers. The

experiments recorded number forty-eight, and included extirpation of the adrenals in rabbits and dogs, extirpation of the adrenal on one side, and removal of a thyroid lobe on the same side or the opposite, in one sitting in rabbits, one-sided thyroidectomy in rabbits and dogs, and repeated intravenous injections of commercial thyroid gland. The result of these and earlier experiments, already published, is summed up by Dr. Friedman thus: Adrenal hypofunction causes lesions in the stomach in rabbits and dogs. An excess of thyroid gland, as produced by repeated intravenous injections, was probably responsible for the gastric lesions of four animals submitted to experiment. Thyroid hypofunction caused the appearance of duodenal lesions in five out of six. An excess of adrenalin, produced by repeated injections of the drug, led to the appearance of lesions in the duodenum of dogs. The simultaneous production of adrenal and thyroid hypofunction did not lead to any lesions in the stomach or in the duodenum of rabbits. Lastly, when after removal of one adrenal the other became hypertrophied, lesions were seen in both viscera of three rabbits and in the duodenum of one.

THE MERCURIAL TREATMENT OF GONORRHOEA.

JOHN HUNTER treated gonorrhoea with mercury, but this was because he confounded gonorrhoea with syphilis. Mercury has, however, been advocated from time to time in the treatment of gonorrhoea since this disease was shown to be distinct from syphilis. Morel-Lavallée, in 1881, recommended iodide of mercury in the treatment of gonorrhoeal rheumatism; Thomas, in 1901, intramuscular injections of calomel; and Oro, in 1903, intravenous injections of mercuric chloride. J. W. Taylor, in 1899, pointed out that gonorrhoeal salpingitis was often improved or cured by prolonged treatment with mercury and iodides provided it stopped short of pyosalpinx. More recently B. L. Wright¹ has reported good results in cases of gonorrhoeal arthritis from intramuscular injections of succinimide of mercury. He began this form of treatment in cases of tuberculosis and has since extended it to the majority of bacterial infections, on the theory that mercury is the chemical affinity for every vegetable parasite. G. B. Lake² has applied this method to cases of gonorrhoeal urethritis with apparent success. In the 20 cases reported 13 became clear of gonococci in an average time of six to seven days, and remained so for periods of three weeks to seven months. In other words, it is claimed that 65 per cent. were cured in less than a week. In most of the cases local treatment of the urethra was used also. The dose of succinimide given was 40 mg. in the earlier cases and 65 to 78 mg. in the later. A second dose of 40 mg. is recommended if the gonococci do not disappear in six days.

GOITRE IN FISHES.

It is interesting to learn that one order of vertebrates, which lives largely in water where there is a good supply of iodine, is not free from enlargement of the thyroid gland. A. T. Cameron and Swale Vincent, working in the Physiological Laboratory of the University of Manitoba, have recently published a note³ on an enlarged thyroid occurring in an elasmobranch fish (*Squalus sucklii*). Among 217 specimens of this fish, a dog-fish from the North Pacific Ocean, they detected in one specimen a thyroid about three times larger than usual. The gland, instead of being flat and leaf-like, its normal form, was pear-shaped and nodular. It contained large cysts with proliferating growths, adenomata no doubt, but in certain regions there were infiltrations of the interstitial tissue,

¹ *Med. Record*, July, 1914.

² *Ibid.*, April, 1915.

³ *Journal of Med. Research* (Boston, U. S. A.), May, 1915, p. 251.

with appearances suggesting round-celled sarcoma. Scott and Gaylord have already detected a so-called cancer in the thyroid of teleostean fishes, where the gland is unencapsuled, a fact which influences the mode of growth of the neoplasm. The clasmobranch thyroid is definitely encapsuled. Two other points deserve notice. First, these changes were detected in wild fish, and as Gaylord has pointed out, such occurrences are rare. Secondly, they affected animals for which a constant amount of iodine is readily accessible. Cameron and Vincent add that in fresh water fishes iodine is a valuable curative agent, whether given inorganically or in organic combination in the American butter fish, which is not, it must be remembered, the *Gunellus*, a marine fish so-called by English naturalists, but the *Stromateus triacanthus*, allied to the mackerel.

LIGHT ARMOUR.

THE possible advantage of light armour as a protection against bullets and fragments of shell seems to have appeared more to the French than to the other nations at war, but even in France opinion is by no means unanimous. Dr. Caradee of Brest speaks well of plates of sheet steel moulded to cover the head, the heart, and the lower abdomen. If these three vital regions could be effectually protected, he says, 60 per cent. of serious wounds would, according to the estimate of Dr. Pouliquen, be prevented. The armour plates which have been designed by M. Boulevard, of the same seaport, weigh only 115 to 120 grams, and have stood the test of experiment well. On the other hand, an official communication, of which the following is a translation, has been issued to the French press: "The attention of the Minister for War and the military authorities has on several occasions been called to the dangers attending the use of cuirasses and other protective appliances invented and sold since the outbreak of hostilities by certain tradesmen in France. Experiments have been made which show that these cuirasses and appliances are often not strong enough to afford effective protection against bullets. Their only effect is to deform or deflect the bullets, or sometimes to give them a movement of rotation. In this way wounds which might not have been dangerous acquire an extremely serious character. In consequence it is important to call the attention of the public to the dangers attending the use of various types of cuirass on sale in commerce."

VACCINATION IN AUSTRIA.

THE steadily-spreading epidemic of small-pox in Austria has led to an organized agitation for the introduction of compulsory vaccination. Hitherto this agitation has not convinced the authorities that the populace would submit to compulsory vaccination, but where legislative measures might have failed, the presence of small-pox has induced great numbers to submit voluntarily to vaccination. Dr. Ernst Mayerhofer states,¹ as the result of investigations on the frequency of vaccination among children in Vienna, that in 1914 of the children in the second to the fifth year inclusive 82.4 per cent. were unvaccinated. Between the sixth and seventh years there was a sudden rise in the number of vaccinated children, and between the seventh and fifteenth years as many as 86.3 per cent. were vaccinated. Down to the end of 1914 it was as rare to find an unvaccinated adolescent among the working classes as it was to find a vaccinated infant. Towards the end of 1914 and early in 1915 the spread of small-pox evoked a great demand for vaccination. The public was urged by the medical and lay press not to neglect vaccination, with the result that during the first quarter of 1915 the proportion of vaccinated children under school age was 56.7 per cent. as compared with 17.6 per cent. for the same age in

1914. Of the children between the ages of 7 and 15 years, 96.2 per cent. were vaccinated as compared with 86.3 per cent. for the same age in 1914. It has been estimated by v. Jaksch that 96.2 per cent. of the adults in Prague were vaccinated in the decade 1902 to 1912. Dr. Mayerhofer does not consider this percentage high enough, for the remaining 3.8 per cent. of the adult population is quite sufficient to feed the present epidemic indefinitely, especially as the unvaccinated belong to the lowest strata of society. Again, the popular practice of deferring vaccination till children have reached the school age or later is, he urges, a grave source of danger. In the absence of legislation, revaccination is commonly neglected, as the public is apt to overestimate the value of the first vaccination in early childhood. For these reasons Dr. Mayerhofer urges the necessity for compulsory vaccination, and argues that such a measure, so far from curtailing the liberty of the individual, would enable him to avoid the far stricter measures, including compulsory isolation, to which persons are subjected who have contracted small-pox, or are merely suspected of having been in contact with the victims of this disease.

WAR GRADUATES IN FRANCE.

A THESIS for the doctor's degree has lately been presented to the University of Paris by M. Perrin of Grenoble in somewhat unusual circumstances. It was written in hospital while the author was recovering from severe shell wounds of the leg, and dealt with the treatment of conditions which he had seen in the field and the trenches, and of which he had had experience in his own person. His courage had won for him, besides a mention in army orders, the Military Medal and Cross. Professor Landouzy, Dean of the Faculty of Medicine, who was present at the ceremony, recalled that on July 16th, 1815, some military surgeons had presented their theses to a jury of which Larrey, Percy, Puel, and Desgenettes were members. Among them was Professor Landouzy's grandfather. The dean said the medical officers of 1915 were more fortunate than those of a century ago, for whereas their predecessors had to appear before their examiners while the Allies were encamped in the Champs Elysées, M. Perrin and his fellows had victory before them. M. Landouzy took the opportunity of congratulating not only the candidates, but all the French doctors at the front and in the hospitals on the admirable work they were doing. In the long line stretching from the plains of the Yser to the ridges of the Vosges already sixty auxiliary officers and nearly one thousand médecins-majors had lost their lives. Professors Letulle, Couvchaire, and Hartmann also congratulated M. Perrin, who was wearing his decorations.

THE President of the French Republic recently received a deputation representative of the Association Générale des Médecins de France. M. Poincaré consented to become patron of a fund which the association is raising in aid of doctors who are serving with the army. The number is estimated at 14,000. Many of these must be ruined by the loss of their practices. Among the members of the committee are Dr. Langlet, Mayor of Rheims; Professor Combemale, Dean of the Medical Faculty of Lille, and the deans of all the other medical schools of France; the presidents of the principal medical societies; the doctors who are members of the Senate and Chamber of Deputies, and representatives of the medical press. Before any public appeal was issued a sum of nearly £2,000 was contributed.

A MEETING of the War Emergency Committee for England, Wales, and Ireland will be held at the offices of the British Medical Association on Wednesday next, August 25th.

¹ *Wien. med. Woch.*, June 19th, 1915.

THE WAR.

RECENT BRITISH EXPERIENCES IN THE TREATMENT OF INJURIES IN WAR.

A Memorandum on the Treatment of Injuries in War based on Experience in the Present Campaign has been added to the list of publications issued by the War Office.

In a short preparatory note Sir Arthur Sloggett, K.C.B., the Director-General in France, states that the handbook has been prepared with a view to summarizing the experience gained in the military hospitals in France during the last ten months, and of obtaining some uniformity of methods of treatment based upon the definite observations that have been made. The recommendations contained in the volume are designed to meet the conditions under which the medical service has been working, and therefore have regard to the actual character of the wounds, including the special features dependent on climatic conditions, environment, and new methods of warfare, and to the primary transport of sick and wounded men from the field and the rapid transference of patients to home hospitals, which restricts the treatment of any individual case to a limited part of its course. In the various sections a distinction is, where possible, drawn between methods suitable for the front and the base respectively. The conditions of the campaign in France have caused the surgical treatment of patients to be divided into three more or less distinct stages: (1) At the field ambulances and casualty clearing stations; (2) at the various medical bases in France; and (3) at the actual medical bases at home.

General Management of the Wounded.

The first part of the book deals in a general way with wounds at field ambulances and casualty clearing stations. The practical point is at once made that in every convoy of wounded there are always some men in a serious state of collapse due to bleeding, exposure and hunger, serious visceral injury, extensive shell wounds, especially when associated with fracture of the long bones, and particularly of the femur, or to the infliction of multiple injuries by shells and bombs. Such men should be allowed to rest quietly for an hour or two before an attempt is made to dress their wounds. If the collapse be severe, and especially if it be due to hæmorrhage, the injection of normal saline subcutaneously, intravenously, or continuously by the rectum is indicated, and pituitary extract has been found very useful in many cases. Subject to this qualification, it is pointed out that it is of the utmost importance that the first field dressing should always be removed as soon as possible; it may have been applied by the soldier himself or his comrade; it has been soiled by dirty clothes and with dirty hands and often applied to a dirty skin, and it has almost always been put on too tightly. Medical officers and orderlies are instructed to wear clean aprons or gowns, and to use sterile rubber gloves if wounds are explored with the finger or opened up for drainage.

Antiseptics and Drainage.

In discussing the methods of cleansing the wounds it is pointed out that drainage tubes will often be required, and the use of very large tubes, $\frac{3}{4}$ to $\frac{1}{2}$ tubes with numerous large lateral openings, is recommended. It is stated that observation of a very large number of cases has shown that the provision of adequate drainage suffices to prevent any serious extension, general or local, of infection which has already occurred, and in conjunction with proper mechanical methods of cleansing forms the essential element in the primary treatment of gunshot wounds.

Experience has, it is said, been disappointing as to the efficacy of any antiseptic medium to inhibit bacterial growth within the soiled wounds produced either by shell fragments or shrapnel or by rifle bullets where the apertures of entrance and exit depart from the simplest type; antiseptics enumerated as having been found useful in the primary treatment of wounds are 2 per cent. solution of iodoine in spirit, solutions of carbolic acid in strength of 2½ to 5 per cent., lysol solution (1 drachm to 1 pint), biniodide or perchloride of mercury (1 in 1,000), and 1 per cent. picric acid which is a useful anodyne for multiple superficial wounds caused by small fragments of high explosive shells or bombs and by dirt and stones which they drive in. Hydrogen peroxide (5 to 10 volumes) has,

it is stated, been extensively employed in wounds soiled with soil, and it has often been used as a preliminary to the application of one or other forms of antiseptics or mixed with them. The importance of sending down with the men a proper account of what has been done is insisted upon in a paragraph headed "on the filling up of tallies," and directions are given for their completion. Next the secondary cleansing of wounds and their later treatment is discussed, and it is stated that the application of powerful antiseptic media to the wound has been found undesirable. The advantages of the hypertonic solution described by Sir Almoth Wright in our columns last April are mentioned, but it is stated that its substitution for all antiseptic media in military hospitals cannot be considered safe or advisable; a hypertonic solution, it is added, may form the basis, to which an addition of carbolic acid, 2 per cent., may be made.

Gas Gangrene.

There is a short discussion on the etiology and pathology of gas gangrene and gaseous cellulitis, and it is stated that the general indication for treatment consists in the removal of as much blood clot and devitalized tissue as possible, provision of free access to the air and efficient drainage.

Tetanus.

The next section of the book deals with tetanus. The results of directing that a preventive dose of serum should be given to every wounded man are stated to have been excellent. A large number of cases occurred during the first two months of the war, but in the last six months there were only 36 cases of the disease among those who received a preventive dose of serum within twenty-four hours of being wounded. In the same period 34 cases of severe tetanus were reported among the very small fraction of wounded men who, for one reason or another, did not receive a preventive dose of the serum within twenty-four hours; 32 of these men died, a case mortality of 94.1 per cent., whereas among the 36 cases which occurred among the enormously larger class of wounded who received a preventive dose only 28 died, a case mortality of 77.7 per cent. The preventive dose recommended is 500 units given subcutaneously at the earliest possible moment; it is added that though doses of 1,500 units have not infrequently been given there is no evidence that the smaller dose is insufficient if promptly administered.

Injuries of Bones and Joints.

After notes upon recurring and secondary hæmorrhage, upon amputations, upon wounds of the great vessels and aneurysms, we come to an important section on the treatment of fractures. Particular attention is given to the treatment of fracture of the thigh, and in an appendix the application of certain splints, including the modified Thomas's splint recommended by Mr. Robert Jones in our columns last January, and the splint designed by Mr. Page and described, also in our columns, last May, are illustrated. The treatment of wounds of joints is next considered. In an introductory paragraph the common types of injuries are summarized in four classes. First mentioned are cases of effusion without lodgement of the projectile in the joint, which are said to be obvious subjects for expectant treatment. The second class is constituted by cases in which the projectile has lodged within the synovial cavity or in one of the articular ends; a rifle bullet retained within a joint may in favourable circumstances, it is held, be left until firm union of the primary track has occurred; free fragments of shell or bombs or distorted rifle bullets should be promptly removed. If embedded in one of the articular ends, bullets may often be left, but fragments of shell, since practically all carry in infective material, should be removed by the shortest and safest route. The third class of cases enumerated are those in which the synovial cavity has been more or less widely opened; in such cases careful treatment of the wounds and immobilization of the joint may lead to sealing of the opening, though drainage of the joint is often called for at a later period. The fourth class of cases is constituted by those in which serious comminution of one or more of the constituent bones has occurred. It is stated that, generally speaking, if the joint is extensively shattered and soiled, especially if the main vessels or nerves are torn, primary amputation may be

necessary, but that comminution of the condyles or of the head of the tibia, for example, does not necessarily indicate operation. The importance of immobilization is insisted upon, and it is stated that one of the best splints for the less severe cases is the gutter "fracture splint" recommended by Major Robert Jones.

Injuries of the Head.

With regard to the treatment of head injuries, it is pointed out that some of the symptoms of injury to the brain—such as the effect of shock, local oedema, or concussion—are only temporary, and that before undertaking any operation it is desirable to have a clear idea as to what its aim is, what result is to be anticipated from it, and how best that result is likely to be attained. The objects enumerated are the relief of symptoms of cerebral injury, the prevention of complications in the future, and the cleansing of the wound and removal of bone fragments and missiles. Loss of consciousness, headache, slowing of the pulse, and blurring of the optic discs which often occurs quite early, are produced by pathological increase of intracranial pressure due to traumatic oedema and small haemorrhages not confined to the neighbourhood of the injury, for the whole brain is bruised and oedematous. The pressure is rarely sufficiently high to require relief by operation. The course of cases due to destruction of cerebral tissue cannot be influenced by immediate operation. The conclusion, therefore, is that early operation is very rarely called for on account of cerebral symptoms whether general or local. In severe cases the essential point in treatment must be the provision of adequate drainage for damaged brain tissues. With regard to decompression it is stated that in view of the facts that the early rise of intracranial pressure is rarely of sufficient degree to require a decompressive operation, and that lumbar puncture will give at least temporary relief, that progressive haemorrhage is in these cases a condition of great rarity, and that when widespread infection exists the majority of cases are hopeless (local abscesses excepted), it is clear that an operation of decompression is rarely called for. When such is required, however, it may be done locally or contralaterally, and the disadvantages of the local operation are briefly indicated.

Injuries of the Chest.

The pathology and treatment of penetrating chest wounds are next considered. The importance of absolute rest at first in the recumbent or semirecumbent position is insisted upon. A third of a grain of morphine given subcutaneously as soon as possible has been found to relieve the pain and spasm, and to allow the other lung to do its work; the morphine may be repeated in a similar dose for the first day or two. No movement should be permitted for several days, but at the end of a week the patient may be sent to the base. With regard to treatment it is stated that "it has repeatedly been found by autopsies on those who have died with progressive dyspnoea and cyanosis from the fourth or fifth day onwards that the fatality was not the result, as is generally supposed, of continued bleeding, but that it was due to the rapid development of an infection in the haemothorax."

Wounds of the Abdomen.

In discussing wounds of the abdomen it is stated that haemorrhage and perforation of the hollow viscera are the two chief complications of all abdominal wounds. The majority of the patients, it is stated, who arrive at the clearing stations are too ill to permit of any operation being done. When the question of making an exploration arises due weight must be given to the condition and surroundings of the patient before and after its performance. Useful hints are given as to the symptoms which may assist in determining what viscus is injured, and it is stated that "when a bullet traverses the abdominal cavity the injuries it inflicts are commonly multiple. Not only are several coils of small bowel usually shot through, but the same bullet may wound also the large bowel or extensively lacerate the mesentery or the vessels of the omentum, and may injure also the solid viscera. It necessarily follows that such patients bleed from many injured places, and it may be said truly that if a man with a wounded intestine dies within thirty-six hours his death is due to bleeding, and not to the fact that a hollow viscus was perforated. In the majority of cases of wounds of

the small intestine there is practically no escape of the contents."

Injuries of the Ear and Eye.

With regard to the treatment of injuries of the tympanic membranes due to shell explosions, the dangers of syringing or the introduction of lotions, especially hydrogen peroxide, are insisted on, and it is stated that the best treatment has been found to be a light application of 2 per cent. iodine solution in spirit to the cartilaginous portions of the external auditory meatus, and light plugging with cotton wool.

A short essay on the treatment of injuries of the eye is followed by notes on trench foot or frost-bite, in which prophylactic measures are described.

Gas Poisoning.

The last section of the book deals with gas poisoning. In the symptoms produced by "drift gas" three stages are recognized: (1) That of direct poisoning, which may cause death in a few hours; (2) that of oedema of the lungs with general asphyxia, which may cause death at any time from the first to the fourth or fifth day; and (3) the secondary infections of the bronchial passages and lungs which, when they occur, cause purulent bronchitis, bronchopneumonia, pleurisy, or even pyæmia or gangrene of the lungs. Such cases may end fatally in the second or third week. Most men who have survived to the third week have recovered, at any rate from the acute illness. The symptoms also are divided into three classes: (1) Those due to irritation of the respiratory tract; (2) those due to gastric irritation; and (3) general toxic effects. To check bronchial spasm and lessen the oedematous flooding of the lungs during the first twenty-four hours atropine is given in doses of $\frac{1}{16}$ grain every four hours, and it is stated that ammonium carbonate in 10 grain doses every six hours is also useful. Vomiting, which relieves the stomach, and may help to empty the lungs temporarily, appears to be advantageous and may be provoked: oxygen inhalations have been found useful. When, from the second day onwards, the oedema of the lungs is established and bronchial spasm has ceased, oxygen still gives relief, but extreme cyanosis with a full pulse requires venesection to about 15 oz. Except when secondary infection occurs the men who have escaped death in the first few days recover quickly, and, so far as is known, completely, but all cases should remain in hospital until the fine rales have vanished from the axillae and base of the lung.

The book has a good index and is of handy size for the pocket. No more practical work could be imagined. It is concise and seems to deal with every debated point likely to cause perplexity to the surgeon first confronted with wounded men. It states briefly but fully the lines of treatment which those who have had experience in the present war have found to be the best, and it contains enough discussion of pathology to make plain the reasons for the recommendations made.²

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

SCIENCE AND THE ARMY.

Mobile Laboratories.

At no time during the last ten years and more has it been possible to charge the Medical Department of the War Office with failure to take advantage of the progress of medical knowledge. Very numerous examples of its full recognition of the value of science could be adduced, but perhaps none has been quite so concrete and striking as the introduction into field operations of the mobile laboratories whose general construction was the subject of a recent note in the BRITISH MEDICAL JOURNAL.

In the early stage of the war there were only one or two of them, but there is now quite a fleet. They differ to some extent in minor detail, but each is so constructed that it can follow the section of the army to which it is attached wherever this goes, so that it can do its work if necessary even in a neighbourhood where buildings are

² The volume has not been placed on sale, but it is, we understand, being circulated to medical officers at home and abroad.

entirely lacking. The practical mobility of the laboratories is still further increased by small vehicles, one of which is attached for work with each laboratory and used for the collection of specimens, or for visiting other localities at moments when it is not considered desirable to move the laboratory itself.

The common aim of the laboratories is to provide any additional scientific data which may from time to time be required when the general principles of preventive medicine are being applied at the real front. In other words, they are part of the general machinery for maintaining the health of the troops, and for lessening the wastage due to contagion, or to air-borne, food-borne, or water-borne disease.

Their precise work seems to vary from time to time, but I understand that while a few are habitually occupied with questions relating to the maintenance of adequate supplies of potable water, the rest are engaged in the bacteriological diagnosis of suspected cases of zymotic disease, and the discovery of the infection in recognized cases.

An idea of the work they do may perhaps best be conveyed by a few notes as to what the writer has himself seen at more or less frequent visits to three of these laboratories, which will be designated "A," "B," "C."

At "A" laboratory the principal work in progress seemed on different occasions to be—

(a) The testing of the urine of every man of one whole division who was known or suspected to have previously suffered from enteric fever, with a view to the discovery and removal of typhoid carriers.

(b) Testing the effect of the inoculations of living cultures of *B. typhosus* in acute cases of true typhoid. The underlying idea was that if such inoculations proved to be harmless (as might be anticipated from the results of the researches on the effects of living plague vaccines as published on various occasions in the *Journal of Hygiene*) it would be desirable to try them therapeutically on a large scale. Apart from the possibility of the inoculations setting up natural antigen factories in the subcutaneous tissues, there were many reasons for believing that the antigen contained in a living culture must be more normal and therefore more potent than that in a killed culture.

(c) The diagnosis of cases of cerebro-spinal meningitis and the watching of contacts.

(d) Supervising bacteriologically the treatment of acute cases of this disease by various specific means, including a living culture of the meningococcus, and comparing the results.

At "B" laboratory most of the time of my visit was spent in the study of a series of annotated maps relating to work of two quite distinct classes. One set bore upon the possible sources of potable water in the district behind a considerable section of the Allied line, and showed that at one place the outfall of a natural catchment area had been raised; that at another an artesian well had been sunk; that at a third the equivalent of a sedimentation reservoir and of a distribution reservoir had been created in connexion with an existing water source.

The second set of maps, charts, and figures related to work which had for some time been completed and was of quite a different order. This was the task of dealing with the epidemic of typhoid fever among the Flemish which led to the opening of the hospital at Mallassise described in the *JOURNAL* some months ago. I gathered that the measures adopted included compulsory notification of typhoid fever and that the position of a Belgian civilian sanitary authority had been conferred upon those engaged in the work, who were thus empowered to remove cases for isolation and to insist on antityphoid inoculation. In the event it does not seem to have been found necessary to use compulsion of any kind; the whole of the part of Belgium concerned is Roman Catholic, and the village priests co-operated heartily with the British authorities. The net result, in addition to all actual cases being brought under treatment and the homes of the patients put into proper sanitary condition, was that over 20,000 people sought the protection of antityphoid inoculation, and that about 80 per cent. of these returned for the desirable second dose.

At "C" laboratory, which I found at a place behind the fighting line, the work was varied. Investigation of suspected cases of typhoid formed the staple occupation, but other forms of disease, such as diphtheria and cerebro-

spinal fever, had also been investigated, and, in addition, a good deal of work in general pathology was done.

It was, for instance, in this laboratory that I gathered the information furnished in one of these notes a little time ago as to the *post-mortem* appearances in cases of gas poisoning that succumb within a few hours. It was also in "C" laboratory that I heard of a case on which might perhaps be founded an interesting contribution to the study of the so-called gas gangrene. In a patient who had a gunshot wound of the arm gas gangrene occurred not only in the wound itself, but at several distant spots where there was no visible lesion. One of these was in the sound arm at the spot where a dose of morphia had been introduced at a casualty clearing station. It is clear that the gas-forming organisms concerned in this case must have possessed an exalted capacity for multiplying themselves; yet this did not seem to be accompanied by any evidence of special virulence. At all events, the patient made a good recovery.

Some other facts mentioned to me by the officer in charge of this laboratory on the occasion of one of my visits possibly explain why there has been so much acute difference of opinion as to what is the organism to which the occurrence of gas gangrene must be ascribed. Early in the war, when working at a hospital at home, he had found a class of organism to predominate in gas gangrene cases which he had encountered comparatively rarely after he had begun to work at the real front with quite fresh wounds.

The day's work seemed to be fairly equally divided, as a rule, between indoor and outdoor occupation. The early hours were devoted to examining the previous day's cultures, and assessing the results, to dispatching telegrams and other reports on completed investigations, and then starting a new series of cultures and fresh investigations. In the afternoon a visit had generally to be paid to some unit for the purpose either of obtaining material for the investigation of a case, or of consulting with the medical officer in direct charge of the men among whom a suspected case of typhoid had occurred, or with the A.D.M.S. of the division to which the detachment belonged. In the evening a certain number of field telegrams notifying cases requiring examination or bearing on questions already under investigation generally arrived, and replies stating the steps it was proposed to take had to be sent.

The problems that arose were varied, but in most cases the primary question was whether bacteriological evidence supported a suspicion that a given patient was suffering from typhoid fever and should therefore be sent to the base. If the answer was in the affirmative the next question was, "How did the patient become infected?" In deciding the latter point the rule was to hunt not only for some inanimate source of infection, but also for a carrier or previous case of typhoid among the patient's companions or among civilians with whom he might have been in contact when in billets or elsewhere. The procedure in regard to other zymotic disorders was of an analogous kind, and it was clear that the co-operation between all persons concerned—namely, the regimental medical officer, the divisional A.D.M.S., the bacteriologist, the D.M.S.Armey, and the D.G.M.S. was very close.

I also learnt that spot maps and charts relating to the history of every unit in respect of typhoid and general zymotic disease were kept both at the head quarters of divisions and at the principal sanitary base. As this had been the rule from the beginning the amount of information now acquired must be so large and complete as to put the sanitary authorities of the army in a very good position for controlling outbreaks of epidemic disease—so far as this task depends on knowledge of the probable sources of any outbreak—despite the constant growth in the size of the army and the numbers of its units. It is impossible, in fact, not to feel much impressed by the way in which the whole business of dealing with zymotic disease is managed, including in this statement the steady endeavours made to bring the percentage of typhoid protected men up to 100 in every unit.

The net result has been to keep the zymotic morbidity curve, and especially the typhoid curve, down to a level which has so far been satisfactorily low, and which will probably be deemed quite remarkably low when information as to the corresponding figures for the armies of our

allies and of the enemy becomes more complete and general.

As for the part played in the matter by the mobile laboratories, the account already given of their work is sufficient to indicate its importance.

Being an entirely new departure in the medical history of war their introduction has given rise to a good deal of interest and discussion, and I have heard it claimed that the same scientific needs could have been met by less original and less expensive means. This, of course, is an arguable proposition, but the fact remains that these mobile laboratories, besides being effective in themselves, anticipate all the possibilities of a campaign more completely than could any laboratory which was dependent on its environment for its ability to work, and that the responsibility for their introduction rests upon shoulders well able to bear it—namely, those of men who have nothing to learn from anyone as to possible ways of bringing science to bear on the problems of active service, and their respective advantages and disadvantages.

It may be noted, in conclusion, that to take charge of one of these mobile laboratories cannot be regarded as any man's job. To perform its duties successfully the holder of such a post must be a good deal more than a mere laboratory expert. He has to deal with problems which have clinical and military as well as scientific aspects, and he sometimes has to influence men—combatant officers and others—who have no profound respect for science in itself. He must also be a man who, whatever his enthusiasm, is capable of refusing to allow his attention and energies to be diverted from his direct duties by the hundred and one interesting side issues that they open up. Finally, if he be in charge of one of the more advanced laboratories, he must not only be physically strong, but be prepared to shrug his shoulders at the risk involved by visiting areas which are at times, in soldier's parlance, more or less "unhealthy."

NOTES ON SOME CASES UNDER TREATMENT AT THE 2ND EASTERN GENERAL HOSPITAL, BRIGHTON.

BRIGHTON has become one of the chief centres in England for the treatment of sick and wounded, and we have from time to time published notes of interesting cases treated there. The following are some further notes of cases:

Bullet Wound of the Face: Facial Paralysis and Total Deafness.

A man was shot in the face by a bullet which entered a little to the outside of the external canthus and made its exit behind the mastoid process. It caused complete facial paralysis which has not improved during the time—three months—which has elapsed since the man was shot. Undoubtedly the facial nerve was severed. There is also total deafness on the left side, due probably to an injury of the eighth nerve during the passage of the bullet.

Cases of Compound Fracture of the Leg not due to Bullet Wounds.

Although the great majority of cases of compound fracture admitted to the hospital have been caused by gunfire, there are a few instances which have been due to other causes. The first case was that of a man who was kicked by a horse on the shin; both bones were broken, and the fracture was compound. The fracture could not be got into good position by the ordinary methods of reduction. The wound in the soft parts soon healed, and the patient was operated on; the broken ends of the bones were secured in position by means of a plate.

In a second somewhat similar case no union occurred after two months, and the bones were not in good position. The fracture was accordingly cut down upon, and a piece of bone, about 3 in. long, removed from the tibia was used as a splint to keep the broken ends together. The result was to increase considerably the callus formation, although there was no improvement in the position of the broken bones.

Many Wounds of Hand by High Explosive Shell.

A man was shot in the hand, receiving a very large number of small wounds. An x-ray photograph showed

a number of tiny pieces of metal, some dozens in all. A few which were causing trouble were removed. Only a high explosive shell could have caused this wound, as shrapnel does not break up into such small fragments.

Fracture of the Necks of Four Metacarpal Bones.

A man was shot in the hand by a bullet which entered on the dorsal surface of the neck of the fifth metacarpal bone. It made its exit at the level of the second metacarpal, fracturing all four inner metacarpal bones at their necks. The wounds of entry and exit soon healed, and the hand is now in good condition, with the exception of slight swelling and stiffness, which probably massage will soon correct.

Some Examples of Explosive Wounds.

By an explosive wound is meant a bullet wound in which the destruction of tissue, especially on the exit side, is very great. In practically all cases the bullets have shattered the bones, though there are a few examples recorded in which the bullet has only traversed soft parts. In an explosive wound the exit wound is much larger than the entry wound, being represented by a funnel-shaped cavity which extends to the bone, which is pulverized and comminuted, especially if a long bone, fragments being driven in all directions, often for a considerable distance, leaving a space between the ends of the shaft. The soft parts—vessels, muscles, tendons, and nerves—are lacerated, and project from the cavity of the wound, which is bounded by jagged skin flaps. With this extensive injury on the exit side, the wound of entrance may be quite small.

Such extensive injuries were at one time supposed to be due to the employment of explosive bullets or small-arm shells, contrary to the Geneva Convention, but this is now proved to be, at least in the great majority of cases, incorrect. Solid rifle bullets, provided they strike with sufficient velocity, and encounter considerable resistance, can, and do, produce explosive wounds.

All the various theories—the theory of hydraulic pressure, of rotation of the bullet, of heating of the bullet, of deformation of the bullet, of the structure of the bullet, of compressed air, etc.—are, on careful testing, found to be incorrect. The true explanation is that the explosive wound is due to the high velocity of the bullet, and therefore the large amount of energy inherent in it at the moment of impact. This energy is communicated to the resistant bone, which is shattered, the pieces acting on the neighbouring parts as secondary missiles and causing laceration of the soft tissues.

In one case of explosive wound of the lower jaw caused by a rifle bullet there was a wound of the lower jaw on the right side, showing a large lacerated cavity with several pieces of comminuted bone. The jaw was kept in good position by means of the ordinary jaw bandage, and the wound healed with only slight deformity after the separation of several pieces of bone.

In a case of explosive wound of the shoulder from a rifle bullet the wound of entry in front of the shoulder was quite small. The exit wound at the back of the shoulder was of a typical explosive character—a cavity as large as one's fist. The head of the humerus was blown right out of the wound.

Explosive wounds of the wrist, of the metacarpus, and of other parts of the body have also been met with. This type of wound, although not uncommon, does not form a very large percentage of the cases admitted. It is impossible to ascertain at what range these injuries are received, as under present conditions of fighting very few men know where the weapons of their opponents are fired from.

"Wind Contusion."

In former times severe cases of gunshot injuries were met with without any sign of wound or contusion of the skin. These injuries were said to be due to "the wind of the shot." This explanation is denied by modern military surgeons. Stevenson, in the latest edition of his book on wounds in war, says: "But the question of the so-called 'wind contusion' hardly requires discussion in these days. So many cases of shot passing as close as possible to men without absolute contact in which wind contusions were not produced are now on record, that it is evident that the wind theory does not explain the condition of things referred to. These injuries are always the result

of solid shot, unexploded shell or grape, or of large fragments of shell."

"The results of the explosion of the latest very powerful high explosive shells make it almost certain that this statement will require revision, and that this old theory of "wind contusions" is, in some cases at least, accurate. Men are knocked out by the concussion of these shells without being touched by them.

A high explosive shell from a gun of about 8 in. calibre struck the ground and exploded, blowing to pieces a large number of men. An officer standing quite close to the spot where the shell struck the ground was knocked down and lost consciousness. He was certain that he was not struck by any part of the shell; it was simply the force of the concussion which knocked him over. He stated that this was a quite common occurrence. He must have regained consciousness rapidly, for the first thing that he remembers is that on recovering his senses he was breathing asphyxiating gas. He pulled his smoke helmet down at once. "This saved his life, for thirteen of his men died from the poisonous fumes given off by this shell.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed.

COLONEL NEVILLE MANDERS, Army Medical Staff, was killed in the Dardanelles on August 8th or 9th. He was born at Marlborough on December 12th, 1859, the youngest son of the late Major Thomas Manders, 6th Dragoon Guards (Carabineers) and educated at Marlborough. After qualifying as M.R.C.S. in 1883, and L.R.C.P.Lond. in 1884, he entered the army as surgeon on August 2nd, 1884, becoming surgeon-major on August 2nd, 1896, and lieutenant-colonel on August 2nd, 1904, and being promoted to full colonel on December 21st, 1913. He served in the Soudan in 1885, at Suakin, receiving the Egyptian medal with a clasp and the Khedive's bronze star; and in Burma in 1885-89, when he was severely wounded, and gained the Indian Frontier medal with two clasps. On promotion to colonel, he was appointed Principal Medical Officer in Egypt, and in January, 1915, went from Egypt to the Gallipoli Peninsula as Assistant Director of Medical Services with the Australian and New Zealand Army Corps. He is the first medical officer of the rank of full colonel who has fallen in the war.

Major Samuel Jabez Richards, of the Australian Army Medical Corps, the bare fact of whose death was announced last week, died of wounds received in the Dardanelles, at the age of 51. He was then in command of the first Australian Clearing Hospital. He attained the rank of major on March 8th, 1913.

Captain Arthur Kellas, R.A.M.C.(T.F.), is also reported as having been killed in the Dardanelles on August 6th, aged 31. He was the youngest son of the late James F. Kellas, Superintendent of Mercantile Marine at Aberdeen, and was educated at Aberdeen University, where he took the M.B. and Ch.B. in 1906, the D.P.H. in 1907. After qualifying, he held the post of resident physician and surgeon of the Royal Aberdeen Hospital for Sick Children, and, when called up for active service, was senior assistant physician of the Royal Asylum, Aberdeen. After serving in the university troop of Scottish Horse, he joined the 1st Highland Field Ambulance, in which he became captain on August 2nd, 1912, and was serving as second in command of this ambulance, with the 29th Division, when he was killed.

Died of Disease.

We regret to have to record the death of Lieutenant-Colonel G. A. Edsall, R.A.M.C.(T.F.), commanding officer of the 13rd Home Counties Field Ambulance. He had been at the front for several months, and had contracted pleurisy. He was invalided home, but died at his house in Surbiton on August 15th.

Wounded.

Major D. S. Skelton, R.A.M.C., Dardanelles.
Lieutenant (temporary) E. W. Adcock, R.A.M.C., Dardanelles.
Lieutenant (temporary) M. J. Cronin, R.A.M.C., Flanders.
Lieutenant (temporary) C. M. Harris, R.A.M.C., Flanders.

Lieutenant C. R. Dudgeon, R.A.M.C. (Flanders).

Lieutenant R. P. Nash, R.A.M.C., attached 1st Battalion Lincoln Regiment (Flanders).

DEATHS AMONG SONS OF MEDICAL MEN.

Chisholm, William Malcolm, who died at Ligny on August 27th, 1914, from wounds received on the previous day, was the son of Dr. William Chisholm of Sydney. He was educated at Sydney Grammar School, entered Sandhurst in 1911, passed out in 1912, and received his lieutenancy in the East Lancashire Regiment in 1913.

Morgan, John Cecil, Captain 6th Battalion Yorkshire Regiment, only son of John H. Morgan, C.V.O., F.R.C.S., consulting surgeon to Claring Cross Hospital, was killed in the Dardanelles, aged 39. He joined the 3rd York Militia in February, 1899, and served in the South African war, became captain in 1906, and resigned in 1909. He rejoined the army with the rank of captain on October 4th, 1914. He was educated at Trinity College, Oxford, where he took the M.A. degree.

Payne, Henry Tonkin, Second Lieutenant 3rd Battalion Essex Regiment, son of Dr. Payne, of Witham, Essex, killed in the Dardanelles on August 6th, aged 22. He was a tea planter in Ceylon, and came home and enlisted in the 5th Battalion of the Essex Regiment when the war began, receiving a commission in the 3rd (Reserve) Battalion of the same regiment on March 6th, 1915.

Pirrie, R. Bowen, Lieutenant 1st King's Shropshire Light Infantry, who was killed on August 10th, while leading his men to the assault on the Hooge trenches, was the eldest son of Lieutenant R. R. Pirrie, M.D., R.A.M.C., of Ryton-on-Tyne. He was 21 years of age.

Medical Student.

Sutherland, James Gilbert, Second Lieutenant 11th Battalion Highland Light Infantry, son of Andrew Sutherland, of 7, Hope Park Terrace, Edinburgh, died in France on August 11th of wounds received on the previous day. He was educated at Edinburgh University, where he was a corporal in the O.T.C., and, after taking the M.A. degree, was pursuing the medical course with a view to qualifying as a dental surgeon. He got a commission on August 30th, 1914, and went to the front in May, 1915. His brother, also a dental student, is serving in the artillery.

NOTES.

MEDITERRANEAN DISPATCH.

ON August 16th the Admiralty published a dispatch from Vice-Admiral John M. de Robeck, dated July 1st, reporting the landing of the army in the Gallipoli peninsula on April 25th and 26th. Among a large number of officers specially mentioned in this dispatch are the following medical officers: Surgeon P. B. Kelly, R.N., attached Royal Naval Air Service; temporary Surgeon W. D. Galloway, H.M.S. *Cornwallis*.

Honours.

Among the honours conferred on officers mentioned in this dispatch, the D.S.O. is bestowed upon Surgeon P. B. Kelly, R.N. The following is the record of the services for which he received the distinction:

Surgeon P. B. Kelly, R.N., was wounded in the foot on the morning of the 25th in *River Clyde*. He remained in *River Clyde* until morning of 27th, during which time he attended 750 wounded men, although in great pain and unable to walk during the last twenty-four hours.

Among those medical naval officers honoured for service prior to April 25th and 26th—that is, during the first attack on the Dardanelles by the navy alone—occur the names of Surgeon Martyn Henry Langford, R.N., who receives the D.S.O., and of Fleet Surgeon Edward Henry Meaden, R.N., and Surgeon John Harding Baynes Martin, R.N., who are commended for service in action.

The honour of D.S.O. received by Surgeon Langford is shared by three engineer officers of H.M.S. *Inflexible*. While the ship was steaming to Tenedos after having struck a mine, the engine-room being in semi-darkness and great heat, and the ship in possible danger of sinking on passage, Surgeon Langford brought up the wounded from the fore distributing station in the dark. Fumes permeated the place, rendering five men unconscious. Surgeon Langford, though partially overcome by the fumes, continued his work.

NAVAL LOSSES.

During last week the loss was reported of three minor units of the navy, all within two days: H.M.S. *Ramsey*, patrol vessel, sunk by the German armed liner *Meteor* on August 8th, the *Meteor* herself being blown up by her own crew to avoid capture a few hours later; H.M.S. *India*, armed liner, torpedoed by a submarine near the Lofoden

Islands; and H.M.S. *Lynx*, destroyer, mined and sunk in the North Sea, both on August 9th. In the first and third cases the majority of the ships' complements were saved, including three medical officers: temporary Surgeon F. W. Lawson and Surgeon-probationer J. T. Johnston on the *India* and Surgeon-probationer R. P. Langford-Jones on the *Lynx*. The *Ramsey* does not appear to have carried any medical officer. Unfortunately the loss of life on the *India* was large. The list of casualties occurring in connexion with the sinking of the transport *Royal Edward* in the Egean on August 14th has not yet been published.

ARRIVAL OF HOSPITAL SHIP IN DUBLIN.

On August 7th the hospital troopship *Oxfordshire* again arrived at Dublin from Havre with 611 wounded soldiers. A staff of officers and orderlies of the St. John Ambulance Brigade, under the direction of Dr. Lumsden, Deputy Commissioner, were ready on the quay to receive them, and to transfer them from the ship into the numerous motor ambulances and conveyances waiting for them. Of the 611 wounded men on board 597 were non-commissioned officers and men and 14 were officers. About fifty different regiments were represented; 150 men were dispatched in the Great Northern ambulance train to Belfast; of these 20 were stretcher cases. The Great Southern and Western ambulance train took 150 cases, leaving 50 at the Carragh and taking 100 to Cork. The remaining 311 men, about half of whom were stretcher cases, were distributed among the various Dublin hospitals. The fact that room could be made for these cases so soon after the arrival of the previous hospital ship was largely due to the opening of the Princess Patricia Hospital at Bray, which contains 200 beds, and is intended for soldiers who are not in need of active surgical treatment. This hospital was formally opened by His Excellency the Lord Lieutenant and Lady Winborne on August 3rd. Up to the present the Dublin hospitals have been considerably hampered in their work by being overfilled with chronic cases, as there were only a few small convalescent homes to which such cases could be sent.

HOTEL FOR PARALYSED SOLDIERS.

To those who are familiar with "fair Richmond's green retreats," as the poet physician, John Armstrong, called them in his *Art of Preserving Health*, there is something to touch the imagination in the announcement that the famous Star and Garter Hotel on the summit of the famous hill is to become a permanent home for paralysed and totally disabled soldiers and sailors. The splendid building, which in its time has lodged such personages as Louis Philippe, Victor Emmanuel when King of Sardinia, Napoleon III, the Empress Eugénie, the ill-fated Archduke Maximilian, and the father of the present German Emperor, will have a lease of new though more subdued glory. The hotel estate is being purchased by the council of the Auctioneers' and Estate Agents' Institute of the United Kingdom for presentation to the Queen, and her Majesty proposes to hand it over to the British Red Cross Society, which has undertaken to equip and maintain it. It is intended to devote the building chiefly to the purposes of a home for paralytics who are totally disabled, but that in addition to these bedridden cases it is proposed to assign the first floor to disabled men who are still able to walk up and down stairs. The ample ground floor, containing a number of large and lofty rooms which will form exceptionally fine wards, is to accommodate about 135 beds for the absolutely helpless (and for these alone). Each bed is to be provided with large wheels on ball-bearing joints, so that at every suitable opportunity the sufferers can be taken out on the beautiful terraces and grounds which command a view stretching away to Windsor Forest and the Surrey hills. In addition, it is intended to provide accommodation for fifty further cases of the same class by building in the garden, which is on the steep crest of Petersham Common, a little street of cottages and bungalows, each with one good room capable of accommodating four beds. These "garden city" residences will be of a permanent kind, built for use in winter as well as in summer. Thus, apart from the undetermined number of men who are able to walk, the totally helpless cases dealt with in the hotel and grounds will be 185. The upper portion of the building is to be devoted to the staff, save for a series of rooms forming guest chambers for relatives of the men, who will be invited to occupy them for

two or three days at a time. The soldier, when afflicted with incurable paralysis, is discharged from the army on a small pension, and the public dismiss him from their minds under the comfortable impression that he is well tended by his friends. Usually, however, neither his own means nor the means of his friends enable him to command the skilled and special nursing, nor the particular type of bed and other appliances desirable for his comfort. The result is that he becomes more or less a prisoner in a cottage bedroom, and any kind of outdoor life is an impossibility. The Richmond hostel will be handed over to Her Majesty as soon as the contracts are exchanged, and the annex will be opened for the reception of cases in about three months, although the extensive alterations necessary to the main building will take longer to complete, and plans for remodelling the interior are still under consideration. We understand that the hotel, which originally cost over £80,000, is being purchased for £21,500. To assist in raising funds for its acquisition, the president and council of the Auctioneers' and Estate Agents' Institute are appealing for gifts of real or personal property, which they will provide machinery for collecting and selling by means of Red Cross auctions similar to that held recently at Christie's. Any surplus will be handed over to the British Red Cross Society for equipment. Sir Howard Frank, of 20, Hanover Square, W., is the chairman of the joint executive committee which has the arrangements in hand.

AMERICAN COMMITTEE FOR WAR RELIEF IN FLORENCE.

When Italy decided to take part in the war a meeting of Americans resident in Florence was held to organize help for the Italian wounded. It was resolved to equip and maintain a hospital for convalescent privates discharged from the military hospitals but not yet able to rejoin the colours or return to their homes. For this purpose a committee was formed, and at its disposal the Villa della Sole di Camerata, with the sanction of the Red Cross authorities, was placed by its owner, Dr. E. Modigliani. It has accommodation for 100 patients, and stands in a large park and garden. It is fitted with modern appliances for heating, lighting, and sanitation, and is admirably suited for a hospital. The medical staff will be appointed by the American Committee. That Committee will further undertake such work as may be delegated to it by the medical authorities. The initial expense of equipment for 100 beds is an equal amount, and the monthly cost of maintenance at the hospital will be not less than £10,000 for one year. Towns resident more than £4,000 has been promised by America, and public in Florence, and an appeal is made to the general public of America for active support.

MEDICAL OFFICERS WANTED.

1st London (City of London) Sanitary Company, to fill Medical men with sanitary qualifications are required for vacancies for commissions in this company. Applicant to the Officer Commanding, 1st London (City of London) Sanitary Company, Duke of York's Head Quarters, Chelsea, S.W.

33rd Northumbrian Field Ambulance, R.A.M.C./T.F. Medical officers are required for this unit. After a period of training they will be drafted to replace casualties 1st Lt. or six in the Ambulance (now overseas). Promotion to Captain after 12 months' mobilized service. Pay and allowances as in regulations. Recently qualified men will be accepted. Applicant to Major Wm. A. Thompson, Commanding 33rd Northumbrian Field Ambulance, Royal Army Medical Corps (T.), 3rd Lt. Col., The Camp, South Dalton, near Beverley.

21st South-West Mounted Brigade Field Ambulance. Medical officers are wanted to complete this unit. Must be of Imperial Service obligation. Apply Captain Edwards, 2nd Lt. South-West Mounted Brigade Field Ambulance, Bowood Camp, Caine, Wilts.

Scottish Women's Hospital.

The Scottish Women's Hospital for Foreign Service invites applications from medical women for the post of pathologist and bacteriologist on the staff of the Wales and London Unit for Serbia, Honorarium at the rate of £200 per annum, together with uniform and all travelling expenses. There are also vacancies in this unit for qualified women assistant physicians and surgeons without remuneration, but uniform and travelling expenses are provided. Application to the Secretary of the Personnel Committee, Scottish Women's Hospital, 2, St. Andrew Square, Edinburgh.

Ireland.

REGISTRAR-GENERAL'S ANNUAL REPORT FOR IRELAND.

The following are the outstanding features of the Registrar-General's report of the marriages, births, and deaths registered in Ireland in the year 1914: The birth-rate (22.6 per 1,000 of the population) was low, the marriage-rate (5.41 per 1,000 of the population) was the highest since 1867, the death-rate (16.5) was the lowest recorded in Ireland since 1868, and the emigration-rate (4.6) was much below that for any year since emigration returns were first compiled in 1851. The estimated population in the middle of 1914 showed an increase of 2,386 on the estimate for the middle of 1913.

The marriages registered during the year numbered 23,695, the births 99,806, and the deaths 71,345. The marriage-rate showed an increase of 0.33 per 1,000 of the estimated population as compared with 1913, and of 0.22 as compared with the average rate of the last ten years. The birth-rate was 0.2 per 1,000 under that for the preceding year, and 0.7 under the average for the previous ten years; the death-rate was 0.8 per 1,000 below the rate of 1913, and the same below the average rate for the preceding ten years. The counties with the lowest death-rate per 1,000 of the population were: Mayo 12.8, Kerry 12.8, Roscommon 13.2, and Clare the same. The counties or county boroughs with the highest rates were the following: Dublin County Borough 23.7, Belfast County Borough 18.3, Limerick County and County Borough 17.5, and Monaghan 17.5.

Deaths from tuberculosis in Ireland numbered 9,089, the lowest number recorded for 51 years, beginning from 1864. The number of deaths from the disease in this country in 1914 was 298 under the number registered in 1913.

Evidence of the progress of elementary education in Ireland is afforded by the signatures of the contracting parties in the marriage registers or certificates. In the year 1914 there were 22,405 or 94.6 per cent. of the husbands, and 22,845 or 96.4 per cent. of the wives, who wrote their names, and the remainder signed by "mark," as against 20,584 or 89.6 per cent. of the husbands, and 21,122 or 92 per cent. of the wives, in 1904; and 17,912 or 82.9 per cent. of the husbands, and 18,039 or 83.5 per cent. of the wives, in the year 1894.

THE BELFAST TUBERCULOSIS SCHEME.

We have received the following letter from our correspondent in Belfast:

Sir.—Dr. Andrew Trimble, Chief Tuberculosis Officer of Belfast, has replied in your issue of July 31st (p. 195) to some remarks I had previously made on the Belfast Tuberculosis Scheme. A short holiday and consequently unopened JOURNALS are my excuse for delay in thanking him for his correction.

I am afraid he has caught me napping, and I acknowledge I have been guilty of a *supplicatio veri*, but inadvertently. It is common knowledge that Dr. Trimble went to endless pains to qualify himself for the post he now holds with distinction, that he devotes endless energy to the work, and is insistent in season and out of season in the advancement of the cause he has at heart. Some time ago I had the pleasure of seeing and admiring his methods and his organization. I should have made this statement preliminary to any stricture I felt called upon to advance on the progress of the scheme in general; the figures he gives in his second paragraph are proof of what can be done under difficulties.

But there are other responsible authorities besides Dr. Trimble—there are boards, committees, and sub-committees; my censure—if such passing remarks should be dignified with such a term—deals with the action and inaction of these bodies; Dr. Trimble is not touched personally in the slightest. Of the subject matter he has neither disproved nor, indeed, contradicted one single statement, nor disputed the accuracy of one single set of figures. Large sums of money have been held up, by which apparently the town should have been benefited; public boards have been wrangling; new posts were created long before the City Council had any practical experience of the working of the sanatorium; the record of this institution under its previous board and medical officers was good; why rush into change and fresh expense? There are fewer patients now in it than there were when it was taken over from the Poor Law guardians.

Surely these facts form legitimate subject for comment in the medical press. If Dr. Trimble makes a bad case it is because the defence of these boards, committees, and sub-committees is well nigh hopeless.

There are many other points of great interest; their discussion would have to be in detail to be satisfactory, and the profession cannot be expected to be concerned just now with local matters. As regards medical salaries, I feel sure they will have to be ere long increased, but surely, again, this is all the more reason for economy at the start. I can with confidence deplore with him the want of centralization, but it is not the only failure to be deplored. Dr. Trimble misquotes me in his fourth paragraph; he quotes me as saying, "£13,000 a year was to have been obtained," etc. My words were, "A sum of £13,000 was to have," etc. Throughout I have quoted from the public press, and I often compare two papers to ensure accuracy and independence; if I have misunderstood or wrongfully interpreted my source of information I can only express my regret.

To avoid the possibility of a wrong impression or of the suggestion of suspicion, it is perhaps better to say definitely, although it sounds like an impertinence, that neither publicly nor in private conversation does one hear anything but eulogiums of the individual officers in their difficult and trying, but most beneficent, work.

Sydney.

THE MEDICAL PROFESSION AND THE WAR.

It has been announced that the University of Sydney is prepared to allow students of medicine who have offered their services at the front to take their final degree examinations earlier, so that they may qualify within a shorter period than the regulation five years. This arrangement has practically arisen out of the attitude of the students towards the war. They have been long anxious to take a more active part, and they presented an offer in writing to the effect that the greater number of the present fifth year would try to qualify earlier so that they might be able to get away this year, and the whole of the present students of the fourth year would submit to a more strenuous course of study, so that they might be ready early next year. This offer was submitted to a meeting of the Faculty of Medicine, and it was unanimously agreed that nothing should be omitted from the regular teaching of any subject, but that the whole of the work should be done by packing the courses of study into a shorter time. To do this the students agreed to give up every vacation between Easter and Christmas, and the teachers to sacrifice their personal convenience. The Faculty, however, was determined that there should be no lowering of the standard in any subject, but decided that the final examination should be divided into two parts. This, it is believed, will do much to relieve the strain of work, and tend rather to raise the standard in the individual subjects.

The Sydney Medical School is well represented in the number of the profession on active service abroad. Already 154 graduates in medicine are on active service. Out of 84 students in the present fifth year 54 have offered to go this year as soon as they can be got ready. Of 75 students in the fourth year 3 are women who hope to graduate early next year so as to relieve men who could go; 65 students have volunteered unconditionally for service at the front next year. All the third-year students are accelerating their course, and undergoing earlier examination in order to bridge the gap between the third and fourth years, and to be in a position to volunteer should occasion arise. Some 30 undergraduates from the earlier years in medicine, impatient of delay, have already joined the forces. As a result of this great demand for medical men for the front there is a serious shortage of medical men for resident posts at the hospitals. Several are now very short-handed as regards both resident medical men and nurses.

NEW QUARANTINE REGULATIONS.

Several new regulations under the Quarantine Act, 1908-1912, have recently been published. One regulation provides that every overseas vessel arriving at any port in the Commonwealth must bring a bill of health from the port of departure, which must contain information as to the existence or non-existence of small-pox, cholera,

plague, yellow fever, typhus fever, or any other pestilential disease at or in the vicinity of the port concerned during the fortnight preceding the visit of the vessel. The most important amendment is in relation to the notification of cases of disease by the master of the vessel. The regulations state:

The master of any vessel in port shall give notice in writing to the Chief Quarantine Officer of the State in which the said port is situated of every case on his vessel of any of the following diseases: Small-pox, chicken-pox, plague, cholera, yellow fever, typhus fever, leprosy, anterior poliomyelitis, cerebrospinal meningitis, Malta fever, scarlet fever, measles, whooping-cough, gastro-enteritis, typhoid fever, diphtheria, malarial fever, gonorrhoea, and syphilis.

Gastro-enteritis has been included in order that mild cases of cholera should not be overlooked. The inclusion of the venereal diseases is an important step, and the operation of this regulation will be watched with interest. For besides the notification of these diseases the regulations give the power to detain and isolate if necessary any patient suffering from any of these diseases.

Correspondence.

MEDICAL STUDENTS AND THE WAR.

SIR.—On the strength of an answer given by Mr. Tennant in the House of Commons the authorities in medical schools have advised the students to remain there until they are qualified, instead of joining the forces. Contrary views have, however, been expressed, and on account of this uncertainty I have been asked from the War Office. These students are quite willing to become recruits if their services are needed, but they do not like the idea of being forced to do so later if, and when, universal service is adopted, while they have a chance now of joining the forces voluntarily. I therefore wrote to the Secretary of State for War and ventured to express my own opinion that medical students, like munition workers, should not be called upon to go the front, for medical men will be urgently needed in the future for both the civil and combatant population.

I append the reply I have received from Lord Kitchener's secretary; it will be seen that he views the matter less widely than I do, but although I regret his decision, it is only right that medical students should know exactly how the War Office regards the question.—I am, Sir,

King's College, London
August 16th.

W. D. HALLIBURTON.

[COPY.]

Dear Sir,—Lord Kitchener desires me to say in reply to your letter of the 1st inst. that it is advisable for medical students in their fourth and fifth years to continue their studies, with a view to qualifying as soon as possible. The War Office would be unwilling to suggest that junior students should be discouraged from taking combatant commissions.—Yours very truly,

W. D. Halliburton, Esq.
11th August, 1915.

H. J. CANDY,
Private Secretary.

INDIAN DOCTORS AND VACANT APPOINTMENTS.

SIR.—I am glad that at a meeting convened by the British Hospitals Association at Charing Cross Hospital on July 30th, and reported in the JOURNAL on August 7th, Sir William Collins called attention to the claims of Indian medical men to a share in filling medical appointments in this country. Seeing that the Indians are just now proving their mettle in the battlefield and fighting side by side with the English, it is time the old prejudice against them, like many other fallacies which the war has exposed, should be adjusted and modified according to present conditions and needs. Only two or three weeks ago the appointment of an Indian to the post of house-surgeon somewhere in Cornwall was cancelled at the very last moment after it had been duly made because of his nationality. A single case like this would do more harm now to the English cause in India than a thousand Indian sedition mongers. My long experience enables me to say that Indian doctors in their various appointments, after the first feeling of strangeness caused by the difference of colour is over, not only give satisfaction to their autho-

rities, but endear themselves by their gentleness and abstemious qualities.

One can quite understand and even justify the preference of an Englishman when he is competing for a post with an equally able and efficient Indian candidate, but one feels prejudice has triumphed over justice when an Indian is rejected even though he is proved superior in talents and ability to his English rival. Especially now, when all the world is praising the bravery of the Indian troops, their wonderful patriotism in rallying round the British flag, their devotion in giving freely their lives and treasure, the least the hospital authorities and governors can do is to give the Indian an opportunity to compete on equal terms with others (he asks for no favour) without prejudicing his candidature because of his colour and nationality.—I am, etc.,

Wells, Aug. 16th.

C. MCTHUR.

LEGAL RESPONSIBILITY FOR CRIME.

SIR.—In your issue of June 12th Dr. Mercier writes:

My medical colleagues never venture to adopt any doctrine of mine until it has been stolen by a German and sent back here as having been made in Germany.

Now, I do not exactly know to whom he refers as his "medical colleagues." If he means only those of light and leading in mental science, I cannot at all answer for them; but if he includes asylum men generally, then I can assure him it is far otherwise, and that there are many of us who are proud to declare ourselves his disciples, and gladly and gratefully to own that we owe all we know to his teaching.

Speaking for myself, I simply floundered about in confusion of ideas until his writings made smooth the way for me and cleared away my difficulties. That being so, I need not try to express the respect and admiration in which I hold him.

We Britishers are apt to think ourselves very fine fellows, and do not hesitate to say so, but it would be more seemly if we generalized less in this way and tried to overcome our peculiar shyness and give honour more freely where it is justly due, and I think it would be difficult to do too much honour to the author of *Conduct and its Disorders*, *Criminal Responsibility*, *Sanity and Insanity*, and many other notable works.—I am, etc.,

Fort Beaufort, South Africa, July 10th.

C. G. CASSIDY.

RESEARCH IN ANTISEPTICS.

SIR.—The statement which you make of my part in the discovery of the new antiseptics is entirely misleading. Dr. Dakin is a chemist and physiologist, and not a bacteriologist. The scheme of research was planned exclusively by him, and my part has been to act as his chemical assistant. I can claim no further share in his researches. He was invited at the beginning of the year by Dr. Carrel to join him at Compiegne, where the various substances prepared by Dr. Dakin and myself have been submitted to careful bacteriological tests by a specialist attached to the hospital and then applied clinically.—I am, etc.,

The University, Leeds, Aug. 15th.

J. B. COHEN.

THE USE OF IODINE AS AN ANTISEPTIC AND STERILIZER.

SIR.—So long ago as the year 1886, when I was dressing for Mr. Henry Morris (now Sir Henry Morris, Bt.) at the Middlesex Hospital, it was his practice to use a weak solution of iodine for washing out cavities, such as the pleural cavity, or sinuses of whatever description that required thoroughly sterilizing. Sir Henry Morris distinctly impressed upon us the high value of iodine as an antiseptic. This information I have always found useful, and have since been in the habit of using it often.

Combined with this knowledge I have associated the teaching I received when a pupil at the Royal United Hospital, Bath, 1883-4, when each case of ringworm and tinea kerion was subjected to a vigorous painting with tincture of iodine, with absolutely certain result of quick cure. For a long time past I have used the much stronger solution, liquor iodi fort., for first treatment of cuts, scratches,

and other injuries which readily permit of such an application. I would not use it for injuries in or about the eye, mouth, or other mucous openings. The liquor iodi fort. is still sure to cure housemaid's-knee, and other such enlargements, if applied with sufficient regularity and perseverance. I cannot understand how it is that iodine has only now been discovered as an antiseptic.—I am, etc.,
Jos. Wm. GILL, M.D., D.P.H.,

Billa Mill, Cornwall, Aug. 16th.

Obituary.

SIR PETER EADE, M.D., F.R.C.P.LOND.,

CONSULTING PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL,
AND TO THE JENNY LIND HOSPITAL FOR CHILDREN, NORWICH.

It is not often that we record in these obituary columns the decease of a member of our profession in the tenth decade of life, yet it is our painful duty this week to place on record the death of Sir Peter Eade at his residence in Norwich on August 12th last, in his 91st year. If a man reaches this advanced age he must be exceptionally well preserved, and this was the case with Sir Peter Eade, who was carrying on the ordinary activities of his life until a few days before death claimed him. He was the last of the generation of Norwich doctors which included Cadge, Bateman, and T. W. Crosse.

Born at Acle, Norfolk, in 1825, Sir Peter was the only son of Mr. Peter Eade, a surgeon in that village, and grandson of the Rev. Peter Eade, Rector of Cotton, Suffolk. His early years were spent at Blofield, about seven miles from Norwich, to which village his father moved soon after his birth. In due course "indentures" binding him to his father as pupil for five years were executed, though the last year of this pupilage was passed at the Norfolk and Norwich Hospital under the supervision of the eminent surgeon, John Greene Crosse. During this year the boy rode into Norwich from Blofield and out again daily. In 1844 he was entered as a medical student at King's College and King's College Hospital, where he had a distinguished career, carrying off many prizes. The eminent physicians, Drs. Todd, G. Budd, Guy, and Boyle, were his teachers at the hospital. Later, King's College elected him as an Honorary Fellow. In 1847 he took the degree of M.B.Lond., when he was awarded the "University Medical Scholarship" and three gold medals, and in 1850 he proceeded to the degree of M.D.Lond. In 1873 he was elected a Fellow of the Royal College of Physicians.

Having proved his ability at the University of London, Eade received the distinction of being offered an assistant-surgery in the Indian Medical Service, an appointment made by nomination at that time, and not by examination, as now; he declined this complimentary offer, however, and returned to Blofield to help his father with his country practice. This work, however, did not satisfy his ambition, and in 1856 he started to practise in Norwich as a physician. Two years later he was appointed to succeed Dr. Goodwin on the staff of the Norfolk and Norwich Hospital. In 1858 he was promoted to the consulting staff, which he held until his death, so that for a continuous period of fifty-seven years he was a member of the staff of that institution, thus beating all previous records, including that of Dr. Rigby, who for forty-three years was surgeon to the hospital and physician for a further period of seven years, namely, until 1821. It is impossible to record in this short notice the many valuable services that Sir Peter rendered to this hospital; his interest in it never waned, and up to within a few weeks of his death he was a constant attendant at the staff meetings and at the weekly Board. He will, perhaps, be best remembered by his history of the hospital.

There are few medical charities in Norwich with which Sir Peter Eade was not in some way or other connected during his long and distinguished career, and at the time of his death he was on the consulting staff of the Jenny Lind Infirmary for Children and of the Norwich Dispensary, and for very many years he was one of the trustees and for some time chairman of St. Helen's Hospital, an almshouse for the deserving poor of the city. He was also one of those who started in 1883 the Children's Convalescent Home at Yarmouth, an institution in which

he took the greatest interest, and he was the first chairman of its committee.

His enthusiasm for the writings and character of Sir Thomas Browne was second only to that of Sir William Osler, and it was largely due to his initiative and untiring efforts that the statue to this most distinguished citizen of Norwich was erected and publicly presented to the city on October 19th, 1905.

In spite of his very busy professional life, Sir Peter was able to find time to engage in public work. He was a great advocate of temperance and of increased open spaces and recreation grounds, and his efforts in the latter direction bore much fruit in Norwich, where a central public garden was laid out, and a people's park established on Mousehold Heath. As far back as 1863 he served on the Norwich Board of Guardians. In 1869 he was first returned as a member of the town council, upon which body he served until well into the eighties. In 1880-1 he was Sheriff of Norwich, and on three occasions served the office of mayor—namely, 1883-4, 1893-4, and part of 1895. It was during the last year of his mayoralty that he was presented with the freedom of the city, the scroll being contained in a handsome silver-gilt casket, subscribed for by the citizens. In 1885 he received the honour of knighthood. For many years he was a director of the Norwich Union Life Assurance Society and of the Norwich and London Accident Insurance Society, both of which appointments he held up to his death. Our readers interested in the subject will remember Eade's "Remarks on some medical aspects of life insurance," which appeared in the JOURNAL of April 1st, 1899. It is as a public-spirited citizen that the memory of Sir Peter Eade will be handed down to posterity, and in this respect he has set an example to medical men which it were good for others to follow. He married, in 1868, Ellen, the daughter of Mr. Robert Rump, surgeon of Wells, Norfolk, and widow of Mr. Ling, Lady Eade survives her husband. He was buried at Blofield on August 16th; the first part of the funeral service being held at St. Giles's Church, Norwich, at which the Lord Mayor and Corporation attended in state.

At the Norwich meeting of the Association (1874) Sir Peter Eade was President of the Section of Medicine. It was a peculiarly brilliant assembly, for, as was noted in the pages of the JOURNAL, Sir James Paget, like Eade a Norfolk man, gracefully stepping down to a second place, delivered an admirable address as President of the Section of Surgery, in which he informed his audience that forty years earlier, regularly every market day at Yarmouth, where he was apprenticed to a surgeon, he used to bleed patients till they fainted. Paget declared that not one of those patients suffered harm, and he believed that there was at the time he spoke (in 1874) no remedy employed from which the immediate relief derived was so great or so complete as it was from bleeding. At the same time Peter Eade was addressing his Section, dwelling, like Paget, on old methods. Within a stone's throw of the spot where he was delivering his address, Sir Thomas Browne had lived, written his famous essays, and died. Many of those "vulgar errors" which Browne exposed had ceased to be believed, yet Peter Eade feared that many equally important unrealities and misconceptions remained or had grown up, and he trusted that it might hereafter be said that in the city of Norwich, and with Browne's philosophic spirit, his Section had done something to cut down some of the scientific weeds of our own age, and to add something to the great store of knowledge which it was one of the main objects of the Association to accumulate. Sir Peter Eade was justified in his hopes, as may be proved by reference to the second volume of the JOURNAL for 1874. Sir David Ferrier, Sir Rose Cornack, Sir W. R. Gowers, Dr. Sidney Ringer, Dr. Ogle, and other eminent physicians, read and discussed papers on questions of high importance; M. Michel Peter of Paris read a highly suggestive monograph on accidents that might happen to pregnant women suffering from disease of the heart, and the President himself read notes on a disease of carpenters. Sir Peter Eade stated that its special symptoms were shortness of breath, vague pains in the chest, ascending to the neck, face, and head, a peculiar fidgetiness of manner, and, especially, a constant secretion of salivary mucus.

As recently as in 1900, when the annual meeting was

held at Ipswich, Sir Peter Eade joined in the important discussion on influenza as it affects the nervous system, introduced by Dr. Judson Bury in the Section of Medicine under the presidency of Dr. Buzzard. Eade laid stress on the fact that influenza was still being discussed by the Association ten years after the latest invasion. He expressed his opinion that the coma, or sleeping sickness, occasionally met with, was due to the slow or bradycardiac condition, which added defective brain circulation to the already impaired nutrition of the nerve matter.

In 1859, shortly after Eade had established himself in practice in Norwich, he recorded in the *Lancet* reports of some cases of paralysis after diphtheria, which were amongst the first distinctly noted examples of this sequela of the disease in England. Eade's experience in the treatment of diphtheria became very large, as Norfolk was one of the first counties ravaged when that disease first appeared in England in 1857. He wrote several articles on the subject from time to time which he published in a collected form as *Medical Notes and Essays; Notes on Diphtheria, and particularly on this Disease as it has occurred in Norfolk*, in 1883. This little treatise, though now of relatively small value from a therapeutic point of view, will without doubt remain of permanent importance as the record of a distinguished physician's practical experience of the appearance of one of the gravest diseases which developed in the last century. Eade's experience in collecting his own writings on diphtheria having proved satisfactory, he was induced some years later—namely, in 1892—to collect some more medical notes and essays, this time devoted to influenza in East Anglia, 1847, 1848, and 1890 to 1896; these notes were so much appreciated that a second edition was published in 1896. Among Sir Peter Eade's contributions to this JOURNAL is a paper on the treatment of boils and carbuncles, published in the issue of July 1st, 1876. He advocated the application of small quantities of strong solutions of carbolic acid in oil or glycerine.

Sir Peter Eade's book, entitled, *The Norfolk and Norwich Hospital, 1770 to 1900*, which appeared in 1900, is a complete history of that institution from the anonymous letter published in 1744 in the *Norwich Gazette* advocating the establishment of a county hospital in the city of Norwich, and the establishment of the first Norfolk and Norwich hospital in 1771, with Bishop Yonge's sermon, down to the opening of the new hospital in 1883, and of the Fletcher Convalescent Home at Cromer in 1893, whilst all improvements and innovations from that date till the last year of the nineteenth century were included. This work is freely made use of to the present day by the governing body. Eade previously, in 1886, had written a large volume, *Some Account of the Parish of St. Giles*, in which he lived and practised. A second edition was issued in 1896. This important work was based on a lecture on St. Giles's parish delivered in 1870, which attracted so much attention that Eade was induced to compile a treatise of more enduring value on the subject.

Dr. SAMUEL J. BARTON, Senior Physician to the Norfolk and Norwich Hospital, writes:

A dear old friend and colleague and a highly esteemed citizen of Norwich has passed to his rest in the person of Sir Peter Eade at the ripe age of 90. Others may detail the works he accomplished during his long life. I wish merely to speak of him as a personal friend of thirty six years' standing. In June, 1888, Sir Peter resigned his position as honorary physician to the Norfolk and Norwich Hospital after thirty years of devoted work in the wards and in the interests of the institution generally. He was then appointed consulting physician, and I succeeded him on the acting honorary staff. Sir Peter, however, retained his position as chairman of the honorary staff at its weekly consultations until recent years. Thus his colleagues were in constant touch with him, and had the benefit of his vast experience, which they appreciated. He kept up almost to the last his deep interest in his profession. He read with regularity his *Lancet* and *BRITISH MEDICAL JOURNAL*, and followed with deep attention the rapid strides in scientific and practical medicine. I recollect a long talk with him when "606" was introduced by Ehrlich. He maintained that it would save more lives than vaccination against small-pox.

Sir Peter was vigorous in argument, taking a very strong

line on his personal conviction, but he never was known to bear the slightest malice to his opponents five minutes after the most heated controversy. He was a staunch friend to many, but an enemy to none. Honourable to a degree in all transactions, he would go out of his way to do a kind action for anybody requiring it. This I can testify to from personal experience. His purse was ever open to the poor of his parish, and they made free use of it. As a host he could not be excelled; his luncheons to the profession of the city and county, and his society dinners of twenty years ago were widely known and much appreciated. Sir Peter was genuinely loyal to all his colleagues, even at times under trying circumstances, and I cannot recall having ever heard him make an unkind remark about a member of the profession. *Requiescat in pace.*

Mr. HAYNES S. ROBINSON, President of the Norwich Union Life Insurance Society, of which Sir Peter Eade was vice-president, writes:

The death of Sir Peter Eade has robbed the profession of one of the most eminent physicians in the Eastern Counties, and the city of Norwich has lost a very distinguished citizen. He has left us at the mature age of 90 years with all his faculties unimpaired, and able to take a keen interest in the affairs of life to within a few days of his decease.

Having been intimately connected with him for more than fifty years professionally and otherwise, I could but admire the energy he displayed in all he undertook and his patient attention to the smallest details. As a physician he was well known as a consultant of the best type, and when gradually withdrawing from his professional duties at the age when most are glad to retire altogether, he kept up his reading and took the greatest interest in all modern modes of treatment and ever interested himself in the welfare of the Norfolk and Norwich Hospital, with which he had been so long and honourably connected, and also in all the philanthropic movements in the city and the parish in which he lived.

Of small stature and frail physique he was ever quick and active in his movements, with which the activity of his mind seemed to correspond. Although holding strong opinions on many subjects, he was most tolerant of those who differed from him, and generous and honourable in all his actions, with an extremely kindly disposition. He lived his long life amongst us gaining not only the esteem and admiration of all, but the affectionate regard of those who best knew him and with whom he was almost in daily contact.

ALFRED MANN, M.D., C.M., J.P.,
CHESTER.

By the death of Dr. Mann, at the age of 56, Chester lost one of her prominent citizens, and the medical profession of the district an able and much valued colleague.

It was evident to those who knew him well that a severe attack of pneumonia, which he contracted some years ago, had left its mark upon his health, but he continued to discharge his duties, both civic and professional, with apparently undiminished activity. An operation, the issue of which gave rise to considerable anxiety, was in the end completely successful, and he returned to his home with every prospect, it was hoped, of a safe convalescence. Shortly afterwards he was seized with an attack of heart failure, and died in the early morning of August 3rd.

Dr. Mann was a native of Bridlington and received his medical education at the University of Edinburgh, where he graduated M.B., C.M. in 1886, taking his doctor's degree in 1889. After holding a resident surgical appointment in the Nottingham General Hospital, he went to Chester as visiting surgeon to the General Infirmary, and afterwards commenced practice in the city, being associated for the first ten years in partnership with the late Mr. James Taylor. He earned the confidence and affection of his patients, whilst his counsel and advice were highly esteemed by his colleagues in the deliberations of the Chester Medical Society, of which he was past president. During the closing year of his life he rendered valued service in the treatment of wounded soldiers as a member of the honorary medical staff of the Richmond House Red Cross Hospital.

Dr. Mann took a prominent part in the civic life of the city, having been a member of the city council for twelve years, chairman of the Public Health Committee for four years, and sheriff of the city in 1904-5. During his tenure of the chairmanship of the Public Health Committee he did much to further the efficiency and working of that department, the housing of the poor being a question in which he had always taken a burning interest, and which formed the theme of his first, and also of his last, speech in the council. He was a good speaker, with a clear and incisive style, marshalling his facts accurately, so that it was always a pleasure to listen to him.

Pressure of professional work necessitated his retirement from the council in 1912, at a time when his fellow councillors would willingly have accorded him the highest civic honours. The regret, freely expressed in the council, at his retirement found its counterpart in the opinion of the citizens generally.

In 1913 he was appointed a magistrate for the city, an appointment which gave universal satisfaction. He was a member of the Chester Port Sanitary Authority, and represented the council on the Chester Insurance Committee.

He married Miss Lillian Skelton of Norwich, who survives him with their family of two sons.

CAPTAIN JOHN CHARLES GILMAN, I.S.M.D., died in the General Hospital, Calcutta, on July 2nd. He was born on July 27th, 1862, and entered the service in 1881, rising to commissioned rank as lieutenant on July 23rd, 1908, and becoming captain on September 23rd, 1912. He served in the Sikhian war of 1888, gaining the frontier medal with a clasp, and also a special promotion to 1st class assistant surgeon. Most of his service, however, was spent in civil employ in Bengal, where he held the posts successively of medical officer to the pilot brigades at the Sandheads; the civil surgeries of Sainibhurn, Ruri, Dinajpur, Serampur, and Sambalpur; while since 1909 he had been medical inspector and certifying surgeon of factories in Bengal. He was also medical officer of the Cossipur Artillery Volunteers. He qualified as L.S.A. in 1886.

Medico-Legal.

A GERMAN DRUG COMPANY AND THE PATENT MEDICINES STAMP DUTY ACT.

We take the following report of proceedings at the Mansion House Police Court on August 16th from the *Morning Advertiser* of the following day:

Knoll and Co., Ltd., of Harp Lane, and the secretary of the company, Walter Braun, whose address was given as Stradella Road, Herne Hill, were summoned before Alderman Sir John Knill for uttering, sending, and exposing for sale certain medicines or medicaments for the prevention, cure, and relief of diseases and complaints incident to and affecting the human body, without the stamp required by the Patent Medicines Act. There were eleven summonses.

Mr. Frank Dart, solicitor to the Customs, in opening the case, stated that since these proceedings the secretary of the company had been interned in the Isle of Man as an alien enemy, and he proposed to withdraw the case against him, and to go on with the case against the company only.

Mr. Kerby, K.C., defending, said that the only person able to give him proper instructions was this Mr. Braun, and they had applied for an adjournment, but this had been refused.

Mr. Dart said the company, although registered as an English company, was a German company pure and simple. It was run entirely by Germans, and all the directors, he was instructed, were Germans with addresses out of England. The case was an extremely bad one for the company never stamped any of their articles, and in this way competed unfairly with firms who did properly stamp their articles. None of the articles, he contended, came within the exemptions as being an entire drug, but all were preparations and mixtures.

Mr. Chas. Simmonds, analyst to the Board of Customs, gave evidence as to the admixtures. In cross-examination, he said that the starch and sugar added to overaden might be for the purpose of holding the drug together. Strictly speaking, the coating of sugar on pills might be against the statute, but in practice the Commissioners of Customs did not so regard it.

Mr. Kerby submitted that there was no evidence to support the case as there had been no holding out of the preparations to the public. The price list of the firm was addressed to chemists and doctors, and such was not a recommendation of the whole preparations to the public, which was the essence of the whole case. He also urged that the preparations were entire drugs, as they were mixed by something which had no medical effect.

They were dealing at present only with summonses regarding overaden, and if the decision was against him he should ask for a case to be stated, as he regarded it as a test case.

Sir John Knill decided to convict, and imposed a fine of £5, with 5 guineas costs on the first summons.

Mr. Kerby asked the alderman to state a case for the consideration of the High Court.

Sir John Knill: Certainly.

Mr. Kerby said that in the circumstances he would agree to a conviction on each of the ten remaining summonses, the penalty to be the same in each case, without costs.

The Services.

INDIAN MEDICAL SERVICE.

WAR CONDITIONS.

Retention on Active List after Retirement has become Due.

The following is the text of the letter of the Government of India, Army Department, dated April 8th, 1915, conveying the decision that the period for which an officer of the Indian Medical Service is retained on the active list, in consequence of the war, after his retirement becomes due, will be permitted to count for pension:

No. H.-4098.

Government of India.

Army Department.

Simla, April 8th, 1915.

To the Director General, Indian Medical Service.

Sir,—I am directed to acknowledge the receipt of your letter No. 90-357-A, dated February 10th, 1915, inquiring whether officers of the Indian Medical Service, who would have been compelled to retire under the operation of existing rules, but who have been retained on the active list in consequence of the war, will be permitted to reckon for enhanced rates of pension the service rendered by them after their retirement ordinarily becomes due.

2. In reply I am to say that the period of retention of the officers referred to will count towards pension—that is, their pensions will be calculated with reference to their total service at the time of retirement.

3. I am to add that the extra pensions of £100 each per annum granted under Army Regulations, India, Volume I, paragraph 734, should be allotted in the ordinary way to selected officers, but payment should be held in abeyance till they actually retire.—I am, Sir, your most obedient servant,

(Signed) B. HOLLOWAY, Brigadier-General,

Secretary to the Government of India.

Reversion to Military Duty.

The following is the text of Army Department letter, dated July 3rd, 1915, intimating that it has been decided that officers of the Indian Medical Service reverting to military duty from permanent civil employment, in consequence of the war, whether they proceed on active service or remain in India, are entitled to pay not less than that of an officer of their standing in permanent medical charge of a regiment:

No. H.-6006.

Government of India.

Army Department.

Simla, July 3rd, 1915.

To the Director, Medical Services in India.

Sir,—I am directed to say that the Government of India have decided that officers of the Indian Medical Service reverting from permanent civil employment in consequence of the war, whether they proceed on active service or remain on military duty in India, are entitled under paragraph 153 H, Army Regulations, India, Volume I, to pay not less than that of officers of their standing in permanent medical charge of a regiment.—I am, Sir, your most obedient servant,

(Signed) B. HOLLOWAY, Brigadier-General,

Secretary to the Government of India.

TERRITORIAL FORCE.

EXCHANGE DESIRED.

LIEUTENANT A. G. S. LOUIE, R.A.M.C.(T), 21st South-Eastern Mounted Brigade Field Ambulance, Maresfield Park, Sussex, wishes to find a substitute so as to enable him to transfer to a unit going on foreign service. He would exchange with an officer in a unit going abroad or already abroad.

Universities and Colleges.

UNIVERSITY COLLEGE, DUNDEE.

At a meeting of the Council on August 11th it was announced that a bursary in memory of Mr. Robert Hepburn had been founded by his sister. It will be open to any male or female student of medicine at the College, and will be tenable for three years.

Medical News.

THE French War Ministry has issued an official communication intimating that the statements to the effect that the French troops have used poisonous gases is incorrect.

THE Hygiene Committee of the Chamber of Deputies has nominated a committee composed of MM. Pottevin, Mélin, and Foucher to proceed to the Dardanelles to study the working of the French medical service there.

MESSRS. SMITH, ELDER, and CO. will publish a book in which Mr. Ian Malcolm, M.P., who has been serving with the British Red Cross, has embodied his experiences. The text is illustrated from original documents.

THE Swedish Academy has decided that the Nobel prizes shall not be awarded this year. It is stated that the funds which will thus be accumulated will not suffice to cover the special Swedish tax for national defence.

THE *Revue de Laryngologie, d'Otologie et de Rhinologie*, the editor of which is Dr. E. J. Moure of Bordeaux, has resumed publication, suspended since August last. Owing to difficulties created by the war it will for the present be issued every two months. The present number (August 15th) will continue the series interrupted in August, 1914.

WITH the issue of the *Athenaeum* for July 3rd was published the first instalment of a subject index to periodicals undertaken at the request of a committee appointed for the purpose by the Library Association. The progress of science and technology in 1915, with special reference to the war, is the first subject to be indexed.

SIR LAURENCE GODME contributes a preface to Mr. Frederic Swann's *Primer of London Citizenship*, which Messrs. King of Westminster will publish shortly. The work is intended to explain the system of local government in force in London, to elucidate some of its intricacies, to point out some of its defects, and to examine those measures that have been proposed for its simplification and improvement.

A SPECIAL convalescent home for the French aviation services has been established in a country house with a large park at Viry-Châtillon, near Juvisy, where is the great aerodrome. The estate has been lent by Dr. Mougin, who is the medical officer in charge of the home, which has been recognized as an auxiliary military hospital. It has been equipped by public subscription, among the subscribers being the President of the Republic and the Presidents of the two Chambers. It provides forty beds, and not only pilots and observers but also mechanicians mobilized for service in the army or navy aviation corps are eligible for admission.

ON July 28th a miner, named Coates, was buried in a fall of roof in the South Pelaw Colliery, near Chester-le-Street, Durham. The accident happened some time after 7 a.m., and he was found about 9 a.m. It was impossible to extricate him, and Dr. W. A. McKellar of Chester-le-Street, who had been sent for, went down the pit about 11.30 a.m., reached the man at the coal face by crawling for some distance, and, after several attempts, was able to inject strychnine into his back. As the right arm was terribly crushed, Dr. McKellar advised that an attempt should be made to hew away some of the fall so that the limb might be amputated. This was found impossible, and Dr. McKellar was able with difficulty to give another injection; when eventually, about 6 p.m., it was found possible to relieve some of the pressure, the man died. Dr. McKellar remained with him throughout. The coroner, in commenting on the incident at the inquest, said that Dr. McKellar's conduct in doing all that was possible in such difficult circumstances, and in remaining with the man till the end, was in the highest degree creditable. The jury heartily concurred with the coroner's remarks, and an official who prefers to remain anonymous, in calling our attention to the incident, expresses the opinion that Dr. McKellar's attempt to liberate the man under the conditions which obtained was highly commendable. This opinion, we are sure, will be shared not only by the miners, but also by the profession which Dr. McKellar has honoured.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atholweg, Westrand, London*; (2) GENERAL SECRETARY, *11, GERRARD, GERRARD*; (3) MEDICAL SECRETARY, *Medicivra, Westrand, London*; telephone 253; (4) MANAGER of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUESTIONS.

BUMBLE BEES.

INQUIRER writes: I recently noticed hundreds of "bumble bees" (the one with the two yellow stripes, one on thorax, the other on body) scattered on the ground deep under a lime tree in full flower, but the bodies (thorax) of nearly all had been hollowed out and the contents removed. In some cases their heads were off, but the abdomen and contents seemed untouched. Upon the branches of this lime and also in adjoining trees and on a tennis net, were numerous and attempting to fly about the birds (*Musca-capa orisida*), continually on the wing and picking flies whilst in the air. Were these hundreds of bumble bees the victims of inebriation from the honey of the lime tree flowers or were they destroyed whilst feeding by the birds? Is this an observed phenomenon?

ANSWERS.

SHOULD SURGEONS WITH INFECTIVE THROAT LESIONS OPERATE?

COLONEL JOHN SMYTH, I.M.S.—A surgeon with a primary or secondary syphilitic lesion in the mouth or pharynx is not justified in operating or attending cases of confinement, even if he wears a mask. A man with active tuberculous ulcers on his tonsils would doubtless feel absolutely incapable of attempting such a task. The infective activity of tubercle in the air passages varies greatly in different cases. In cases of lupus it is so slight as to be practically negligible. In the case of milary tuberculosis it is so active as to be dangerous.

HARE-LIP.

DR. J. E. MIDDLEMISS (Leeds) writes: The first of "R's" queries can be definitely answered in the negative. The types of deformity which are associated with neuropathic inheritance and which are recognized as stigmata of degeneracy rarely include hare-lip or cleft palate. Fregdoff, in discussing the malformations of the palate associated with amentia, says: "Cleft palate appears to be on quite a different footing, and it is doubtful if this condition and its common associate, hare-lip, can be regarded as real stigmata of degeneracy. It is but rarely met with in amentia. Langdon Down finding it only in 0.5 per cent., and Ireland in 1 per cent., of idiots; while I have examined 1,971 feeble-minded children without meeting a single instance. These proportions do not differ materially from the normal, for Grenzer (quoted by Talbot) found 9 cases on examining 14,466 presumably normal children. I have seen many instances of cleft palate and imperforate anal whatever." Questions 2 and 3 are partly answered by the above. The probability of similar abnormalities in subsequent births would appear to depend on the ordinary laws of chance. Even the double occurrence of hare-lip, however, does not imply the probability of other developmental anomalies. The type of malformation which is likely to recur, and which depends on hereditary causes, is that which is associated with some degree of mental defect, of which in this case there is no question.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 493, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive posts from letters addressed either in initials or numbers.

TREATMENT OF GUNSHOT WOUNDS BY EXCISION AND PRIMARY SUTURE.

By COLONEL H. M. W. GRAY, A.M.S.(T.O.),
CONSULTING SURGEON, BRITISH EXPEDITIONARY FORCE.

THE number of cases of gunshot wounds to which treatment by excision and primary suture is applicable affords ample justification for attempting to make the method more widely known and popular.

I began this method of treatment of certain lacerated "furrow" wounds in November, 1914, and was so impressed by its utility that I have since then urged that it should be carried out whenever possible.

The advantages claimed for its use are:

1. Healing by first intention is assured in the vast majority of properly selected cases.
2. Much time is thereby saved. Some wounds, which would otherwise require months to heal, are soundly united in the course of ten to fourteen days. The soldier is thus available for duty again at a much earlier date.
3. The amount of attention required to be given by the medical officers and nursing sisters, etc., is greatly reduced.
4. Much pain is avoided.
5. The amount of dressings required is reduced to a minimum, and in this way expense is lessened.
6. Complications which may arise from the presence of a septic wound are avoided.
7. A more sightly scar is obtained.
8. Because of the absence of contraction which would accompany formation of a large cicatrix, there is less impairment of function in the part concerned.
9. In the case of head injuries, excision of the wound, especially in some, apparently trivial, injuries, provides a means of ascertaining, with greater certainty than by any other method, whether depressed fracture or injury to the brain coexists.

Healing by first intention may be procured in practically all cases in which the surfaces of the new wound can be brought into accurate approximation without much tension. In rare cases, when the wound is deep, approximation in the depth has to be dispensed with and drains are introduced for a short period—until one is assured that aseptic healing will occur. In some cases it is necessary to adjust and fix the parts of the body adjacent to the sutured wound so that the fullest relaxation is secured.

The mere length of a wound is no bar to operation. Some very long wounds have been excised. A missile may inflict what resembles an incised wound, but, by dividing the tissues at right angles to the line of their greatest tension, may, owing to the contractility of these tissues, cause a large gaping wound. In such cases there will be little tension when sutures are inserted and tied, if too great a mass has not to be excised. One can test roughly what the amount of such tension will be by attempting to push the surfaces of the wound together.

It is not necessary to wait until the wound is surgically clean—in fact, in most cases the sooner the excision is made the better. The wound will probably be soundly healed in a shorter time than it will take to clean. During the "cleaning" process the adjacent parts become so softened that sutures do not hold well. Only when a large "bank" of inflamed tissue surrounds the wound is immediate excision inadvisable on account of the septic condition of the wound. In such cases it is probable that organisms have penetrated to a considerable depth, and will cause trouble when the tissues invaded by them are subjected to the pressure of sutures. By vigorous "salting" (hypertonic treatment) such wounds are usually rendered suitable for excision in twenty-four to forty-eight hours.

Other contraindications are the presence of marked pocketing in the wound and the exposure of vascular or nerve trunks in the depth or of bone which it is inadvisable or impossible to remove.

In any case excision of the soiled edges of skin and of the superficial connective tissue and muscle may be done with advantage. The healing process in the wound as a

whole is thereby accelerated. Certain bony prominences—such as a vertebral spine or the edge of the acromion process—may be capable of removal with the other infected tissues.

The presence of pocketing in a wound is very important. If part of such a pocket, or, indeed, if any septic focus be left, the operation will probably prove a failure. The technique is therefore very important. The operation can usually be done under infiltration anaesthesia of the neighbouring parts. It is well to add plenty of adrenalin to the anaesthetic solution, so that haemorrhage during the operation is avoided. Accurate haemostasis is important for success. The parts around are shaved and disinfected very thoroughly. The wound is wiped out, dried, and packed with gauze.

For disinfecting purposes in these cases I favour the use of very strong iodine solution (5 to 10 per cent. in spirit or ether). This is painted thoroughly into every part of the wound and over the surrounding skin for a considerable area. It has the effect of drying the surface of the wound in a remarkable manner. The strong iodine is wiped off the skin with spirit or ether at the end of the operation.

The skin close to each extremity of the wound is caught up by tissue forceps or a loop of thread, and slight traction is made in a direction away from the centre of the wound at an angle of about 45 degrees with the sound skin. The whole wound is then cut away *en masse* (skin, flesh, and, if necessary, bone) at a distance of about one-third to half an inch from the raw surface. Care must be taken that pockets or general surfaces of the wound are not cut into during this procedure. Bony prominences are removed along with the soft parts by dividing them with bone-pliers, gouge-forceps, or chisel.

If the wound is deep, it is sometimes of advantage to insert the finger into the wound as a guide to where the tissues must be divided.

A very sharp scalpel is invaluable. Cutting out the wound in pieces makes success precarious.

The new wound surfaces should now be washed with saline solution and packed with gauze, and the surrounding skin wiped free of blood or discharge.

Fresh towels, fresh instruments, and, if the wound has been handled, fresh gloves should now be used. The wound should be closed by wide sutures which undererr on its floor so that no dead spaces are left. It may be necessary to suture in layers. If so, the suture of each layer should include some of the tissue of the deeper layer. The skin should be accurately approximated by a few fine sutures. Further relaxation sutures are not often necessary.

The following dressing should then be applied. The line of sutures and the adjacent skin for several inches should be painted with a wound varnish, of which mastic, dissolved in some rapidly evaporating solvent, forms the important part (40 to 50 per cent.). When the varnish has become "sticky" (after one and a half to two minutes), a covering of gauze, at least two layers thick, should be stretched tightly and smoothly over the sticky area, gently patted down, and cotton-wool and bandages applied fairly firmly. If it is desired to inspect the wound at any time, after removing the bandage and wool, the top layer, or layers, of gauze should be peeled off by traction at right angles to the surface, the layer next the skin and wound being at the same time retained by the other hand. Perfectly satisfactory inspection can be made through the single layer of gauze. The loose edges of the gauze should be neatly trimmed.

In many cases no further dressing is required until the stitches are to be removed. The final layer of gauze is then peeled off.

If fine catgut sutures have been used for the skin, it is often found that the knots come away with the layer of gauze, the deeper parts having been digested. A fresh application of the mastic varnish and gauze should then be made and left until the wound is firmly healed.

The varnish should on no account be painted over the gauze after it has been applied, otherwise the gauze cannot be peeled off as described.

The varnish and gauze dressing is important for success. It is the best I know. It gives wide support, relieves tension, and prevents any dragging on the stitches. These factors are of great value in preventing stitch abscess.

ON THE USE OF CERTAIN ANTISEPTIC SUBSTANCES IN THE TREATMENT OF INFECTED WOUNDS.

By H. D. DAKIN, D.Sc., F.I.C.,
THE HERTZ LABORATORY, NEW YORK.

In order to make a judicious choice of the antiseptic most likely to give useful results in the treatment of infected wounds many different factors have to be considered in addition to germicidal activity, including the irritating properties of the substances, their toxicity, solubility, ability to penetrate tissues and to be absorbed, and their chemical reactions with proteins and other tissue constituents.

The killing of bacteria by ordinary antiseptic substances is essentially a chemical reaction between the antiseptic on the one hand and the proteins and other cell constituents of the micro-organism on the other. The destruction by antiseptics of bacteria suspended in water is easily effected, because no proteins are present in the mixture other than those derived from the micro-organism. The destruction by antiseptics of bacteria mixed with blood serum, pus, and other exudate is much more difficult because the antiseptic acts not only on the micro-organisms but on other protein substances as well. Therefore, in judging of the antiseptic action of a substance suitable for the treatment of wounds, it is essential that its germicidal action be tested against micro-organisms mixed with blood serum or similar substances, and not simply tested against bacteria suspended in water.

The germicidal activity of all known antiseptics is greatly reduced by the presence of blood serum or similar substances, and in some cases this reduction is so great that the compound loses all practical antiseptic value.

The following table contains results which illustrate this enormous reduction in germicidal action by blood serum in the case of several common antiseptics. I am greatly indebted to my colleague, Dr. Maurice Daufresne, for all the bacteriological results referred to in this communication.

Antiseptic.	Without Blood Serum.	With Blood Serum.
Phenol	1: 250- 1: 500+	1: 50- 1: 100+
Salicylic acid	1: 2,500- 1: 5,000+	1: 100- 1: 250+
Hydrogen peroxide ...	1: 3,500- 1: 8,000+	1: 1,700- 1: 2,000+
Iodine	1: 103,000- 1: 3,000,000+	1: 1,000- 1: 2,500+
Mercuric chloride ..	1: 5,000,000- 1: 10,000,000+	1: 25,000- 1: 50,000+
Silver nitrate	1: 1,000,000- 1: 10,000,000+	1: 10,000- 1: 25,000+
Sodium hypochlorite...	1: 500,000- 1: 1,050,000+	1: 1,500- 1: 2,000+
Benzene sodium sul- phochloramide	1: 500,000- 1: 1,000,000+	1: 1,000- 1: 2,000+
Paraldehyde sodium sulphochloramide	1: 750,000- 1: 1,500,000+	1: 2,000- 1: 3,000+
A acetylchloramine- dichlorobenzene	1: 500,000- 1: 1,000,000+	1: 2,500- 1: 5,000+

The figures indicate the concentration of antiseptic necessary to sterilize one drop of a fresh culture of *Staphylococcus aureus* in a total volume of 5 c.c.m. acting for two hours. + indicates growth; - indicates complete sterilization.

But in choosing a suitable antiseptic many other factors than germicidal action need to be considered. Mercuric chloride, which among the substances referred to in the table shows the highest germicidal action, is probably the least useful and most objectionable as an antiseptic for the treatment of infected wounds. It may be of use to consider some of the limitations of the commonly used substances referred to in the above table.

The work described in this communication was carried out in Laboratories at Compiègne supported by the Rockefeller Institute for Medical Research attached to Hospital 23 of the French Army. For cordial co-operation in the preparation of a large number of chloramines and other substances, upon which a detailed report will be published later, I am indebted to my former teacher, Professor J. B. Cohen, F.R.S., of the University of Leeds, and to Dr. J. Kenyon, who was appointed by the British Medical Research Committee.

Phenol is characterized by very low germicidal power, especially when acting in the presence of serum. When used in sufficiently high concentration for germicidal efficiency it is decidedly destructive of healthy tissue.

Hydrogen peroxide gives encouraging results when tested against bacteria in the test tube, but when used on wounds the substance has little germicidal action, for it is decomposed with the greatest ease by the enzyme catalase present in all tissues and in the blood cells. Hence its action can only be exerted during a trifling interval of time. The mechanical detergent action connected with the rapid disengagement of oxygen gas on infected surfaces is probably of greater value than any antiseptic action exerted by the hydrogen peroxide.

An interesting experiment related to me by Professor E. K. Dunham may be quoted here. A rabbit which had received an intravenous injection of the Welch bacillus (*B. aerogenes capsulatus* or *B. perfringens*) was killed, and the infected liver was removed and carefully sectioned. It was found that cubes of the infected liver only 1 mm. in size could be immersed in and incubated with hydrogen peroxide of moderate concentration without destruction of the micro-organisms.

Hydrogen peroxide, as regards its antiseptic action, must be regarded as of slight value, even against anaerobic organisms.

Mercuric chloride readily loses most of its antiseptic action in presence of many tissue constituents, and, as is well known, is irritating even in dilute solution. It is useless for the sterilization of pus when employed at any reasonable concentration.

Silver nitrate is of greater value than mercuric chloride, but when used in sufficiently high concentration is irritating. Many tissue constituents inhibit its action markedly. The photo-sensitiveness of the silver compounds formed is objectionable.

Iodine, which has proved so valuable for the disinfection of skin, has given much less satisfactory results when used for deep wounds owing to protein coagulation and irritation of the tissues. The penetrating power of iodine is slight, and wounds which have been freely treated with it are apt to cicatrize more slowly than others.

Sodium hypochlorite has high germicidal action, and has many other desirable properties. But sodium hypochlorite as ordinarily prepared is of extremely variable composition, contains free alkali and sometimes free chlorine, and is consequently irritating when applied to wounds. By a simple process, which will now be described, it has been possible to render the hypochlorites much less irritating while retaining their antiseptic action unchanged.

PRINCIPLES INVOLVED IN THE PREPARATION OF THE HYPOCHLORITE SOLUTION.

Solutions of sodium hypochlorite always contain free alkali even when prepared with the greatest care. A so-called "neutral" solution of sodium hypochlorite has an alkaline reaction. This is due not only to free alkali which may remain from the process of preparation, but also to the fact that the hypochlorite in solution undergoes hydrolytic dissociation giving free sodium hydroxide and hypochlorous acid.

The extent of this dissociation has been measured by Dnyk, and quantitatively it is very considerable. The irritating action of ordinary hypochlorites is largely due to this formation of free alkali. The extent of this hydrolytic dissociation increases with dilution, so that practically hypochlorites cannot be effectively rendered non-irritating by simply reducing the concentration, for a point is soon reached at which germicidal action is impaired while the irritating properties of the solution persist. In addition to the above sources of free alkali, it must not be forgotten that alkali may be liberated by the action of sodium hypochlorite on proteins, a reaction in which the chlorine of the hypochlorite is attached to nitrogen in the proteins, as will be shown later.

Now it is well known that certain fluids, such as blood and some other body fluids, also contain artificial salt solutions containing mixture of salts of polybasic acids—for example, phosphoric acid—are able to retain their essential neutrality even after the addition of limited quantities of acid or alkali. This is due to the fact that the addition of acid or alkali simply changes the relative

proportion of two or more salts of the polybasic acid present in the solution.

Starting with this idea, and employing the feeble polybasic acid, boric acid, it has been possible to prepare a simple hypochlorite mixture which maintains approximate neutrality under all conditions, is practically non-irritating, and which, when properly applied, has given most encouraging results in the antiseptic treatment of wounds. It must be understood that the insignificant antiseptic action of boric acid has nothing to do with the employment of this acid; nor is the boric acid employed for the purpose of liberating hypochlorous acid, as in Lumière's or Lorrain Smith's preparations.

The principle of the preparation is as follows: Chloride of lime (bleaching powder) is decomposed with a solution of sodium carbonate and the filtered solution containing sodium hypochlorite together with a slight excess of alkali is mixed with boric acid in such quantity that the solution is acid to phenolphthalein suspended in water but still alkaline to litmus. The resultant solution contains a balanced mixture of hypochlorite and polyborates of sodium with small amounts of free hypochlorous and boric acids. Thus the irritating action of free caustic alkali is avoided, for even if momentarily formed it would be at once neutralized by the boric acid or acid borates present in the solution.

Preparation of Solutions.

The preparation of a solution of suitable concentration for direct application, containing 0.5 to 0.6 per cent. of sodium hypochlorite, may be carried out very simply as follows:

One hundred and forty grams of dry sodium carbonate (Na₂CO₃), or 400 grams of the crystallized salt (washing soda), is dissolved in 10 litres of tap water, and 200 grams of chloride of lime (chlorinated lime) of good quality is added. The mixture is well shaken, and, after half an hour, the clear liquid is siphoned off from the precipitate of calcium carbonate and filtered through a plug of cotton; 40 grams of boric acid are added to the clear filtrate, and the resulting solution is ready for use. A slight additional precipitate of calcium salts may slowly occur, but it is of no significance. The solution should not be kept longer than one week. *The boric acid must not be added to the mixture before filtering, but afterwards.*

A stronger solution may be prepared by decomposing chloride of lime with sodium carbonate in the proportion of 150 grams of the former to 105 grams of the latter dissolved in a litre of water. The mixture is filtered and a measured portion of it (20 c.c.m.) is rapidly titrated with a boric acid solution of known strength (51 grams per litre), using phenolphthalein suspended in water as indicator, in order to determine the amount of solid boric acid to be added to the rest of the filtrate. An excess of boric acid should be avoided, so that it is best to add slightly less than the calculated amount. An ordinary alcoholic solution of phenolphthalein cannot be used as indicator, as the alcohol is at once attacked.

The concentrated solution thus prepared contains about 4 per cent. of sodium hypochlorite, and should be mixed with six parts of water before use. It can be kept for a month without serious decomposition. Such a solution is now prepared by Poaleuc Frères, 123, Boulevard St. Germain, Paris, but it can easily be made at a negligible cost by any competent chemist, and I hope that it may be so made generally.

APPLICATION AND RESULTS.

To obtain the best results it is essential to commence the antiseptic treatment of the wound at the earliest moment possible, and to bring fresh quantities of the antiseptic solution in contact with all parts of the wound as frequently as possible for a considerable period of time. This is naturally a difficult problem, requiring different methods for various types of wound. The methods of applying the solution which have been found useful at Compiègne will be described by Dr. Carrel. But to give some idea of the quantities of solution employed it may be mentioned that 5 to 10 c.c.m. may be introduced every two hours by means of rubber tubes into small wounds, using a pipette or syringe, while for the irrigation of such wounds as fractured femurs, accompanied by much destruction of tissue, as much as 1, or even 2, litres a day may be employed. The dilute solution, prepared as described, may

be used in large quantities for the continued irrigation or instillation of wounds for more than a week without producing visible irritation. It is extremely rare for slight irritation of the skin to occur, and this may be guarded against by the application of vaseline to the skin adjacent to the wound. As a wet dressing the solution may be used almost indefinitely. A few comparative tests on similar surface wounds do not indicate that cicatrization is delayed, even by its continued use.

The solution has the valuable property of assisting in the rapid dissolution of necrosed tissue, this being doubtless due to the ability of hypochlorites to attack the (NH) groups present in proteins with formation of soluble products. It has a certain haemostatic action as well but is actively haemolytic, and should not be injected intravenously.

It is difficult in a printed communication to produce simple convincing evidence of the usefulness of an antiseptic. Records of a few individual cases treated with brilliant results are, of course, of no great value, for many infected wounds do well with a minimum amount of treatment, but the clinical results obtained during six months' use of the solution by a number of observers in different hospitals warrant the belief that the solution is of genuine value. By far the most striking results are seen in ambulances, where treatment can be commenced a few hours after the wound has been received. Among these cases the proportion of cases which at no time show a significant rise in temperature and in which healing without suppuration occurs is very large. In many cases it has been possible to make comparative tests, with and without antiseptic, on similar wounds with striking results. Records obtained by means of serial coloured photographs of the gradual changes in wounds of the most varied kind under different conditions show definite differences in favour of the solution, and in no case has any objectionable after-effect been traced to the action of the antiseptic. It should be stated that most of the cases treated with the antiseptic were kept under observation for several weeks until discharged as convalescent. This is, of course, important for judging of the ultimate value of the treatment.

An idea of the antiseptic properties of the solution may be gathered from the following figures: Staphylococci suspended in water are killed in two hours at a concentration of hypochlorite between 1 : 500,000 and 1 : 1,000,000, while in the presence of serum the necessary concentration is between 1 : 1,500 and 1 : 2,000. Streptococci are more readily killed, while pyocyanus suspended in water is killed in two hours at a concentration between 1 : 100,000 and 1 : 1,000,000, while in serum between 1 : 2,500 and 1 : 5,000 is necessary.

Hypochlorites are extremely active substances chemically, and they should not be used in conjunction with other antiseptics nor with alcohol or ether. Wounds which have been previously treated with much iodine may take on a dark colour, due to the re-liberation of iodine, but this is of no importance.

Many other preparations of hypochlorites have been employed at various times by different workers. The more commonly recommended preparations are the ordinary alkaline solutions of the hypochlorites of sodium, potassium (eau de Javelle), or calcium; while mixtures of powdered chloride of lime with boric acid have been employed by Vincent, Lumière, and by Lorrain Smith and others. It is believed that the solution previously described, when properly applied to all parts of the wound, gives better results than can possibly be obtained from powdered preparations of partially soluble materials. The local production of hypochlorites, hypochlorous acid, or chlorine in high concentration, such as results from the use of the powdered mixture, is much more dangerous for healthy tissue than is the continued application of a weak neutral solution of sodium hypochlorite. Generally speaking, our experiments with powdered substances have given much less good clinical results than have aqueous solutions. It is true, however, that aqueous solutions need more care for their successful application, for it is essential that they reach every part of the infected area, and that the antiseptic should be renewed from time to time.

MODE OF ACTION OF HYPOCHLORITES.

When a solution of a hypochlorite or of free hypochlorous acid acts upon organic substances containing the

=NH group the first reaction almost always consists in the replacement of the hydrogen by chlorine with formation of substances of the group known as chloramines. All protein substances contain an abundance of these groups, and they readily react with hypochlorites:

The antiseptic action of hypochlorites doubtless depends upon reactions of this type. It was therefore interesting to examine many different varieties of the large group of chloramines in order to study their antiseptic actions. In this work I have enjoyed the co-operation of Professor J. B. Cohen of the University of Leeds.

In the first place, it may be stated that all substances containing the -NCl group were found to be strongly antiseptic, and some of them will probably be found to have practical value. Proteins, such as blood serum, egg white, casein, etc., when treated with hypochlorites, give products of high antiseptic value, and undoubtedly compounds of this type are formed *in situ* when wounds are treated with hypochlorites. This is doubtless an advantage, as in this way a certain antiseptic action may be expected to persist even after the free hypochlorite has disappeared.

Substances such as acetanilide when treated with hypochlorous acid under appropriate conditions, carefully studied by Chattaway, give chloramines—for example, acetylchloraminodichlorobenzene—which are sparingly soluble in water, but which may be dissolved in vaseline or lanoline. Although the germicidal power of these compounds is very high indeed, the action on infected wounds of strong solutions of them in vaseline or lanoline was not markedly superior to that of plain vaseline. It appears that, generally speaking, active germicidal action can hardly be hoped for from sparingly soluble antiseptics mixed with fatty substances. Anaerobic organisms can readily grow under the fatty film covering the surface of the infected area.

On the other hand, certain aromatic chloramines which form soluble sodium salts have given most encouraging clinical results. The best of these compounds are the benzene or paratoluene sodium sulphochloramides, both of which have been described by Chattaway.

These substances are extremely powerful antiseptics, are practically non-irritating, and can be used in much higher concentration than can the hypochlorites. A 2 to 4 per cent. solution may be conveniently employed. In general, the action of these substances is similar to that of the hypochlorites, but more powerfully antiseptic. They have, however, no special solvent action on necrosed tissue, this being doubtless due to the fact that the active chlorine in these compounds is already attached to nitrogen. While the number of cases thus far treated with these antiseptics is smaller than those treated with the hypochlorite mixture, excellent results have been obtained in a number of badly infected wounds, notably compound fractures of the femur. It appears probable that these chloramines, which are relatively easily prepared at low cost, and which have the advantage of being stable solids, may be found useful for other purposes than for the treatment of infected wounds. Their possible applications will be the subject of further study.

Benzene sodium sulphochloramide kills staphylococci suspended in water in two hours at a concentration of 1:500,000, and the toluene derivative kills at 1:1,000,000. In the presence of serum the necessary concentrations are about 1:1,500 and 1:2,500 respectively. *Bacillus pyocyaneus*, *B. typhosus*, and *B. coli* are slightly more resistant than staphylococci, while *B. aerogenes capsulatus* and streptococci are more readily killed. The concentrations refer to the weight of the crystallized salts. It will be seen that the molecular concentration of toluene sodium sulphochloramide necessary to kill staphylococci in the presence of serum is only about one-fifth of the correspondingly active molecular concentration of sodium hypochlorite.

ON THE USE OF A SLEEVE OF VEIN IN NERVE SUTURE.

By ANDREW FULLERTON, M.Ch., F.R.C.S. (IREL.),
COLONEL (TEMPORARY) A.M.S.; CONSULTING SURGEON TO THE
FORCES IN FRANCE; SURGEON IN CHARGE OF OUT-PATIENTS,
ROYAL VICTORIA HOSPITAL; SURGEON, ULSTER
VOLUNTEER FORCE HOSPITAL.

DURING the present war many cases of nerve injury have been recorded. The injuries are produced for the most part by rifle bullets, fragments of shell, and shrapnel. Primary suture is frequently out of the question, and the wounds are allowed to heal without any attempt being made to suture the divided nerves. Later, secondary suture is required, and often the divided ends have to be

sought for in a large amount of scar tissue. It is essential in cases of this sort to protect the junction so as to avoid ingrowth of scar tissue between the nerve ends, and consequent failure of the operation. To prevent this various substances have been used, including decalcified bone tubes, gelatine tubes, animal's artery, paraffin wax, Cargile membrane,* and human vein. Sherven (*Injuries of Nerves*) prefers chlorinized Cargile membrane.

For some years I have been using portions of vein in the manner here illustrated. The most suitable vein for nerves of the upper extremity—as, for instance, the musculo-spiral, the median, and the ulnar—is the basilic vein at a spot between its commencement and the point at which it pierces the deep fascia of the upper arm. A segment of the vein about 1½ in. or 2 in. in length is excised and threaded on a sinus forceps as in Fig. 1. One end of the nerve is then caught by the forceps, and the sleeve pulled over as in Fig. 2. The ends of the nerve are then freshened with a sharp scalpel and sutured with fine catgut. When the suture is complete the sleeve is pulled over the junction, as in Fig. 3, and fastened to the nerve sheath by a few points of suture. The vein thus applied is intended to form an aseptic sheath for the nerve, to keep the ends in secure apposition, to direct the growth of the new axis cylinders, and to prevent the ingrowth of scar tissue from the outside. Any vein of suitable size will, of course, do, and in the lower extremity a portion of the internal or external saphenous will probably be the most convenient.

The sleeve must be pulled over the first nerve end before trimming so as to avoid damage to the freshly cut end.

Possibly this method has been in use by others, but I have not seen it used or described up to the present.

* Peritoneum of the ox.

THE TREATMENT OF GUNSHOT FRACTURES OF THE LEG WITH POSTERIOR WOUNDS.

By CHARLES A. MORTON.

PROFESSOR OF SURGERY, UNIVERSITY OF BRISTOL; SENIOR SURGEON IN THE GENERAL HOSPITAL; MAJOR R.A.M.C.(R.F.).

IN THE BRITISH MEDICAL JOURNAL for July 10th there is a description by Captain Barber of a splint for use in cases of compound fracture of the leg with posterior wounds, which induces me to place on record another form of splint I have been using for a case of this kind.

The difficulty, as Captain Barber says, is to fix the fracture and yet not to block wounds on the posterior aspect of the leg. In a case of gunshot fracture, with perhaps great comminution and a flail-like limb, the splint which Captain Barber describes would not, I think, give adequate support to the leg. The slings which he uses, he says are supplementary, and he relies mainly on extension. Extension from around the lower part of the leg, just above the ankle, is a very painful thing. I had a fracture of my own leg with great displacement, and although I knew the value which such extension would have, I was not able to bear the pressure over the malleoli. I doubt if the extension as used in Captain Barber's splint is really continuous extension; it seems to me only fixation. Unless the traction is made with an elastic band, or weight extension, it is not continuous extension. Moreover, the extension at the upper part of the leg is not required; the patient's body, if the foot of the bed is raised, is always sufficient counter-extension. But the "extension" in Captain Barber's splint does not seem to me to provide adequate support for the fracture. The fractured ends would tend to fall down into the space beneath the leg, and the support of the leg here with slings seems to be the really essential thing. Another objection to Captain Barber's splint seems to me to be the piece of wood under the bed. Rarely will a heel stand any pressure.

When, at the end of May, a patient was admitted to the military hospital under my care with a flail-like leg, profusely suppurating, the result of great comminution of both bones about their middle from gunshot wound, with several wounds not only on the anterior but also on the

Fig. 1.

posterior surface in the lower half of the leg, I planned the splint for its support which I will now describe (Fig. 1).

It consists of a back splint of wood covered with some waterproof material, with a foot-piece. At the two upper corners of the back splint two pieces of wood are fixed, and from these to the foot-piece a rod of metal passes on each

side, and from these rods the leg is suspended as shown in Fig. 2, the knee being fixed by a bandage. I find it a great advantage to have small metal loops along the bar to fix the slings and prevent their slipping up or down the bar. The slings are, I think, best made of battiste, which is better than jaconet for the purpose, as it is waterproof on both sides. In some parts of the leg the sling may be carried straight across, but when the leg is somewhat round in form, as at the upper and lower parts of the calf, they should lie obliquely, so as to fit the convex surface. If injurious pressure seems to be exercised by any sling a pneumatic pad may be placed between it and the limb, and for this purpose I have found Barnes's bags, which were at one time used by obstetricians for dilating the cervix, very useful. When there is great oedema of the leg, the narrower slings will sink into the oedema, or rather, they prevent the oedema from forming where they press, and it occurs above and below, and the sling seems to be cutting into the leg, but this is only apparent. When treating ordinary Pott's fracture in civil practice, in cases with great displacement of the foot backwards, I have sometimes tried to prevent the dropping

Fig. 2.

back of the heel by a sling arrangement supported by an attachment to the top of the foot-piece. In some cases I have found this answer very well, but I have seen it cause sloughing of the heel, just as pressure with a pad under it is apt to do. When I put up this gunshot fracture on the special splint, I tried a sling under the heel, but it caused sloughing and had to be abandoned. Possibly a sling with a pneumatic pad on it might not cause any injurious pressure there. On this special form of splint the leg is quite firmly fixed, and yet free drainage from the posterior wounds can be secured. For continuous irrigation such a splint would be particularly useful, as a shallow metal receptacle with an outlet pipe could be so conveniently placed beneath the suspended limb. In my case such continuous irrigation has not been required, as by frequent syringing of lotion through the wound, from front to back of the leg, free drainage has been maintained. There has not been any serious pyrexia. But the arrangement has been very convenient for this process, as a shallow receptacle could so readily be placed beneath the leg. In a case of compound fracture of the leg requiring continuous irrigation, even though this form of splint may not be required because there are posterior wounds, yet it may be found more convenient than the usual arrangement of mackintoshes to carry off the fluid.

THE American Medical Association will hold its sixty-seventh annual session at Detroit, June 12th to 16th, 1916.

THE Mansion House Committee of the Captain Scott Memorial Fund is about to erect a bronze bas-relief in St. Paul's Cathedral, bearing the following inscription, written by Earl Curzon of Kedleston: "In memory of Captain Robert Falcon Scott, C.V.O., R.N., Dr. Edward Adrian Wilson, Captain Lawrence E. G. Oates, Lieutenant Henry R. Bowers, and Petty Officer Edgar Evans, who died on their return journey from the South Pole in February and March, 1912. Indefatigable of purpose, steadfast in courage, resolute in endurance in the face of unparalleled misfortune. Their bodies are lost in the Antarctic ice. But the memory of their deeds is an everlasting monument."

ON THE EXTRACTION OF FOREIGN BODIES.

BY

J. R. CALDWELL, CAPTAIN R.A.M.C.

SINCE the commencement of the present war the number of so-called new methods of localizing foreign bodies lodged in the tissues of the human frame has been enormous. Obviously such an expenditure of energy in the planning of these was a response to some weakness in those systems in existence previous to the present struggle. The localization of projectiles has in these days been forced into a position of prominence under the pressure of work entailed in the examination of large numbers of wounded men. Of paramount importance in work of this nature is the question of speed. Complex work entailing the taking of several radiographs, or involving the use of complicated measuring instruments, must go by the board. Simplicity is an essential, as work may have to be done under the most adverse conditions, and any ordinary apparatus should be sufficient at a pinch with which to do good work. Many methods have been evolved; indeed, there is scarcely a radiographer of experience who has not thought out for himself a method of localization, and yet on the operating table vexing failures may occur. It matters not what method is employed, complex or simple, when it comes to the actual extraction of projectiles from the tissues and from accessible situations defeat is still a possible termination of a search.

The rock bottom principle of localization is practically the same in all systems; the main difference lies in the mode of application. Diagram I represents, say, a section

Fig. 1.—Scheme of general arrangement (see text).

of a patient lying on a couch. The x -ray tube is in position under the table, while above is the screen. The essential of localization resolves itself into a geometrical calculation—we know the distance of the anticathode of the tube from the surface of the patient's body. We shift the position of the tube a known distance, and we note the apparent distance traversed by the foreign body on the screen. Given these three measurements, it is obvious that the extent of the movement of the shadow on the screen will depend absolutely on the depth of the foreign body. The nearer the projectile is to the screen the less will be its apparent movement. As has been said, the modifications in the method of application are innumerable. Most of those of recent introduction make for greater speed, but the fundamental principle underlying is the same in all. The radiographer fancies his duty finished when he is able to state that below a certain mark on the patient's skin, at a certain depth will be found the foreign

body in question. The value of such information has been overrated. Unhappily when the surgeon has hunted down a foreign body he may verify his radiographer's findings to a millimetre, yet, before the commencement of the operation, the information given could at the most give the slenderest help as to the anatomical situation of the foreign body. The unknown variations in thickness of the tissues overlying the muscles, and in the muscles themselves, and moreover the variation brought about by the inflammatory reaction around the new body, render the most accurate localization of but the slightest assistance. It has been suggested that an atlas of frozen transverse sections of the human trunk and limbs might provide information on which to base the data supplied by the radiographer, and so to furnish us with the ideal and anatomical localization, but the sources of error are most obvious, and render this but of little help. Another important source of error in the extraction of projectiles is the difficulty of repeating exactly on the operating table the conditions which obtained when the localization was made. The surgeon is told that vertically below a certain mark on the skin at a certain depth he will find the foreign body in question. It is at once obvious that the slightest change in position of the patient may produce a deviation from the vertical path and so lead astray. Open to criticism also is the custom of marking the skin, as, after the preliminary toilet, there may be little left of the guiding point. Moreover, when the case is a multiple one and the surgeon is faced with the removal of perhaps half a dozen pieces of shell, his difficulties are enormously magnified. An anatomical localization, then, seems an almost unattainable ideal, as, unfortunately, stereography, which is the nearest approach we can have to this, is often erroneous and misleading. Moreover, the taking and developing of two plates takes time, and the help of these should only be employed as accessory in the extraction of projectiles from very difficult and dangerous situations.

To have speed in this class of work we must approach the subject from a somewhat different point of view. Why should we still grope in the dark when we can so readily work in the light? In war work the operating table and the x -ray table should be combined. The operating theatre and the x -ray room must be in one as the x -ray theatre.

During the past few months, as surgeon radiographer for two *clais* hospitals, one French and one Belgian, I have been permitted to treat on the x -ray operating table over 350 cases involving the removal of foreign bodies from the tissues. Shell, shrapnel, bullet, and hand grenade have been removed with a facility and speed which grew with experience, but in no case from the very first in which an attempt was made has a failure been recorded. Moreover, many of these were multiple (as many as thirteen pieces of shell have been removed from one patient), and many were old and healed and showed the scars of previous fruitless search. The beginning was necessarily small and the technique now employed was evolved step by step, difficulties being met as they arose, until ultimately practically all cases of foreign bodies became the property of the x -ray theatre.

The apparatus employed is of the simplest description and was supplied by Mr. A. Dean, of London. The table is of the ordinary type with a large tube box underneath giving transverse and longitudinal movements. The top used for operations is of thin well-polished wood, and an extension in the form of a flap is attached to one end to accommodate the patient when dealing with the lower limbs. The high tension wires approach the tube box from the opposite end that operations may be performed from both sides of the table.

A troublesome question was the lighting of the theatre, as the strong light necessary for dissections interferes with that visual acuity so essential in x -ray work. The difficulty has been met by using an old automobile headlight above the table. With a powerful condenser this concentrates the light only on the field of operation, while the remainder of the room is in comparative darkness. A blue glass in the lamp still further improves the light for x -ray purposes, and does not strain or tire the eyes, while still giving sufficient light for minute dissection.

It is rarely necessary for the anaesthetic to be administered for any lengthy period in the dark, but in the

event of such a necessity arising the anaesthetist is equipped with a small pocket lamp also giving a blue light. This permits him to examine his patient without interfering with the screening.

The protection of the surgeon from the harmful effects of the x ray is of the utmost importance. The tube box is entirely encased in lead 3 mm. thick with the exception of the opening above for the passage of the acting rays. Additional protection is afforded by the use of a leaden screen of ample dimensions, and of the same thickness as that covering the tube box. This should be hung on to the front of the table, between the box and the operator, and should be freely movable along the length of the table, and easily detachable to give ready access to the tube. Operations are always performed with the smallest diaphragm possible, and hence it becomes feasible, with care, to keep the hands out of the direct line of fire, but to afford still further protection lead plates 3 mm. in thickness and with circular openings in the centre varying in diameter from 1 in. to 4 in. are used. These serve to cut off stray rays, and being readily sterilizable can be laid in the field of operation in a manner which will be described later. Long slightly curved Spencer Wells forceps are used in extraction, the curve involving the handle only, forceps which have a rectangular bend being more difficult of control. It is usual here for two pairs of gloves to be worn during an operation on the x ray table, an outer thick pair such as are worn by housemaids, and an inner thin pair of the ordinary type. The outer pair can be removed on the completion of the actual extraction, or to permit of delicate work.

Each case on admission is subjected to a preliminary radioscopic examination, and if a foreign body is present its position is determined roughly by parallax. Advantage is taken of any neighbouring bony structure, the position of which is fixed and known, and the relative rates of apparent movement of the bone and the projectile on shifting the source of illumination are studied with the help of the screen. A brief glance at Fig. 2 will show

and also the most suitable position for the patient at the actual operation. When it is possible to cut vertically down on the foreign body—that is to say, when it can be approached by a route which is at right angles to the screen—there is no difficulty as a rule, and the operation is a matter of a few minutes, but such a method of approach is not always feasible, for on the x-ray operating table you cannot put your patient into all the positions permissible on the ordinary table. In operating, for example, on the upper and outer aspect of the thigh, the patient must lie on his back or face in order that the opposite thigh may not come in the way and interfere with the screen. If a bullet were situated in such a position, the procedure of turning the patient on his side is impossible, as the screen could not for obvious reasons be employed. In such a case the patient must be placed on his back, and the forceps must approach the foreign body in a plane parallel to that of the screen. How, then, are we to find the most suitable site for the incision in this type of case? The method I adopt is that of prodding the part from above downwards in a plane parallel to that of the screen. When the point of maximum excursion of the foreign body is reached, this is noted and used as the site for the incision (if not forbidden for anatomical reasons). The method, though apparently somewhat rough, is very accurate, and a little experience will soon indicate the types of cases to which it is applicable; but, briefly, they are the lateral aspects of the trunk and neck, the axilla, and the upper parts of the thigh. In the great majority of cases no further localization is necessary, but in dangerous situations stereographs are useful accessories. Methods giving detailed measurements are never employed here.

At the operation the care of the apparatus and switch turning is in the hands of a trained orderly, while the screen is in charge of a second. The patient is anaesthetized, and the part is prepared in the usual fashion. The sterilization of the skin should be wide, and when one of the extremities is involved the entire circumference should be made ready. Mackintosh sheeting should not be used, as it is too opaque, but the table should be covered with thin jaconet. The towels are then applied, and over the now cleaned and prepared area is laid the screen towel. This is of sufficient size to cover completely the under surface of the screen with a margin all round of about 2 inches. The screen orderly pushes the tube box into the vicinity of the part involved and lays the screen on the towel. This is now clipped all round and securely fastened on with Diffenbach's bulldog forceps. When the screen is laid on the part the rays are turned on and the lights off and the foreign body is located. The tube box is manipulated by the orderly until the projectile is in the centre of the illuminated field, using always the smallest diaphragm possible. Over the apparent position of the foreign body on the skin the point of a pair of long forceps is now laid and the lights are turned on. The incision is made as near to this point as possible and the skin, superficial and deep fasciae are divided. One of the sterilized lead plates, previously described, is placed over the part, the circular opening surrounding the incision, and keeping the hands in the shadow of the plate under the rays, closed forceps are pushed down on the projectile. This is grasped, but, before extracting, the light is turned on and, if the case be a septic one, the track is well opened up to facilitate drainage and, above all, to permit of the removal of "wardrobe." Should, however, the part affected contain delicate structures, the operation should merely be controlled and guided by occasional reference to the screen. Where it is not possible to cut vertically down on the foreign body, but where we are forced to approach it in a plane parallel to the screen, or nearly so, the sterile lead shield is placed on the table and under the part in such a way as to direct the pencil of almost parallel rays on to the foreign body. The prodding manoeuvre is now repeated, the site of the incision determined and made as before. When the forceps have been introduced it is very useful to make a slight movement of the tube and to note the relative rates of apparent movement of the foreign body and the forceps point. The information to be gleaned from this simple manoeuvre is often very helpful, and is explained by reference to Fig. 2, if in imagination we substitute for the bone a forceps point.

The removal of foreign bodies in septic cases greatly

Fig. 2.—The diagram represents, say, a section of a thigh with two foreign bodies, one, A, in the same lateral plane as the bone, the other, B, anterior to it. Two screens, for the sake of simplicity, are shown. On moving the tube from C to B the foreign body A apparently moves the same distance as the bone ($x-x'-y-y'$) (screen 1). The foreign body B makes a smaller apparent movement ($x-x' < y-y'$) (screen 2).

that if a foreign body is in the same lateral plane as the shaft of some long bone, its rate of apparent movement upon shifting the source of illumination will be similar to that of the bone. A foreign body anterior to the bone will move less, and when under the skin will scarcely move at all. On the other hand, when the projectile is situated in a plane posterior to that of the bone the conditions are the opposite of those just described. At this preliminary examination one determines the site of the skin incision

promotes healing, for it is usually possible at the same time to take away fragments of cloth, which are such a potent cause of prolonged suppuration. The adoption of such a method as that described makes for such speed and such certainty of success that the more routine removal of all projectiles of any size should be the rule. Moreover, the man in the trenches can never understand that a piece of shell left in his leg is anything but an unmixed evil.

Thus he ponders, he worries, and ultimately its presence becomes a source of irritation to him. It may cause him real pain, or it may be imaginary or assumed, but in any case it interferes with the proper discharge of his duties. Unless there are contra-indicating factors present, the rule should be to remove all foreign bodies of any size from accessible situations, and as soon as possible after the infliction of the wound.

OPEN-AIR TREATMENT FOR WOUNDS.

A SIMPLE AND INEXPENSIVE FORM OF OPEN-AIR WARD, AS USED AT THE V.A.D. HOSPITAL, HENLEY-IN-ARDEN.

BY

W. ERNEST NELSON, M.A.CANTAB., M.R.C.S., L.R.C.P.,
MEDICAL DIRECTOR, WARWICKSHIRE BRANCH, BRITISH RED
CROSS SOCIETY.

During the present war open-air treatment has played a large part in the cure of wounded soldiers, and any medical man who has had charge of wounded knows what excellent results can be obtained by this method, especially in the more serious kinds of suppurating wounds and in cases of general infection.

I submit this short account of an open-air ward because I think it may be of interest to your readers and also because it has one or two features which may specially commend it.

The ward was built for use at the V.A.D. Hospital, Henley-in-Arden, of which hospital I am Commandant and Medical Officer, and is specially adapted for such hospitals, as it has the merit of being cheap and at the same time efficient.

This particular ward has accommodation for eight beds, though I have had as many as nine beds in it at one time, but buildings on these lines to take two or three beds, or twenty or thirty.

The chief features which I claim for this particular form of building are as follows:

1. It is open to the air on both sides, the ends only being closed in. Most open-air wards that I have seen are closed in on three sides. The protecting screens, at the back of the bed-heads, seen on the right hand side of the view of the interior, are 4 ft. high, and afford ample protection from draught. The left hand side is open down to the ground, except for an open balustrading. Thus there is a free current of air continually passing over the heads of the patients as they lie in bed, and yet they do not feel any draught.

2. The deep sloping eaves are set at such an angle that the rain cannot drive in, even on the most windy and rainy days. During the past month of July, in which we have not had a single day without rain and have had some of the most severe thunderstorms I have ever seen, the interior of this ward has always remained dry and the patients have suffered no inconvenience from wind or rain.

3. If it is desired to close in one side completely, this is done by a system of spare screens, which either fit into grooves provided or are hinged on to the already existing screens at the back of the beds, and are then thrown upwards and bolted to the wall plate or roof. In this way either side of the ward, or both, can be entirely or partially shut in.

4. It is easily built, the materials being wood and asbestos sheeting, the latter being cheaper than wood, besides having the additional merit of being fireproof. The roof is of match-boarding, covered with rubberoid. The floor is constructed of boards, tongued and grooved, so that no draught can come through. The whole structure is raised some twelve inches from the ground on small brick current of air under the time does not kill the necessary to erect such a building on a lawn or in a field.

5. It is quickly and easily erected. This particular building was put up complete in four days—ten days from the date of the order being given.

6. It is easily connected with the main building of the hospital by a covered way, so that nurses and patients can pass to and fro in any weather.

I shall be pleased to give further details to anyone interested in the subject, or these can be obtained direct from the architects, Messrs. Osborne,

Pemberton and White, 40, Bennetts Hill, Birmingham.

THE late Mr. Arthur Rich Saunders, M.B., of Victoria Park, Dover, formerly President of the Jamaica Medical Council and Board of Examination, left estate valued at £15,117.

THE PUBLIC HEALTH WORK OF THE BRITISH MEDICAL ASSOCIATION.

BEING THE PRESIDENTIAL ADDRESS DELIVERED TO THE
WORCESTERSHIRE AND HEREFORDSHIRE BRANCH OF
THE BRITISH MEDICAL ASSOCIATION.

BY

LIEUT. COL. HERBERT JONES, D.P.H., R.A.M.C.(T.),
MEDICAL OFFICER OF HEALTH, HEREFORDSHIRE COMBINED
DISTRICTS.

THE President of the Worcestershire and Herefordshire Branch may be justifiably proud of recalling that the British Medical Association came into being at Worcester, and that his presidential address is delivered to the lineal professional descendants of those who listened to the first address of Sir Charles (then Dr.) Hastings, the outcome of which was the formation, with a membership of 140, of an Association whose members now number some 25,000, and wields a power and possesses an influence that are at once the envy and the admiration of many similar organizations.

The honour of presiding over the deliberations of this Branch is one which cannot fail to be gratifying to any one who is chosen by you to occupy the position. It is peculiarly so to me, because more than twenty of my thirty years of professional life and activities have been spent exclusively in the public health service. For this reason my thanks are specially due to you, not alone from myself, but also on behalf of medical officers of health generally. I hope, indeed, that I shall not be thought guilty of any personal ingratitude when I say that I felt, and felt with pride and satisfaction, that your choice last year of President was intended to be a testimony to the confidence and good feeling which exists, and which I have at all times striven to foster, between the general practitioners of this country and medical officers of health. I like to think also that, while honouring me, you desired to pay tribute to the Society of Medical Officers of Health, with which I have been closely associated officially for many years, and the presidential badge of which I have now the honour and gratification of wearing.

Among the purposes and objects of the new Association outlined by Charles Hastings at Worcester in 1832 was the "investigation of endemic and epidemic disease." The transactions of the Association from that day to this give ample evidence that there has been no neglect of this object not only in its earlier days but in later years, when public health became so specialized that other bodies for the discussion and elucidation of sanitary problems were established—the Epidemiological Society in 1855 and the Society of Medical Officers of Health in 1856. While the public health historian would naturally go to the records of these two societies for reliable information, he would be unable to fulfil his task faithfully and completely if he neglected to explore the pages of the BRITISH MEDICAL JOURNAL or failed to make himself familiar with the papers and discussions on public health matters that have been included from time to time in the proceedings of the great annual meetings or of the Branch meetings of the Association.

Quite apart, however, from the assistance that has been rendered by the Association to the scientific side of public health invaluable help has been given medico-politically to medical officers of health. Adequate remuneration, security of tenure of office, and superannuation for medical officers of health, have all long been planks in the policy of the Association, and no one is more qualified than I am to testify, as I do most heartily, to the untiring labours on our behalf of the Association committees, of its officials and editorial staff, in connexion with these three important questions. A successful stand has been made against inadequate salaries, while year after year bills have been introduced into Parliament, at the instigation and at the cost of the Association, having for their object the provision of superannuation allowances for medical officers of health and a reasonable security for these officials against capricious dismissal at the hands of the electing authorities. For years the Government of the day was deaf to all appeals for what seemed to those who had closely studied the question bare justice to an important body of public officers, but the persistent efforts of the Association

and the Society of Medical Officers of Health, backed up as they were by the BRITISH MEDICAL JOURNAL, by the *Lancet*, and by the *Medical Officer*, have at last borne fruit, for the principle of superannuation has been admitted and an order of the Local Government Board is, I understand, to be promulgated, which will ensure that all whole-time medical officers appointed in the future in the English and Welsh provinces will hold office on the same terms as their colleagues elsewhere in the British Isles—that is to say, dismissal by a local authority will only be effective after receiving the approval and sanction of the Local Government Board.

This success could not have been achieved had there not been the most cordial and generous co-operation between the Society of Medical Officers of Health representing the public health service, and the British Medical Association representing the general practitioners of the country. The attitude of the Association testifies to the long views that are taken by those who guide its policy. Medical officers of health constitute only about 6 per cent. of the members of the Association, and it might well have been thought that our interests were of too little importance to be considered, but, as I have endeavoured to show, quite the contrary has been the case.

Although the Association and the society have been and are the friendliest of allies it is almost inevitable that on occasion there should be some friction between individual members of the two bodies. This usually arises not from any mean or despicable motive, but rather because the general practitioner, on the one hand, is anxious to safeguard the interests of his patients, while the medical officer of health is zealous, sometimes perhaps over-zealous, for the welfare of the community. In this connexion I will refer to what is perhaps the commonest cause of misunderstanding between the private practitioner and the public officer. In the "investigation of endemic and epidemic disease" it is absolutely essential that the investigator should have precise and accurate knowledge of the existence of such disease, and as regards a large number of these diseases the general practitioner is required by law to send certain information to the medical officer of health, who is thus enabled to carry out his investigations. The primary object of those investigations is the prevention of the spread of the disease in question; and if the medical officer of health is not satisfied that all due precautions are being taken to that end, he is required under the terms of his appointment to advise those competent to act as to the remedial measures that appear to him desirable to take. There are still a few medical officers of health who seem to consider that they cannot make complete investigations without actually seeing the patient—a course which in my view is not only quite unnecessary but is reprehensible. The views of the Local Government Board on this point are very precise, for in a memorandum issued by the Board in 1910 it was stated that

A medical officer of health will bear in mind that the examination of patients in their own homes can be made only with the consent of the patient or of those in charge of the patient. If a medical practitioner is in attendance his co-operation should always be sought.

My own practice has always been never to see a patient who is being attended by a doctor unless the latter is present or his consent has been obtained. If this were made a rule by all medical officers of health, the number of cases of misunderstanding and irritation that now occasionally arise would be considerably reduced. A still further reduction would take place if the diagnosis of the practitioner were always loyally accepted, exceptions only being made after consultation and opportunity given to the practitioner to revise his opinion.

If the relations between the general practitioner and the medical officer of health are to be such as to produce the best results to the community generally, each must realize that the other has difficulties of his own to contend with. Due allowance must be made for those difficulties. Above all we must beware of the mischief that is so often made through the patient or his friends misinterpreting a casual remark. It is a good working rule never to believe a hearsay statement that is detrimental to a professional colleague. If you are attending a scarlet fever patient, and on your second visit are told that the medical officer of health has been to the house and has said that the case is not one of scarlet fever, do not believe it. The medical

officer of health, on his part, should not believe a repeated conversation attributing improper conduct to him. More harm is done by these tales than is generally imagined.

It is now my privilege and pleasure to invite my successor to take my place. My year of office has been in a period in the history of our nation unexampled. The thoughts of all of us have been absorbed in the terrible conflict in which we are engaged, and we have all done our best to shorten it and to lessen its horrors. Dr. Wilkinson is known to us all as a practitioner of high repute, and we feel that in electing him to the presidential chair we are conferring an honour that has been well earned. Among the members of the public health service he occupies an honoured position, and it is a special pleasure to me to introduce as my successor another medical officer of health. I can wish nothing better.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

VACCINE TREATMENT OF GONORRHOEA.

ANY method of treatment which will shorten the period of detention in hospital of men suffering from gonorrhoea is worthy of full trial, and, if found beneficial, of being recorded.

Of 33 cases admitted into hospital with acute gonorrhoea, all were treated with gonococcus vaccine, and were discharged cured after an average detention of 13½ days each. No case was marked cured until there had been an interval of sometimes four and in other cases of five consecutive days since the appearance of the last sign of discharge, including gleet. This gives an average of about nine days during which alone there were manifestations of active gonorrhoea.

The method of treatment I adopted was the following: On the morning after admission a dose of *mistura alba* was given, the patient placed on a milk diet, and rest in bed enjoined. An injection into the buttock of 1 c.cm. of gonococcus vaccine (Burroughs, Wellcome, and Co.), 200 million strength, was given, and the man directed to wash out the urethra three or four times daily with a weak solution of potassium permanganate. There was generally a slight rise of temperature in the evening (never higher than 99.9°) with slight headache. On the following morning the discharge was usually said to be heavier, lessening, however, during the day and being less again the next morning. Forty-eight hours after the first injection of vaccine a second dose was given, this time of 1,000 million strength, the same routine followed, and unless the discharge showed symptoms of marked diminution and of approximation to gleet, in two or three days afterwards a third injection of 1,000 million was given, a fourth being rarely necessary. When the discharge had become clear the patient was allowed to be up in the ward; all exercise, however, was forbidden.

Noteworthy points about the washing out of the urethra are that it was effected by gravity and through a No. 8 catheter, which was passed well down the urethra so that the whole of the canal should be cleansed, this being done under the supervision of an orderly, to ensure thoroughness. In some of the cases a valuable adjunct, suggested by Colonel Butt, was used. The patient was placed and kept for some time in a hot bath, and whilst there in a recumbent position the urethra was thoroughly washed out. These cases were not selected, but in each the discharge was purulent and had been present from one week up to several months—ten months in one case which had been treated by electric and other methods to no purpose. In the latter case, too, gonococcus vaccine had been tried and had failed, but the maximum dose was only 40 million. Gonococcus vaccine is not a very stable preparation and failure in some cases may be due to this cause; there is no doubt also that the strains vary in potency, but I cannot help thinking that failures are mostly due to insufficient doses being employed, a too extended interval between each injection, and the lack, in addition, of thoroughly cleansing the urethra several times daily. Except *mistura alba*, no medicine was given.

W. G. BRETT, Lieutenant R.A.M.C.

TYPHOID FEVER WITH SUPPURATING OVARIAN CYST.

THE patient, a woman aged 22 years, unmarried, was admitted into hospital on May 12th, 1915, with a preliminary diagnosis of typhoid fever.

She had not had any illness up to four months previously, when she had a cough and was "feverish"; since then she had had amenorrhoea. In January, 1915, she was inoculated once against typhoid fever. Shortly afterwards she was wounded in the left shoulder by shrapnel, but the wound healed quickly.

The illness for which she was admitted had begun four weeks previously with diarrhoea and abdominal pain. She was feverish and was bleeding from the nose, but had no headache. When she was admitted she was well nourished, but looked flushed and feverish; the temperature was 100.8° F. and the pulse 120. Her tongue was coated with a thick white fur, but was moist. The abdomen looked full, and was very tender and rigid, especially so in the right iliac fossa. On palpation a large, firm, smooth swelling was felt extending from above the symphysis pubis to the umbilicus; it was almost central, but was inclined slightly to the right. The swelling was dull upon percussion, and there was no fluctuation. A catheter was passed; only two ounces of highly-coloured urine were withdrawn, and the swelling persisted.

Upon vaginal examination the cervix was found to be pushed far over to the left side, and the uterus was behind the tumour and to the left of it. The tumour appeared to be distinctly to the right of the middle line, and was very tense. There were no breast changes, and the other organs appeared to be normal. A blood culture proved to be negative.

The patient's condition remained much the same, with fever and a rapid pulse, until May 16th, when she seemed to get worse; the temperature rose to 102.2° F., and she started vomiting. It was decided to operate, and on May 17th laparotomy was performed by Colonel S. Guise-Moore under ether given by the open method. A large unilocular ovarian cyst was found; this originated from the left ovary, and its pedicle formed a continuation of the left broad ligament. There were some adhesions to the pelvic wall. The cyst was removed, leaving the ovary behind.

The cyst contained about two pints of a grumous semi-purulent fluid, from which the *Bacillus typhosus* of Eberth was obtained in pure culture.

At 7 p.m. the patient was very feeble; the pulse was 140, and the temperature 100.8° F. A pint of saline solution was given by the rectum, and a hypodermic injection of digitalin $\frac{3}{16}$ grain and strychnine $\frac{1}{16}$ grain was given every four hours. She had a fair night, without much pain, and on May 18th was better, the temperature being 98.6° and the pulse 120. There was no vomiting. A slight haemorrhagic vaginal discharge was noticed, and persisted for two days.

She made a rapid and uneventful recovery.

H. G. C. MOLD, Lieutenant R.A.M.C. (S.R.).

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

NORTH STAFFORDSHIRE INFIRMARY.

ARTERIO-VEINOSUS ANEURYSM OF POPLITEAL VESELS.

(By ERNEST CONNELL, L.R.C.P. and S.I.)

PRIVATE A. J., Belgian soldier, received a bullet wound on October 28th, 1914. The point of entry was two inches above the internal condyle of the left femur, and the exit over the middle of the popliteal space. He was admitted suffering from acute pneumonia and arterio-venous aneurysm of the popliteal vessels.

One month later he was transferred to the surgical side under Mr. Hartley's charge. He complained of pain and swelling in the left knee and leg, and of "music in his leg." A pulsating swelling was felt in the popliteal space, and the limb below was bluish. A marked thrill was felt, and a loud musical bruit could be heard over the

swelling. No pulsation could be made out in the tibial arteries. On applying pressure over the superficial femoral artery the pulsation, thrill, and bruit disappeared.

Operation.

On June 4th, 1915, Mr. Hartley, after the application of a tourniquet, opened the popliteal space by a median incision. The popliteal nerves and their branches were carefully retracted and preserved. The aneurysmal sac, about the size of a small hen's egg, was then dissected out. Next the artery was ligatured with silk, proximal to the sac, which was then incised, dark clotted blood being squeezed out. The four large openings of the vessels were easily found in the sac. A closed pair of Spencer Wells artery forceps was carefully inserted into the artery distal to the sac, which was thus readily defined and ligatured. The opening into the sac was closed by a continuous suture of fine catgut, and the suture line invested by a continuous Lembert suture of fine silk. On releasing the tourniquet the vein became enormously distended, and free oozing was seen, but in a few seconds the vein became much smaller, and the oozing so slight that no points needed ligature. A drainage tube was, however, inserted, and retained for five days, the rest of the wound being closed. A back-splint was applied, the limb raised, and kept warm.

On the day after operation the patient complained of severe pain in the leg, but otherwise recovery was uneventful. He was kept recumbent for three weeks and then went home, very pleased that the "German band" in his knee had ceased its music.

I am indebted to Mr. Hartley for kind permission to publish this case.

Reviews.

A HISTORY OF THE HOHENZOLLERNs.

DR. CABANÈS, well known by his researches in the bypaths of history, especially in its relations to medicine, has written the history of the Hohenzollerns¹ with the object of throwing light on the mentality of its present representative. The name occurs for the first time in the eleventh century, but the dynasty was really founded by the Great Elector, Frederick William, who reigned from 1640 to 1688. In his proclamation to his people he called himself Margrave of Brandenburg, Arch-Chancellor and Elector of the Holy Roman Empire, Duke in Prussia, Prince of the Pomeranians and the Vandals, Burgrave of Nuremberg, and so forth—a "silly stately style" recalling the enumeration of the titles of Lord Talbot by Sir William Lucy in the first part of *King Henry VI*. At the revocation of the Edict of Nantes, the Great Elector received some 10,000 French refugees, who brought with them arts and manufactures into a country which had previously been little more than a barren waste inhabited by a half savage population. Their intellectual activity as lawyers, physicians, engineers, and architects greatly helped the future development of Prussia. The Great Elector died at the age of 67 at Potsdam, leaving a son by his first wife. This was Frederick, who first assumed the title of King of Prussia, putting the royal crown on his head with his own hand. Ceremonies were the chief occupation of his life. Such was his love of theatrical display that it is recorded that his chief regret, when he died in 1713, was that he could not see his own funeral. He was succeeded by Frederick William I, who for English readers lives in fading colours in the pages of Carlyle and Macaulay. He ruled his subjects and his family with the brutality of a Prussian sergeant, and on one occasion he was with difficulty prevented from putting his son to death with his own hands. Though his stinginess made him a byword throughout Europe, he spent huge sums in kidnapping tall men wherever they were to be found. These he enlisted in his guards, and he tried, as Dr. Johnson says, to propagate procreancy by laying hands on all the big women he could find, and marrying them by force to his gigantic soldiers. The result, however, was disappointing. With age his

savage temper became ever more irritable; he had attacks of epilepsy and actual mania, though to the end there was generally a method in his madness. After him came Frederick the Great, a man of high intelligence, but without moral principle. He did much for the greatness of Prussia, but it was by unscrupulous trickery and downright robbery. He had no regard for agreements, oaths, treaties, or diplomatic "scraps of paper" of any kind. His policy, cynically avowed, was that there was no tribunal before which kings could be tried, and that they had the right to take what they could. He was, in fact, like the freebooter who lived by

The good old rule, the simple plan
That he should take who has the power
And he should keep who can.

His intellectual power preserved him from the worst eccentricities of his father, but he had much in common with him, though he concealed his native brutality under a veneer of culture. He was mean to the degree of miserliness. His temper was imperious and irritable to the point of ferocity; he was fond of cruel practical jokes and ingenious in devising means of annoying and wounding the feelings of those about him. Yet, like many persons who are unkind or indifferent to their fellow creatures, he was fond of his dogs; he always had the animals about him and allowed them every liberty. Probably to show his contempt for mankind, he directed in his will that he was to be buried among them. It is impossible, however, to deny him some of the qualities of greatness. To the very end he persisted in directing every department of his Government. His devotion to work seems to have been largely due to his desire to distract his mind from melancholy, and his incessant scribbling and verse, which otherwise might be regarded as a form of mania, may be ascribed to the same cause. He said that for him these things took the place of drink.

Frederick was succeeded by his nephew, Frederick William, a superstitious visionary, during whose reign Germany was overrun by *Illuminati*, freemasons, and mystics, who sought for the philosopher's stone and plotted the overthrow of kings and priests. Cabanès gives an account of the initiation of candidates, but a fuller description of these fantastic ceremonies will be found in the Abbé Baruel's history of secret societies and in George Sand's *Comtesse de Rudolstadt*. The King is said to have attended some of these initiations in disguise, and the excitement caused in him by the calling up of the spirits of the dead is said to have contributed to his death, which took place in 1797. His successor, Frederick William III, was a man of great simplicity but of weak will, whose wife, Queen Louise, a very beautiful and charming woman, tried in vain to conquer Napoleon after the defeat of Prussia in 1806.

Frederick William III died of influenza in 1840 and was succeeded by Frederick William IV, who is said to have declared that he would never allow a "scrap of paper"—that is to say, a constitution—to stand between him and his people. His idea was to unite feudalism with absolute monarchy. The troubles of 1848 seem to have been too much for his reason, and during the last ten years of his life he was mad. He was succeeded by William I, who was proclaimed German Emperor during the war of 1870-71. He was an honest man, who had the wisdom to leave the management of affairs to Bismarck and Moltke. The chief business of his life seems to have been to change his uniform several times a day.

Frederick III, father of the reigning Kaiser, was a man of simple tastes and straightforward character, who had nothing in him of the mountebank or the swaggering Prussian. Had his life been spared the development of Germany would probably not have followed a course that made her a constant menace to her neighbours, and the world would not now be struggling against her devastating ambition.

Of the present Kaiser, Cabanès says he is an actor clad in the Imperial purple, constantly striving to keep himself in the limelight and posing for the admiration of the world. One can imagine him when the time comes for him to leave the stage of life, sighing with Nero *Qualis artifex pereo!*

Dr. Cabanès has traced the origin and rise of the Hohenzollerns with a careful choice of detail which brings out clearly the evolution of the race and the means by

¹ *Foite d'Empereur. Une Dynastie de Dégénéris. Guillaume II jugé par la Science. Par le Dr. Cabanès. Paris: A. Michel. 1915. (Cr. 8vo, pp. 460; 63 illustrations. Fr. 3.50.)*

which, beginning as "wee bit German lairdies," to quote a Jacobite song, they have reached their present place among the rulers of the earth. He is to be congratulated on having produced a book which is a contribution to historical literature at once solid and readable. It is illustrated by sixty portraits and other figures, and there is an appendix by M. Rougement in which he analyses the peculiarities of the Kaiser's handwriting.

ROSE AND CARLESS'S MANUAL OF SURGERY.

It is a remarkable tribute to the vitality of a textbook that with unflinching regularity since its first issue a new edition has been called for every three years. We have already, in noticing the previous edition of ROSE AND CARLESS'S *Surgery*, indicated our opinion that it ranks easily amongst the best textbooks of surgery in the language, and we see no reason to alter that opinion after contemplating the newest issue. In the preface to the eighth edition Professor Carless lamented the loss of his co-worker, Professor Rose; in the preface to this, even greater oppression of spirit and soreness of heart are reflected when he considers the war and all its losses. The changes in the book are only those necessary to keep it quite up to date, bearing in mind its double purpose to instruct students and to help practitioners. Cautious pronouncements on the achievements of salvarsan and radium, a chapter on modern methods of treatment by physical agencies like heat, light, and electricity, and some illustrations are new features. The book is no bigger than formerly. We hope the publishers will always keep its size within the limits of a single volume easy to handle and convenient for reference. From the bibliographical point of view the publishers have left nothing undone in clearness of type, aptness of illustration, and security of binding, which permits the book to lie flat open at any page. Men who have found their familiarity for this book grow into affection will gladly welcome their old friend after its triennial rejuvenation; while those who do not yet know it will speedily learn to treasure it for its real worth.

INFECTIOUS DISEASES.

The volume by Dr. J. A. KOLMER, of Philadelphia, entitled *A Practical Textbook of Infection, Immunity, and Specific Therapy*,³ is an amplification in permanent form of a course of instruction given during the past few years to students and post-graduates in the medical school of the University of Pennsylvania.

The aim of the writer, as stated in the preface, has been threefold: (1) To give to practitioners and students a concise account of the manner in which the body may become infected, and the method, in turn, by which it serves to protect itself against infection, and to describe the practical application of this knowledge to the diagnosis, prevention, and treatment of disease; (2) to give physicians and others engaged in laboratory work a guide to the various immunologic methods; (3) to outline a laboratory course in experimental infection and immunity for medical students and others.

The work is divided into five parts. In the first the writer describes simple methods for preparing capillary pipettes and similar laboratory apparatus, the various methods for obtaining human and animal blood, the technique of animal inoculation, the methods for effecting active immunization of animals, and the methods for preservation of serums.

In the second part the principles of infection are discussed, and an account given of the production of disease by the formation and action of exogenous and endogenous toxins, bacterial proteins, mechanical blocking of vessels, and formation of pomeanes.

The third part, which constitutes the largest and most important portion of the work, deals with the principles of immunity and special immunologic technique, and contains a full description in their historical, theoretical, and practical aspects of opsonins, vaccines, antitoxins, ferments

and antiferments, agglutinins, precipitins, cytolysis, bacteriolysis, haemolysis, complement fixation reactions, cytotoxicity, the relation of colloids and lipoids to immunity, and anaphylaxis. Three chapters, containing more than a hundred pages, are devoted to the important subject of complement fixation reactions. The Wassermann reaction and its modifications are described in detail, and an account given of complement fixation in other diseases, such as gonococcus infections, glanders, typhoid fever, tuberculosis, cancer, and echinococcus disease.

In the fourth part, which deals with applied immunity in the prophylaxis, diagnosis, and treatment of disease, the writer first exposes the relation of anaphylaxis to infection and immunity, and describes the various anaphylactic or allergic reactions, such as the tuberculin tests, the lectin reaction, the mallein reaction, and allergic reactions in other diseases. In the following chapters of the fourth part the prophylactic and therapeutic use of vaccines and serums and chemotherapy are discussed.

The fifth part, which may be regarded as an appendix, is a laboratory course consisting of sixty exercises, and is based upon the course given by the author in the Laboratory of Experimental Pathology at the University of Pennsylvania, and in the laboratories of the Philadelphia Polyclinic and College for Graduates in Medicine. In many of the experiments the exact technique of a given test is described, thus rendering a separate book unnecessary. Each of the exercises is followed by a number of questions, the answers to which are to be found in the body of the work.

Dr. Kolmer is to be warmly congratulated on his achievement. The work is well up to date, and maintains a high standard throughout. The clearness of description, wealth of detail, and mastery of the literature make the book a most valuable work of reference, which should be consulted not only by the laboratory worker, but by all who take an intelligent interest in the problems of modern medicine.

GERMANY'S FOOD PROBLEM.

In his preface to the English version of *Die deutsche Volkernahrung und der englische Aushungersplan* Dr. RUSSELL WELLS, the translator, explains that it has been issued because "it was thought that there was no better way of bringing before the English public the facts of the case as seen through German eyes." The original is the work of Professor PAUL ELTZBACHER, assisted by a committee of fifteen Berlin professors and experts, and from the eminence of its authors, as well as the fact that many of the economic measures advocated in its pages have already been enforced in Germany, it may safely be assumed that in this volume we have the official textbook on which the German Government and people are acting in their endeavour to defeat the so-called "English starvation scheme." *Germany's Food: Can it Last?*⁴ is the title of the translated version, and those who read it with care and attention will be in almost as good a position to answer this vital question as any German could have been at the time when the original was issued.

The writers assume the success of our endeavour to prevent the importation of all foodstuffs or fodder into Germany, and, by an elaborate estimate of the available resources and possibilities of increased production, as well as of diminished and reformed consumption, endeavour to demonstrate the ability of the German nation to provide for itself under war conditions for an indefinite time. The consumption of food in Germany during the two years preceding the war is taken as the basis of comparison, but is held to have been considerably in excess of physiological requirements, especially in regard to its protein constituents, where the danger of shortage is considered to be greatest. In 1912 and 1913 Germany is said to have consumed annually 2½ million tons (116 grams a man a day) of protein food. The authors believe that Germany can manage, if need be, with rather more than 1½ million tons (80 grams a man a day), of which the unrefined internal resources of the country will provide nearly all. But by adopting the suggestions of the authors, those resources can, they assert, be so

³ *Rose and Carless's Manual of Surgery for Students and Practitioners*. Revised by A. Carless, M.B., M.S. Lond., F.R.C.S. Ninth edition. University Series. London: Halkiell, Tinsall and Cox. 1914. (Demy 8vo, pp. 1428; 16 plates, 629 figures. 2s. net.)

⁴ *A Practical Textbook of Infection, Immunity, and Specific Therapy, with Special Reference to Immunologic Technique*. By John A. Kolmer. With an introduction by Allen J. Smith, with 145 illustrations, 45 in colour by Edwin P. Faber. Philadelphia and London: W. B. Saunders Company, 1915. (Roy. 8vo, pp. 829; 25s. net.)

⁴ *Germany's Food: Can it Last? Germany's Food, and England's Plan to Starve her out. A Study by German experts*. Edited by Professor Paul Eltzbacher of Berlin. English version, edited by R. Russell Wells, M.D., F.R.C. With a critical introduction by A. D. Waller, M.D., LL.D., F.R.S. London: University of London Press, 1915. (Demy 8vo, pp. 263. 2s. net.)

improved as to provide rather more than two million tons of protein food (102 grams a man a day). In calorimetric values the case appears more favourable, the ante-bellum consumption being 50.42 billion calories, the essential minimum estimated at 56.75 billion, the unreformed production 67.68, and the possible production 81.25 billion. Hence—to quote Professor Waller's introduction—"in this account given by the Berlin professors of the measures by which the so-called 'hunger war' of Great Britain against Germany can be defeated, the hypothetical conclusion is drawn that if measures of economy are adopted Germany cannot be starved out."

As a specimen of forethought, zeal, and industry the book is remarkable, but the impression left on most minds will perhaps be that it amounts to an attempt to calculate the incalculable.

NOTES ON BOOKS.

At a time like the present, when both the medical and the nursing professions are being strained to the utmost of their powers, it is obvious that a considerable proportion of the younger workers must depend more upon books and lectures for elementary teaching than upon personal tuition. Hence such works as Dr. F. J. SMITH'S little book on *Domestic Hygiene for Nurses*,² of which a second edition has recently appeared, may serve a useful purpose. The writer has evidently formed a high opinion of the intelligence of the average probationer, and to the more highly educated among them his chemical and physical definitions may appeal, but the ordinary girl who "takes up nursing" may find it difficult to form a mental conception of a molecule, and will perhaps be content to recognize boiling water when she sees it cease to bubble without troubling her head as to the nature of the physical phenomena. Apart from a tendency to overburden his teaching with explanation, the writer supplies a vast deal of useful information, dividing his work into two parts, dealing first with the chemical and physical properties of matter, heat, light, air, and water, and afterwards with the practical application of the knowledge thus imparted. The use of clothing as a regulator of body heat, the management of ventilation, and the fallacies which often lead to its mismanagement, the intelligent employment of light, and many other such matters which a nurse should know, are passed in review, and discussed in a pleasant colloquial style.

Aids to Tropical Medicine,³ by GILBERT E. BROOKE, M.A., L.R.C.P., has now reached a second edition. New chapters on three-day fever, verruga peruana, snake bite, disinfectants, fleas, flies, mosquitoes, and rats add to the usefulness of the work. The articles are arranged alphabetically, as in the former edition. A number of mistakes to spelling have crept into the text, which is especially unfortunate in a manual primarily intended for students—*for example, histolytica is spelt "hystolittica,"* Veddler's name is spelt as "Keddler," and Sand with as "Sandwich." In other points the work is not perhaps quite up to date—for example, *Filaria loa* gives rise to symptoms ("calabar swellings"); the filaria embryo takes longer than a week to develop in the mosquito's muscle; the old mistake of considering *Stegomyia fasciata* the intermediate host of *Eilaria bancrofti* is perpetuated, though the error has recently been pointed out. Again, *Stegomyia pseudo-cellularis* is said to carry nothing, whereas it is the carrier of *Filaria bancrofti* in Fiji. Under the South American form of Leishmania there is no description of forest yaws or uta. On page 206, heading 3, "2 grains" are evidently meant instead of 2 quarts, and solution is wrongly spelt. Such mistakes and omissions as those mentioned should be corrected, as they diminish the value of an otherwise useful little work.

² *Domestic Hygiene for Nurses, with so much of Chemistry and Physics as are necessary to the Reasonable Understanding thereof.* By F. J. Smith, M.D., F.R.C.P. Second edition. London: J. and A. Churchill, Ltd. (Cr. 8vo, pp. 172; 20 figures. 2s. 6d. net.)
³ *Aids to Tropical Medicine.* By G. E. Brooke, M.A., Camb., L.R.C.P., Edin., D.P.H., F.R.G.S., etc. Second edition. Students' Aid Series. London: Baillière, Tindall, and Cox. 1915. (Fcap. 8vo, pp. 232; 31 figures. Paper 3s. net, cloth 3s. 6d. net.)

MEDICINAL AND DIETETIC ARTICLES.

Hydrous Wool Fat.

AMONG the various drugs of which supplies were drawn principally or entirely from Germany before the war, one was lanolin or wool fat; the latter has been a shortage of this valuable ointment base. British manufacturers have turned their attention to supplying the deficiency, and we have received from Messrs. Corbyn, Stacey, and Co., Ltd.

(673, Commercial Road, London, E.), a sample of hydrous wool fat of their own preparation. This has the familiar light yellow appearance; the sample contained 20 per cent. of water, which is rather below the proportion given in the *British Pharmacopoeia*, and had an acid value of 7.9; the latter figure is well within the limits of the *B.P.* test, which represents an acid value of 14, although it would not have passed the much more stringent requirements of the *British Pharmacopoeia* of 1898. While it would be too much to say that the product is in all respects equal to the German article which it is to replace, it appears to be quite satisfactory for use.

MEDICAL AND SURGICAL APPLIANCES.

Needle for Muscle and Fascia.

MR. C. HAMILTON WHITEFORD (Plymouth) writes: A few years ago Messrs. Allen and Hanbury made, at my request, a needle for muscle and fascia, which I have found most useful. The needle is 4½ in., round-bodied, with a Paterson eye and a Moynilhan § circle curve. There are two sizes, the stouter being the more suitable for general work. The needle is used without a holder, and to any one who has not actually used it gives a suggestion of clumsiness which is apparent rather than real.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee (on August 10th) nineteen cases were considered, and £144 was granted to seventeen of the applicants. The following is a summary of the cases relieved:

Daughter, aged 56, of M.R.C.S.Eng. who practised at London, Halifax, and Manchester. Has earned a living as housekeeper until recently. Health broken down, so requires a rest. Voted £5, and referred to the Guild.

Widow, aged 62, of M.R.C.S.Eng. who died in 1887, and had practised at Ambleside. Until the war commenced she had managed to earn a living by teaching and taking in boarders, mainly from France who came to learn English. Since the war has scarcely earned anything, and is in great difficulties. Voted £10.

M.R.C.S. and P. Edin., aged 64, who practised in the Midlands. In this crisis frayed and scarcely able to practise. Two sons who assisted in the upkeep of the house joined the army, and one has been killed and the other dangerously wounded. The applicant badly wants a short holiday. Voted £5.

Widow, aged 57, of L.R.C.P. and S. Edin. who practised at Walsall. Husband, who died in 1902, left no provision for his widow and two daughters, both of whom are training for the teaching profession. Applicant's only income is about £20 from literary work and £20 from a relative. Relieved nine times, £94. Voted £12 in twelve instalments.

Daughter, aged 65, of M.R.C.S.Eng. who practised at Liverpool. Lost all her income in consequence of an Australian bank failure. Is a confirmed invalid and practically bedridden. With the help given by the Fund and several friends applicant just manages. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 70, of M.R.C.S.Eng. who practised in East London. Left totally unprovided for at husband's death in 1913. Has five children, three of whom are married, and with the other two unable to help. Has a small pension from another society, and relatives help a little. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 66, of L.R.C.P. and S. Glas. who practised at Heaton, and died in 1899. Was left totally provided for at husband's death, with six children. The two eldest now married and unable to assist. One son and one daughter working, and earn 20s. per week between them. Applicant endeavours to increase her income by taking lodgers, but this is very precarious. Relieved thirteen times, £154. Voted £12 in twelve instalments.

Widow, aged 43, of L.R.C.P. and S. Glas. who practised at Flessmere Fort, and died in 1910. Applicant was left practically unprovided for with seven children, aged 5 to 19. Only certain income £45 per year, and sister helps to pay the rent. The eldest daughter hopes to obtain work soon as a teacher. Relieved three times, £36. Voted £12 in twelve instalments.

Daughter, aged 58, of M.D., M.R.C.S.Eng. who practised at Wyndham. Income was invested by a guardian who appropriated all the capital and left the applicant destitute. Only income £13 a year from a relative. Not strong enough to work. Relieved seven times, £35. Voted £5.

Daughter, aged 77, of M.R.C.S.Eng. who practised at Bungay. Only income a small annuity purchased by friend, and owing to the increased cost of food, and having recently to remove to another lodging, requires a little help. Relieved some years ago, twice, £23. Voted £5.

Widow, aged 73, of L.R.C.P. and S. Glas. who practised at Leiston. Has five children, none at present able to help. Has a pension from another charity. Relieved three times, £18. Voted £3.

Widow, aged 60, of I.S.A.Lond. who practised at Rotherhithe, and died in 1897, leaving the applicant with eight

children, seven of whom are now married, and unable to assist. The son at home does all he can, but it is not sufficient to keep both he and his mother. Applicant just recovering from a severe illness. Relieved eight times, £120, the last several years ago. Voted £5.

Daughter, aged 65, of M.R.C.S.Eng. who practised at Ford and died in 1901. Applicant left unprovided for, and, owing to ill health and age, unable to work. Only income the amount received from the Fund and the Guild. Relieved eight times, £99. Voted £12 in twelve instalments.

Widow, aged 56, of L.R.C.P. and S.Glass, who practised at Bibbo and Winecombe, and who died in 1898. Was left with two young boys, since dead, quite unprovided for. Has derived her income from taking in boarders, but, owing to district in which she had established herself having deteriorated and the war, was unable to make the place pay. Had received the chance of a good house in the country, and wanted help for removal expenses. Granted by the Fund £10, the Guild £15, and two other societies assisted to enable the applicant to remove.

Daughter, aged 47, of M.D.St. Andrews. Has recently undergone an operation, and not yet strong enough to work. Earned a living as a school teacher, but all her savings gone in consequence of ill health during the last two years. Father unable to help, as he can scarcely keep himself owing to old age and ill health. Relieved once, £5. Voted £3 with leave to apply later in the year.

Daughter, aged 59, of M.R.C.S.Eng. who practised in Suffolk. Applicant has continual ill health, and only income derived from letting her furnished cottage and amount given by the Fund. Relieved ten times, £106. Voted £12 in twelve instalments.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, II, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild appeals for gifts of secondhand clothing, boots, and shoes in good condition, also household linen. The gifts should be sent to the Secretary, Royal Medical Benevolent Fund Guild, 43, Bolsover Street, W.

PROTECTIVE GOGGLES FOR WORKMEN.

MANY workmen, among them glass-blowers, puddlers, electric welders and forgers, are exposed during their labours to excessive glare and heat; others, including photographic process block makers, work near a source of light rich in violet and ultra-violet rays. Men in the first category—glass-makers and puddlers—are liable to a characteristic type of cataract; those in the second to a painful form of conjunctivitis—"ophthalmia electrica"—which seems to be identical with snow blindness. Sir William Crookes has shown by spectroscopic examination that ultra-violet rays are not emitted from the surface of molten glass, and also that α rays are absent. It is in consequence generally held that bottle-maker's cataract is caused by the infra-red rays, which are present in excess in the light from the glass furnace. Ophthalmia electrica and snow blindness are certainly caused by ultra-violet rays. These do not penetrate beyond the lens, which absorbs them, and fluoresces.

The mercury vapour lamp, and in higher degree the quartz mercury lamp, furnish a light rich in violet and ultra-violet rays, which is strongly actinic. In consequence, these lamps are occasionally chosen for process block making. This lamp is very economical in current, and has the advantage of being a diffused source of light, which in this respect approximates daylight and only throws a slight shadow. For these reasons it is used for factory lighting. The arc lamp, and especially the iron arc, is only second to the mercury lamp as regards wealth of ultra-violet radiation. In electric welding the iron carbon arc exposes the welder to the evil effect of these rays.

It is obvious that the choice of suitable goggles for a workman presents a complicated problem which must be solved by a scientific consideration of the physical characteristics of the light to which he is exposed. For some purposes we require a glass which will exclude heat and glare; for others the elimination of ultra-violet radiation is demanded. A great deal of work has been done in investigating the matter, with the object of producing glass which will effectively filter out any desired rays. Mr. Lackeisch, the physicist to the Hecla Research Laboratory of the National Lamp Works of the General Electric Company at Cleveland, Ohio, published about a year ago an account of his researches in this field. He examined

with the spectroscope various specimens of glass, using a variety of sources of light, including the iron arc. In many trades, such as electric welding, it is necessary to exclude ultra-violet rays from the eye and simultaneously to reduce the glare to a safe degree. By so doing the welder is shielded from conjunctivitis and from glare blindness, which, typically in "eclipse blindness," is characterized by a positive central scotoma—scotoma heliclipticum. As a general solution of this problem, Lackeisch proposes to combine a yellow-green glass totally absorbing ultra-violet rays with a shade of smoked neutral glass sufficiently dense to reduce the brilliancy of the light to a safe degree. Euphos glass has a great reputation as an ultra-violet filter, and was used by Shackleton and Amundsen in their Antarctic expeditions. Lackeisch found that euphos glass transmitted a large amount of ultra-violet rays. Amber glass is an effective filter of these radiations, but it modifies colour perception to such an extent that men who have to temper steel by quenching when it exhibits a certain hue are deceived, and are therefore unable to wear this glass. Lackeisch found that a glass called "Akopos" was the most satisfactory specimen that he examined—a greenish-yellow glass, it absorbs ultra-violet rays almost completely, and, combined with neutral glass, is eminently suitable for welders and temperers. We have, however, tried in vain to obtain a specimen of akopos for the use of a cinema operator who suffered from glare conjunctivitis, although application was made to the largest firm in America. Akopos seems to be a scientific curiosity.

Fortunately the researches of Sir William Crookes have given us a glass which is very satisfactory as a filter of noxious light. He conducted a series of laborious experiments primarily, we believe, to discover a glass which would prevent bottle-makers' cataract, by absorbing the infra-red rays. His work is published in *The Philosophical Transactions*, vol. 214, Series A, 1914. In order to examine the question of heat absorption, he passed the light through a plate of biolite and received the heat rays upon a special thermometer and a radiometer balance. The metals—cerium, chromium, cobalt, copper, iron, lead, manganese, neodymium, nickel, praseodymium, and uranium—were in turn incorporated with a soda flux, and the resulting glass examined. Cerium was found to be valuable, affording a colourless glass with a high power of absorbing ultra violet rays. Ultimately a series of glasses were obtained whose characteristics were classified under the heads: Infra-red absorbing power, impermeability to ultra-violet rays, and power of light transmission. From these specimens it ought to be possible to choose a glass suitable for any form of goggles. Science has solved the problem, but it seems that hitherto, as has so often happened in other instances, the product of science seems to have been rendered of little practical utility by commercialism. Only two types of the Crookes's glass are manufactured. So far as we have been able to ascertain practically the whole output of an English firm which utilizes the formula of a British scientist has been secured by an American company, which controls the output, places it in the hands of the wholesale optical trade, which in turn hands it to the retailers.

However this may be, the actual position in this country is to-day, or was very recently, that the final price of Crookes's glass is so high that it is not used for goggles for workmen. A second even more vital objection is that neither variety is nearly dark enough for most of the trades which demand goggles. A double glass would be necessary—a neutral to exclude glare, and a Crookes's to absorb the ultra-violet rays. The ordinary blue or neutral glasses used in most factories are made in France, and cost eightpence a pair. A goggle made of Crookes's glass with a neutral glass mounted in the same frame would cost about eight shillings. These spectacles do not last long; in electric welding they are rapidly covered with metal particles, which appear on both sides of the glass—in fact, they bombard a glass used behind them. It is quite obvious that a satisfactory goggle can be produced, but that it is not "a commercial proposition." The labours of Sir William Crookes, which might have conferred benefit upon thousands of workmen, have only produced a glass which is useful for those like draughtsmen, who work long hours by electric light, and can afford to buy spectacles which exclude ultra-violet rays.

British Medical Journal.

SATURDAY, AUGUST 28TH 1915.

THE MENTALITY OF THE KAISER.

A QUESTION much debated at the present time is the mentality of the Kaiser. There are some who have won the right to be regarded as authorities of the mind who have not hesitated to express the opinion that he is definitely insane. This is not a novel view. Long ago a German scholar discovered many points of resemblance between him and Caligula; and in the *North American Review* for October, 1904, the well-known psychologist, Dr. McLane Hamilton, wrote that in the history of the Hohenzollerns "it is not difficult to find a distinct insane trace which in times more remote found expression in cruelty, oppression, and unmistakable insanity of other kinds, or in recent times by a mental degeneration which is strikingly exemplified in the present German Sovereign." "His childhood and youth," it is added, "were characterized by peculiarities of conduct that may safely be said to be psychopathic, while his early manhood was punctuated with frequent instances of decidedly insane behaviour which have become more conspicuous and continuous." In a further article which appeared in the same *Review* for June of the present year Dr. McLane Hamilton repeats the opinion expressed in his previous paper, and declares the Kaiser to be "a menace to the world, for the reason that he not only has shown the exceedingly bad judgement that belongs to those who are mentally inferior, but has delusive ideas of grandeur and consequent power of persecution and conspiracy." His enmity towards England is said to be especially unbounded and morbid. Dr. Hamilton concludes with the following prophecy: "In these civilized days theatrical display and the warlike methods of Attila, 'the scourge of God,' may for a time succeed, but when a madman directs the conduct of war, it can only end in defeat."

Another distinguished American psychologist, Dr. Morton Prince, has devoted a book to a study of the sentiments and obsessions of the Kaiser.¹ He finds the secret of his psychosis in a fear of democracy because of the danger with which it threatens himself and his house. This, he says, is a subconscious phobia that "induces a defence reaction of an intensely emotional character, which aims to direct his activities in a direction that will protect him against the danger of democracy." For this he relies upon his soldiers, whom upon a famous occasion he called upon to be prepared at his command to shoot down their parents and brothers in the street.

Elsewhere in this issue of the *BRITISH MEDICAL JOURNAL* there appears a review of a history of the Hohenzollerns by Dr. Cabanès, one of the subtitles of which is "A Dynasty of Degenerates." In presenting this work to the Académie de Médecine, Professor Landouzy, dean of the Paris Faculty, expressed a strong conviction that the Kaiser is suffering from the mental degeneracy which is the fate of men invested with sovereign power, whose will no man disputes and no law controls.

For our own part we feel that we are not in a position to express so positive an opinion on the mental state of the German Emperor. Although the literature that has gathered about his name would form a considerable library, we place little reliance on the gossip of courtiers, which is either flattery inspired by flunkeyism or malicious misjudgement. The facts are too few to warrant a definite verdict on the mentality of the Kaiser, and such information as we have comes from doubtful or tainted sources. But there is enough in his megalomaniac proclamations about his "destructive sword," and his alliance with the "old God" of the Prussians, to justify us in pronouncing him a man of abnormal mind. History, which has been described as philosophy teaching by examples, shows the effects of the "degeneration of the neurone" in the members of families of what Othello calls "men of royal siege"; this is illustrated by the decadence of the Caesars. We do not altogether agree with Dr. Cabanès in regarding the Hohenzollerns as a "dynasty of degenerates." Although there have been among them remarkable instances of eccentricity and even distinct mental aberration, there have, on the other hand, been examples, such as William I and Frederick III, of perfect sanity, though neither exhibited any conspicuous intellectual power.

William II has a superficial brilliancy which was entirely lacking in his two immediate predecessors, but his pretensions to universal knowledge and especially to artistic skill, have made him a laughing stock among his own countrymen. A picture which he called "The Yellow Peril," and which he sent to the Czar at the beginning of the war in the Far East, is said to be suggestive of insane art. He has excited the indignation of the sculptors and architects of Germany by tampering with their designs and plans. But such eccentricities do not justify us in calling a man insane. All that can be said is that in the Kaiser are exhibited some of the evil consequences of unrestrained power wielded by hands incapable of guarding the forces which the doctrine of "the right divine of kings to govern wrong" has by the accident of an accident placed in them. Human nature at its best cannot resist the demoralizing effect of absolute power; and a man of mediocre intellect necessarily falls a prey to exaggerated ambition when his own conceit and the intoxicating incense of a nation which bows the knee before him makes him fancy himself a demigod. Never before in the world's history has the truth of the words of Horace, *Quidquid delirant reges plectuntur Achivi* received a more terrible proof than in the present war. But it is one of the miseries of our human lot that the madness of kings which sends millions of men to death for the gratification of their lust of dominion does not come within the category of certifiable insanity.

RESEARCH IN ANTISEPTICS.

IN an article published under this heading a fortnight ago (p. 261) the results of the research into the antiseptic action of hypochlorous acid and its application to the treatment of wounds, conducted by Professor Lorrain Smith and his colleagues in Edinburgh, were briefly reviewed, and some account was given of a similar research carried out by Dr. H. D. Dakin of the Herter Laboratory, New York, who has been working in the laboratories supported by the Rockefeller Institute in connexion with the French Military Hospital at Compiègne, to which Dr. Carrel is surgeon. We are glad now to have the opportunity

¹ *The Psychology of the Kaiser*, By Morton Prince, LL.D. 2s. 6d. Oct. Fisher Cowin.

of publishing (at p. 318) a paper written for this JOURNAL by Dr. H. D. Dakin on the use of certain antiseptic substances in the treatment of infected wounds. It will be read with great interest, not only because it contains a full account of the method of preparation and use of the hypochlorite solution described, but also because it gives an indication of the direction in which antiseptics still more efficient and convenient may be sought.

When a solution of a hypochlorite, or free hypochlorous acid, acts upon organic substances containing the $-NH$ group, the first reaction almost always consists in the replacement of hydrogen by chlorine with the formation of substances of the group known as chloramines. Dr. Dakin considers that the antiseptic action of hypochlorites depends upon reactions of this kind. Proteins, such as blood serum, egg white, and casein, when treated with hypochlorites give products of high antiseptic value, and there seems to be no doubt that compounds of this type are formed in wounds treated with hypochlorites. In this way a certain antiseptic action may be expected to persist even after the free hypochlorite has disappeared.

The general considerations indicated above led to the conclusion that it would be well worth while to examine different varieties of the large group of chloramines, and in this work Dr. Dakin has had the co-operation of Professor J. B. Cohen, of the University of Leeds. Certain aromatic chloramines which form soluble sodium salts have already given most encouraging clinical results. It has been ascertained that both benzene-sodium-sulphochloramide and paratoluene-sodium-sulphochloramide are extremely powerful antiseptics. They are practically non-irritating, and can be used in much higher concentration than the hypochlorites. They are relatively easily prepared at low cost and have the advantage of being stable solids. In general their action is similar to that of hypochlorites, but more powerfully antiseptic. The molecular concentration of paratoluene-sodium-sulphochloramide necessary to kill staphylococci in the presence of serum is only about one-fifth of the correspondingly active molecular concentration of sodium hypochlorite. The number of cases thus far treated with these chloramide antiseptics is smaller than those treated with the hypochlorite mixture, but excellent results have, Dr. Dakin states, been obtained in a number of badly infected wounds.

As a practical point, it may be interesting to add that Dr. Carrel is, we learn, using a simple device for introducing hypochlorite solution or other solutions into the depth of a wound. It is not applicable to suppurating wounds, but it has been found very advantageous in wounds that have not become infected or have been efficiently sterilized; if supuration occurs the use of the appliance must at once be abandoned. It consists of a length of about eight inches of red rubber tubing of small calibre (about one-eighth of an inch internal diameter); one end is closed by a thread, and in its neighbourhood for about two or three inches small apertures are cut. The tube is then surrounded by a single layer of bath towelling four or five inches in length, which is firmly attached to the lower end, and stitched around the tube so as to form a sheath. The tube with its covering is inserted into the depth of the wound, and the solution is introduced (every two hours by day and two or three times during the night) into the wound through a syringe inserted into the free end of the tube. A considerable number of tubes may be used if necessary. The results of this treatment have, we are informed, been very satisfactory in suitable cases.

PAUL EHRLICH.

By the death of Professor Ehrlich Germany loses her most distinguished man of science, and the science of chemotherapy its founder and most able exponent. Professor Ehrlich was trained, some forty years ago, to be a medical practitioner, but, although he served for seven years as chief assistant at the Berlin clinic of Professor Frerichs, it had been apparent from the outset of his career that his natural bent was towards chemistry, and particularly towards the chemistry of the processes of life, rather than towards the practice of medicine. Even in his schoolboy days he appears to have been engaged in speculations as to the importance of oxidation in the animal body. The subject proposed for his leaving essay when he was in the highest class at the Breslau Magdaleneum was "Life considered as a dream." We are told that his essay described life and mental activity as normal processes of oxidation, and dreams as the results of a peculiar oxidation causing phosphorescence of the brain. Naturally such an essay was returned with the mark "non satis"; the idea that underlay it, however, was sound, and found a fuller and more reasonable expression in his book on the oxygen requirement of the organism, published in 1885. During his university days at Strassburg, where he first took up the study of medicine, he investigated the distribution of the metal lead in the various organs of patients with lead poisoning, employing fuchsin as a staining reagent for the purpose.

Ehrlich's admirers are apt to divide his life-work into four epochs, in accordance with the main problems he set himself to solve. According to this scheme, the first period was occupied with studies in the chemistry of dyeing animal tissues with aniline colours. In the second period, from 1890 to 1899, he was investigating toxins, antitoxins, and the chemistry of immunity to infectious diseases, making great use of his well-known side-chain theory. The third period, from 1899 to 1906, was occupied with the study of haemolysins and malignant disease in rats and mice; in the former he developed the theory of amboceptors with which the side-chain theory was completed. This work, through Bordet and Gengou's previous study of antibodies, led to the discovery of Wassermann's reaction for the diagnosis of syphilitic infection.

From 1906 onwards Ehrlich was occupied with the study of systematic chemotherapy, a science he misnamed "chemotherapy." This, the fourth epoch of his scientific activity, began with the investigation of the action of trypan-red, a highly complex polyazo-dye-stuff, in the cure of trypanosomiasis in the lower animals. This led him on to study the organic compounds of phosphorus, antimony, and arsenic, elements chemically related to the nitrogen to which he attributed much of the curative action of trypan-red. These investigations led, as is well known, to the discovery of salvarsan, or "606," in 1910, neo-salvarsan, or "914," in 1912, and sodium-salvarsan, or "1206a," in 1913.¹ The whole of his work during the last five-and-twenty years may be regarded as based on the leading idea that chemical substances, such as foods, drugs or poisons, only act as such after they have become fixed by chemical union to the cells or protoplasm upon which their specific action is to be exerted. This notion he sententiously summed up in the thesis, *Corpora non agunt nisi fixata*, "Substances act only when combined." His side-chain theory and theory of amboceptors really do nothing more than afford mechanical illustrations or analogues whereby this thesis may be

brought home more vividly to the mind. His hope was that these theories would help in the first steps of the solution of the problem of the constitution of protoplasm. They have left a profound impress upon the recent literature of experimental pathology, using the term in its widest sense.

Nature intended Professor Ehrlich to be a biological chemist. He was always a hard worker, and, as a list of his published works shows, his literary output was enormous. An excellent example of his style will be found in the address in pathology he delivered at the XVIIth International Congress of Medicine, held in London two years ago, printed in the *BRITISH MEDICAL JOURNAL*, 1913, ii, 353.

In this country he has often been reproached, particularly by men of science of the older school, with an undue fondness for speculation and hypothesis. His side-chain theory, too, has been severely criticized as a childish attempt to give mechanical representations of chemical relationships that are too complex for any such method of depiction. Yet his speculations, like his work, should be judged by their results in the last instance, and not by *a priori* considerations as to their value or rationality. We believe it to be generally admitted that his conceptions of the actions and relationships of toxins and antitoxins, fanciful as they may have seemed at first, have proved very useful, and, more important still, have inspired and directed a vast amount of experimental pathological and clinical investigation during the last ten or fifteen years. The great scope and value of the fundamental researches resulting in the discovery of salvarsan and its successors, discoveries due to design and not to accident, are self-evident; the inception of the methods of experimental chemotherapy and their execution have both been due to Ehrlich. As a hard worker constantly in touch with the realities of experiment in the laboratory, he was able to check the indications of his many theories by the results of his own experiments and those of his many collaborators. His was an original mind, and he had the common sense to see that theory and practice should go hand in hand. The loss which science has suffered by his death is great. It is notorious that in Germany the professors are servants of the State, and therefore political propagandists at need. Ehrlich was no exception to the rule, and accordingly subscribed his name a few months ago to a notorious declaration of faith made by ninety-three German men of science. The fact is an unfortunate illustration of the intellectual prostitution to which a rigorous system of State service leads.

THE WAR EMERGENCY.

At the meeting of the War Emergency Committee on August 25th it was reported that it had recently been brought to the notice of the Scottish Emergency Committee that statements were in circulation which seriously interfered with the success of the effort to provide the necessary medical men for the army. The Convener, therefore, at the request of the Committee, wrote to the Director-General detailing the statements which were being made, and asking an official reply which could be used to controvert them. The statements were that the needs of the Army Medical Department were exaggerated, that the War Office had already as many medical men as were required, and that offers of service had been declined. The reply authorized by the Director-General may be summarized as follows: To outfit the new armies and to supply reinforcements for six months, it is estimated that at least 2,500 more medical men of military age (that is, under forty) will be required. During the last six months temporary commissions have been granted in

every case where the applicant was prepared to fulfil all the conditions of the contract for service. In some cases where the offer of service was accompanied by restrictive conditions it was not possible to accept it. No official in the medical branch of the War Office has ever told any one that more medical men are not required. Indeed, it has been found necessary to make special provision to bring medical men from Canada, Australia, and New Zealand. It is specially incumbent on every young doctor who is physically fit to offer himself for military service. All will be needed, and practically all will have an opportunity of serving with the troops overseas. The duty of the older men is to set free the younger men by arranging to carry on their practices for them in their absence, or by engaging for home service. Any medical man preventing or dissuading his colleagues from assisting the medical service of the army during the war is doing a serious disservice to the empire. These being the facts, the Committee feels confident that now that all doubts as to the needs are cleared away, the response from every part of the country will be such as the country expects. The question of the representation of Ireland was considered, and it was resolved to recommend that a War Emergency Committee should be formed in Ireland on the same lines as the Scottish War Emergency Committee, and that it should nominate a member to be co-opted on the Central War Emergency Committee. The Committee resolved to ask the Director-General to instruct the Deputy and Assistant Directors of Medical Services not to accept or retain for work in military hospitals at home medical practitioners of military age who are physically fit, but to encourage them to accept commissions in the R.A.M.C. The Committee also resolved to call the attention of the governing bodies of civil hospitals to the importance of relieving from their hospital duties those junior members of their resident and consulting staffs eligible for commissions in the R.A.M.C., and to communicate with the British Hospitals Association to the same effect.

ENDOWMENT OF A LECTURESHIP IN PATHOLOGY AT GUY'S HOSPITAL.

The trustees and executors of the will of the late Sir William Dunn, Bt., an Alderman of the City of London, have handed to the Governors for, and on behalf of, Guy's Hospital Medical School £25,000 new War Loan $4\frac{1}{2}$ per cent. fully-paid stock for the purpose of endowing a lectureship in pathology in the medical school, to be called the Sir William Dunn Lectureship in Pathology. Rather more than two years ago Mr. A. J. Balfour opened the new buildings of the Medical School of Guy's Hospital. The new buildings consist of three main blocks. In the first accommodation is provided for the departments of physiology, chemistry, and physics, and include the Willis Library, the Gordon Museum, and administrative offices. The second block—a building of five stories—is occupied by the departments of pathology and pharmacology. The whole of this building is devoted to teaching and research, the routine pathological work of the hospital being carried on by other workers in a separate laboratory at the expense of the hospital. The third part of the new buildings affords accommodation for the dental school. In addition, the old department of anatomy was rebuilt and extended to provide for the teaching of operative surgery, and the department of biology was enlarged and refitted. The whole work of rebuilding and extension occupied many years, and has cost approximately £100,000. Of this sum, a great part had already been subscribed by the generosity of the Governors and other friends of the school at the time of Mr. Balfour's visit. In appealing for further subscriptions in order to extinguish the debt upon the school buildings and to provide endowment for the school, Mr. Balfour expressed his conviction that a sum of £200,000, which was needed to complete all the improvements desired, would ultimately be obtained. We

learn from the report of the Dean for 1914-15 that Mr. Balfour's appeal has so far met with an encouraging response, and the result has convinced the school that it has been wise in boldly undertaking the heavy expenditure now necessary to support an efficient school of medicine. Last year subscriptions to the amount of £16,800 were received and devoted to the extinction of the debt upon the buildings, and during the present year a further sum of £5,600 has been received for the same purpose. The bequests made to the school during the year include a legacy by the late Mr. Targett, at the time of his death lecturer on midwifery and diseases of women, the income from which fund is to be devoted to the expenses of upkeep in the pathological department; and an anonymous donation of £500 to the Medical School Research Fund. The Medical School of Guy's Hospital believes that the separation of its finances from those of the hospital, as demanded by the King Edward's Hospital Fund for London, has been a distinct advantage. It has removed from the minds of generous donors any confusion that may have existed as to the respective parts played by the hospital and by the Medical School, and has thus assisted them to recognize the paramount importance of providing buildings, equipment and staff, for the teaching of medicine and for the progress of research.

THE WHITE MAN IN THE TROPICS.

ALTHOUGH there are many who still deny that the white man can ever establish himself permanently in the tropics, Sir Patrick Manson believes that successful colonization in hot climates is a matter of acquisition of knowledge as to the conditions of healthy life and of the practical application of that knowledge. The problem is largely one of the discovery of efficient means of protection against the many microscopic enemies which almost seem to resent the invasion of the tropics by the white man. The poisons injected by these organisms vary in their nature and composition, but to all of them in general may be applied almost literally the description of the "Iperous distilment" poured into the ears of Hamlet's father:

whose effect
Holds such an enmity with blood of man,
That swift as quicksilver it courses through
The natural gates and alleys of the body,
And with a sudden vigour it doth posset
And curd, like eager droppings into milk,
The thin and wholesome blood.

Less than a quarter of a century ago no systematic attempt was made to fight these scourges, and men went to the tropics in a fatalistic spirit that led them to gamble their lives against the too likely chance of disease and death. Now all this is changed, and many vigorous campaigns are being conducted for the sanitary reclamation of the tropics. Already much has been done, notably in the prevention of malaria, a disease which has made waste some of the fairest and most fertile parts of the earth, and which has caused the ruin of flourishing states. Of its devastating effects the most terrible example is seen in the decay of ancient Greece. We need only recall here the chief triumphs of modern science in the domain of tropical medicine. The most conspicuous of these has been the banishment of yellow fever from Havana, and the sanitary cleansing of Panama where yellow fever, malaria, dysentery, and other diseases had defeated the enterprise and skill of the French engineers, who would doubtless, but for these scourges, have succeeded in making a canal through the isthmus. The French effort was baffled by the conditions which at that time made the Panama zone a most active breeding ground of the germs of tropical disease: That the Americans succeeded where the French failed is due to the progress of medical science and the application of the knowledge gained by research under the direction of General William C. Gorgas, a man who combines in a rare degree scientific resourcefulness with the power of organizing victory as a leader of men. It is with much

gratification, therefore, that we see from a report of an address delivered by him in Cincinnati, which appears in the *Boston Medical and Surgical Journal* of August 5th, that he shares the view we have often expressed as to the possibility of the white man establishing himself in the tropics. His opinion carries such weight that we quote it in full: "The real scope of tropical sanitation, which has been almost entirely developed within the last fifteen or twenty years, I believe, will extend far beyond our work at Panama. Everywhere in the tropics, to which the United States has gone in the past fifteen years, it has been shown that the white man can live and exist in good health. This has occurred in the Philippines, in Cuba, and in Panama, but the demonstration has been most prominent and spectacular at Panama, and therefore has attracted there the greatest world-wide attention. Here among our large force of labourers we had for ten years some ten thousand Americans—men, women, and children. Most of these American men did hard manual labour, exposed to the sun, rain and weather conditions day in and day out, yet during that time their health remained perfectly good, just as good as if they were working at home. The same remark as to health would apply to the four thousand women and children who lived at Panama with their husbands and fathers. Both the women and children remained in as good condition as they would have been had they lived in the United States. This condition at Panama, I think, will be generally received as a demonstration that the white man can live and thrive in the tropics. The amount of wealth which can be produced in the tropics for a given amount of labour is so much larger than that which can be produced in the temperate zone by the same amount of labour that the attraction for the white man to emigrate to the tropics will be very great, when it is appreciated that he can be made safe as to his health conditions at a small expense. When the great valleys of the Amazon and of the Congo are occupied by a white population more food will be produced in these regions than is now produced in all the rest of the inhabited world."

DEFECTIVE ADMINISTRATION OF THE SERVICE FOR THE FRENCH WOUNDED.

THE debate in the French Chamber on the military medical administration was resumed on August 20th, when the reply of the Minister of War, M. Millerand, was heard. Before this, however, Dr. Navarre resumed his interrupted speech, and criticized in particular the organization of the service of hospital trains and motor ambulances. Dr. Bousset, who had served for six months in the medical department at the front, complained that the motor ambulances were not directly under the control of the medical authorities, and hinted that of the 480 motor ambulances now supplied not all were properly utilized, owing to a failure to co-ordinate the needs at the front with those at the base. He complained also that the services of surgeons with operating experience were wanted. Another speaker, M. Fernand Merlin, said that the medical service was too much in the hands of officials, and that the proper work of physicians and surgeons was interfered with. M. Millerand made a vigorous defence, but was frequently interrupted. He said that the war broke out at a time when the medical service was being transformed, but asserted that the difficulties thus created had now been overcome. One hundred and ten hospital trains had, he said, been organized since August, 1914, and every army corps had 45 motor ambulances; altogether the medical service had from 1,800 to 1,900 motor vehicles. At the outbreak of war only about one-tenth of the 15,000 medical officers necessary were immediately available, but the distribution of the medical and surgical personnel had now been reorganized, so that the allocation of individuals according to their particular personal experience had been greatly improved. We may

recall at this point that three new Under Secretaries of State for War have recently been appointed: one of these—M. Godart—is Under Secretary for Health, that is to say, for medical administration, and M. Millerand took credit for having, at the suggestion of the new Under Secretary, displaced the medical director, who has been placed in charge of medical stores. M. Godart did not consider that both an under secretary and a director were needed. While we do not presume to say whether in the particular circumstances this was or was not a wise course, we are confident that the principle is wrong. The true principle is the autonomy of the medical service within its own sphere. The less non-medical Ministers responsible to Parliament meddle with professional details the better will it be for the health of the army, for the wounded man, and for the efficiency of the medical service. The debate was not concluded, and it was arranged that, for the first time for forty-four years, the Chamber should meet *in camera*. So far as the whole incident is a political attack upon M. Millerand and the Ministry of War it is not a subject for comment here, but, as we have indicated, there is a principle involved for which we had to fight hard in this country. The result of according proper recognition and proper authority to medical officers has been, as this war has shown, most happy, and we venture to think that the example of this country may be worthy of the study of our neighbours at this time.

A PUFF IN A PENCIL.

It is a characteristic of that common type of humanity which Renan called *l'homme sensuel moyen* that he finds a subtle pleasure in getting something for nothing. To this instinct the commercial tout directs his dainty devices with a success which encourages him to fresh efforts of invention. Doctors are favourite objects of this variety of the piscatorial art, and, till experience makes them wary, their innocence is often apt to be led astray. Could anything be less free from any appearance of guile than the harmless necessary pencil which nearly all of us keep in constant use? And as there is no article more easily lost or mislaid, is it not pleasant that so indispensable an instrument should come to us, as it were, from the skies? especially when it is "unique," and sent to us by benevolent persons who say "it has been specially produced to our design by the first makers in the country." And when we are further assured that "the stones of the seals are particularly beautiful by reason of their deep faceting, brilliancy, and rich colouring, but the durability of the pencil is its chief point," who in the first glory of possession of such a gem of art but must feel a glow of satisfaction that his profession, which brings him so little remuneration in the ordinary way, should be the means of procuring him such gifts? But alas!

Medio de fonte leporum
Surgit amari aliquid.

On reading the letter accompanying the offer we find that the gift is not a token of gratitude for services rendered or a recognition of our general social merits, but a shrewd anticipation of favours to come. The "unique" pencil is, in fact, intended as a lure to induce the practitioner to order a "delicate leaf edge-tea," which is declared to be free from the evil effects on the digestion of other teas. It is almost needless to add that a sample of the tea is offered, and, to make things easy for the busiest doctor—if it be assumed to be possible that there is any such unacquainted with its virtues—a "request form" is enclosed. We had occasion some years ago (BRITISH MEDICAL JOURNAL, July 15th, 1907, page 106) to refer to another form of puffing its wares adopted by the firm which offers the "unique" pencil now dangled before the eyes of the profession. We said then that

commercial enterprise might, when not dishonest, be allowed the use of methods of advertising which are forbidden to members of a profession. The vendors of any special brand of tea which they may believe to be superior to others have a right to say so. But we do not think they are wise to try to induce doctors by the bait of gifts to help them in pushing their goods. We say, further, that any doctor who allows himself by the gift of a pencil case, however "unique," to be made to figure as a tout for a tea company will have only himself to thank should suspicion be aroused in the mind of an uncharitable public.

CHOLERA IN CENTRAL EUROPE.

A QUARANTINE notice issued from Lloyds on August 24th quotes a Foreign Office statement that cholera is reported to be prevalent at numerous districts in Germany, and also in Riga and Petrograd. In Germany, Reuter reports that the disease is most severe in Silesia, but has also occurred in the districts of Wiesbaden, Berlin, Breslau, and Frankfort. The statistics published in the monthly *Bulletin* for July of the Office Internationale d'Hygiène Publique indicates that the disease has been in existence both in Austria and in Hungary for the last year at least. The returns for the period from September 23rd to December 26th, 1914, showed 3,633 cases and 932 deaths in Austria. During the period from December 27th, 1914, to June 12th, 1915, there were in Galicia 389 cases and 104 deaths, in Silesia 366 cases and 58 deaths, in Croatia 774 cases and 263 deaths, and in Bosnia-Herzegovina 360 cases with 145 deaths. In Hungary, from January 11th to June 13th, 782 cases with 282 deaths were recorded; but Reuter's representative, telegraphing from Zurich on August 23rd, states that 565 cases with 310 deaths occurred between August 2nd and 8th.

ADVERTISEMENTS, which seemed to convey the sanction and approval of the St. John Ambulance Association, of a secret remedy named Phosferine, appeared last week in several newspapers. The attention of the St. John Ambulance Association was called to the matter. Action was immediately taken, and the St. John Ambulance Association has, we are informed, received an assurance that the advertisement will be withdrawn.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

THE following additional subscriptions to the Fund have been received by Dr. Des Voeux:

Thirty-eight List.

G. H. K.	£ s. d.	Channel Islands Divi-	£ s. d.
Dr. Barrs (collected by)—	1 0 0	sion, B.M.A. (per Dr.	
Dr. Taylor	0 10 6	Hon. Sec.)—	
Dr. Sykes	1 1 0	H. Draper Bishop,	
Mr. S. W. Daw	2 2 0	Dr. Carruthers	0 5 0
Dr. Gordon Black	1 1 0	Dr. Bishop	0 10 0
Dr. Teusset	1 1 0	Dr. Wallace	0 5 0
Dr. Moorhouse	1 1 0	Dr. Bullock	0 10 0
Dr. Thomas	0 10 0	Dr. Gibson	0 5 0
Dr. S. M. Salaman	1 0 0	Dr. Bisson	0 5 0
		Dr. Bostock	0 5 0

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE General Council of the Rhône has voted a sum of £2,000 for the fitting up of large departmental buildings at Alix for use as a hospital for tuberculous soldiers. The sanatorium is in a hilly region amid pinewoods which have never felt the touch of the axe. It will receive men who have become tuberculous during the war and within six months of its cessation.

THE WAR.

WAR HOSPITALS IN DEVON.

VOLUNTARY AID ORGANIZATION.

Information which has reached us during the last few years as to the work of the Voluntary Aid Organization in Devonshire, and during the last few months as to its work in the present emergency, produced the impression that it was being very well done, and it therefore seemed desirable to get some first hand information on the spot.

We may say at once that the results are very remarkable, and that if they are equalled or approached in excellence elsewhere, it can only have been through a similar combination of foresight and executive ability.

The story is all the more interesting because it is an example of women's work and is an achievement of which all women may well be proud. The county director is Mr. J. S. C. Davis, but he has wisely left by far the greater part of the work to the deputy county director, Miss Buller, daughter of the late Sir Redvers Buller, and her staff officer, Miss Davy, daughter of Dr. Henry Davy of Exeter. They have been ably assisted in the organization of the movement and in administration by many willing workers. The following are the departments of the head quarters staff, with the officers in charge:

Quartermaster-General's Department and Accommodation of Nurses: Mrs. Mortimer, Miss Templeton, Miss Wallis.

Commissariat: Mrs. Phillpotts, Miss Kay, Miss Hare.

Medical and Surgical Stores: Miss Thomas, Miss Dalzell, Miss Walsh.

Hospital Personnel and Reserve: Miss Jepson.

Hospitals Registry, Furloughs, etc.: Miss Newlyn, Miss de la Pasture.

Convalescents' Central Registry: Miss Kirk, Miss Threlkell.

Stationery Department: Mr. W. F. Robinson, Miss Bailey.

Inquiry Department: Miss Campbell, Miss Kennell.

Clothing Store: Miss Dave.

Finance Department: Mr. J. Ellett Lake, Mr. J. Campbell.

Central Registry: Mr. H. Lammcraft.

Transport Officer: Mr. J. Bart.

other centres in the county hospitals with varying numbers of beds have been provided. In addition there are many convalescent houses; the number in use is governed by the demand, the arrangements being such that any of the houses can be opened to meet a demand and closed when it has ceased.

The provision of some 1,400 beds fully equipped and officered and their maintenance in a constant state of efficiency is a very striking result to be achieved wholly by voluntary effort, and its remarkable character is not diminished when it is remembered that the county has within its boundaries the 4th Southern General Hospital (Territorial) at Plymouth, and has contributed from among its civilian medical practitioners its share, and perhaps more than its share, in response to the call of the army for medical officers.

The success has been in large measure due to the foresight which led Devonshire women to organize in pence. As became a county which, since the days of Elizabeth, has always been among the foremost in the defence of these realms, Devon responded to an

appeal of Queen Alexandra to women in 1905 by establishing a branch of the British Red Cross Society. This was formed in 1907; precision was given to the movement by the promulgation, two years later, of the War Office scheme for Voluntary Aid Associations, whose primary duty it was to supplement the medical service of the Territorial Force in case of invasion. The scheme proposed separate detachments for men and for women, and circumstances, at any rate in Devon, have caused most

of the work to be done by women, although a necessary and important element in the scheme is the provision by the men's detachments of an efficient transport section for stretcher bearing, escort duty, etc.

One secret of the success attained is that it was recognized some years ago that a central staff was necessary to co-ordinate the work of the Voluntary Aid Detachments in the county. A head quarters staff was accordingly established in Exeter, and when the war broke out the machinery was

The Episcopal Modern School for Girls, in which No. II Military Hospital (V.A.) Exeter, is established.

No. II Military Hospital (V.A.) Exeter: The marquees in the grounds.

The co-ordination of all these departments is in the hands of the deputy county director and her staff officer.

Briefly stated, the result of the work in Devon is that 1,394 beds have been provided for wounded and sick in the county. In Exeter itself there are five temporary hospitals and at Torquay a hospital with 100 beds in the town hall and 25 for slighter cases in a private house. In sixteen

ready and all that was necessary so far as head quarters work was concerned, was to enlist more women workers. One conspicuous advantage of this county centralization of Voluntary Aid Organization is that it greatly simplifies administrative work, since all communications with the army medical authorities go through the Voluntary Aid Organization head quarters at

Exeter. Each Voluntary Aid hospital in the county is responsible to Voluntary Aid head quarters in Exeter, which in turn is responsible to the A.D.M.S. Plymouth. The Voluntary Aid head quarters also has charge of the allotment of men leaving hospital to convalescent homes when necessary, and is responsible, under this heading, for the placing of some eighty convalescents a week.

The Voluntary Aid Organization since the outbreak of war has been concerned with the care of wounded and

sick men from the front, who are sent direct from the port of disembarkation to a hospital in Exeter or elsewhere in Devon. The Voluntary Aid head quarters receives information daily as to the number of beds vacant in each hospital; it serves, therefore, as a clearing office both in and out. Here records are kept, the nursing and Voluntary Aid personnel maintained, and through it all stores and appliances are supplied. The whole machinery is working smoothly and efficiently. It appears that the success with which

No. II Military Hospital (V.A.), Exeter: One of the marquees.

the scheme is working is in large measure due to the untiring zeal and energy of the head quarters staff, and more particularly to the very unusual organizing ability possessed by the staff officer.

The magnitude of the work may be gauged by the fact that in Exeter alone 570 beds—more than the establishment of a military general hospital—have been provided in hospitals well equipped and officered without disturbing the work of the civilian county hospital further than that that it has been asked, and has consented, to set aside a certain number of beds for ophthalmic cases, so that the Eye Infirmary in Exeter may be free to devote all its space to military cases.

There are five military hospitals in Exeter, as follows:

No. I. The West of England Eye Infirmary.

No. II. In the Episcopal Modern School for Girls.

No. III. In the Children's Home, lent by the Exeter Guardians.

No. IV. A small hospital (32 beds) at Topsham Barracks for troops quartered there.

No. V. In the Women's Hostel and Congregational Church Schools near the Castle.

Nos. I, II, III, and V are independent units as far as the medical and nursing arrangements are concerned, but in administrative respects are practically sections of one hospital, with 535 beds, having a central office administration at head quarters.

Since last October, when the first hospitals were mobilized, to the middle of August, in round numbers 3,500 have been treated in them. The great majority have been sick or wounded from the British forces in France or the Dardanelles, and nearly all have been admitted direct from the place of disembarkation, usually Southampton. The hospitals have also received a certain number of men from the forces at home, including cases requiring operation, amongst the local troops in Exeter and the surrounding districts over a large area.

No. I Hospital.

No. I Military Hospital, Exeter, is established in the West of England Eye Infirmary; it was mobilized on October 4th, and received its first patients on October 7th. Since then, down to the middle of August, 938 patients have been admitted, nearly all direct from overseas. The cases have been for the most part surgical, and 211 major operations and 80 minor have been performed. The medical cases have included some instances of gas poisoning. There have been 6 deaths—2 from tetanus, 2 from gas gangrene, 1 from embolus following gunshot wound of femur, and 1 from pneumonia.

The building having been designed for hospital purposes, and being amply provided with all the appliances and facilities of a modern hospital, including a well-appointed operating theatre, called for relatively few and minor alterations to fit it for military work. Owing to the special purpose for which it was built, it contains, in addition to

large wards, a number of smaller rooms with one to three beds, which have been found very convenient for special cases and for officers. A certain number of officers and men have received massage and electrical treatment as out-patients. The total number of beds provided is 110.

The medical officer in charge is Mr. A. L. Candler, F.R.C.S., and medical officers attached are Dr. William Gordon, F.R.C.P. (physician), Mr. G. T. Clapp, M.B., and Dr. Mabel Gates, who, in addition to doing general duty, acts as anaesthetist.

No. II Hospital.

No. II Military Hospital, Exeter, established in the Episcopal Modern School for Girls, was mobilized on October 5th, 1914. The first patients were received on October 16th. The building, a photograph of which is reproduced, was well adapted for conversion into a hospital, as it contained several large rooms which make good wards; another room with a north light, designed for art classes, has been converted into an operating theatre which meets all the essential requirements of modern surgery. One of the subjects taught in the schools was cookery, and the hospital is therefore fortunate in

No. II Military Hospital (V.A.), Exeter: Interior of one of the marquees.

having excellent kitchens. In addition two marquees, one containing sixteen and the other twenty-four beds, have been erected in the grounds, and have proved popular both with the medical staff—the up-to-date open-air treatment being remarkably successful—and with the men themselves. Photographs of the marquees are reproduced. The sanitary arrangements of the building were ample, and special latrines have been established for the use of the patients in the marquees. The medical officer in charge is Mr. R. A. Worthington, M.B.Cantab., F.R.C.S.; the other members of the staff are Dr. Henry Andrews, Dr. Solly, and Dr. Lovely (resident medical officer). Altogether 124 beds are provided.

No. III Hospital.

No. III Military Hospital, Exeter, is in the Children's Home, Heavitree Road, lent by the guardians. It was mobilized on October 31st; it provides 100 beds, reserved for medical cases chiefly; special provision is made for the isolation of infectious disorders, such as measles. In addition, arrangements have been made in the grounds for the open-air treatment of suitable cases. Some have been accommodated in a small brick shed open at the front, and used by the school as a playground, others in temporary shelters borrowed from the tuberculosis authority, and formerly used for the open-air treatment of phthisis at home.

This hospital was mobilized primarily to meet the needs of the largely increased garrison in Exeter and the district, and during the winter and spring the accommodation was used to its utmost capacity for this service. Among the diseases treated were pneumonia and cerebro-spinal meningitis. During the summer it has been possible to place the greater number of the beds at the disposal of the Expeditionary Force.

The medical officer in charge is Dr. S. E. Atkins, the medical officers attached are Dr. Henry Davy and Dr. Bingley Pullen.

No. V Hospital.

No. V Military Hospital, established in the College Hostel for Women and Congregational Church

Schools near the Castle, was opened in May, in response to a request from the War Office for a further increase in the accommodation at Exeter. The buildings required more alterations to suit them for their present purpose than in the case of the other hospitals mentioned. These have been ably carried out under the supervision of the medical officer in charge, Mr. Brennan Dyball, M.B., F.R.C.S., and the architect, W. J. Jerman. The other medical officers are: Mr. Marmaduke Shield, Dr. Sanways, Dr. Wilton, Colonel J. Raglan Thomas, M.D., A.M.S. (T.F.), and Dr. Robin, who is resident medical officer. This hospital puts up over 200 beds, of which 177 are contained in seven wards of from 20 to 40 beds each. Of these beds, 100 were ready for use and were filled on May 14th; the remainder were available on June 1st. The number of patients admitted to July 31st was 342. There has been one death (from gas gangrene); the number of operations performed down to July 31st was 71—major 23, minor 43.

The Children's Home, in which No. III Military Hospital (V.A.), Exeter, for medical cases chiefly, is established.

No. II Hospital.

The Military Hospital No. II was organized in February, 1915, by the Voluntary Aid Organization, at the request of the Officer Commanding R.F.A., for troops quartered at Topham Barracks, where there was an epidemic of influenza and pneumonia. The building was originally used as a storehouse. It has been converted into a hospital of five wards, containing 30 beds.

Special Departments.

In addition to the medical staff of each hospital, certain specialists assist at all the hospitals—for ophthalmic cases Mr. A. C. Roper, for dental cases Mr. J. Ackland, for radiology Dr. J. D. Harris, for pathology and bacteriology Dr. R. V. Solly. The last named does his work in the laboratories of the Devon and Exeter Hospital. In all the hospitals provision for x-ray work has been made or is being installed.

Administration.

At each hospital there is a medical officer in charge, who has supreme control, subject to the head quarters officer, to whom he is directly responsible. Great importance is attached to this point in administration.

Each hospital has a matron and a staff of fully trained nurses in the proportion of seven or eight to each hundred beds. In addition, each hospital has Voluntary Aid assistants, some of whom have had a short

training in the county hospital and act as probationers in the wards; the quartermaster's and steward's departments (that is, equipment, linen, commissariat), the clerical work, and the cooking are also entirely carried on by Voluntary Aid workers. Cleaning and housemaid's work is mainly done by charwomen, and there are in addition orderlies for certain classes of work for which men are considered to be better suited than women.

The duties of the Voluntary Aid nurses are similar to those of the ordinary hospital probationer. The hours of those on day and night duty respectively are from 7.30 a.m. to 9.30 p.m., and from 9.30 p.m. to 8.45 a.m. Many of them have now been working in these hospitals since the date of mobilization, nearly a year ago, and very few indeed have been found unequal to the strain of the work. The trained nurses who supervise them give a most satisfactory account of these probationers and of the standard of efficiency to which they have attained.

Experience has undoubtedly proved that Voluntary Aid nurses are capable of really valuable service, and that the organization of Voluntary Aid has, in fact, provided resources without which the enormous demands made upon the nursing profession at this time could not have been met.

Since, in peace time, the Voluntary Aid nurse has often been the object of criticism it is only

just to realize that, within her limitations, she is performing a service of vital importance to the country.

Of the surgical and medical work done in the temporary military hospitals in Exeter it will suffice now, as we hope to be able to publish fuller particulars shortly, to say that down to the middle of August 3,500 men had been treated in Exeter alone, and that 484 major and 366 minor operations had been performed.

As has been said, practically the whole Voluntary Aid Organization in Devon is administered by women, doubtless for the good reason that the men of Devon are mostly occupied elsewhere. It is a striking illustration of the fact that many of the duties one has been accustomed to associate exclusively with men can be as effectually performed, in emergency, by the other sex.

A NOTE ON "WIND CONTUSIONS" IN WAR.

SURGEON-GENERAL W. F. STEVENSON writes: In the notes on cases seen at the 2nd Eastern General Hospital, Brighton, published in the JOURNAL of August 21st, the writer refers to a class of injury which, in former times, was considered to be due to "the wind of the shot," and points out that, in view of the experiences met with in the present war, my statements with regard to them in the last edition of *Wounds in War* will almost certainly require revision, because men are knocked out by the concussion of the modern high explosive shells without being actually touched by them or their fragments. But really no revision of the conclusions arrived at with regard to the former class of cases need be made; the old "wind contusion" cases are a class quite apart from those now being observed as the results of the bursting of high explosive shells. The former were cases in which the long bones of the limbs were shattered and the solid and hollow viscera of the cavities of the body were ruptured, while, at the same time, no injury—not even an abrasion of the skin—was made to show where any missile had been in contact with it. There was nothing new in the conclusions regarding these cases which I put forward in *Wounds in War*. Baron Larrey's experiences led him to hold similar ones.

The conditions produced on men by the bursting of high explosive shells in their immediate neighbourhood are quite different; they are all due to interference with the

brain and the nerve centres controlling the special senses—concussion of the brain, blindness, deafness, dumbness, and occasionally paralysis, and these symptoms are frequently accompanied by general tremors of the voluntary muscles.

The victims of these explosions are often blown many yards away from their positions, and, if not killed outright at the moment, mostly make good recoveries after a more or less prolonged interval of rest. I have never seen or read of cases of fractured long bones or of rupture of internal viscera due to these explosions, but we all can read in the medical journals of their effects as seen in this war, and some of us can observe them for ourselves in the hospitals at home, and get detailed accounts of the cases from the men suffering from them.

On the other hand, I am glad to see that the writer of the notes agrees with what was published in the *JOURNAL* (October 24th, 1914, p. 701) by me regarding the so-called "explosive wounds," that they are not the results of explosion within the body, but that solid and unbroken bullets may produce these extensive injuries—given high velocity in the missiles, combined with considerable resisting power in the tissues met in the bullet track; these are the two and only essentials necessary for their production.

GERMAN EXPERIENCES OF WAR SURGERY.

VAGARIES OF THE GERMAN RIFLE BULLET.

AS WAS NOTED in the *JOURNAL* a couple of months ago, a vigorous campaign has been conducted against the English rifle bullet in the German press. Many German surgeons have bolstered up the charge that the English bullet is of dum-dum type and has an explosive action by numerous illustrations, including skiagrams, of bones and other structures freely peppered with fragments of lead, nickel, and aluminium. The German lay press has not been slow to follow this lead, and the reproduction of the skiagrams seems to have had a positively hypnotic effect on the German mind. We may add in passing that, in such circumstances, the effects of a skiagram on the minds of laymen seem to be as overwhelming as that of the blessed word "Mesopotamia" on the mind of the pious old woman. One result of this libellous campaign has been the fomentation in the German mind of anger as great, though not as just, as that which is felt in this country with regard to poisonous gases. It is most regrettable that even the medical press of a neutral country has found it consonant with its dignity to reproduce some of these libels against the British bullet. Fortunately a reaction has now set in, and statements have lately appeared in the German medical press to the effect that, not only is the use of dum-dum bullets by the British "a product of the fantasy,"¹ but also that the regular German infantry bullet, which consists of a lead core in a nickel case, may, under certain conditions, have an explosive action indistinguishable from that of a dum-dum bullet.

Flaws in the Casing.

Medizinalrat Dr. August Fischer² has lately recorded the case of a German non-commissioned officer who, with a patrol, had to pass at night through a line of German *Jaegers*, stationed near Rheims. The patrol notified the *Jaegers* that they must not fire on it on its return. In spite of this injunction, the *Jaegers* fired on the returning patrol at a range of about 3 metres. The non-commissioned officer was wounded in the left shoulder, the wound of entry being in the neighbourhood of the coracoid process, and the wound of exit in the back of the upper arm. Both wounds were a little smaller than a mark piece. When the patient was admitted to hospital on September 23rd, eight days after he was wounded, the wound was explored under a general anaesthetic, as there were fever and discharge. The bones forming the shoulder-joint were much shattered, and the Roentgen rays showed a transverse fracture of the humerus, running through the surgical neck. The head of the humerus was broken up into fragments, one of which was in the neighbourhood of the glenoid cavity, while two fragments lay beside the shaft of the bone. A fracture passed obliquely through the glenoid cavity, the normal outline of

which was lost. There was also a fracture of the clavicle in its outer half. There were numerous small fragments of bone scattered throughout the wound, as well as particles of lead. A large piece of lead appeared to have penetrated the humerus. At the wound of entry, and quite near the surface, the outer case of the bullet was found in its entirety, though much torn and distorted. Dr. Fischer points out that in this case the bullet had produced an explosive effect, which would have been attributed to the use of a dum-dum bullet had not the history of the case and the discovery of the nickel casing belonging to a German bullet given the lie to such an assumption. He also argues that the non-commissioned officer's account excludes the possibility of the wound being inflicted by a bullet previously deformed by ricocheting. Evidently the bullet must have broken up on contact with bone, and while the outer casing was left behind in the wound of entry, the scattering fragments of lead must have inflicted further injuries to the bone and soft tissues, and also have made the wound of exit. This kind of wound must not, according to Dr. Fischer, be confused with the wound inflicted at point blank range, when the core and outer casing do not part company. He suggests that an explosion of the bullet, as in his case, can only occur when there is a flaw in the outer casing. But it was obvious in his case that there was no flaw in the point of the bullet. He quotes the observations made in the Balkan wars by Vollbrecht and Wieting Pacla, who found that complete laceration of the outer casing and scattering of the lead core could only occur when the union between the core and the outer casing was imperfect, or the lead core was overheated by its passage through the barrel of a machine gun.

Dr. Karl Kolb³ has reported a somewhat similar case. The patient was a Frenchman, wounded in the left leg. Both the wound of entry and of exit were as large as a hand, the muscles of the calf of the leg were completely ploughed up, and the fibula was shattered. It was thought that the wound of entry was on the outer side of the leg, although it was difficult to distinguish with certainty between the wounds of entry and exit. The bullet was found in the muscles of the calf, and was easily removed. It proved to be a German rifle bullet, the outer casing of which had been torn open and the leaden core flattened. The casing and core had not, however, parted company. On further scrutiny a flaw was found in the outer casing, about 2 mm. from the point. Traced towards the base of the bullet this flaw became wider and wider. About 5 mm. from the point of the bullet the outer casing was completely torn open, revealing the leaden core. Dr. Kolb suggests that the explosive effect of this bullet must have been due to the flaw in the outer casing, which may very likely have been caused by a particle of sand in the barrel of the rifle from which the bullet was discharged.

A case similar to Dr. Fischer's is also recorded by M. Nippe.⁴

Explosive Effect.

At a meeting of military surgeons in Strassburg⁵ Dr. Chiari demonstrated the calvaria of a young man the muzzle of whose rifle was in contact with his left temple when the cartridge, containing a German infantry bullet, was discharged. The bullet perforated the temporal portion of the parietal bone, traversed the left central convolution, and emerged through the left parietal bone. Death occurred three and a half hours later from haemorrhage into the ventricles. The most striking feature of this case was, according to Dr. Chiari, the explosive effect of the bullet on the calvaria, which was broken up into numerous fragments.

WOUNDS OF THE LUNGS TREATED BY ARTIFICIAL PNEUMOTHORAX.

At a meeting of the *Medizinisch-naturwissenschaftliche Gesellschaft in Jena* Dr. Reichmann gave an account of his experiences with artificial pneumothorax in the treatment of wounds of the lungs and pleurae. In one case there was an effusion of cloudy haemorrhagic fluid,

containing staphylococci, into the pleural cavity. According to 1,000 c.c.m. of this fluid were aspirated, and an equal quantity of nitrogen was injected into the pleural cavity. Previous to this operation there had been fever of a remittent type, and the temperature was still 38.5° on the following day, but after this it fell and the patient made a rapid recovery. In a second case there was an interlobar effusion of cloudy fluid in the left side of the chest. Puncture of the chest yielded 50 c.c.m. of fluid, which were replaced by an equal quantity of nitrogen. At a second operation the exploring needle encountered much resistance, showing that extensive thickening of the pleura had already taken place. This process was progressive, and was apparently accompanied by the development of a tumour of the lung; and though the patient remained afebrile he did not make a satisfactory recovery. In a third case the patient's general vitality was much reduced by septic fever, complicating a wound of the lung. He also suffered from an extensive bedsore. About 800 c.c.m. of purulent fluid, containing streptococci, were aspirated from the pleural cavity, and were replaced by nitrogen. Ten days later there was a reaccumulation of the fluid to the previous level in the chest. The operation was accordingly repeated, and all the fluid was withdrawn. It slowly began to reaccumulate, but in spite of this the patient's general health improved, the bedsore healed, his appetite improved, and there was a gain in weight.

CANADA.

THE HOSPITAL COMMISSION AND CONVALESCENT SOLDIERS.

A HOSPITAL COMMISSION was recently appointed by the Canadian Government to make necessary arrangements for the care of convalescent soldiers on their arrival in this country. The Commission met for the first time on July 20th at the militia head quarters, Ottawa. The Hon. Senator Longbeed presided. The members in attendance were Colonel Sir H. M. Pellatt, Toronto; Mr. Smeaton White, Montreal; Mr. John S. McLennan, Sydney; Lieutenant-Colonel Thomas Walker, St. John, New Brunswick; Mr. F. W. Avery, Ottawa; Mr. C. B. Smith, Montreal; and Major Potter, Acting Director-General of Medical Services. The Deputy Minister of Militia, Surgeon-General Fiset, Lieutenant-Colonel Munnell, of Ottawa, and Lieutenant-Colonel Delaney, of Quebec, were also present. A large number of private houses and other buildings have been offered for convalescent homes, but the uncertainty as to the number of invalided soldiers who will require such accommodation makes it impossible for the Commission to accept all the offers at present. Arrangements are being made to utilize part of the immigration building at Quebec as a distributing hospital. This building, which was recently erected by the Government, lends itself admirably to the purpose. The head quarters of the Commission are at 22, Victoria Street, Ottawa. The office in England of the Director of Medical Service, Canadian Contingent, is in Cecil Chambers, 86, Strand, London, W.C.

No. 5 GENERAL MILITARY HOSPITAL.

This hospital was mobilized at Victoria on July 31st, and is now in camp at Macaulay Plains, Esquimaux, British Columbia. The unit was offered to the Government last April, the offer being made through Major (now Lieutenant-Colonel) Hart, of Victoria; it was accepted early in June, and mobilization was at once commenced. The corps is now up to full strength; it numbers about 176, including 73 nursing sisters. The officers are: *Commanding Officer*: Lieutenant-Colonel E. C. Hart, P.A.D.M.S., Victoria. *Staff*: Lieutenant-Colonel F. C. McTavish, Vancouver; Lieutenant-Colonel Herman Robertson, Victoria; Lieutenant-Colonel Pantou, who is now in France, and will join the hospital overseas; Major H. L. Burris, Kamloops; Major H. S. Monro, Vancouver; Majors F. P. Patterson and A. P. Proctor, Vancouver; and Major Gillies, who is also at the front at the present time. Captains J. A. E. Campbell, W. A. Clarke, H. C. L. Lindsay, H. H. McIntosh, W. B. McKechnie, C. S. McKee, F. J. Nicholson, A. B. Schimbin, of Vancouver; Captains R. L. Miller, W. P. Walker, H. A. Whillans, W. A. Wilson, of Victoria; Captain D. A. Dunbar, of Barnaby; Captain A. C. Frost, of Ladysmith; Captain T. B. Green, of New

Westminster; Captain D. P. Hanington, of Wilmer; Captain D. J. Millard, of North Battleford; Captain L. J. O'Brien, of Nauyasno; Captain J. T. Wall, of Prince Rupert; and Captain Taylor, who is now at the front. The Quartermasters are Captains R. F. Winch, of Vancouver; J. Lewin, of Victoria; L. Jartman, of Victoria, dentist; and the Warrant Officers are Sergeant-Major R. Glass, C.A.M.C., of Victoria, and Sergeant-Major A. Morrison, of Vancouver. Miss F. Wilson, formerly Lady Superintendent of the Winnipeg General Hospital Training School, is acting matron, with Miss Tripp and Miss Campbell, of Victoria, as assistants. Each member of the unit has been inoculated against typhoid, and the rank and file have received careful training in first-aid and stretcher-bearer work in addition to the military course. The corps was inspected on August 2nd by General Lessard, of Winnipeg, who is Inspector-General of the Western Forces.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed.

CAPTAIN K. LEVI, Australian Army Medical Corps, 1st Australian Field Ambulance, killed in Dardanelles, reported in casualty list of August 20th.

Lieutenant P. T. Warren, R.A.M.C.(T.F.), 3rd Welsh Field Ambulance, killed in the Dardanelles, reported in casualty list of August 19th.

Died.

Major Thomas Copland Savage, of the New Zealand Army Medical Corps, died at the New Zealand Military Hospital, Pont Kouba, Egypt, on August 14th, aged 41. He was the second son of the late Warwick Savage, of Burslem, and was educated at University College, London, where he had a distinguished career, gaining the gold medal and exhibition in anatomy in 1898, and the Atkinson Morley scholarship in surgery in 1901, also acting as assistant demonstrator of anatomy. He took the B.R.C.S. and L.R.C.P.Lond. in 1900, the M.B.Lond. in 1900, the B.S. (gold medal) in 1901, and the F.R.C.S. in 1901. After qualifying he acted as clinical assistant for out-patients at University College Hospital, and as clinical assistant at the Royal London Ophthalmic Hospital. He then went to New Zealand and settled at Auckland, where he was honorary surgeon to Auckland General Hospital, consulting surgeon to North Auckland Hospital, and examiner in surgery for the University of New Zealand. When the contingent from New Zealand was raised last year for service in the war, he joined the medical department with the rank of major, and accompanied the force to Egypt.

Wounded.

Lieutenant-Colonel E. V. Gostling, R.A.M.C.(T.F.), 1st East Anglian Field Ambulance, Dardanelles.

Major H. N. Butler, Australian Army Medical Corps, Dardanelles.

Major L. W. Dunlop, 1st Field Ambulance, Australian Army Medical Corps, Dardanelles.

Captain T. R. Ritchie, New Zealand Army Medical Corps, Dardanelles.

Lieutenant J. C. Scimes, Australian Army Medical Corps, Dardanelles.

Lieutenant (temporary) G. Fleming, R.A.M.C., Dardanelles.

Lieutenant (temporary) A. J. O. Wigmore, R.A.M.C., Dardanelles.

Lieutenant (temporary) N. H. Haskins, R.A.M.C., Dardanelles.

H.M.S. Royal Edward.

The transport *Royal Edward*, 11,117 tons, formerly one of the Canadian Grand Trunk liners, running from Avonmouth, Bristol, to Quebec, was torpedoed by a German submarine in the Aegean Sea on August 14th, and sank with great loss of life. She had on board 32 military officers, 1,350 troops, and a ship's complement of 220 officers and crew; total 1,602. The troops consisted of reinforcements for the 29th Division in the Dardanelles and details of the R.A.M.C. Great and regrettable as is the loss of life—about a thousand—this is the first instance of successful attack upon a transport during a war of now over a year's

duration, during which an army larger than Britain had ever before put in the field has been transported overseas. According to the published list there appear to have been ten medical officers on board, of whom two—Lieutenant-Colonel Danber and Major Mowat—are reported as missing, the other eight as saved. The names are as follows:

54th Casualty Clearing Station.—Lieutenant-Colonel J. H. Danber, Major J. Mowat, Captains W. Redpath and F. W. Lewis, Lieutenants R. C. S. Smith, W. J. Deighan, J. Green, Lieutenant and Quartermaster J. W. Price, **1st East Lancashire Field Ambulance.**—Lieutenants W. L. Cockcroft and J. Cowan.

Lieutenant-Colonel John Henry Danber was educated at Middlesex Hospital, where he took an open entrance scholarship, at University College, London, at King's College, London, and at Oxford. He qualified as M.R.C.S. and L.R.C.P. Lond. in 1890, also taking the M.A. Oxon. in 1892, the M.B. and B.Ch. in 1892, the M.R.C.S. Lond. in 1895, and the F.R.C.S. in 1899. He had filled the posts, successively, of surgeon to the Chelsea, Brompton, and Belgrave Dispensary, registrar to the Hospital for Women, anaesthetist to the Royal Hospital for Women and Children, and surgeon to the Hospital for Women, Soho. He was an ex-president of the Westminster Division of the British Medical Association, an F.R.G.S., a Fellow of the Royal Society of Medicine, and a member of the Société Internationale de Chirurgie. He entered the R.A.M.C. (T.F.) as Lieutenant in the Sussex Yeomanry on January 7th, 1903, becoming Captain on January 16th, 1908. The June Army List shows him as Major in the East Anglian Casualty Clearing Station, head quarters Ipswich, from February 25th, 1915.

Major J. Mowat is shown in the same place as Major in the same unit from April 29th, 1915. There are three medical men of this name in the *Medical Register*.

DEATHS AMONG SONS OF MEDICAL MEN.

Alexander, Jack A. E., Lieutenant 12th Battalion Highland Light Infantry, younger son of the late Dr. Alex. Alexander of Wick, killed in France on August 15th, aged 21. He was born at Wick, and educated at George Watson's College, Edinburgh, where he was in the O.T.C. and at Edinburgh University, where he was a student in the Forestry course. He received a commission as Second Lieutenant on September 16th, 1914, and was promoted to Lieutenant last February.

Delépine, H. G. S., Second Lieutenant Duke of Cornwall's Light Infantry, who died on April 17th of wounds received in Northern France on the previous day, was the son of Professor Sheridan Delépine, Professor of Public Health and Bacteriology and Director of the Public Health Laboratory of the University of Manchester. Born in 1888, he entered the University of Manchester in 1907, and after gaining experience in Canada and the United States, he returned to the Manchester University in 1913 to take up the appointment of Junior Instructor in Drawing, and Demonstrator in the Engineering Department of the University. In August, 1914, he was in camp with the O.T.C., and at the outbreak of war immediately volunteered for active service, and subsequently received his commission as Second Lieutenant in the Duke of Cornwall's Light Infantry. After undergoing training at Falmouth he was sent to Northern France in January.

Evan on-Jones, T. A. E., Second Lieutenant 11th Battalion Manchester Regiment, only son of Dr. Evan on-Jones, of Ashdon Old Road, Manchester, killed in the Dardanelles, between August 7th and 11th, aged 19. He got his commission on September 1st, 1914.

Fowler, Theodore Humphrey, Corporal Honourable Artillery Company, who died at the London County Hospital on August 17th, aged 36, was the youngest son of the late Dr. O. H. Fowler, of Wincobster.

Marten, Henry Humphrey, Lieutenant 2nd Battalion Manchester Regiment, younger son of Robert Humphrey Marten, M.D., of Adelaide, South Australia, killed in Flanders on August 13th, aged 21. He was educated at St. Peter's College, Adelaide, at Cheltenham, and at Caius College, Cambridge, where he was in the O.T.C. He got a commission in the 6th Reserve Battalion of the King's Royal Rifle Corps on August 15th, 1914, and was subsequently promoted to Lieutenant and transferred to the Manchesters. He was mentioned in dispatches in June.

Moody-Ward, Richard Guy Torrington, Captain and Adjutant 2nd Battalion Royal Berkshire Regiment, eldest son of the late Dr. Moody-Ward, of Reading, killed in action at Fromelles, March 24th, aged 27. He became Captain on December 11th, 1914.

Porter, Harold J., Lieutenant 5th Battalion Manchester Regiment, whose death occurred in hospital at Alexandria, was the son of Dr. Thomas Porter, of St. Anne's. He received his education at St. Anne's and Manchester University, and was a medical student.

Pringle, Norman Douglas, Captain 6th East Yorkshire Regiment, killed in the Dardanelles, was the youngest son of Dr. H. T. Pringle, J.P., of Ferndown, Dorset, and was educated at Lincoln College, Oxford.

Sawers Scott, Second Lieutenant 2nd Battalion King's Own Scottish Borderers, was killed on April 23rd. He was the son of Dr. Sawers-Scott of Withington, and entered the Manchester University in 1911. He was an active member of the O.T.C., was secretary of the O.T.C. Shooting Club, and a member of the shooting eight. He subsequently gained both A and B certificates and carried off Major Thorburn's Cup for general efficiency. In June of 1915, he was gazetted to the Special Reserve and attached to the 2nd Battalion, King's Own Scottish Borderers; on taking his degree was nominated by the university for a commission in the regular army, being the first student to benefit by this right which the university had recently acquired.

Silcock, Bertram Baber, 2nd Lieutenant 7th Battalion Royal Welsh Fusiliers, younger son of the late A. Quarry Silcock, F.R.C.S., of 52, Harley Street, killed at the Dardanelles on August 10th, aged 23. He was educated at Hurdell's School, Tiverton, and as a medical student at University College Hospital, being captain of the Rugby fifteen both at his school and hospital. He served in the Balkan war as a dresser in the British Red Cross unit with the Greek forces at Salonica, and received from the King of the Hellenes the Cross of Knight of the Order of Our Saviour. When the war began, he joined the hospital ship *Rohilla* as a surgeon-probationer, being subsequently transferred in the same capacity to the *Oriz*. In spring he rejoined the Artists Rifles, of which he had previously been a member for four years, got a commission in June, and left for the Dardanelles in July.

Walsh, Geoffrey Fenell, Lieutenant 2nd Battalion, Sherwood Foresters, son of the late Fleet Surgeon Walsh, R.N., H.M.S. *Good Hope*, and Mrs. Walsh, of Szeben-probationer, being subsequently transferred in the same capacity to the *Oriz*. In spring he rejoined the Artists Rifles, of which he had previously been a member for four years, got a commission in June, and left for the Dardanelles in July.

Wills, Arthur George, Lieutenant 9th Sherwood Foresters, was the youngest son of the late Lieutenant-Colonel C. S. Wills, C.B., R.A.M.C. He was educated at Charey Hall and at Marlborough College, and had completed his second year at Oriel College, Oxford, in 1914, and was a keen oarsman, and rowed in his college eight in 1913 and 1914, and was in the Oriel boat that won the Thames Challenge Cup at Henley in 1914.

MEDICAL STUDENTS.

Chell, H., Lieutenant 8th Royal Fusiliers, died in Flanders on August 10th, as the result of wounds received in action the previous day. He was the youngest son of the Rev. G. R. and Mrs. Chell of Ealing, and was born in 1889. At the time of obtaining his commission he was a student at St. Mary's Hospital, Paddington.

Snell, P. S., Second Lieutenant 6th Battalion Royal Irish Fusiliers, killed in the Dardanelles, in August, aged 22. He was a Dublin man, educated at Campbell College, and was a medical student at Trinity College, Dublin, and a well-known cricketer. He got his commission on September 29th, 1914.

NOTES.

RED CROSS WORK IN THE DARDANELLES.

A FORTNIGHT ago, in giving some particulars of the British Red Cross work in the Dardanelles, it was stated that Sir Conrauld Thomson, the Chief Commissioner of the Joint Committee of the British Red Cross Society and the St. John Ambulance Brigade in the Mediterranean, had reported that more motor boats were needed to tow barges containing wounded to the hospital ships or transports, and generally for keeping up communication with the shore and to facilitate the Red Cross work in supplying stores to those vessels. The Joint Committee in this country has already been able to procure a twin-screw patrol boat (32 h.p.) for the picket and two motor launches (20 and 45 h.p.) and to dispatch them. Mr. John Masfield, the poet and novelist, whose name will be known to many readers, has provided the money for the picket boat and also for a barge 45 ft. by 12 ft., which has been specially fitted for the transport of wounded. Mr. Masfield has already left for Mudros, where he will take charge of the picket and barge as soon as they arrive. The Joint Committee have also been able to provide two motor launches to serve the Persian Gulf expedition.

The Union des Femmes de France is appealing for help for the soldiers of the Expeditionary Force in the Dardanelles. Its efforts are directed to the supply of necessaries and medical comforts for the sick and wounded in the temporary hospitals; to the development of the organization and working resources and to the increase in the number of the hospitals of the Union in Egypt. Already ten hospitals with a total of 1,074 beds have been established in Alexandria. Hospitals have also been established at Cairo, Port Said, and Ismailia, but the Union is anxious to enlarge the scope of its work in the East.

MOTOR AMBULANCES FOR ITALY.

The British Red Cross Society has presented a fleet of twenty motor ambulances to Italy for the use of the

wounded, and has undertaken to provide for their maintenance. The personnel consists of fifty-five officers, interpreters, medical men, drivers, mechanics and cooks. Nearly all are volunteers, many of them being English University men. The unit, which is under the command of Mr. G. M. Trevelyan, left England on August 20th. The medical staff includes Dr. G. S. Brock, physician to the British Embassy in Rome, and Dr. Dakin, until recently gynaecologist at St. George's Hospital; Mr. Tonks, head of the Slade School of Art, who was formerly a member of the medical profession, will assist the medical officers as assistant surgeon. The funds are being furnished by the British Committee in Aid of the Italian Wounded, of which the British Ambassador in Rome, Sir Rennell Rodd, is president and is acting as Italian agent. The treasurer is Sir Laurence Gomme, whose office is at 38, Conduit Street. The gift has been gratefully accepted by the Italian military authorities.

THE WORK OF THE AMERICAN RED CROSS.

In the *BRITISH MEDICAL JOURNAL* of May 29th there appeared a list of the donations sent by the American Red Cross to Europe for the use of the various belligerents. This information is supplemented in a statement recently issued by Miss Mabel T. Boardman, chairman of the American Red Cross Relief Committee, showing the exact amount and kind of relief sent to the various countries, which was published in the *Boston Medical and Surgical Journal* of August 5th.

The Red Cross sent to the warring countries 367 persons engaged in humanitarian enterprises. Of that number 71 were surgeons and 253 nurses, while 43 were members of the Serbian Sanitary Commission. England, France, Russia, Germany, Austro-Hungary, Serbia, and Belgium each received one or more units, which means one or more complete hospitals, with doctors, nurses, and other attendants, and with all necessary supplies and equipment. The administrative expenses of the huge undertaking amounted to 11,291 dols. (about £2,253), and this has been paid by the Red Cross itself and not taken from the fund contributed for relief.

The report shows that the Red Cross has sent into the war zone almost 1,000,000 lb. of cotton for the hospitals, 882,000 yards of surgical gauze, 65,000 yards of crinoline, 727,000 assorted bandages, 35,000 yards of adhesive plaster, 9,240 stretchers, 10,267 blankets, and other supplies in proportion, and 19 motor ambulances for the Red Cross personnel. There were also 4 army field hospital outfits, 50 army hospital tents, and 35 field medical tents.

Following is a summary of services rendered each belligerent Government:

Austria, 11 shipments, value 97,653 dols.; Belgium, 12 shipments, 96,708 dols.; England, 13 shipments, 87,843 dols.; France, 24 shipments, 216,150 dols.; Germany, 8 shipments, value 182,795 dols.; Italy, 2 shipments, 14,451 dols.; Montenegro, 3 shipments, 15,326 dols.; Poland, 1 shipment, 7,200 dols.; Russia, 9 shipments, 89,613 dols.; Serbia, 8 shipments, 120,867 dols.; Turkey, 2 shipments, 12,556 dols.

The financial statement shows expenditures of 1,450,306 dols. (about £290,621), leaving a balance of 174,818 dols. (about £34,965) on hand, for which the donor Governments are responsible.

The *New York Medical Journal* states that while in all probability the American Red Cross physicians and nurses will be withdrawn from European war hospitals on October 31, American Red Cross funds will still be used in sending medical and surgical supplies to Europe and in aiding the Red Cross societies of the nations at war. The sanitary work in Serbia will be continued.

MILITARY HONOURS.

A special *Gazette* issued on August 25th announces the bestowal of decorations for gallantry and distinguished service in the field. Thirteen officers receive the Companionship of the Distinguished Service Order, and nineteen officers and two warrant officers receive the Military Cross. Among the recipients of the D.S.O. is

Captain Stanley Alwyn Smith, No. 3 Field Ambulance, Canadian Army Medical Corps. For conspicuous gallantry and devotion to duty at Festubert on the night of May 20th, 1915. Captain Smith, with a party of eight men, went out voluntarily to remove the wounded from an orchard whilst under heavy fire, and eventually succeeded in bringing all into safety. Four of the eight men of the rescue party were wounded, and two of these have since died.

Major H. Stedman, R.A.M.C.(T.F.)R., has been nominated a Chevalier of the Belgian Order of Leopold, in recognition of his services to the British Red Cross Ambulance at Calais placed at the disposal of the Belgian army.

SERBIA.

According to the *Medical Record*, the American Red Cross announces that Dr. R. P. Strong, chief of the Inter-

national Health Board at Nish, recently cabled that with £4,000 additional at his disposal he can finally free Serbia from typhus and put the country on a thoroughly sanitary basis. The money has been sent to him, £2,000 of the amount having been given by the Rockefeller Institute and the rest by the Red Cross. The *Boston Medical and Surgical Journal* of August 12th publishes some extracts from letters written by Dr. Strong to his sister, which give an idea of his work in Serbia and Montenegro. He arrived at Nish on April 22nd. A general health board to supervise and unify work throughout the country was organized with the Crown Prince Alexander as president, Sir Ralph Paget as vice president, the chiefs of the French, British, Russian, and American commissions, the chiefs of the Serbian Military and Civil Departments, and a representative of the Serbian Parliament as members, and Dr. Strong as medical director. It began its work at once. Serbia was divided into fourteen sanitary districts. Seven of these were allotted to the English, French, and Russian commissions; the other seven, comprising the southern half of new Serbia, being assigned to America. No accurate information being available as to the distribution of typhus among the civil population, a house-to-house inspection was instituted. Dr. Strong, writing of the Paget Hospital, which he visited on May 1st, notes:

A feature, of which no mention is made in our textbooks of medicine regarding typhus, is the occurrence of gangrene of the toes and sometimes about the nose and mouth. Another striking feature is the condition of the pharynx, a swollen appearance of the mucous membrane being observed in many instances in the early stages of the disease. In fact, the mouth requires frequent cleansing with disinfectants. This is another fact which seems to suggest that the virus may sometimes be thrown out into the air into the immediate vicinity of the patient. The nurses working in the hospital are carefully protected by their uniforms, and they all wear rubber gloves. I understand they have one-piece garments, made together with the stockings, and over these they wear high boots. It is difficult to see how some of them could become infected with these uniforms. Lady Paget wore such a uniform whenever she went near cases, yet she became infected, as did others of the staff of the hospital.

Dr. Strong states that at the beginning of the war Serbia had 400,000 men in the army. When he wrote on May 12th there were 200,000; over 100,000 had died of typhus. At the beginning of the war there were 360 doctors in all Serbia, of whom 121 had died, leaving 239 Serbian doctors for a total population of some 5,000,000. At Kragujevatz on May 14th he went to see Mrs. Stobart's field hospital.

This is in tents and is situated on the outskirts of the town. As it had been raining for three days and most of the tents had no floors, only a thick piece of canvas serving as a floor in some of them, you can imagine the camp was in a very muddy condition. Mrs. Stobart received us in rubber boots and trousers. She apologized for being without her skirt. All her assistants are women doctors and nurses.

The rest of the day was spent in inspecting Serbian hospitals. One of these had 1,000 beds for typhus cases.

The Graupman Engineering and Motor Company, Ltd., Stirling, has sent us an illustration showing a train load of thirty-five large portable steam disinfectors intended for Serbia. In the covering letter it is stated that this "represents part of a contract placed with us by the British War Office and illustrates very forcibly the prompt and drastic measures which the authorities have taken to suppress the spread of infectious disease which has unhappily been so rampant in Serbia."

We are informed by the Wounded Allies Relief Committee that the doctor in charge of the Committee's unit at Kragujevatz states that, by reason of war and pestilence, Serbia has lost half her doctors, while the remaining half is mobilized with the army. In Kragujevatz which has a population of 50,000, there is only one Serbian civil practitioner. The Wounded Allies Union has opened a dispensary in the town. Originally consisting of 100 beds, the unit has been given two extra buildings by the Serbian Government, and now constitutes the 3rd Base Hospital with 600 beds. The last typhus cases were discharged at the end of July, and the entire capacity of the hospital is adapted for the many surgical and medical cases which any new movement of the army must inevitably bring. Contributions will be welcomed by the Honorary Treasurer of the Committee, T. O. Roberts, Manager London County and Westminster Bank, 217, Strand, W.C.

MEDICAL OFFICERS WANTED.

1st North Midland Field Ambulance, R.A.M.C.(T.F.).
Wanted urgently for service overseas (three medical men for commissions; also two others for third line unit. Apply Lieutenant-Colonel Dawson, 2 1st North Midland Field Ambulance, Watford.

3rd Home Counties Field Ambulance.

There are a few vacancies for medical officers in the 3rd Home Counties Field Ambulance, R.A.M.C.(T.). Apply to Commanding Officer, Smith's Lawn Camp, Windsor.

England and Wales.

AUXILIARY HOSPITAL IN CARDIFF.

A VERY successful fête for the benefit of Division No. 1, Glamorgan Branch of the British Red Cross Society, was opened at Roath Park, Cardiff, on August 14th, by the Countess of Plymouth, who said that the funds were required to equip the old Mansion House as an auxiliary hospital to the No. 3 Western General Hospital. Lady Plymouth praised highly the work done by the British Red Cross Society in the war, and, in reply to a vote of thanks, moved by the Lord Mayor of Cardiff, thanked the Glamorgan branch of the society for the great help it had given in the collection she made for Serbia. Mr. Lynn Thomas, C.B., in proposing a vote of thanks to the Parks Committee and to Mr. A. W. Pettigrew for the great assistance he had given to the committee in making the arrangements for the fête, said that, thanks to the hard work of the Countess of Plymouth, the county of Glamorgan had as strong a voluntary aid organization as almost any county in the British Isles. The work done by voluntary aid detachments in the war had exceeded the expectations of even their most sanguine supporters. The programme of the fête included ambulance and nursing competitions, gymnastic displays, and concerts. Music was rendered by the band of the 3rd Battalion of the Welsh Regiment. The ambulance competition, carried out under the supervision of Dr. Sparrow, Commanding No. 1, V.A.D., Lieutenant H. Davies, 5th Welsh, Dr. Howell Rees, J.P., and Dr. F. E. Smith (Lord Mayor-elect), was won by Glamorgan No. 1, V.A.D. (Red Cross), with 123 marks, and No. 75, V.A.D. (St. John), was second with 12½ marks. The nursing competition was won by Penarth Nos. 86 and 108 (Red Cross), under the command of Miss Gatheridge. Much of the success of the fête was due to the hard work of the Ladies' Committee, of which Mrs. Lynn Thomas is chairman and Miss Perry the able honorary secretary. The estimated proceeds of the fête amount to £280.

THE BRITISH ASSOCIATION MEETING IN MANCHESTER.

The arrangements for the coming meeting of the British Association in Manchester are now fairly complete, and in spite of the inevitable gloom cast over the meeting by the war there is every prospect of a successful meeting. In one respect indeed the war may add to the interest, as in so many aspects of the war scientific problems have to be faced which will undoubtedly receive much attention. For the benefit of the members of the association a *Hand-book* has been published by the Manchester University Press and Messrs. Longmans, Green and Co., under the editorship of Mr. H. M. McKechnie, which, while of chief use for visitors, will also prove of permanent interest to Manchester citizens. It commences with a brief historical sketch of Manchester and Salford by Professor Tail, and an account of "Manchester of To-day" by Mr. W. H. Mills. A fairly full account is also given, by Councillor E. D. Simon, of the municipal enterprises of Manchester, including sanitation in all its aspects, methods for the prevention and treatment of disease and the preservation of infant life, the water supply, and so on, while another article by Mr. S. P. Grundy gives some account of the various organizations for social amelioration. Canon Scott has written a most interesting account of the Manchester Cathedral, and Professor Tout a valuable article on the Manchester University in its historical and sociological aspects. Professor Wild is responsible for an article on the medical charities of the district and there are numerous other articles dealing with the literary, dramatic, musical, artistic, and commercial activities of Manchester. The

book also contains some excellent illustrations, including reproductions of some of the Town Hall frescoes of Madox Brown, and an impression of the university by night by Lieutenant Delcigne, who was recently killed in action.

The first general meeting of the association will be held in the Manchester Free Trade Hall on Tuesday, September 7th, when the president-elect, Professor A. Schuster, F.R.S., will deliver his presidential address. The various sectional meetings will commence on Wednesday, September 8th, and will end on Friday, September 10th. On the evening of the Wednesday there will be a reception by the Lord Mayor at the Municipal School of Technology, and arrangements have been made for a number of popular evening lectures not only in Manchester, but in Salford, Bolton, Rochdale, and Oldham. For the convenience of members attending the meetings rooms will be set apart at or near the university for refreshments, and for writing and postal accommodation. The secretaries who have charge of all local arrangements have their offices at 38, Barton Arcade, Manchester.

PROVISION IN SALFORD FOR PANEL PRACTITIONERS
AWAY ON ACTIVE SERVICE.

The difficulties that have occurred in numerous towns throughout the country with regard to the allowances which panel practitioners have agreed to make to their fellow practitioners who are away on active service have in some respects been lessened in Manchester and Salford by the fact that all the money available for the payment of panel doctors is first pooled, and it is thus easy to allot any sum decided on for the absentees. The system adopted as regards insurance practices is, with some differences in detail, the same in Manchester and Salford. In Salford account is first taken of the amount received during the previous year by each man now away with the forces. This is, of course, definitely known, and during his absence with the forces each practitioner will receive 60 per cent. of his previous year's receipts, this payment being made a first charge on the panel pool. Account will, of course, be taken of the fact that the panel fund is now considerably reduced owing to the large number of insured persons who have enlisted, and the 60 per cent. will suffer some reduction in this way just as all the panel doctors will have to suffer on this account. The total panel fund has never been sufficient to pay at the full tariff rate for all the attendances actually rendered and, in order to legalize the deduction to pay the absentees anything, the written consent of each panel practitioner has had to be sought beforehand. With very few exceptions, this consent has been obtained, and the method, on the whole, has worked well. In Manchester, as it happens, the majority of the doctors who have joined the forces have not been among those with the largest insurance practices, and the charge on the pool to pay them the full amount of their previous year's receipts will hardly amount to more than about 5 per cent. of the whole pool. But in Salford it happens that several of those now with the forces had large insurance practices and 60 per cent. of their previous takings amounts to a very large sum. The panel fund in 1915 is estimated to be fully 16 per cent. less than it was in 1913, the pool having fallen from £29,387 to about £24,750 as nearly as can be estimated. This means a great reduction in the income of all the panel practitioners. In addition, to pay to all those away on active service 60 per cent. of their previous takings would have meant a further reduction of the pool to the extent of nearly 10 per cent., and if any other members of the panel joined the forces, the charge on those remaining at home threatened to become unbearable, and it was considered that some limit must be fixed.

A meeting of the Salford panel practitioners was accordingly held last week, and it was decided that in no case should more than a total of 10 per cent. of the pool be allowed for the payment of the absentees. As this amount was already almost reached, and as it was felt that on no account should any obstacle be placed in the way of any other panel practitioner joining the forces, it was decided that the maximum allowance to any one should be £300 for a whole year. With this proviso the 10 per cent. deduction from the pool will, it is believed, suffice to pay 60 per cent. of their previous takings to as many doctors as can be spared consistently with leaving a sufficient

number at home to look after the insured patients in a satisfactory way. From the unanimity of the general meeting it is not anticipated that there will be any difficulty about this scheme. Under the Salford system of payment by attendance, insurance patients may change their doctor whenever they think fit, and this right cannot be interfered with. If the patients of the absentee doctors distributed themselves evenly among all the doctors remaining at home the matter would be plain. But naturally it happens that most of the former patients of the absentee doctors go to the doctor who resides nearest to the surgery of the absentee, while doctors living at a distance get no increase in their patients. This leads to some unfairness, as the reduction of the pool affects all the panel. The meeting was accordingly adjourned for a week in order that some scheme to remedy this inequality might be considered. At the adjourned meeting it was not found possible to remove this difficulty entirely, but in order to minimize it as much as possible it was provided that no allowance should be made to any absentee doctor who makes any arrangement for his patients to go to any particular doctor during his absence.

Scotland.

THE DEMAND FOR A MIDWIVES BILL FOR SCOTLAND.

It was stated a fortnight ago that a memorial was being signed in Scotland asking for the introduction as a Government measure of a Midwives Bill for Scotland. The memorial, which is dated August 19th, has now been presented, and copies have been sent to members of Parliament for Scottish constituencies. The following is the text of the memorial:

Memorial to the Right Honourable H.M. Secretary for Scotland, and to the Right Honourable the Lord President of the H.M. Privy Council.

We, the undersigned, representing the Medical Faculties of the Universities, the Royal Medical Corporations, and the Medical Officers of the Maternity Hospitals in Scotland, desire strongly to urge the importance of the passing without delay of a Midwives Bill for Scotland.

It will be within your recollection that the need for such a measure was unanimously expressed by the medical and nursing professions in Scotland last year: that the private members' bill on the subject (which passed through the House of Lords) was dropped in the House of Commons mainly for want of time at the end of a busy session.

Since then a situation of very grave urgency has arisen out of the war.

A large number of medical practitioners throughout Scotland have been called away for war service. The result of this is that it will be impossible for those practitioners who still remain to overtake all the attendance on midwifery cases that is necessary.

A large amount of midwifery practice will therefore of necessity fall into the hands of midwives and unqualified women. These persons, many of them absolutely untrained, are under no such official or medical supervision as is provided in England.

The situation constitutes, in our opinion, a national emergency, and calls for an immediate remedy, which we believe is only to be found in the enactment of a Midwives Bill for Scotland similar to the bill of last year.

The need for such a bill was already great, independently of the present war conditions. The war has, however, made this need a most pressing one, and it will continue to exist for many years to come owing to the depletion of medical practitioners throughout the country.

In favour of taking immediate action, we would further urge the recent precedent by which the Notification of Births Act was by special legislation made applicable to the whole country in order to meet a national emergency arising out of the war conditions. This measure will fall of its full beneficial effect in Scotland unless it is supplemented by the Midwives Act, for which we desire to plead.

JOHN A. KYNOCN, M.B., F.R.C.P.E., F.R.C.S.E., Professor of Midwifery and Dean of the Faculty of Medicine, University of St. Andrews; Obstetric Physician, Dundee Royal Infirmary.

THOMAS H. BRYCE, M.A., M.D., F.R.F.P.S.Glasg., F.R.S.E., Dean of the Faculty of Medicine, University of Glasgow.

MURDOCH CAMERON, M.D., Regius Professor of Midwifery, University of Glasgow; Obstetric Physician, Royal Maternity Hospital, Glasgow.

JOHN M. MURDOCH, M.D., F.R.F.P.S.Glasg., Professor of Obstetrics and Gynaecology (Murdoch Chair), University of Glasgow; Obstetric Physician, Glasgow Royal Maternity Hospital.

THEODORE SHEPPAN, M.D., F.R.C.S.E., Dean of the Faculty of Medicine, University of Aberdeen.

WILLIAM STEPHENSON, M.D., LL.D., F.R.C.S.E., Emeritus Professor of Midwifery, University of Aberdeen.

E. W. JOHNSON, M.D., M.D., F.R.C.S.E., Assistant to the Professor of Midwifery, University of Edinburgh; Secretary of the Royal Obstetrical Society.

J. LAMOND LECTURER, M.D., F.R.C.P.E., Assistant Physician, Royal Maternity Hospital, Edinburgh.

H. OLFBRANT NICHOLSON, M.D., F.R.C.P.E., Assistant Physician, Royal Maternity Hospital, Edinburgh.

LELLIAN L. RHEE, M.D., F.R.F.P.S.Glasg., Honorary Consulting Physician, Royal Maternity Hospital, Glasgow.

JAMES RITCHIE, M.D., F.R.C.P.E., F.R.C.S.E., Examiner in Midwifery, Royal College of Surgeons, Edinburgh.

C. F. BARBOUR SIMPSON, M.D., F.R.C.P.E., F.R.C.S.E., F.R.S.E., Assistant Physician, Royal Maternity Hospital, Edinburgh; Lecturer and Examiner on Midwifery, School of Medicine of the Royal College, Edinburgh.

A. MAXWELL WILLIAMSON, B.Sc., M.D., Examiner Royal College of Physicians, Edinburgh; Medical Officer of Health for the City of Edinburgh.

MILITARY APPOINTMENT FOR EDINBURGH SURGEON.

It is announced that Mr. Alexis Thomson, Professor of Surgery in the University of Edinburgh, who recently went to France with the rank of Major to take charge of the surgical side of a base hospital, has been appointed a consulting surgeon with the British Expeditionary Force and has been promoted to the rank of Colonel temporary.

Ireland.

THE DUBLIN HOSPITALS.

DURING the last year the Dublin hospitals have passed through a time of considerable stress, many members of the medical and nursing staffs having left to work with the medical branches of the King's forces. Notwithstanding the strain which the loss of their colleagues has put upon those who remained behind to carry on the routine work, the city hospitals have enlarged their obligations by receiving large numbers of wounded soldiers. The Board of Superintendence, in its report to Parliament on those institutions which are in receipt of grants, is generous in its praise. Despite the universal anxiety caused to the managing bodies by the large supplies, for example, as well as drugs and appliances—a high standard of efficiency is reported in every case. Only in one instance is there any qualification—that of the Hardwicke Hospital, which is old and unsuitable in many ways. Even there good work is done in difficult circumstances. The accommodation and equipment, as well as the personal services of managers, staff, and friends, in all the other cases receive

high praise. The Board expresses interest in the open-air treatment which is in practice at Stevens's Hospital. "The patients," happy, contented, and doing well," are in the open air night and day, with no protection from the weather except what is given by plentiful bedclothes and a lean-to shelter.

POOR LAW MEDICAL OFFICERS WHO HAVE JOINED THE ROYAL ARMY MEDICAL CORPS AND THEIR SUBSTITUTES.

Some of the Irish Poor Law medical officers who have joined the Army Medical Service have recently found considerable difficulty in arranging with boards of guardians for their substitutes. Many boards have given every facility to their Poor Law medical officers to join the Army Medical Service, undertaking to pay them half, and in some cases their full, official salaries and that of their substitutes during their absence. It is to be regretted, however, that a Kerry board of guardians recently refused, not only to pay during his absence the salary, or any portion of it, of one of their medical officers who had received a commission in the R.A.M.C., but refused to appoint the doctor he nominated to discharge his official duties and take charge of his private practice during his absence; the guardians instead appointed, by a majority, a medical certifier under the Insurance Acts. It is understood that, rather than accept the unsuitable arrangement made by the board of guardians, the doctor in question feels that he has no choice but to resign his commission in the R.A.M.C. It has been agreed upon as an ethical rule in the Poor Law medical service in Ireland that no doctor should undertake to discharge the official duties of another except on the invitation of the doctor going on leave, and this custom has been approved of by the Irish Local Government Board, which recommends boards of guardians to appoint the doctor nominated by the Poor Law medical officer seeking leave, so long as the convenience and interests of the sick poor are safeguarded. In the present national crisis the necessity for observing such a rule both by doctors and boards of guardians is all the more urgent, as it means that the doctor appointed will be available to discharge the official duties and attend to the private practice of the doctor joining the R.A.M.C.

In pleasing contrast to this may be mentioned the proceedings of a board of guardians in the west of Ireland, where a guardian, when proposing that one of their medical officers should receive his annual holiday, said that they could not do too much for their medical officers, as all three of them had sons fighting at the front, and in one instance an only son.

MILITARY APPOINTMENT FOR A BELFAST SURGEON.

The many friends of Mr. Andrew Fullerton, M.D., M.Ch., F.R.C.S.I., will be glad to hear of his appointment to the post of consulting surgeon to the army in France, with the rank of colonel in the R.A.M.C. Mr. Fullerton has been one of the workers in the Belfast Medical School, and has been distinguished more especially perhaps in his urological work, but also in general and children's surgery. He is at present surgeon to the Royal Victoria Hospital, surgeon to the Queen Street Hospital for Sick Children and to the Ulster Volunteer Force Hospital, and has been examiner in surgery in the Royal College of Surgeons of Ireland. The profession in Ulster will thoroughly and unanimously endorse the suitability of the appointment, and will with confidence look to Mr. Fullerton to uphold the high traditions of Irish surgery.

LOCAL GOVERNMENT BOARD INQUIRY.

Arising out of a recent Local Government Board inquiry as to an allegation of neglect of duty preferred against Dr. Hart, medical officer of the Killoughy Dispensary District, and medical certifier under the Insurance Act in Ireland for the Killoughy and adjoining districts, the following letter was read from the Local Government Board at the last meeting of the Tullamore Board of Guardians:

The Local Government Board for Ireland have had before them minutes of the proceedings of the board of guardians at their special meeting held on the 13th inst. (July) to consider the Board's letter of the 3rd inst., communicating the result of the recent sworn inquiry into charges preferred against Dr. Hart, medical officer of the Killoughy Dispensary District, in the case of the late Mrs. Gorman, a dispensary

patient. The two final paragraphs of the Board's letter were as follows:

"The Local Government Board, on consideration of the evidence, are of opinion that the charge of drunkenness put forward in this case has fallen through, but they think that Dr. Hart was seriously wanting in his duties towards the patient in abandoning her at a critical time, and that he should have remained in attendance and administered restoratives and requisitioned the assistance of a second doctor, so that if he succeeded in reviving the woman he could then, with the extra professional help, have made further attempts to complete delivery. The Board take a grave view of Dr. Hart's conduct in this case, but before arriving at a final decision, they would be glad to be favoured with an expression of the guardians' opinion on the subject. A special meeting should be summoned to deal with this important matter, and the guardians, when considering it, should also take into account their local knowledge of Dr. Hart's general conduct and attitude toward the sick poor and the manner in which he discharges generally his duties as medical officer."

The guardians' unanimous resolution in reply stated that "the guardians are not in a position to give an opinion on indirect hearsay evidence, and they consider that if any other action is required that the Local Government Board inquire into the matter themselves in the district of Killoughy." The Local Government Board, on a review of the facts, are of opinion that Dr. Hart, by his gross neglect in the case of the late Mrs. Gorman, has forfeited his rights to his position, and they request that the guardians will have the goodness to call on him for his resignation.

J. E. DEVLIN,
Secretary, L.G.B.

KILKENNY BOARD OF GUARDIANS AND THE INSURANCE ACT.

As the result of the unsatisfactory state of medical certification for sickness benefits under the Insurance Act in Ireland, the Kilkenny Board of Guardians passed a resolution calling on the Insurance Commissioners "to dissolve themselves."

WORKHOUSE MEDICAL OFFICERS AND THEIR HOLIDAYS.

As the result of an order made by the Cork Board of Guardians, their workhouse medical officers addressed the following letter to the guardians:

Cork District Hospital,
July 23rd, 1915.

We see by a report of the proceedings of a meeting of the board of guardians held on last Thursday that the guardians have declined to appoint a substitute for a member of the medical staff during his vacation, and have given him vacation provided his duties be performed by other members of the medical staff. We would call the attention of the board to the fact that they have paid for substitutes on our annual holidays for nearly twenty years, and continue to do so for the dispensary medical officer. As we have over a thousand patients under our care, and are liable for duty for the whole twenty-four hours, we regret we are unable to act for each other in the manner suggested, and we ask the board to kindly reconsider this resolution referring to provide a substitute for each of us during vacation.

(Signed) W. ASHLEY CUMMINS, M.D.,
J. GIBSON, M.D.,
D. MORRISSEY,
JAMES T. O'CONNOR.

After a good deal of discussion the guardians, by a majority of 13, passed a resolution declining to pay their contribution towards the expenses of medical substitutes for their workhouse medical officers when on holidays, and requiring their duties to be discharged, without extra remuneration, by other members of the medical staff. At the same meeting of the guardians a member handed in notice of motion calling on the Local Government Board to dissolve the Cork Board of Guardians and appoint two paid guardians in the interest of the sick poor and the ratepayers.

DUBLIN PUBLIC HEALTH.

At the last fortnightly meeting of the Public Health Committee of the Dublin corporation, Sir Charles Cameron, C.B., reported that the death-rate from all causes in the city during the two weeks ended August 14th was 14.8 per 1,000 persons living, and that this was 3.9 below the mean rate for the corresponding period in the previous ten years. The deaths from the principal infectious diseases, exclusive of tuberculosis, were in the ratio of 2.5 per 1,000, and were 0.5 below the average. In the first quarter of the present year there was a very high death-rate both in the city and in the township and in many English towns. In this period the death-rate in the city was 31.4 per 1,000, and in the township 23.2 per 1,000. In the second quarter, ended

June, 1915, the rate in the city was only 20.8 and in the township 19.0, or only 1.8 less than in the city. In the city the rate from infectious diseases was unusually low, 1.4, whilst in the township it was 1.7. The committee expressed a strong opinion that during the warm weather it was of the utmost importance that there should be a daily removal of the contents of ashbins, specially those of the tenement houses. As this is the season in which the fly peril is most pronounced, it is most desirable that all refuse in which they breed should be promptly removed.

VACCINATION.

At the last meeting of the South Dublin Union the vaccination question was again discussed; it came up on a notice of motion protesting against the carrying out of vaccination, and asking that the board should take no further action in enforcing the vaccination laws in the union. The chairman said that the Local Government Board had already obtained a mandamus against some boards of guardians in the High Courts and compelled them to carry out the Vaccination Acts. The same course would be adopted in regard to the South Dublin Union if the Acts were not enforced, and while he was chairman he would not have that done. One guardian said there were three children in the new Kilmainham ward in "an awful state," due to vaccination. On the motion of the chairman a resolution was unanimously adopted requesting the medical officers in the case of two unsuccessful vaccinations to report direct to the board of guardians.

The Wexford Board of Guardians has decided by 19 votes to 6 to prosecute a number of vaccination defaulters, of whom there are 2,500 in the district.

Sydney.

SECRET REMEDIES.

THE Board of Health has recently been active in prosecuting some firms for selling a patent medicine known as "Vitatadio." Messrs. Elliott Brothers were prosecuted under the provisions of the Pure Food Act for distributing this preparation, as it was claimed by the prosecution that the information set out in a pamphlet descriptive of this preparation was false. The pamphlet stated that "Vitatadio is a great herbal remedy for Bright's disease; it has cured Bright's disease, hydatids, stricture, cancer, consumption, and ringworm, and it will cure the most severe cases of hydatids, tumorous growths, lung trouble, and heart trouble." An analysis carried out by Dr. Cooksey, the Government analyst, showed that the preparation contained alcohol, 11 per cent. by weight (=2.5 per cent. proof spirit); salicylic acid, 0.5 grain to the pint; tannin and vegetable extractives, including gentian, sarsaparilla, and a trace of senna or rhubarb. Evidence was given by Dr. J. Burton Cleland, principal Government microbiologist, by Dr. W. Palmer, the Medical Superintendent of the Waterfall Sanatorium, and Dr. Arthur A. Palmer, the Government Medical Officer, that any preparation compounded in accordance with the analyst's report could not cure Bright's disease, cancer, or hydatids. In defence, the proprietor stated that, as far as he knew, the claims that the preparation had cured the diseases named were true. He maintained that the analysis put forward was incorrect; that the preparation contained some spirit and salicylic acid but no tannin, sarsaparilla, rhubarb, or senna. In addition to the two preservatives named there were only two ingredients: one was a herb known to witness and the other he had purchased in Tasmania. The ingredients cost him 3d. a bottle, and he estimated that the cost of compounding, etc., brought the amount up to 10d. He sold the mixture at 4s. a bottle, and had sold about £6,000 worth last year. The magistrate held that the case against the defendants had been proved and imposed a fine of £10, with 6s. costs.

During the hearing of a case brought against Messrs. Washington H. Soull Pattinson and Co., Ltd., by the Board of Health it was stated that the manufacturer made the preparation at a cost of less than 1s. per bottle, that the defendants obtained it at 4s. and retailed it at 5s. 6d., thereby making a profit of 37½ per cent. on the sale of a

bad article. The defendant firm was fined £10, with 6s. costs.

The Director-General of Public Health of New South Wales has directed attention to a notice appearing in the *Government Gazette* prohibiting the advertisement or sale of the drugs and appliances used in connexion with the treatment of the "Natura Health Company"—namely, Natura capsuled suppositories, the Natura cerate massage, and the Natura herbal tea. According to Section 17 of the Pure Food Act, 1908:

No person shall advertise or sell any food or drug or appliance in contravention of any notification as aforesaid, and no proprietor or manager of a newspaper or other public print shall publish any advertisement prohibited under this section, and no person shall print any such advertisement.

Correspondence.

A-NOCI-ASSOCIATION.

SIR,—Like most people, I supposed this ungainly name, or phrase, was but an extempore use, and was soon to be superseded by some more appropriate and better knit word. But it goes on, and seems to be edging itself into general acceptance. It is holding its ground, I presume, because its author does not take the trouble to improve it. Meanwhile, however, let us not use without modification a term which carries illiteracy on the face of it. The negative of "noci" is, of course, not a-noci but in-noci; this everybody should know. It would be pedantic to say that, in making names, a blend of two languages should never be permitted—for example, certain affixes, such as "itis," having a specific meaning, must be taken into general service. But it is another matter when composing a new term to compose it awry without reason.—I am, etc.,

August 17th.

INNOCCUS.

NOTIFICATION OF BIRTHS.

SIR,—Dr. T. W. H. Garstang, in your issue of August 14th, puts himself right in reference to the actual words of Section 1 (1) of the Notification of Births Act, and I agree that he did tell the Representative Meeting that "a person shall not be liable if he satisfies the court that he had reasonable ground to believe that the notice had been duly given by some other person." Indeed he emphasized this qualification. Further, he insisted that the term "medical practitioner" is not mentioned in the Act; and he urged these considerations apparently for the purpose of minimizing the contention that the Act compelled medical practitioners to reveal information gained while acting in a confidential capacity. The attitude seems a strange one on the part of the Chairman of the Medical-Political Committee of an Association which conducted an active agitation against the measure when it was originally before Parliament, and, however dexterous a verbal defence may be constructed for the argument, there remains the hard fact that practitioners have been summoned and fined for failing to effect notification. It is quite true that the Act does not mention the medical practitioner in so many words, but it puts under a possible penalty "any person in attendance upon the mother, at the time of, or within six hours after, the birth," and in view of this phrase the comment that the term "medical practitioner" is not specifically recited can hardly be regarded, whatever be its forensic worth, as a serious contribution to the discussion.—I am, etc.,

London, W., Aug. 23rd.

C. O. HAWTHORNE.

DE MULTIS REBUS.

Sir Peter Eade.

SIR,—Sir Peter Eade was a fine specimen of the general physician, interested in every department of medicine, and keeping himself abreast of the vanguard of knowledge to the end of a very long life. Though he had not the fine presence of the typical East Anglian, he had the mental characters of the race, and preserved to the last the pleasant East Anglian pronunciation of English, the most grateful to the ear of all varieties of English speech, and with the exception of Welsh-English, which is spoken with the syllabic separation of a foreign tongue, the most

distinctly pronounced. The most notable event of Sir Peter's life has not been mentioned by any of your contributors. He was in the terrible railway accident at Thorpe in 1874, and was one of the few passengers who escaped uninjured. There was but a single line between Norwich and Yarmouth, and owing to the mistake of a telegraph clerk, who was subsequently convicted of manslaughter, two trains were started from the opposite ends at about the same time. As soon as they were started, and were beyond reach—for there were no intermediate signals—it was known that a collision was inevitable, and doctors and appliances were collected in Norwich and sent in a following train. Sir Peter Eade's experience, as he related it to me three or four years afterwards, was that he was sitting in the train reading the newspaper, when he suddenly found himself lying in a meadow by the side of the rails gazing at the wreck of two trains. How he got there he never knew, but supposed he must have been slung out of the window; and, of course, he could only guess how long he had lain there unconscious. He was attended to by that fine surgeon, his friend Mr. Cadge, who, like himself, received all the civic honours that the city of Norwich, once the third city in the kingdom, could bestow.

Pruritus ani.

Ne autor, etc., is a good rule, and it may seem a violation of it if I comment upon Mr. Lockhart-Mummery's paper on pruritus ani; but it is not really a violation of the rule, because one of the matters I hammer on my last is the assignment of causes, on which I have just written a book. Mr. Lockhart-Mummery tells us that some writers put down the cause of pruritus ani as constitutional, others think it is due to enlarged anal papillae, and so forth. I wonder what the writers who call the cause constitutional have in their minds. I should suppose they mean that the cause is not local; that is, that it is not a local lesion or the local application of an irritant. If this is all they mean, surely it would be far better to say so in those words than to use a term like "constitutional"; that may mean anything, from hereditary transmission to a general microbic invasion. The other causes, except that assigned by Mr. Lockhart-Mummery himself, appear to have been assigned, as so many "causes" of disease are, without rhyme or reason, merely as vague speculations, based on no evidence, and of no value except as hypotheses for testing. And from what Mr. Lockhart-Mummery says it appears that they have not been tested, and in that case they ought not to be adhered to. Mr. Lockhart-Mummery does test his own hypothesis, and it stands the test. The result of operations is quite consistent with his hypothesis, and he is entitled to hold it exclusively until another hypothesis is proposed that also is consistent with the facts. There is good evidence in favour of his view, but this evidence is not proof until it is shown to be inconsistent with any other hypothesis. Until then at least it holds the field. May I ask Mr. Lockhart-Mummery—and here I am wandering from my last—if he has considered diet as a possible cause of pruritus ani? I have satisfactorily proved, by valid methods of assigning causes, that some cases of this troublesome complaint are due to a diet of cheese. In cases that I have observed the consumption of cheese is always followed in a few hours by an attack of pruritus; no such attack ever occurs in these persons except after eating cheese; and the severity and duration of the attack are roughly proportional to the amount of cheese consumed. These observations, if they are correct, leave no doubt that the consumption of cheese is a cause of pruritus.

Insanity.

It is difficult for me to find terms to express my acknowledgement of Dr. Cassidy's extremely handsome appreciation of my work. As I read his letter I rubbed my eyes and pinched myself, for I thought I must be reading my own obituary notice. When I say that my medical colleagues ignore my doctrines, I mean those of them who have written on insanity. In the great multitude of publications on this subject that pour from the press there is scarcely one in which any doctrine of mine is mentioned, or in which my name appears in the index or the bibliography. Now, my doctrines may be wrong from top to bottom and from beginning to end, but, whether right or

wrong, they are revolutionary. They propose a complete revolution in our notion of insanity, in our way of contemplating its causes, in our mode of studying it, and in the law applicable to it; and therefore I contend that they are worth notice. They are worth attention. They are worth discussion. At any rate, books which pretend to give a complete account of the present knowledge and doctrine about insanity ought to mention them. But they do not. They ignore them, and treat them as if they had never been published; and they emphasize the omission by glorifying in exaggerated terms every trumpery innovation that is suggested by a German, even if it is only, as most German innovations in insanity are, a change of name. I have received the most handsome acknowledgements of the value of my doctrines from lawyers of eminence, both in this country and in the United States, from psychologists, from doctors who are not members of my speciality, and from members, interested in insanity, of the general public; but, with the exception now of Dr. Cassidy, there is scarcely one member of my own speciality who has made a sign to indicate that he has ever heard of these doctrines of mine, though they have been issued at pretty frequent intervals for the last five-and-thirty years. I do not attribute this prolonged and persistent ignoring of my teaching to any concordant design on the part of my friends the alienists. I attribute it to the fact that they are all drawn from the same intellectual class. Men whose mental constitution is such that they can adopt *locus-holus* such doctrines as those of dementia praecox and psychoanalysis are naturally unable to appreciate such teaching as mine, founded as it is upon rigorous deduction from hard facts. I do not complain that they do not adopt my views; but I think I have a right to complain that they studiously ignore them and treat them as non-existent.

Indian Doctors and Vacant Appointments.

Finally, I wish to endorse Dr. Muthu's plea for the employment of our Indian colleagues in this country. It has been my privilege to have the assistance in my practice of an Indian gentleman, and a more able, assiduous, loyal, and courteous colleague no one could wish to have. He did not remind me, though he might have done so, that his ancestors were cultured gentlemen, possessing a great literature, when mine were naked savages, painted with woad, living in caves and wattled cabins, and making, with flint knives, human sacrifices to savage gods. Our neolithic ancestors were, I am afraid, an uneducated people, but in one respect, at any rate, they were superior to their descendants—they did not idolize German teaching and treat their native teachers with contemptuous neglect.—I am, etc.,

Moorcroft, Parkstone, Dorset,
Aug. 21st.

CHAS. A. MERCIER.

EARLY MEDICAL HISTORY.

Sir,—Overlooking breadth or laxity over medical history in England may satisfy a rough general survey of details or tied examination, but thereby broader views are apt to be misapprehended, if not hidden, by these countless unrelated and tabulated facts from wide sources under tireless tied examination, an example of which is the equally popular and colourless archaeological tracings. There should be some recast or change from this older prescribed overbearing recital and limitation. In fact, I would rather rely upon a proper estimate of what may here be called Historical Sequence. Twenty-one years ago, when I was attending the lectures of the Paris University, there was a chair of many years' foundation in medical history. It was at that time kept a big detail subject; they were studying some of the French and older personal sides biographically. But the lectures would have been enhanced by this equal concordance or sensitization with a running historical sequence and not the single tabulated procession of details.

Dr. Major Greenwood in his late address, after lightly sketching in the rise of the medical practitioner, but more probably a poetic confusion of different types, from the appearance of some one or other type presented in the poetry of Langland and Chaucer, further supposed he could trace them in direct lineage to the Medici of Rome in a hereditary sense, much after the fashion of church dignitaries; however, the latter must be regarded differently, for they stand apart, with fair claim to definite lineage.

If this principle of historical sequence be adjusted, not accepting any looser literary prescription, we shall get, I think, a justness of view. As the *Don-bok* indicates a British or Saxon law, and not only a Roman descent of law, so these different types of doctors could not have descended from one type like the *Medici*. Doubtless *Medici* came over with Caesar's army, and with many subsequent generals during the nearly four hundred years of Roman domination in England. But English *Medicine* does not thereby descend from Rome. The medical families of Rome, if I remember rightly, begot *Medici* in a hereditary sense or custom. Many new *Medici* arose through the apprenticeship of slaves, who when distinguished became freed. But did the Africanus or Numidian Apuleius become Roman because of his training? Pythagoras and then Hippocrates equally certainly influenced medicine, but Rome topographically alone or separately developed the most characteristic Roman hygienic side of the medical art and practice. Europe developed many shades of medical practice, yet they did not descend from Rome simply because of the fathers (Galen and Celsus or the universally read *Flora Medicinarum* of the Salerno school (or university?). Therefore, in England, as elsewhere, the local exercises predicated and formulated the special types of doctors, and the gross or individual embarrasements were evolved out of the various sources of inspiration, all out of the essential medical-historical sequence. Brute force, at any rate in learning, cannot conquer culture. Neither willordes, nor the abominable English thraldom of examinations, nor these particular and stray *Medici* entirely account for the erring or peculiar genius, or the ordinary personnel, or the variety of callings occurring in the English history of medicine: the earlier question of English medical history must be spread to its wider issue. And, considering the early fondness for baths prevalent in Germania and in Rome and elsewhere, the bathmen, equally with the *Medici*, must have tended to spread to Britain and acted as teachers of the practice of medicine and surgery. Small operations and operators were to be seen in the baths. Traced to England, the remains of these baths I have seen unearched at Bath, London, and even at country places like Bignor. The ancient cutters for stone followed both army and peaceful vocations. Again, before the popes forbade them, the monks practised and no doubt taught surgery and medicine. So, narrowing down to the British surgeons, they would certainly have plenty of scope to train in pure surgery and surgical appliances, and not be restricted to phlebotomy and barbary.

In my first volume of *Medical Reform Measures*, 1908, when dealing with the two main channels of English medicine, I gave the concise annals from early to later days of the Royal Colleges of Physicians and Surgeons, and I there laid down, for the first time, this doctrine of the differential status of surgeons, apart from the barbers or barber-surgeons, so often described and relied upon by other writers. Of course, there occurred the subsequent junction with an equally existing Guild of Barber-Surgeons, but I claim it was dictated by the community influence of a larger commercial union, not by the community sense of learning, and that aspect should be recognized. Dr. Major Greenwood interestingly quotes the entry of a surgeon, of one type or other, to the freedom of London. A few years afterwards the records of London, as I showed in my book, acknowledged the more important proof of the full strength of an actual Guild of Surgeons and a Master. Indeed, both of these indications are useful and supporting annotations of my earlier conclusions.—I am, etc.,

H. ELLIOT-BLAKE.

Beer, Devon, Aug. 17th.

INDIAN DOCTORS AND VACANT APPOINTMENTS.

SIR,—Concerning remarks of Sir William Collins at the British Hospitals' Association¹ regarding the prejudice against the employment of Indian and other coloured medical practitioners, my experience is typical of the treatment Indian qualified practitioners get in this country at the hands of responsible people.

I first applied for a house-surgeonship at the Westminster Ophthalmic Hospital; then I applied at the Royal Eye Hospital; Sir William Collins himself supported my

application, but what the result was he has already said in his speech. On applying at the Oxford Eye Hospital I was informed the post had been duly filled, but the original advertisement which I answered is still appearing in the *BRITISH MEDICAL JOURNAL*. Six weeks back I applied at the Birmingham and Midland Eye Hospital; the original advertisement is still appearing; but I have not received any reply to my application. It is a matter of common knowledge that many of my Indian medical friends who expressed their readiness to supply the want of the War Office by their services have been told that their words "British subject" cannot include an Indian because he is not of a "pure European descent." I do not know whether a Spanish or a Swiss naturalized as a British subject could be preferable to an Indian. Is an Indian after all an equal citizen of the British Empire?—I am, etc.,

HOMI KHARAS, M.B., B.S.

London, E.C., Aug. 19th.

THE IMMEDIATE EFFECTS OF THE INHALATION OF CHLORINE GAS.

SIR,—Sir Edward Schäfer's conclusion that administration of chlorine causes no obstruction of the airway is somewhat surprising.

There is, as he points out, little or no previous evidence on the point.

Dr. Cow has, however, recently (*Lancet*, May 29th, 1915), described symptoms from inhalation of chlorine which suggested bronchiolar spasm. Hence it seemed of interest to repeat, with chlorine, observations recently made in this laboratory with the vapour of bromine (*BRITISH MEDICAL JOURNAL*, July 3rd, 1915, and *Proc. Physiol. Soc.*, July 3rd, 1915).

These have been carried out with artificial respiration, by our aspiratory method (*Proc. Physiol. Soc.*, June 7th, 1913, and *Journ. Pharmacol. and Therap.*, v, 1913), and have shown obvious obstruction of the airway which, when "gassing" was not too heavy, yielded to stramonium fumes, and which was therefore in part attributable to spasm of the bronchioles.—We are, etc.,

F. COLLA,

W. L. SYMES.

Physiological Laboratory,
University of London,
Aug. 24th.

FATIGUE DYSPEPSIA.

SIR,—In reference to Dr. Rankin's article on "Fatigue Dyspepsia" (*BRITISH MEDICAL JOURNAL*, June 19th, 1915), I should like to state that these cases can be easily cured by the treatment advocated by Girdle, Hadson, Austin, Fletcher, and many other so-called food faddists—that is, starvation and purging until appetite returns, and then the feeding on what taste demands, and ceasing when appetite and taste are appeased. The diet recommended by Dr. Rankin remains so forcibly of the diet ordered in a case of enteric fever I took over from a civil practitioner during the Boer war. The case was in about the eleventh day of disease. The diet ordered was roast chicken, with extras of beef steak, mutton chop, fish, champagne, and several other things. I inquired if the patient ate all he was ordered, and was informed that his appetite was poor, but it was hoped he would fancy something from amongst the things ordered.

Most of Dr. Rankin's patients appear to be people of sedentary habits. The diet ordered them would be more than enough for people in hard physical training if ordinary carbohydrates were substituted for "Energex" and other proprietary foods. Another thing I do not understand in Dr. Rankin's diet is why fluids are ordered six times a day, as many of the cases are stated to have a more or less pronounced dilatation of the stomach. A man who eats when hungry and chews his food normally rarely has any desire to drink more than once or twice daily, even in the tropics.

Dr. Rankin's disciplinary treatment is vague, especially the exercises. Clearly in these cases the abdominal muscles are at fault; why, then, are not the exercises directed specially towards them?

No mention is made of the correct action of the diaphragm. Any one can throw back the shoulders and expand the chest, but few people can make the diaphragm massage the intestines during ordinary respiration.

I daily see men carrying to Simla anything between 40 and 120 lb. of grass on their backs. The grass is cut about 1,000 ft. down the hillside and carried 7 to 10 miles. These men eat once daily about 1½ lb. whole wheat flour, 2 oz. unrefined sugar, a little salt, chillies, and 1 or 2 oz. clarified butter. They eat meat when they can, but as they support themselves and their families and save money on under Rs. 15 a month, it is difficult for them to buy it except rarely. Military history shows that all the hardest marches and fighting have been done on half or quarter rations. Even beasts know what the medical profession appears not to know—that is, when appetite is appeased, stop eating; when sick, lie down and starve.—I am, etc.,

F. W. COTTON, Major R.A.M.C.

Station Hospital, Jutogh, July 23rd.

THE STANDARD OPAQUE MEAL FOR RADIOGRAPHIC EXAMINATION.

SIR,—I see by the reports of the Royal Society of Medicine, Section of Electro-Therapeutics, in the *JOURNAL* of August 7th, page 219, that a standard meal for radiographic purposes has been recommended.

The recommendations so definitely stated and supported by such eminent signatories should be welcomed, for the instructions will form a good basis for working upon. Personally, I am pleased to note them, for they confirm me in opinions formed during investigations which I carried out and embodied in a thesis sent in March, 1914, to Edinburgh University for the degree of M.D., and which I hope to have published in the *Practitioner* in the near future.

The following are extracts from that thesis:

That a semi-solid, such as porridge or bread and milk, is the most satisfactory medium.

That barium sulphate is the best opaque substance to use.

That I gave the testing meals not earlier than four hours after the previous feed, allowing what I thought an average time for the stomach to become empty.

That the food was given warm so as to obviate any retarding action that a quantity of cold material might have when introduced into a stomach usually accustomed to a warm meal.

That although bismuth gives a deeper shadow than barium if equal weights are used, yet if one and a half to two parts of barium for one part of bismuth are given, then the barium shadow is quite as intense as that produced by bismuth.

That 4 level teaspoonfuls of barium sulphate (that is, fully 5½) in a 6 oz. feed (for children) produce a satisfactory shadow.

—I am, etc.,

D.P.H.Camb.

Gillingham, Kent, Aug. 16th.

Obituary.

PROFESSOR PAUL EHRLICH.

DIRECTOR OF THE ROYAL INSTITUTE FOR EXPERIMENTAL THERAPY AND OF THE GEORG-SPEYER-HOUSE FOR EXPERIMENTAL CHEMOTHERAPY, FRANKFORT.

On August 21st it was reported from Amsterdam that Professor Paul Ehrlich, of Frankfort-on-Main, had died suddenly the day before in his laboratory. Of Jewish parentage, he was born on March 14th, 1854, in the small town of Strehlen twenty odd miles south of Breslau, in Silesia. He received his schooling at Strehlen and Breslau; his university studies were begun at Breslau, and continued under Waldeyer at Strassburg, Cohnheim and Leidenhain were also his teachers; among his fellow-students were Professor Welch, of Johns Hopkins Hospital, Baltimore, and Professor Salomonsen, of Copenhagen. He qualified as a practitioner of medicine at Breslau in 1877. Throughout his studies he seemed to have been attracted mainly by the chemical aspects of medicine and pathology; none the less in 1878 he was appointed chief assistant to Professor Frerichs' medical clinic at Berlin, remaining there for seven years. Practical medicine was not Ehrlich's forte, and he was lucky in having a junior colleague able to relieve him of the responsibilities of his position.

At this time he was working at the staining reactions of the tissues and the blood, being the first to employ the rapidly-increasing number of aniline dyes for this purpose on a large scale. These researches incidentally led to the

discovery and characterization of the so-called "mast cells" of the blood. In 1885 he published his first important book, on the oxygen requirement of the organism, in which great use was made of the staining reactions of the various constituents of protoplasm in the interpretation of its constitution and properties; the book also contained a first outline of his side-chain theory. In 1884 Ehrlich became titular professor, and in 1887 Docent (lecturer) at Berlin University. In 1888 he developed signs of phthisis, the result of his experimental work with the tubercle bacillus. His studies were interrupted, and for eighteen months he travelled in Egypt and other countries in search of health, and, thanks to a course of treatment with Koch's newly-discovered tuberculin, found it.

Returning to work at Berlin in 1890, he was made extraordinary professor at the university, and took up the experimental study of toxins and antitoxins. In 1896 he was given the Serum Institute at Steglitz, near Berlin, to work in, but it proved too small for his activities. In 1899 he removed to the larger Royal Institute at Frankfort-on-Main, having been appointed Medical Privy Councillor in 1897. At Frankfort he took up the study of haemolysis with Morgenroth, publishing his important volume containing his collected studies in immunity in 1904. In the same year he was made ordinary honorary professor at Göttingen. Following Jensen of Copenhagen, he set to work on the malignant tumours of mice in 1902, and this line of investigation was pushed on the large scale for several years. In 1906 he moved into the extensive laboratories of the newly built Georg-Speyer-Haus at Frankfort, and here he was still working when he died. From 1906 onwards his attention was given mainly to the newly founded science of chemotherapy, and to practical applications of synthetic chemistry and his own side-chain theory to therapeutics. He devoted himself mainly to the study of the organic compounds of arsenic; he and his fellow-workers discovered (and permitted to be patented) "606," or salvarsan, in 1910; neo-salvarsan (or 914) in 1912; and sodium-salvarsan (or 1206a) in 1913. In 1912-1913 he founded the *Zeitschrift für Chemotherapie*, in conjunction with Kraus and Wassermann; this periodical is devoted to the literature of salvarsan and allied subjects on the one hand, and on the other affords a continuation of Pappenheim's *Folia Serologica*. In 1907 he became Chief Medical Privy Councillor; in 1911 Actual Privy Councillor, with the title of Excellency; in 1908 he received a Nobel Prize; and in 1909 a substantial grant from the Rockefeller Institute. In England and America, too, he was not without honour, having been appointed Croonian lecturer and also Harben lecturer; he also delivered a series of Herter lectures at Baltimore. He received honorary degrees and distinctions from universities all over Europe, and was made D.C.L.Oxon. in 1907.

Ehrlich was a man of unceasing intellectual activity. In the concentration of his faculties on the problems of his researches he was absent-minded to a degree rare even among men of science from the days of Archimedes onwards. Between 1877 and 1914 he contributed as many as two hundred and twelve papers and books to the literature of science. During the same period he directly inspired the composition of over four hundred publications by subordinates and workers in his own laboratories. Further, he must be reckoned to have been indirectly responsible for the printing of uncounted thousands of original articles by chemists, clinicians, and experimental pathologists all the world over, whose contributions to the periodicals of science owed their birth to the fruitful conceptions of his brain.

In 1883 he married Hedwig Pinkus, a Silesian lady, who, with her two married daughters, survives him. For several years he lived in his eponymic Paul Ehrlichstrasse at Frankfort-on-Main.

Dr. C. H. BROWNING, Director of the Bland-Sutton Institute of Pathology, Middlesex Hospital, writes:

The death of Ehrlich has deprived the world of one of the greatest minds which have illuminated medical science. It is seldom given to one man by his discoveries to revolutionize the outlook on five or six different departments of knowledge and to open up as many unknown paths along which multitudes of others may make rich

journeys of discovery. Thus, his investigations on the staining of the leucocytes laid the foundation of modern haematology; his observation that methylene blue possesses an elective affinity for nerve endings has been the starting point of a whole school of highly fruitful neurological research; it was Ehrlich who discovered the acid-fast property of the tubercle bacillus and who devised the method of staining this organism which is practically that now in everyday use, and without which, as Koch himself admitted, the demonstration of the organism would have remained an academic accomplishment instead of becoming one of the most valuable diagnostic procedures in medicine. Similarly, by his work on the standardizing of diphtheria antitoxin Ehrlich placed the dosage of anti-serum on a scientific basis, without which von Behring's great discovery would probably have fallen in its wonderful achievement. It is well to recall the earlier work of Ehrlich, because it shows the extraordinary versatility of his mind and the remarkably long period during which he continued to produce results of first-class importance: thus the discovery of the acid-fast character of the tubercle bacillus was published when he was 29 years of age, and the "Oxygen Requirements of the Organism," which contained the germ of his chemotherapy, when he was 31, and before he had attracted the multitude of workers who later sought his laboratories. In his later days, when he was the director of the busy Institute of Experimental Therapy and the Speyer-Haus at Frankfurt, with their numerous assistants, it was occasionally forgotten what the man achieved by himself. Of course, it was true that individual workers unearthed treasures whose existence Ehrlich had not suspected or of whose sterling value he had occasionally to be convinced, but all who were capable of taking an honest and a generous view, knew well that even if Ehrlich did not always foresee the actual nature of the treasure, it was almost invariably he who had discovered the trove.

The writer worked at Frankfurt during the period (1905-7) which immediately preceded the discovery of salvarsan, and being engaged in the biological investigation of a large series of the arsenical preparations which preceded the famous "606," it was his great privilege to be intimately associated with Ehrlich in those themes which were then of all-absorbing interest to him. Ehrlich was in those days, even as earlier, an indefatigable worker, and his mind was the sharp sword which ever turned to wear through the scabbard. Had it not been for the solicitous care of his wife there is little doubt that we should have had to regret his loss still earlier. His knowledge of chemistry, especially in its bearings on biology, was immense; at the same time he possessed a power of concentration which appeared almost uncanny, and which in its capacity for eliminating trifles would quite unfit the average man for the ordinary affairs of life. Ehrlich's writings exhibit a singular felicity of expression; he had a genius for the creation of descriptive phrases, such as his famous *Corpora non agunt nisi fixata*, and this same quality made personal association with him a veritable inspiration and stimulation to fresh effort. He was extremely fond of expressing his ideas symbolically, and the diagrams illustrating his theories on immunity are an example of this; these have probably been taken much too literally, and have produced crude conceptions of the nature of the highly complex class of bodies to which toxins and antitoxins belong, which Ehrlich himself never entertained. Latterly the theories of immunity did not actively interest him, although he was at all times ready to uphold the accuracy of the enormous mass of experimental data on which they were based. It is significant that he did not regard cancer investigation with a very sanguine outlook.

Were I to attempt to characterize in brief the genius of Ehrlich, I should say that it consisted in two striking characteristics—his faculty for escaping the trammels of error in past work, and his capacity for bringing into association as the basis for experiment ideas which purely critical minds would tend to dismiss as fantastic. Having effected a synthesis, he was then pre-eminently able to grasp the essential elements. Ehrlich's power to evade the pitfalls of old error was clearly seen in his researches which led to the elucidation of the constitution of atoxyl: a belief in the accepted view of its composition as an anilide would have

effectually prevented all the further developments which culminated in salvarsan. His synthetic faculty is exhibited by the numerous reactions in pure chemistry with which his name is associated, and his keen gift for analysis is exemplified by his fundamental discoveries on the relationship subsisting between chemical constitution and biological action. This is a time at which it is difficult to see clearly, but one feels sure that the perspective lent by the future will bring into still greater prominence the influence of Paul Ehrlich on the advancement of medicine. It is singular that this man, whose practical contributions to medicine have been so numerous, probably never approached any problem in a utilitarian spirit; pure sciences frequently stand in need of apologists, and Ehrlich's whole career is a striking vindication of the pursuit of knowledge for its own sake. He who seeks finds, and Ehrlich was an inspired secker.

EDWARD LAWRIE, M.B. EDIN.,

LIEUTENANT-COLONEL, I.M.S. (RETIRED).

LIEUTENANT-COLONEL EDWARD LAWRIE, Bengal Medical Service (retired), died at Hove, after a lingering illness of over three months, on August 22nd. He was born on May 17th, 1846, and educated at Edinburgh University, where he took the degrees of M.B. and C.M. in 1867, and at Paris. He also took the diploma of M.R.C.S. in 1867. After acting as house surgeon to Professor Syme in the Royal Infirmary, Edinburgh, he entered the Indian Medical Service as assistant surgeon on March 30th, 1872, became surgeon on July 1st, 1873, surgeon-major on March 30th, 1884, and surgeon lieutenant-colonel on March 30th, 1892. He retired on May 17th, 1901. The *Army List* assigns him no war service. From 1874 to 1879 he was resident surgeon of the Medical College Hospital, Calcutta, acting for some time as Professor of Physiology in the Medical College, in addition to his other duties; from 1879 to 1885 he was professor of surgery in the Lahore Medical College, and from 1885 till his retirement Residency surgeon at Hyderabad, the premier Indian native state, a post which is one of the most important medical appointments in India.

When the hospitals for sick and wounded Indian troops were opened in Brighton in December last, he was appointed anaesthetist, and carried out his duties in the Pavilion and York Place hospitals till the beginning of his fatal illness last May. He was best known, however, for his views on anaesthesia, being an ardent advocate of the claims of chloroform to be the best and safest anaesthetic for general use. His views on the subject were published in a book entitled *Chloroform: A Manual for Students and Practitioners* (1901). It was at his suggestion that the Indian Chloroform Commission of 1889-90, of which H.H. the Nizam of Hyderabad paid the expenses, was appointed; Sir Lauder Brunton went out from England to act as president, and Lieutenant-Colonel Lawrie and the late Surgeon-General Sir Gerald Bomford (then Surgeon-Major) were the members.

Sir LAUDER BRUNTON, Bt., F.R.S., writes:

The death of Colonel Edward Lawrie was to me a great shock, and must have been so likewise to all his friends, for he retained his appearance of youth and his energy to a much greater extent than most of his contemporaries, so that it seems almost impossible to believe that more than fifty years have passed since he and I used to walk in the early mornings to the botanical class in Edinburgh University.

The great characteristic of Lawrie's character was that he was "valiant for the truth." If his zeal for truth sometimes led him to see but one aspect of it, and to be impatient or angry with those who could not see exactly as he did, this was only the result of the excessive truthfulness of his character, a characteristic that led so many of the early Christians to become saints and martyrs. While he was a student and house-surgeon in Edinburgh, Lawrie became thoroughly convinced that the view of his old teacher, Professor Syme, was correct and that chloroform only killed through the respiration and not through the heart. As many people, especially in this country, upheld the opposite view, Lawrie prevailed upon the Nizam to have a series of experiments instituted on monkeys to prove this point.

Without exception these monkeys all died from failure of the respiration. As the result of these experiments did not meet with universal acceptance, Lawrie persuaded the Nizam to have a second Commission to investigate the action of chloroform, and to this, in addition to several men from Hyderabad, he invited the late Surgeon-General Sir Gerald Bomford and myself. The amount of experimental work that we did in three months was so great that it would really have taken a man his whole time for three years to work out all that was shown by the tracings. Even yet the causation of deaths during chloroform anaesthesia has not, I think, been completely ascertained, and I am still disposed to think that shock plays a much greater part than is usually believed, and that most of the deaths occurring during the administration of chloroform occur *in it* but not *from it*. Lawrie's uprightness of character, and freedom from anything mean or petty, gained him the respect not only of the Nizam of Hyderabad, but of all who knew him, and I do not think there is one who can help saying on hearing of his death, "There is another good man gone."

Dr. J. COTTER, Sidney Place, Cork, died unexpectedly at his country residence, Bushmount, Clonakilty, co. Cork, in his 63th year. He received his medical education at Queen's College, Cork, and took the degrees of M.D. and M.Ch. in 1880. Later in his professional career he was appointed lecturer in pathology in Queen's College, Cork, where he was very popular with the students who attended his lectures and practical demonstrations. In 1894 he became a Fellow, by examination, of the Royal College of Surgeons in Ireland. At the time of the foundation of the National University in Ireland, the Queen's College, Cork, became one of the constituent colleges of this university under the name of the University College, Cork; of its governing body Dr. Cotter was made a member. Dr. Cotter was a member of the British and Irish Medical Associations, and President of the latter in 1911. He took an active part in the Insurance Act agitation, and was chairman of the Cork Borough Medical Committee for some years. The attendance at the funeral ceremony was very large, and representative of all classes, particularly of his own profession, amongst whom he was deservedly very popular.

Pro nobis fratrum. Mr. THOMAS BASIL ETHERINGTON-SMITH, Sub-Director-General of Accounts on the Egyptian Ministry of Finance, died at Gezireh, Cairo, on August 20th, of diphtheria. On April 19th, 1913, his brother, Raymond Broadley Etherington-Smith, F.R.C.S. and M.B. Cantab., assistant surgeon to St. Bartholomew's Hospital and warden of its College, died from the results of a poisoned wound. Both brothers were but thirty-six years old at the time of their death. Both were famous oarsmen, as well as men of high intellectual capacity, and they were alike indefatigable in the discharge of their duties. Raymond studied at Trinity College, Cambridge, and "T. B." at Oriel, Oxford. In 1900 "T. B." rowed in the Oxford boat when his brother happened to be one of the rival crew, which gained the victory, and in the succeeding year "T. B." was in the Oxford boat, which on this occasion triumphed by a spirited effort towards the end of the race.

LIEUTENANT-COLONEL JOHN LEES HALL, R.A.M.C. (ret.), died suddenly in London on August 15th. He was born on April 16th, 1855, educated at St. Thomas's, and took the L.S.A. in 1877, the L.R.C.P. Edin. in 1878, and the M.R.C.S. in 1879. After filling the post of house-surgeon of the Hants County Hospital, he entered the army as surgeon on March 6th, 1880, becoming surgeon-major on March 6th, 1892, lieutenant-colonel on March 6th, 1900, and retiring on August 3rd, 1907, and rejoined the army when war broke out from August 12th, 1914. He served in the South African war in 1901-2 as principal medical officer of a general hospital in the Transvaal, and received the Queen's medal with three clasps. He was a Knight of Grace and Honorary Associate of the Order of St. John of Jerusalem.

BRIGADE SURGEON-LIEUTENANT-COLONEL JOSEPH FLEMING, R.A.M.C. (ret.), died at Castlequarter, Inch, on

August 10th. He was educated at Glasgow University, where he took the degree of M.D. in 1863. He held also the diplomas of the L.R.C.S. Edin. (1863) and the F.R.C.S. Edin. (1867). Entering the army as assistant surgeon on March 31st, 1864, he became surgeon on March 1st, 1873, surgeon-major on March 31st, 1876, and retired as brigade surgeon-lieutenant-colonel on March 31st, 1890. He served in the Ashanti war of 1873-4, medal; in the second Afghan war of 1878-80 with the Kuram field force and with the Northern Afghanistan field force, medal; and in the Sudan in 1885, at Suakin, and in the action of Tofrek, when he was mentioned in despatches in the *London Gazette* of August 25th, 1885, and received the Egyptian medal with two clasps and the Khedive's bronze star.

Universities and Colleges.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subject indicated:

SURGERY.—J. L. Hamilton, G. W. Hassall, E. L. Ivens, W. F. Matthews, A. L. Robinson, C. P. C. Sargent, F. Simpson, R. R. H. O. The, A. Traill.
 MEDICINE.—H. M. Arnold, G. T. Baker, R. N. Craig, E. S. Goss, H. L. Hughes, H. S. Jeffries, F. Simpson, R. R. H. O. The, A. Traill.
 FORENSIC MEDICINE.—H. L. Hughes, F. Simpson, R. R. H. O. The, A. Traill.
 MIDWIFERY.—R. M. Gray, E. L. Ivens, S. G. K. Kasiecianski, A. L. Robinson, R. R. H. O. The, R. H. Yolland.

Section I. Section II.

The diploma of the Society has been granted to Messrs. G. W. Hassall, H. L. Hughes, H. S. Jeffries, W. F. Matthews, A. L. Robinson, F. Simpson, R. R. H. O. The, and A. Traill.

Medical News.

THE late Professor Frederick Howard Marsh, F.R.C.S., Master of Downing College and Professor of Surgery at the University of Cambridge since 1903, who died on June 24th, aged 76, left unsettled property valued at £6,903 gross, with net personality £6,581.

THE Institution of Mining Engineers will, it is announced, present the institution medal for 1914-15 at its twenty-sixth annual general meeting, to be held at Leeds in September, to Dr. John Scott Haldane, F.R.S., of Oxford, in recognition of his investigations on mine air.

THE Czar has conferred on Surgeon W. J. Gerrard, R.N.V.R., the decoration of the Order of St. Anne, Third Class, in recognition of war services. Surgeon Gerrard, who is assistant school medical officer in Aberdeen, graduated M.B. at the University of that city in 1909, and has been serving on board H.M.S. *Imperieuse*.

ON August 18th the freedom of Peterborough was conferred on Dr. Thomas James Walker, J.P., "in recognition of his long and distinguished service to his native city." The ceremony took place in the presence of a large and representative gathering. Dr. Walker was born in Peterborough, and has been in practice there for fifty-five years. His fame is not confined to his native city. He is one of the pioneers of laryngology in this country, and as far back as 1863 contributed to the BRITISH MEDICAL JOURNAL a series of papers on the laryngoscope and its clinical application. Dr. Walker was one of the first who removed a growth from the larynx *per vias naturales*. He was educated at the University of Edinburgh, and graduated M.D. at the University of London in 1861. He was for some time medical tutor and demonstrator of anatomy at Queen's College and assistant physician and pathologist at the Queen's Hospital, Birmingham. He then joined his father-in-practice at Peterborough, and was for many years on the staff of the Peterborough Infirmary, of which he is now consulting surgeon. He enlisted in the Volunteer Corps in 1860, and retired twenty years ago with the rank of Lieutenant-Colonel of the battalion. For his services as a volunteer he was awarded the decoration of V.D. Several of his sons are now serving with the forces. Dr. Walker is the author of a valuable book on the *dépôt* for French prisoners of war at Norman Cross, Huntingdonshire, which was reviewed in the JOURNAL of April 11th, 1914, p. 822. Dr. Walker is the second honorary freeman of Peterborough, the first on whom the distinction was conferred being Mr. Andrew Carnegie, who received it in 1905.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atology, Westrand, London, W.1*; telephone, 253, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (ADVERTISING), *Articulate, Westrand, London, W.1*; telephone, 253, Gerrard. (3) MEDICAL SECRETARY, *Medisera, Westrand, London*; telephone, 253, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

M. L. asks: Was the rise of the death-rate, reported in the quarterly return just published, due to the increase in the cost of living caused by the war, and did it occur mainly in any particular section of the community?

TACHYCARDIA.

"SALOT" asks for any suggestions in the following case. A female patient, aged 41, has been troubled for the last seven years with persistent tachycardia. Rest, bromides, digitalis, and strophanthus have all been tried separately and in combination without result. For the last year noises in the head and sensation of the blood circulating at the top of the head, and throbbing and pulsation of the carotids have been specially distressing. The patient menstruates every three weeks. The pulse tension is low, and there is no albuminuria. At present belladonna is being tried. Is adrenalin of any value in such a case?

ANSWERS.

RECURRENT ERYSIPELAS OF LEG.

DR. GHOFFREY PRICE (Kineton, Warwick) writes: My experience of serum and vaccine treatment of erysipelas has been happy. On the other hand, I have never heard of any serum being used prophylactically, since the effects of any serum being used in a few days. I also doubt if a vaccine would be prophylactic for more than a month or so against erysipelas. I had a case of mild recurrence seven months after a severe attack of erysipelas. I suggest that "C.D." should correct the sins of omission and commission of his patient—as regards cleanliness, exercise, diet, and evacuations, etc.—and inject a vaccine, or Parke Davis's "phylacogen," at the commencement of the attack.

THE HYPODERMIC DOSE OF CODEIN.

MR. LANGFORD MOORE, F.C.S. (Chief Pharmacist to St. Bartholomew's Hospital, London), writes, in reply to "Corpus Vile's" inquiry as to the dose of codæia for hypodermic use: My experience may perhaps be helpful. Some few years ago I had occasion to frequently supply this drug in an 8 per cent. aqueous solution of its phosphate salt; the subcutaneous dose of this solution being one cubic centimetre. The clinical symptoms due to the severe collapse produced by their administration. The purgative action of both these drugs being due to their profound depressant effect on the sympathetic ganglia, their administration, in a pathological condition, is not unaccompanied with danger; that objectionable feature now appears to be overcome by the use—hypodermically—of eserine sulphate, which, combined with strychnine, while acting on the muscle, does not produce such medullary disturbances. The untoward after-effects of codæia are central, its elimination is by the rectum, therefore of no pharmacological or clinical importance. If "Corpus Vile" cares to communicate with me I shall be delighted to compare experiences.

LETTERS, NOTES, ETC.

RESEARCH IN ANTISEPTICS.

DR. W. HALE WHITE (London) writes: In your interesting article, "Research in Antiseptics" (BRITISH MEDICAL JOURNAL, August 14th, 1915, p. 262), you state that liquor sodæ chlorinatæ (B.P.) is practically identical with eau de Labarraque, but the *British Pharmaceutical Code* (p. 583) states that Labarraque's solution is one-fourth the strength of the B.P. solution. You also state that eau de Javelle is made by treating chlorinated lime with sodium carbonate, but the *British Pharmaceutical Code* states that it is a solution of chlorinated potash. Both the BRITISH MEDICAL JOURNAL and the *British Pharmaceutical Code* are being so largely used as antiseptics, that I feel sure that many of your readers will be grateful to you if you would kindly tell them which is correct, the BRITISH MEDICAL JOURNAL or the *British Pharmaceutical Code*.

* * * The statement that eau de Labarraque is practically identical with liquor sodæ chlorinatæ (B.P.) was intended to have reference only to its chemical constitution. The "solution officinale d'hypochlorite de soude" of the French

Codex Medicamentarius, for which liquor de Labarraque is given as a synonym, is between four and five times as strong as the B.P. preparation. Although eau de Javelle is a preparation in very common use in France, there seems to be some confusion as to whether it is made with sodium or potassium carbonate. It is not an official preparation, but we understand that when it is prescribed the sodium salt is intended; the potassium salt is unsuitable for application either to wounds or mucous surfaces. We are told that the confusion is probably to be attributed to a trade custom in France by which the solution of caustic soda (*lessive de soude*) used by house-painters is called "potassium." The mode of preparation of the sodium hypochlorite and boric acid solution used at Compiègne is given by Dr. H. D. Dakin in a paper published elsewhere in this issue (page 315). The formula for the similar preparation devised by Professor Lorrain Smith and his colleagues was contained in their paper published in the JOURNAL of July 24th.

SIDELIGHTS ON THE PRACTICE OF MEDICINE FROM ENGLISH LITERATURE.

DR. WM. BRAMWELL (Liverpool) writes: In view of the interesting paper on the above subject by Dr. Major Greenwood, the following extract from Lord Bacon's *New Atlantis* will be interesting as indicating what seems to have been a mediaeval title for the medical officer of health, and will also show that Bacon was not acquainted with prophylaxis against infection, and also with the necessity for quarantine.

My lord would have you know that it is not of pride or greatness that he cometh not aboard your ship; but for that in your answer you declare that you have many sick amongst you, he was wroth by the conservator of health of the city that he should keep at a distance . . . and a while after came the notary to use aboard our ship, holding in his hand a fruit of that country, like an orange . . . which casts a most excellent odour; he used it as it seemeth, for a preservative against infection, . . . and after told us, that the next day . . . we should be sent to, and brought to the Strangers' House.

Whether the designation "conservator of health" was in use at a time when such office was not have been comparatively rare, or whether it is a name of Bacon's numerous originalisms, would be interesting to know. Some philologist, however, in their extremities of refinements, would consider it a more suitable and perhaps a more dignified title than the present one, conveying a far definite meaning, and certainly more concise. "C.H." for instance, would be a better abbreviation than "C.O." though unfortunately at a decided disadvantage with that section of the public whose estimation of a medical man appears to vary with the number of letters attached to his name. Such innovation is therefore not to be thought of. It is interesting to note that what is known as a lazzaretto is referred to by Bacon as the Strangers' House.

EXPLOSION OF A MIXTURE CONTAINING SUGAR.

K. EKHOLO (*Vinska Läckarearskolepets Handlingar*, Malmö, 1915) prescribed the following mixture on April 2nd: B. Codæin, phosphoric, 0.04 gram, aq. distill., 7.00 grams, viii. Tokayensis 30.0 grams. The mixture was put into a plain glass bottle, and was not used after April 7th. The bottle, which was corked, and contained about one-third of the original amount, was kept on a table by a window facing north. On April 13th a loud explosion was heard, and on entering the room a nurse found the bottle in a thousand fragments, and she also noticed a curious sound coming from the bottle. The same mixture had been prescribed for many years in the author's hospital without the generation of gas—at any rate, in appreciable quantities. He suggests that on this occasion the sugar in the wine had fermented and given off carbonic acid. It is surprising that the small quantity of sugar present in about 10 grams of Tokay wine should be sufficient to generate enough gas to burst a 100 gram glass bottle.

A CORRECTION.

THE signature to the letter from Lord Kitchener's private secretary, appended to Dr. Halliburton's letter on medical students and the war (JOURNAL, August 21st, p. 312), should have been printed H. J. Creed.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0	0	0
Each additional line	0	0	0
A whole column	3	10	0
A page	10	0	0

An average line contains six words.

All remittances by Post Office Orders should be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 49, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to send postage stamps to letters addressed either in initials or numbers.

THE

British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, SEPTEMBER 4TH, 1915.

EDUCATIONAL NUMBER. SESSIONS 1915-1916.

THE PROFESSION OF MEDICINE.

The main object of this issue of the BRITISH MEDICAL JOURNAL is to meet the needs of two classes—those who require information as to the course which must be followed in order to become a legally qualified practitioner of medicine, and those who, having already obtained this position, are doubtful as to what particular part in medicine they should choose as a career.

In this country the conditions with which those who desire to enter the medical profession must comply are regulated by a statutory body known as the General Medical Council, and a statement of its requirements will be found on page 355. The task of examining candidates as to their fitness to practise medicine is left to the universities and to certain corporations in England, Scotland, and Ireland. But the Council takes steps to ensure that the tests imposed do not fall below a certain standard, and that none of these bodies admit to their examinations persons who have not undergone certain definite courses of instruction at one or other of the many recognized medical schools.

Successful candidates at such examinations eventually receive from the body holding them either degrees, in the case of the universities, or diplomas or licences, in the case of the corporations, entitling them to claim that their names shall be inserted in the *Medical Register* kept by the General Medical Council. The difference in the result is, however, no criterion of the comparative difficulty of the examinations undergone, nor yet of the expenditure in time and money demanded by the education necessary to pass them. At one time the holders of diplomas and licences formed the great majority of all medical men, especially in England and Wales, but of recent years universities have greatly multiplied. Consequently so many medical men now hold degrees that, save in exceptional circumstances, the wisest course for a medical student is to aim at a degree, though it may be desirable to take also a diploma or licence.

Apart from the degrees and diplomas and licences, on the strength of which the General Medical Council admits to the *Medical Register*, most of the bodies in question bestow on candidates who have passed

further examinations higher titles, such as "Fellow" and "Doctor of Medicine." It may be said that as a rule they are worth obtaining, though the difficulty of doing so, and the added professional status they confer, vary considerably. There are also a certain number of diplomas in special branches of work, such as public health and tropical medicine, which are superfluous in the case of the great majority of medical men, but either useful or absolutely necessary in the case of those who wish to specialize in the work covered by them.

The expenditure involved in successfully completing a medical curriculum varies so much that no single precise statement on the subject can well be made. Apart from differences in the charges made by different medical schools for instruction, there are differences also in the fees for examination, as well as in those charged for the actual certificates given to successful students, whether these relate to degrees, licences, or diplomas. Besides this, not all medical students, however industrious, get through their examinations with equal facility. Since in any case their professional education must continue for at least five years a period exceeded by the vast majority—and since the cost of living in different parts of the kingdom varies considerably, and personal expenditure varies still more, it can only be said that no one should think of entering the profession of medicine who is unprepared to spend on his medical education a sum of about £1,000.

When once a medical graduate, diplomate, or licentiate has obtained the insertion of his name on the *Medical Register* there are many courses open to him. He can aim at becoming a general practitioner; or at entering one of the Government services at home or abroad; or at specializing in public health or asylum work, or in pure science, or in one or other of the many modern subdivisions of medicine and surgery. Most of these different paths in medicine are considered in some detail elsewhere, but a few observations may here be made as to the first and best of them.

A man becomes a general practitioner either by taking a house and waiting for patients to seek his services, or by entering into partnership with some

already established practitioner. The successful conduct of a private practice entails, however, the possession of a great deal of knowledge other than that acquired at the medical schools, and consequently no man is likely to be accepted as a partner, or to prove successful as an independent practitioner, unless he has first gained experience in private practice as an assistant. The pay of assistants was at one time very small, but of late years has risen to what is quite a respectable figure, when consideration is paid to the fact that most assistants are still more or less *in statu pupillari*. Their average pay before the war was probably between £150 and £250 a year.

The path of those whose ambitions lie in the direction of becoming consultants or specialists is rugged. Their eventual success will depend not only upon their mental attainments and capacity for hard work, but on their possession of the various qualities which help to win for a man the confidence both of his colleagues and of the general public. Moreover, since it is certain that, however well equipped they may be, they will not for many years make as specialists enough to pay their outgoings, this particular path is open only to those who are in possession of sufficient means to maintain themselves for an indeterminate number of years, or who are able, by teaching or in other ways, to make sufficient to defray their expenses.

It is not the purpose of this number to put forward any opinion as to what paths in medicine offer the greatest attractions, whether financial or scientific. Whatever the branch of medical or surgical practice chosen, it must be remembered that the large majority of medical men make but a moderate income. The financial returns of even the most successful practitioners compare but ill with those obtained by persons of equal ability in other walks of life. The Insurance Acts stand for a movement that has done much to convert the general practitioner who is on the panel into a part of a piece of official mechanism, but nothing to maintain or improve the status of the medical profession, unless it be by the increased opportunities for scientific work afforded by the Medical Research Committee established under the Act of 1911. The full effects of the National Insurance scheme on the profession cannot yet be estimated, for, in spite of modification by many hundreds of successive orders, circulars, and regulations, it is still far from having reached any stable form. In consequence, the prospects of members of the medical profession must still be regarded as uncertain so far as they are influenced by the Act.

Of even greater importance may be the influence of the present war upon the medical profession. Its immediate effect is obvious. Three months ago Mr. Tennant stated in the House of Commons that nearly six thousand medical men had been taken out of civil practice by the army alone; it is estimated that the naval and military services of the Crown will withdraw several thousand more medical practitioners from their employment in Great Britain and Ireland. The consequent scarcity of doctors already makes itself felt throughout the country, at a time of year when the demands upon their services are normally at their lowest. When autumn passes into winter and sickness is naturally more prevalent among the civil

population, no doubt this scarcity will be much more severely felt. What of the more distant future? The war has naturally reduced the number of medical students very considerably. Without going into detail, it is possible to sum up this aspect of the matter by quoting Sir Donald MacAlister's estimate, given at the opening of the summer session of the General Medical Council three months ago, that during the next few years the diminution in the number of those qualifying for medical practice will be at the rate of about two hundred and fifty a year. In addition, it is necessary to take into consideration the number of medical men—no small number, alas!—who lay down their lives in the service of their King and country, and will never return home when the war is over. Our reserves of professional men are at no time large, and have been depleted long ago. It requires no great gift of prophecy, therefore, to say with some assurance that, though peace will liberate many medical practitioners from military duty, a distinct numerical shortage of medical men some years after the war has been brought to a successful conclusion may be expected. Will there be patients for them to treat? We believe there will. After the South African war there was more than the average amount of sickness. If history repeats itself, the same thing will occur again at the end of the present war. It is justifiable to cleave to the sunnier side of doubt, and to believe, *pace* Mr. Harold Cox, that this exceptional war will not be followed by a long period of national exhaustion and poverty. It would appear, therefore, that those whose minds turn towards medicine as a profession should not be deterred by the conditions prevailing at the moment from embarking now upon their chosen career. The attractions it will offer after peace has been re-stored may well be greater and do not seem likely to be less than they were before the outbreak of war.

Finally, it should be noted that a quality every medical man should possess is a strong sense of *esprit de corps*. Medicine, like the Church, is a profession which the general public—as also public authorities—persistently regards as being of a semi-philanthropic character. Furthermore, it is a profession whose aims and requirements are very ill understood by persons who have not undergone a medical education, including in that term not only a certain number of years at a medical school, but also a certain number of years passed in the actual practice of medicine. Consequently the interests of the medical profession, both on its financial and scientific sides, are continually being attacked, sometimes openly, sometimes insidiously. For this reason it is absolutely essential that medical men should band themselves together for the common protection of themselves and the profession that they represent, and to this end join the British Medical Association¹ as soon as they have entered their names on the *Medical Register*. For the objects of this body are to promote the progress of medical science and the interests of the medical profession, and its past history shows that it has well fulfilled them.

¹ The ordinary subscription of members resident within the United Kingdom is £2 2s., but as from January 1st, 1915, those admitted within two years from the date of their registration pay only 25s. until the expiration of four years from such registration. Members resident outside the United Kingdom pay 25s. to the parent Association.

THE GENERAL MEDICAL COUNCIL.

The General Medical Council is a body which was called into existence by the first Medical Act of 1858. A certain number of its members are elected by the medical profession, and the rest—who form the great majority—are nominated by Government itself and by the universities and such medical corporations of the United Kingdom as have a statutory right to issue diplomas. Its head quarters are at 299, Oxford Street, and it has branch offices at 54, George Street, Edinburgh, and 35, Dawson Street, Dublin. Its duties are to control the medical and dental professions in the interests of the general public, and to that end to maintain a register of legally qualified practitioners. It is admission to this Register, and not the possession of a medical degree or diploma, that constitutes a person a legally qualified practitioner. The Council is bound to admit to the Register those who hold the degrees or diplomas granted by the bodies represented among its members, but it can prescribe the terms on which those bodies shall grant such diplomas or degrees, and it can erase from the Register the name of any medical man or dentist who has been convicted before a court of law of an ordinary crime or of a serious offence against public morality, or who is proved before the Council itself to have been guilty of certain actions which the Council regards as professionally infamous. Its disciplinary powers are strictly limited to legally qualified practitioners, and it has no control whatever over irregular practitioners of any kind.

An account of the regulations that the Council has drawn up in respect of the education of medical students here follows and should be carefully studied. The primarily important things to note about them are that they entail (1) the production of proof of a certain degree of proficiency in subjects of preliminary or general education; (2) application for registration as a medical student either at the head-quarter office in London or at one of the branch offices in Edinburgh and Dublin, although this latter requirement is not invariably enforced.

PRELIMINARY EDUCATION.

The subjects of which proof of efficient knowledge must be produced by applicants for registration as medical students are as follows:

- (1) *English*: Grammar; paraphrasing; composition; questions on English history and geography.
- (2) *Latin*: Grammar; translation into English from unprescribed Latin books; translation into Latin of a continuous English passage, and of short idiomatic English sentences. In the case of natives of India or other Oriental countries, whose vernacular is other than English, a classical Oriental language may be accepted as equivalent to Latin.
- (3) *Mathematics*: Arithmetic; algebra, including easy quadratic equations; geometry, including the subject matter of Euclid, Books I, II, and III, and simple deductions.
- (4) One of the following subjects:
 - (a) *Greek*: Grammar; translation into English from unprescribed Greek books; translation into Greek of short idiomatic English sentences; or
 - (b) *A modern language*: Grammar; translation into English from unprescribed books; translation of a continuous English passage, and of short idiomatic English sentences.

The Council does not hold an examination itself in these subjects, but expects a candidate to prove his knowledge of them by the production of evidence either that he holds a degree in arts or that he has passed one or other of the tests imposed by various educational bodies which it recognizes for this purpose. Such tests include the matriculations of universities at home and abroad, and the "local examinations" held by the Universities of Oxford and Cambridge, the "leaving" and other examinations held by the Education Departments in Scotland, Ireland, and Wales, as also the examinations of the College of Preceptors and the Educational Institute of Scotland. In regard, however, to nearly all these tests the Council qualifies its acceptance of them by some condition, and these vary so considerably and are so numerous that the leaflet issued by the Council should itself be studied.

REGISTRATION OF MEDICAL STUDENTS.

In addition to showing that he has passed one of these examinations, any person applying for registration as a medical student must (1) produce satisfactory evidence that he has attained the age of 16 years; (2) show that he

has commenced medical study at a university or school of medicine, or at a teaching institution recognized by one of the licensing bodies and approved by the Council. The commencement of professional study will not be reckoned as dating earlier than fifteen days before the date of registration.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained on application at the offices either of the General Medical Council itself or of one of the various licensing bodies and medical schools, and when forwarded it should be accompanied by the certificates as to age and general education.

The regulations with regard to registration apply equally to medical and dental students, with the exception that in the case of the latter pupillage with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

PROFESSIONAL EDUCATION.

The rule is that it is only from the date which appears against his name in the *Students' Register* that the medical student's career officially begins; thereafter five years must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts.

There are, however, certain important exceptions to this rule: thus (1) to meet the circumstances brought about by the dates at which sessions of the medical schools commence and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. (2) Graduates in arts or science of any university recognized by the General Medical Council, who have spent a year in the study of physics, chemistry, and biology, and have passed an examination in these subjects for the degrees in question, may be held to have completed the first of the requisite five years. (3) The Council will accept as six months of that year six months passed, subsequent to obtaining a certificate in general education, as a student of chemistry, physics, or biology at any teaching institution recognized by a licensing body and approved by itself. In any case, the period of five years must be one of bona fide study, and during its course education in the following subjects must be pursued and examinations passed:

- (i) Physics, including the Elementary Mechanics of Solids and Fluids, and the rudiments of Heat, Light, and Electricity.
- (ii) Chemistry, including the principles of the science, and the details which bear on the study of medicine.
- (iii) Elementary Biology.
- (iv) Anatomy.
- (v) Physiology.
- (vi) Materia Medica and Pharmacy.
- (vii) Pathology.
- (viii) Pharmacology and Therapeutics.
- (ix) Medicine, including Medical Anatomy and Clinical Medicine.
- (x) Surgery, including Surgical Anatomy and Clinical Surgery.
- (xi) Midwifery, including Diseases peculiar to Women and to Newborn Children.
- (xii) Theory and Practice of Vaccination.
- (xiii) Forensic Medicine.
- (xiv) Hygiene.
- (xv) Mental Disease.
- (xvi) Anaesthetics.

The practical study of Subject (xi) shall not commence until the student has held the offices of Clinical Clerk and Surgical Dresser, and the work done in connexion with it must follow prescribed lines. The Council also expects that study of the Subjects (viii) to (xvi) shall extend over not less than twenty-four months subsequent to success at the examination in Subjects (iv) and (v). It also now recommends licensing bodies to require of candidates at their final examinations evidence of instruction in the administration of anaesthetics and in infectious diseases, and of sedulous attention in hospital wards, out-patient departments, and *post-mortem* rooms, as clerks and the like.

Wherever the first of the five years is spent, the next three must be passed at one of the schools of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858. The final or fifth year the Council recommends should be devoted to clinical work at any public hospital or dispensary at home

or abroad which is recognized by any of the licensing bodies.

SPECIAL CONSIDERATIONS.

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in sufficient detail, but before leaving this part of the subject the steps which the aspirant should take may finally be rehearsed in their due order:

- (1) Pass an examination in arts;
- (2) Enter himself at a medical school or other scientific institution recognized by the Council;
- (3) Get himself registered as a medical student;
- (4) Study for a minimum of five years certain prescribed subjects;
- (5) Meanwhile pass sundry intermediate examinations; and, finally, at the end of the fifth year, one which will entitle him to receive at the hands of a licensing body a legal authority to practise.

The Arts Certificate.—There are, however, other important considerations; thus, it is not a matter of indifference what certificate of proficiency in general education, or arts, the student obtains. The General Medical Council, it is true, will accept any of the large number of tests to which reference has been made, and this, too, is the case with practically all the college corporations in England, Scotland, and Ireland. But all the licensing bodies are not equally accommodating; some of the universities require that their own ordinary matriculation should be passed, others have special matriculation examinations for those wishing to join their medical faculty, and a third and larger number will accept any arts degree and certain matriculation examinations, as well as several other of the tests entered in the Council's list.

The first thing, therefore, the future medical student should, if possible, decide is at what degrees or diplomas he intends to aim, and then find out what arts certificate will be required. If he cannot decide the question in advance, the best course probably would be to matriculate at London University, choosing as two of his optional subjects Latin and one other language, so as to meet the requirements of the General Medical Council with respect to general education. It is a troublesome examination in many respects, but gives a wide choice of subjects, and has the advantage of being accepted as sufficient testimony to general education by a larger number of bodies than is any other analogous examination.

The Minimum Period.—Another point to remember is that the period of five years mentioned is a minimum; a good deal more will almost certainly be required even by the man of good abilities and reasonable industry. Besides these qualities, a student to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Otherwise it is almost inevitable that his career as a student should be prolonged for a greater or smaller number of months beyond the possible minimum. Thus, for instance, a student before presenting himself for any examination has to get what is called "signed up" for the subjects covered by that examination; this means that his teachers have to certify that he has attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place, he may miss a sufficient number of them to make it impossible for him to be "signed up." Then, again, should a student fail to satisfy the examiners at some examination, he cannot present himself again for re-examination for at least three months. This fact generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by his having to give up some time to restudying the subjects in which he has failed, the Examining Boards in the majority of instances insist upon a definite interval elapsing between a student passing one examination and his presenting himself for that which should follow it. Then, again, many Boards refuse to recognize lectures and classes which have been attended at a date anterior to that at which the student has passed the requisite examination in earlier subjects. Failure at an examination may thus not only mean

deferment of the date of examinations, but deferment of the commencement of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a matter of fact, the vast majority of students take very much longer than that period.

Furthermore, in speaking of the minimum period, it is to be remembered that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or a diploma of one of the Royal Colleges. These are quite sufficient for the purposes of general practice, or for entering the Services, etc., but those who wish to take a higher qualification—for instance, the F.R.C.S. Eng.—must prolong their work for another year or more. So, too, must in some cases they who desire to convert their Bachelorship into an M.D. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age, and has practised his profession for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended at the time he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

The Normal Course.

In conclusion, it may be convenient to sketch the general fashion in which the student will pass his five years or more, but discussion of this need not be prolonged, because once a student has entered at a school, and chosen the degrees or diplomas at which he wishes to aim, the dean of the school will guide his steps in every particular.

Whatever the precise final goal, the path thereto is in all cases identical in broad outline. Practically it is divided into three stages, the conclusion of each being marked by an appropriate examination. In the first stage the student acquires a more or less extensive knowledge of the preliminary sciences—chemistry, physics, and biology; in the second he studies anatomy and physiology; and the third he devotes to the real work of his future life—medicine and surgery and their branches. During each of these stages the student must attend not less than the prescribed number of lectures and classes to ensure getting "signed up" in the subjects of the stage, and also do a very considerable amount of practical work. As for the examinations at the end of the stages, these are known by different titles by different examining bodies, but "preliminary science," "intermediate," and "final" are in common use. Some bodies demand that the student should pass in all the subjects of one stage at one time; others allow the candidate to present himself in each of the subjects separately, thus multiplying the actual number of examinations, but limiting their scope. There are also differences in the requirements of the different licensing bodies as to the length of each stage, but practically all demand that the second shall be longer than the first, and the third not shorter than the second. By the length of the allotted stage the candidate may gauge the comparative importance the licensing body attaches to the subjects within the stage and the difficulty of the tests it will impose, and he may feel certain that the time allotted is none too much.

In any case it should be the aim of the student to get through his first two stages as quickly as his abilities and the regulations will allow; and, as a rule, he should have completed the first stage by the end of his first year, and may hope to complete the second stage not later than the end of his third year. He will then have two years in which to prepare for his final examination, and it will prove a very crowded period, for he has to get into it not only medicine, surgery, and midwifery proper, but many other allied subjects, such as pathology and bacteriology, forensic medicine, gynaecology, and therapeutics. In the first of the final two years he may be able to complete his formal lectures, and thus have the fifth year for entirely practical work and private study; during those two years, too, he will take part in the work of his hospital by holding clerkships and dresserships in the wards and out-patient department for the periods laid down by the licensing bodies. Then, at length, after perhaps a few weeks of special coaching, he will be ready to present himself for his final examination, which the regulations of most bodies

will allow him to divide into two or more parts. The final examination passed in its entirety, he will be able to claim registration as a qualified medical practitioner at the hands of the General Medical Council, and become an independent personage. There is still room for him to continue a student's career if he will, for, apart from the higher qualifications to which reference has been made, it may seem to him worth while to devote time to acquiring greater knowledge of some particular branch of medicine, such as ophthalmology or laryngology, or to undergo the courses of study necessary to obtain a diploma of special proficiency in questions of public health (page 385), or in tropical medicine (page 383). Points such as these, however, the student will be fully capable of deciding for himself when he has reached the stage to which our account has now brought him.

The next matters to be considered, therefore, are the requirements in detail of the different licensing bodies, and what they have to offer in the way of degrees and diplomas.

THE WAR.

The Executive Committee of the Council reports that its recommendations respecting the courses of medical study represent, in general terms, the minimum curriculum that should be required by the various licensing bodies. But it recognizes that during the present national emergency it may be advisable for them to modify or even suspend their regulations. It feels sure, however, that the licensing bodies concerned will recognize the importance, in the public interest, of maintaining unimpaired the present standard of knowledge and skill required of all who seek to be admitted to the status and privilege of registered practitioners. It will therefore be desirable to secure in every instance that the requirements of the minimum curriculum are to be substantially fulfilled. The standard of the qualifying examinations, in other words, is to be maintained.

The English Universities.

THERE are eleven universities in England and Wales, and some account of each of them follows. With one exception they all have fully developed medical faculties. The exception is the University of Wales, whose constituent colleges are those of Aberystwith, Bangor, and Cardiff. It is in a position, however, to grant degrees, and has laid down a six years' curriculum for candidates for the M.B. degree, and it already provides, at the School of Medicine at Cardiff—of which an account will be found at page 376—thorough training in the work of the first three or four years.

UNIVERSITY OF OXFORD.

The professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a diploma in State Medicine and a diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, however, the candidate must have taken a degree in Arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period; for some of the subjects chosen for the final stage of the arts course may be the same as those in which examinations would in any case have to be passed for the medical degrees.

THE B.A. DEGREE.

A candidate may obtain the B.A. degree in either of the following ways:

(a) By passing Responsions (or one of the examinations which are accepted as equivalent), Moderations, a Scripture examination, or, in the event of a candidate objecting, an examination in some substituted book; and the Final Pass School in three subjects, two of which may be the

same as two in the preliminary examinations in natural science.¹

(b) By passing Responsions, an additional subject in Responsions, the Scripture examination, some of the preliminary examinations in the Natural Science School,¹ or the Preliminary Examination and the School of Jurisprudence, or the Honour School of Mathematics in the first public examination; and one of the final honour examinations.

Responsions and the additional subject may be passed before a candidate is a member of the university;² Moderations and Scripture can be passed in or after the second term; the final pass school may be taken any time after Moderations; a final honour school may be taken at the end of the third or within the fourth academical year—that is, twelve or sixteen terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions have been passed.

PROFESSIONAL DEGREES.

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First M.B. and the Second M.B. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the First M.B. is examined in human anatomy and also in physiology and in organic chemistry, unless he has previously taken a first or second class in the two latter subjects in the Natural Science School. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine, and hygiene, materia medica, and pharmacology³ (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the twenty-fourth term from the date of his matriculation, and not until a period of at least twenty-two months have elapsed from the date of his passing the first examination, and he must take all the three subjects at one and the same time.

D.M. AND M.Ch. DEGREES.

A Bachelor of Medicine who wishes to proceed to the M.D. must have entered his thirty-ninth term and must present a dissertation for approval by the appointed examiners. If a candidate for the M.Ch., he must have entered his twenty-seventh term and must pass an examination which is held in June.

TEACHING.

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First M.B., and in part those of the Final Examination. For the diploma in State Medicine and the diploma in Ophthalmology certain of the courses can be taken in Oxford.

SCHOLARSHIPS.

The several colleges grant scholarships of £50 a year, tenable for four years, in natural science, chemistry, physics, and biology. Exhibitions of varying value are also awarded in these subjects. Particulars can be obtained on application to the college tutors. A Radcliffe Travelling Fellowship of £200 a year, tenable for three years, is conferred annually; candidates must have taken the B.M. degree. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolleston Memorial Prize, for research in natural science (including pathology), and the C. Theodore Williams Scholarships in Anatomy and Physiology, and in Pathology, of the value of £50 each, tenable for two years. A Burney Yeo King's College Hospital Scholarship of £50 is awarded annually.

¹ The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.

² Membership is constituted by matriculation and by becoming either a member of a college or hall, or a non-collegiate student.

³ A candidate who passed in materia medica and pharmacy under the old regulations in the First Examination before April 14th, 1902, is exempt from the examination in materia medica and pharmacology in the second examination.

FEES.

An annual fee of £2 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are—the B.A., £7 10s.; the B.M. and B.Ch., £14; the D.M., £25; the M.Ch., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £120.

UNIVERSITY OF CAMBRIDGE.

THE professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.C.), which entitle the possessor to admission to the Register by the General Medical Council and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants diplomas in State Medicine and Tropical Medicine to persons who are registered medical practitioners, but not necessarily graduates of the university. A candidate for the M.B., B.C. degrees need not possess a degree in arts; it is sufficient if he has passed the *Previous examination* or some other examination accepted by the university as its equivalent.

PROFESSIONAL EXAMINATIONS.

To obtain the M.B., the candidate must pass three examinations, of which the latter two take place twice a year, in the Michaelmas and Easter terms; those who are finally successful receive the B.C. degree without further examination.

First M.B. or Preliminary Examination in Science.—This comprises (1) chemistry, (2) physics, (3) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the *Previous examination*, paid the matriculation fee, and entered on his first or some later term of residence. The examination is held three times a year—in October, December, and June.

Second M.B.—This examination, which cannot be passed until the first examination has been completed, comprises Part I, human anatomy and physiology; Part II, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No one may enter Part II unless he has passed Part I. The candidate must be signed up in both subjects and have dissected for six months.

Third M.B.—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with surgery and midwifery, must be signed up in these subjects and have completed two years of hospital practice.

Before admission to the second part the candidate must have completed five years of medical study and be duly signed up in all subjects. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination consists of principles and practice of physic, pathology, and pharmacology.

Act for the M.B.—Before receiving his degree, a candidate who has been successful at the Final M.B. has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Medicine. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence, the candidate sending a thesis to the Regius Professor of Physic, which is laid before the Board.

THE HIGHER DEGREES.

The M.D. degree may be taken by an M.B. of three years' standing, after keeping a further Act and writing a short extempore essay, in which he may deal at his choice with either medicine, physiology, pathology, or State medicine. The M.C. degree may be granted to a candidate who has qualified for the B.C. at least three years previously; he is then examined in pathology, surgery, surgical anatomy, and surgical operations, or submits books or writings of his own which constitute

original and meritorious contributions to the science and art of surgery.

FEES.

In addition to college fees, tutorial fees, and the expenses of living, the following examination fees are payable: First M.B., £4 4s.; Second M.B., £4 4s.; Third M.B., £9 9s. For schedules referring to the examinations, lists of schools recognized by the university, and other information, application should be made to the University Registry.

UNIVERSITY OF LONDON.

UNDER the regulations of the University of London, the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in two branches, and Doctor of Medicine in six different branches. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should secure and carefully study the booklets relating to it.

In no circumstances is a degree granted to any one in less than three years after the date at which he passed the Matriculation Examination or obtained registration in some other way; and unless they are already registered medical practitioners of a certain age and standing, all students must pass not less than five and a half years in professional study subsequent to matriculation. Four and a half of those years must be passed at one or more of the medical institutions or schools at home or abroad recognized by the university for the purpose; and not less than one school of the university itself.

PROFESSIONAL EXAMINATIONS.

M.B., B.S.—There are three examinations, the two last being subdivided. They are held twice a year.

The First Examination covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible viva voce test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself.

The Second Examination, Part I, cannot be passed within six months of the passing of the First Examination. It covers organic and applied chemistry, the candidate's knowledge being tested as in the earlier examination. It is a pass examination, but a mark of distinction may be won.

Candidates for Part II must have passed the First Examination at least eighteen months previously besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written oral and practical. Candidates who fail in one subject may offer themselves for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M.B., B.S. examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including therapeutics and mental diseases), pathology, forensic medicine and hygiene, surgery, and midwifery and diseases of women. They may be divided into two groups, one comprising medicine, pathology, forensic medicine and hygiene, and the other surgery and midwifery and diseases of women. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but in the list of successful candidates the names are divided into an honours list and a pass list, in each of which the names are placed in alphabetical order, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

THE HIGHER DEGREES.

M.D.—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S., unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) Medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine; and, if he

wishes may pass *abes* in another branch at a subsequent examination.

The period that must elapse between acquiring the M.B. and sitting for the M.D. in any branch varies with the nature of the candidate's previous work between one year and two years, and in all cases evidence must be afforded of special study of the subject chosen, whatever the branch; both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

M.S.—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are only two branches in which it may be obtained—General Surgery and Dental Surgery.

FEES.

For Matriculation: £2 for each entry. First Examination: £5 for each entry to the whole examination. For re-examination in one subject the fee is £2. Second Examination, Part I: £2 for the first and each subsequent entry. Second Examination, Part II: £8 for each entry to the whole examination. For re-examination in one subject the fee is £4. M.B., B.S. Examination: £10 for each entry to the whole examination, and £5 for examination or re-examination in either group. M.D. and M.S. Examinations: £20, and £10 on re-examination.

THE WAR.

The University of London has made some alterations and additions to the regulations for internal and external students in respect of the war; thus a temporary commission in either the Royal Army Medical Corps or the Royal Naval Medical Service, held during the continuance of the war, will be considered equivalent to an approved appointment.

Clinical service during the continuance of the war for a period of not more than twelve months will similarly be accepted by the University.

UNIVERSITY OF DURHAM.

To its own graduates, who may be of either sex, this university grants the degrees of Bachelor and Doctor of Medicine (M.B. and M.D.) and Bachelor and Master of Surgery (B.S. and M.S.); it also grants special degrees and diplomas in State Medicine, Psychiatry, and Dental Surgery.¹ To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts, or even to commence that period by matriculation. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere, but not less than a year must elapse between the time that the student satisfies the requirements of the university as regards matriculation and his presenting himself for the Final M.B., B.S. Examination.

MATRICULATION.

The university has its own matriculation examination, but accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations for the M.B., B.S. degrees. They are held twice a year—in March and June. The first deals with elementary anatomy and biology, chemistry, and physics; the second with anatomy and physiology; the third with pathology, elementary bacteriology, medical jurisprudence, public health, materia medica, and pharmacy. At the final M.B., B.S., the candidate is examined in medicine and clinical and psycho-

logical medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical gynaecology; therapeutics; diseases of the throat, nose and ear; diseases of the skin; and diseases of the eye.

M.D. A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and satisfy the university that he knows either Greek or German. He then submits a typewritten essay dealing with original work or observations of his own, and is examined in its subject. If the candidate is not an M.B. of the university, he must be a practitioner of fifteen years' standing and submit to special tests.²

B.S.—A candidate for this degree must have passed the examination for the M.B. of the university, and have attended courses on operative surgery and regional anatomy. He must then perform operations on the dead body before the examiners.

M.S.—Candidates for this degree must, like those for the M.D., satisfy the authorities as to their knowledge of Greek or German, and must have been engaged in practice for at least two years subsequent to becoming B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

FEES.

The following fees are payable: Matriculation or its equivalent, £1 10s.; First, Second, and Third M.B. Examinations, each £5; Final M.B., £10; M.D., B.S., and M.S., £5 for each examination and £6 6s. for each degree. Further information respecting the examinations and degrees may be obtained from Professor Howden, at the University of Durham College of Medicine, Newcastle-on-Tyne.

VICTORIA UNIVERSITY OF MANCHESTER.

This university grants the four ordinary degrees in medicine and surgery, M.B. and Ch.B. and M.D. and Ch.M.; a diploma and a degree (B.Sc.) in public health; a certificate in factory and in school hygiene; a diploma in physiological medicine; and a degree and diploma in dental surgery. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof; see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the five years' curriculum, one such year being subsequent to the passing of the First M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history; (4) English history; (5) two subjects at choice, one of which must be a language approved by the Joint Board, the other being elementary mechanics, or physics, chemistry, geography, natural history, or botany. It is held in July and September.

PROFESSIONAL EXAMINATIONS.

M.D., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. At all examinations the subjects, or groups of subjects, prescribed can be taken separately or together, as the candidate pleases. The First M.B. is divided into Part I, inorganic chemistry and physics; Part 2, biology (including animal and vegetable morphology, physiology, and laboratory work); Part 3, elementary organic chemistry and bio-chemistry. The parts may be taken separately or together. At the Second M.B. the candidate is examined in anatomy and physiology; at the Third in pathology, hygiene, and pharmacology and therapeutics (including materia medica and practical pharmacy). The Final Examination includes medicine, systematic and clinical (separate papers being given on mental diseases), and diseases of children, surgery (systematic, clinical, and practical, with a separate paper on ophthalmology), obstetrics and gynaecology, and forensic medicine and toxicology.

M.D.—A candidate for this degree must be an M.B. of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject to be selected by the candidate.

¹ See pp. 282 and 283.

² See p. 282.

Ch.M.—A candidate must have held, since becoming Ch.B., and for not less than six months, an appointment in a public institution affording opportunity for the study of practical surgery, and produce certificates of having attended certain courses of study. The examination comprises the general field of surgery, including ophthalmology and bacteriology.

FEES FOR EXAMINATIONS.

The following fees are payable: Matriculation, £2; on readmission, £1 10s. Each M.B. examination, £5; on readmission, after failure, £2. M.D., including the conferring of the degree, £10. Ch.M., £5 each for the examination and degree. Application for further information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF BIRMINGHAM.

This university confers the ordinary medical and surgical degrees—M.B., Ch.B., M.D., and Ch.M., and also diplomas and degrees in State medicine and dentistry. It has a plan, too, by which, extending his study to six instead of five years, the M.B., Ch.B. candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M.B. those who have passed elsewhere an examination considered to be its equivalent.

All students in the Medical Faculty must either (1) matriculate in mathematics, in chemistry or experimental mechanics, in the English language and literature and history, and in Latin, and one other foreign language; or (2) show that they have passed elsewhere an examination deemed an equivalent. Subject to certain provisos, the following are at present thus regarded:

(a) The Previous Examination of the University of Cambridge if it includes the "additional subjects." (b) Responsons of the University of Oxford, except in mathematics. (c) The Matriculation Examination of a recognized university. (d) The Higher Certificate of the Oxford and Cambridge Boards. (e) The Oxford or Cambridge Senior Local Examination.

PROFESSIONAL EXAMINATIONS.

The candidate for the M.B., Ch.B. degrees has five examinations to pass. In the second and final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

First M.B.—This deals with chemistry, physics, and elementary biology; it may be passed before the student commences residence at the university, provided the regulations as to matriculation have been met.

Second M.B.—This deals with anatomy and physiology, and the student must pass in both simultaneously.

Third M.B.—This deals with general pathology and bacteriology, materia medica, and practical pharmacy.

Fourth M.B.—This takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, therapeutics and special pathology.

Final M.B.—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a *post-mortem* clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, and ophthalmology. In respect to the latter he must show that he has learnt refraction work. He also has to present to the examiners reports drawn up by himself on six gynaecological cases, and certificates drawn up by himself regarding four actual cases of luecy, and notes respecting two others.

M.D.—An ordinary candidate for this degree must be an M.B., Ch.B. of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as regards special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as the holders of the Birmingham M.B., Ch.B.

FEES.

The fee for matriculation is £2, and that for each of the first four professional examinations the same amount; M.B., Ch.B. degree fee, £8; M.D. and Ch.M. examination, £10 each. For further particulars application should be made to the Dean of the Medical Faculty.

UNIVERSITY OF LEEDS.

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, psychology, and in dental surgery.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university subsequently to the date of passing the first examination. They must also have matriculated by satisfying the examiners in (1) English (language or literature); (2) English history; (3) mathematics; (4) three of the following, one of which must be a language: (a) Latin, (b) Greek, (c) French, (d) German, (e) some other modern language approved by the Board, (f) either mechanics or physics, (g) chemistry, (h) geography, (i) natural history. Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., Ch.B. number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation, and at least two or three terms' approved work in the respective subjects indicated.

Second M.B.—This may be taken in two parts, (a) anatomy and physiology, including practical work; (b) materia medica and pharmacy, including actual compounding of drugs. The candidate's certificates must show, among other things, that he has dissected during at least five terms.

Final M.B.—This may be divided into three parts. The first part, pathology and bacteriology, may be taken at the end of the tenth term; the second part, forensic medicine and public health, and the third part, medicine, surgery, and obstetrics, cannot be taken before the end of the fifth year; and before being admitted to the examination in its subjects the candidate, in addition to ordinary certificates, must produce proof that he has done both intern and extern maternity work, and received clinical instruction in gynaecology, in diseases of the eye, skin, or larynx, and in the administration of anaesthetics. This division covers all branches of surgery, medicine (including mental diseases and diseases of children), and obstetrics and gynaecology. Passages for translation from French and German are included in the papers on medicine. First and second class honours may be obtained in this division.

M.D.—A candidate for this degree must be an M.B., Ch.B. of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved, passes an examination which consists in the writing of an extempore essay, and answering questions on the history of medicine and the subject of his dissertation.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. In addition, he must have attended certain special courses, including one on ophthalmology and one on bacteriology; he is then examined in the subject of surgery in all its branches.

FEES.

The matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £5, and £2 on re-

admission. On conferment of the degree of Ch.M. £5 is payable, the same remark applying to the M.D. degree.

UNIVERSITY OF LIVERPOOL.

This university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B. and Ch.M.), gives a degree in dental surgery (B.D.S.), a degree in hygiene (M.H.), and degrees in veterinary science (B.V.Sc. and M.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), public health (D.P.H.), veterinary science (D.V.H.), and in several single subjects.

MATRICULATION.

The Matriculation Examination is governed by the Joint Matriculation Board, 24, Dover Street, Manchester, which accepts under certain conditions the tests of several other bodies as its equivalent. These include the Matriculation of London University, the Senior Local Examination of Oxford and Cambridge, the Higher Certificate of the Joint Oxford and Cambridge Board, Bessonsions of the University of Oxford, the Previous Examination of the University of Cambridge, the Leaving Certificate of the Scottish Education Department, and the Senior Certificate of the Central Welsh Board. Of the five years' curriculum, not less than two must be passed in the university itself, one such year being subsequent to the date of passing the First M.B. Examination.

PROFESSIONAL EXAMINATIONS.

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, inorganic, organic, and physical; (2) biology, including zoology and botany; (3) physics. Section 2 may be taken alone or in conjunction with Sections 1 and 3.

Second M.B.—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology; and (b) (3) materia medica and pharmacy, (4) pharmacology. Candidates may present themselves in (a) and (b) separately.

Final M.B.—This examination deals with six subjects, which may be taken altogether or divided into three parts: (1) General pathology, morbid anatomy, and bacteriology; (2) therapeutics; (3) forensic medicine, toxicology, and public health; (4) obstetrics and diseases of women; (5) surgery, systematic and clinical, including mental diseases and diseases of children.

M.D. and Ch.M.—Candidates for these degrees must have received the M.B. and Ch.B. at least a year previously. The M.D. candidate submits for approval a dissertation covering original work, the M.Ch. candidate undergoing an examination in all subjects of surgery, including ophthalmology. Other information concerning the diplomas of this university and its medical school will be found on page 375.

FELLOWSHIPS, SCHOLARSHIPS, AND EXHIBITIONS.

The university awards Fellowships annually to students of distinguished merit, as follows:

1 Alexander Fellowship in Pathology and Bacteriology, value £100 and tenable for one year. 2 Ethel Boyce Fellowship in Gynaecology, value £100 and tenable for one year, open to fully qualified medical students of either sex. 3 John W. Garratt International Fellowship in Bacteriology, value £100 and tenable for one year. 4 Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year. 5 Holt Fellowships in Physiology and Pathology, two in number, value £100 each and tenable for one year. 6 Johnstone Memorial Fellowship in Bio-Chemistry, value £100 and tenable for one year. 7 Thelwell Thomas Fellowship in Surgical Pathology, value £100 and tenable for one year.

There are, in addition, scholarships and exhibitions open to medical students.

UNIVERSITY OF SHEFFIELD.

The degrees of this university (M.B., Ch.B., and M.D. and Ch.M.) and the diploma in public health are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose.

PROFESSIONAL EXAMINATIONS.

A candidate for the degrees of M.B., Ch.B. must produce

certificates that he will have attained the age of 21 years by the day of graduation; that he has pursued the courses of study required by the university regulations during a period of not less than five years subsequently to the date of his matriculation, three of such years at least having been passed in the university, one at least being subsequent to the passing of the first examination. He or she has eventually to pass the following examinations in due order:

First Examination.—The subjects are chemistry, physics, and biology. The intermediate examination in science—chemistry, physics, and biology—will, on payment of the required additional fee, be accepted instead of this examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology.

Second Examination.—The subjects are anatomy and physiology. The candidate must have completed the third winter session of professional study, must have passed the First Examination, and must have attended (1) lectures on anatomy, and dissections during five terms; (2) lectures on physiology during four terms; practical, experimental, and chemical physiology during four terms, and histology during one term.

Third Examination.—The subjects are pathology and pharmacology. Candidates must have completed the fourth year of medical study and completed the requisite courses in these subjects, including *post-mortem* clerkship for three months.

Final Examination.—The subjects are medicine (including forensic medicine, public health, mental diseases, and diseases of children), surgery, obstetrics and gynaecology. Candidates must satisfy the examiners in all subjects at the same examination. Candidates must have completed the fifth year of study.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.M.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF BRISTOL.

The university grants the following degrees: In medicine and surgery, M.B. and Ch.B., M.D., Ch.M. (the M.D. may be taken in State medicine); in dental surgery, B.D.S., M.D.S. Diplomas in public health (D.P.H.) and dental surgery (L.D.S.) are also granted. Candidates for degrees must pass the Matriculation Examination (or some equivalent examination accepted in lieu thereof; see the Regulations for Matriculation), and study at the university itself for at least three years of the five and a half years' curriculum, two such years being subsequent to the passing of the Second M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) English grammar and composition, (4, 5) two subjects at choice, one of which must be a foreign language. It is held in July and September. The winter session opens on October 1st, 1915.

PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are three examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The First M.B. comprises chemistry, physics, botany, and zoology. The Second M.B. comprises organic chemistry, elementary anatomy (Part I), advanced anatomy, physiology (Part II),

The two groups may be taken separately or together. The Final Examination includes materia medica and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy and bacteriology (Part I), special pathology, forensic medicine, toxicology and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical, and operative), medicine (systematic, clinical, and practical), including mental diseases (Part II). The two groups may be taken separately or together. At the option of the candidate, forensic medicine and toxicology may be taken either with Group I or Group II. First or second class honours may be obtained by a candidate whose work is deemed of sufficient merit, but cannot be awarded to one who has recorded against him a failure at any examination after the First M.B.

M.D.—A candidate for this degree must be an M.B. and Ch.B. of at least two years' standing. He has a choice between presenting an original dissertation, undergoing a general examination in medicine (including medical anatomy, medical pathology and bacteriology, systematic and clinical medicine), or passing an examination in State medicine.

Ch.M.—A candidate must have attended, since becoming M.B., Ch.B., and for not less than two years, a public institution affording opportunity for the study of practical surgery, and produce certificates to that effect; the candidate shall be required to pass a general examination in surgery (including surgical anatomy, surgical pathology and bacteriology, operative and clinical surgery), and to present a dissertation in some department of surgery. He must be of two years' standing as an M.B., Ch.B.

Applications for other information should be addressed to the Dean of the Medical Faculty.

DENTAL DEPARTMENT.

The university grants the degrees of Bachelor and Master in Dental Surgery (B.D.S., M.D.S., and a Diploma in Dental Surgery entitling to the letters L.D.S.). The courses of the University are available equally for these qualifications and for those of other licensing bodies. Both courses are open to men and women alike.

UNIVERSITY OF WALES.

The statutes of the University of Wales provide for a Faculty of Medicine and for the granting by it of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., Ch.B. cannot be admitted to examination until the completion of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed as a student in one of the constituent colleges of the university. He must also hold an Arts or Science degree of the University of Wales, or of some other university approved for this purpose. Some of the courses of study pursued for a B.Sc. or B.A. degree may be counted as part of the courses required for the degrees in the Medical Faculty.

The courses for the M.B., Ch.B. are divided into two sections, of which the first include the preliminary subjects—physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects must extend over at least one academic year, study of the ancillary subjects must extend over at least two academic years, and, excepting organic chemistry, cannot be commenced until all the preliminary courses have been completed; hence the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, medicine, surgery, and obstetrics, and cannot be commenced until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in the earlier subjects are held at the end of each academic year, and in the subjects of the second section each July.

During the continuance of the war clinical service at a medical unit of the forces, or at an approved hospital, will be recognized as hospital practice, under certain conditions, for the purpose of the M.B. degree.

English Medical Corporations.

THERE are three medical corporations in England—the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the "Conjoint Board." Details concerning this body, its component colleges, and the third licensing body here follow.

THE CONJOINT BOARD.

This body deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who satisfy it for the licence and diploma of Membership respectively. The successful candidate is then entitled to admission to the *Medical Register* as an M.R.C.S. Eng., L.R.C.P. Lond. It performs the same task in connexion with diplomas in State medicine and tropical diseases jointly issued by the two colleges in question. It obliges all candidates to pass one of a large number of examinations which it considers satisfactory tests of general education, and thereafter to pass five years in professional study at a recognized medical school, allowing, however, six months to be spent at any institution which may be recognized by the Board as giving efficient education in chemistry and physics. A list of such institutions, as also of the tests accepted in regard to general education, can be obtained from the Secretary of the Board at Examination Hall, Queen Square, Bloomsbury, W.C.

PROFESSIONAL EXAMINATIONS.

There are three examinations for the Conjoint diploma, or M.R.C.S., L.R.C.P., which are commonly known as First Conjoint, Second Conjoint, and Final.

First Conjoint.—This examination is in four parts: (1) Chemistry, (2) physics, (3) elementary biology) (4) practical pharmacy.

A candidate must present himself for examination in Parts I and II together until he has reached the required standard to pass in both, or in one of these parts, but he will not be allowed to pass in one part unless he obtains at the same time half the number of marks required to pass in the other part. A candidate may take Parts III and IV separately, or he may present himself for the whole examination at one time.

Before admission to either part the candidate must show that he has undergone certain courses of theoretical and practical instruction, but these courses need not be completed within one year, nor need they run concurrently, and they may be commenced or attended before the candidate passes the required preliminary examination in general education. A candidate referred in any part or parts will not be admitted to re-examination for three months. If referred in chemistry, physics, or biology, he must produce evidence of further instruction. Those who are already graduates in medicine, or who have passed an examination in the same subjects before a university board for a degree in medicine, may obtain exemption from re-examination in those subjects at this examination.

Second Conjoint.—This examination deals with anatomy and physiology, and both subjects must be passed at the same time. A candidate must have attended at a recognized medical school lectures on anatomy, physiology and a course of practical physiology and histology, and have dissected for twelve months during the ordinary sessions. The study of anatomy and physiology before passing in two of the first three parts of the first examination is not recognized. If rejected, a candidate, before being admitted to re-examination, must continue his studies at a recognized medical school for not less than three months.

Final Conjoint.—This examination consists of three parts: Part I, medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine, and public health; Part II, surgery, including pathology, surgical anatomy, and the use of surgical appliances; Part III, midwifery and gynecology. The examination may be passed at one time or in each part

¹ Candidates who have previously passed in practical pharmacy will not be re-examined in that subject at the Third Examination.

separately. Evidence of attendance at courses of instruction in the subjects of the three parts must be produced, and also of having conducted twenty labours. A candidate will be admissible to Parts I, II, and III of the Third or Final Examination at the expiration of two years (twenty-four months) from the date of passing the Second Examination, and on production of the required certificates of study, provided that the examination is not completed before the expiration of five years (five winter and five summer sessions) from the date of passing the Preliminary Examination. A rejected candidate must produce evidence of further instruction during three months.

NOTE.—A person holding a Colonial, Indian, or foreign qualification which entitles him to practise in the country where such qualification has been obtained is, after a course of study and examination equivalent to those required by the Regulations of the two Royal Colleges, admissible to the Second and Third or Final Examinations without any interval. Members of an English, Scottish, or Irish university are under certain conditions eligible for admission to the Third or Final Examination two years after passing at their university the subjects included in the First and Second Examinations of the Board.

A member of an Indian, Colonial, or foreign university recognized for the purpose, who shall have passed examinations at his university for the degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Conjoint Board, will be eligible for admission to the Third or Final Examination two years after passing in the said subjects.

No special conditions relating to the war have been laid down, beyond allowing candidates to take midwifery before the completion of the fifth year of study. The committee of management, however, are willing to consider special cases where it has been difficult to fulfil certain details of the curriculum, so long as the two main regulations of the requirements are fulfilled—namely, the full curriculum of five years, and an interval of two years between the Second and Final Examinations.

FEEs.

First examination, £10 10s. Re-examinations, Parts I and II, £3 3s.; Parts III and IV, each £2 2s. Second examination, £10 10s. Re-examination, £6 6s. Third examination, £21. Re-examination, Part I, medicine, £5 5s.; practical pharmacy, £2 2s. Part II, surgery, £5 5s. Part III, midwifery and diseases of women, £3 3s. Members of an English, Scottish, or Irish university, £5 5s. For the diplomas, £36 15s.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

This College has three grades—its Licentiate, its Members, and its Fellows. The Licence is only issued through the Conjoint Board, as already stated, unless the candidate commenced professional studies before October, 1884. Its Membership is only granted to those who have passed the final examinations for the Licence; or those who are registered practitioners and graduates of a recognized university; in any case they must be persons over 25 years of age, who do not practise in partnership, dispense medicines, or engage in trade. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce. Those under 40 are also examined in Latin, and either Greek, French, or German. The examination fee is £6 6s., the Membership fee being £42, or the difference between that sum and what the candidate has already paid if a Licentiate. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical

practice of a general hospital recognized by the College after obtaining their degrees. The College also issues a diploma in dentistry.

Fees.—At first examination: £5 5s. At second examination: £12 12s. Diploma fee: Members, £3 3s.; non-members, £13 13s.

SOCIETY OF APOTHECARIES OF LONDON.

This body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A., on those successful at the following examinations:

Primary Examination.—This is divided into two parts, of which Part I includes elementary biology, chemistry, chemical physics, practical chemistry, pharmacy. Part II includes anatomy, physiology, and histology, and cannot be passed before the completion of twelve months' practical anatomy with demonstrations. The subjects cannot be taken separately, except in the event of the candidate having previously passed in one. Candidates will be excused any or all the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Final Examination.—This is divided into two sections, the first of which is subdivided into three parts. Part I includes the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes: (a) The principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology; (b) forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances. A candidate for any part of Section I must have passed not less than three winter sessions and two summer sessions at one or more of the medical schools recognized by the Society. Section 2 consists of clinical surgery and clinical medicine and medical anatomy, and a candidate before appearing at it must have completed five years of medical study.

FEEs.

Primary examinations, £5 5s.; final, £15 15s. Further information may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, E.C.

The Scottish Universities.

There are in Scotland four universities, each of them possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are on all-fours with one another, so that an account can be given of all of them together.

The universities in question are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews, and in point of standing and repute it is not easy to differentiate between them. What provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed an excellent repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also a diploma in psychiatry. As for public health, registrable degrees in this subject are granted both by the University of Edinburgh and that of Glasgow, while diplomas in public health may be obtained from the universities of St. Andrews and Aberdeen. Information as to these will be found in the appropriate sections

dealing respectively with preventive medicine and tropical medicine.

MATRICULATION.

There is a special matriculation examination for medical students, the subjects being English, Latin, elementary mathematics, and either Greek or French or German. Candidates are required to pass in all these subjects either at one or at not more than two examinations, but they can present themselves as often as they please. A large number of corresponding tests held by other bodies are accepted as the equivalent of this examination.

PROFESSIONAL EDUCATION.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and in addition necessitate definite study for stated periods of diseases of children, of the larynx, ear and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended the courses regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the end of June.

PROFESSIONAL EXAMINATIONS.

The distinctive feature of the Scottish curriculum is that, though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may get rid of physics and chemistry. At the end of the first summer session he can finish with botany and zoology, and with anatomy and physiology at the end of the second. Practical materia medica may be taken at any period of examination after the necessary course of instruction has been attended. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery and medicine, and the corresponding clinical subjects at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that, when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with first or second class honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, forensic medicine and public health, and clinical gynaecology. The first three examinations are held three times a year; the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed a degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has previously been approved.

THE HIGHER DEGREES.

It is open to those who are already M.B., Ch.B., to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year at work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Services, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and his thesis being on a surgical rather than a medical subject. He is

examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

FEES.

It is estimated that the class, examination and other fees for the M.B., Ch.B. come altogether to £150, the separate examination fees included in this calculation being as follows:

	£	s.	d.
Preliminary Examination	0	10
First Professional	6	0
Second Professional	5	0
Third Professional	4	0
Finals	7	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 ls. Candidates for the M.D. and Ch.M. pay £15 15s., and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 2d., which is published by Mr. Thiu, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of the University or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that, in connexion with all the Scottish universities, including St. Andrews, there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

Owing to the war, special final examinations may be held for such students as have fulfilled the requirements of the curriculum of the General Medical Council.

The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND.

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P. Edin., L.R.C.S. Edin., and L.R.F.P.S. Glasg. The Board requires all candidates to comply with the regulations of the General Medical Council as set forth on page 355. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council.

PROFESSIONAL CURRICULUM.

Subsequent to registration as a medical student, the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not exact that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held six times every year—four times in Edinburgh and twice in Glasgow; and it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology; the second with anatomy and physiology, including histology; the third with pathology and materia medica, including pharmacy; and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine; (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes; (3) midwifery and diseases of women and of newborn children; (4) medical jurisprudence and hygiene. Candidates may also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the three first examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own; but all candidates for the conjoint licence must sit for the final examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

FEES.

It is estimated that the total cost of lectures and fees for the conjoint licence is about £152. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final, £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects, the fees are smaller.

Information concerning this Board should be sought either from Mr. D. L. Eadie, 50, George Square, Edinburgh, or from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THIS College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, but for the Fellowship women are not eligible. As an original qualification the Licence is only granted after fulfilment of the regulations of the Conjoint Board, but as an additional qualification can be obtained by those already possessed of a registrable qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body. The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

Candidates for the Fellowship must be not less than 25 years of age, and have been in practice subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or an approved diploma obtained as the result of an examination which includes surgery as well as medicine. Candidates are examined in surgery, including clinical and operative surgery, surgical anatomy, and one other subject which they may choose from among the following: Ophthalmology, laryngology including aural and nasal surgery, dental surgery, advanced midwifery with obstetric surgery, gynaecology, surgical pathology and operative surgery, and advanced anatomy. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported

by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials obtained specially for the purpose.

Licentiates of the College pay £35, and others £45. For further information application should be made to the Clerk of the College, Mr. D. L. Eadie, 50, George Square, Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THIS College has three grades—Licentiate, Membership, and Fellowship; to the two latter women are not admissible. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations, they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday, except in September and October. A candidate for the Membership must be either a Licentiate of a Royal College of Physicians or a graduate in medicine of a British or Irish university, and in either case not less than 24 years of age. He is examined in medicine and therapeutics, and in one further subject at his choice. This may be either (a) one of the departments of medicine specially professed; (b) psychology; (c) general pathology and morbid anatomy; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) gynaecology; (h) diseases of children; or (i) tropical medicine. Licentiates of the College pay £21, others £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship, the candidate must have been a member of the College for at least three years, and, if accepted, pays fees amounting altogether to a little less than £65. Any further details required can be obtained on application to the Secretary of the College.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THIS body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s., and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect two Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age. Further information can be obtained from Mr. A. Duncan, B.A., LL.D., Faculty Hall, St. Vincent Street, Glasgow.

The Irish Universities.

THERE are three universities in Ireland, and each of them has a medical faculty. These are the University of Dublin, usually known as Trinity College, Dublin, the Queen's University of Belfast, and the National University of Ireland. The two former teach students, examine them, and grant or withhold degrees accordingly; while the third is by way of being an academic body only, inasmuch as its practical work is divided up among three constituent colleges, situated, one at Cork, another at Galway, and the third in Dublin. The regulations of all these universities in respect of medical degrees are given in the following sections; while specific information as to the arrangements for the education of medical students made at each of them will be found in the section relating to Irish Medical Schools.

UNIVERSITY OF DUBLIN.

This university, better known, perhaps, as Trinity College, Dublin, grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and diplomas in the same subjects and in public health. It also confers two degrees in dentistry. Its degrees it grants only to those who, besides having passed the Professional Examination, have graduated in arts.

PROFESSIONAL EXAMINATIONS.

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing, and though he need not have taken his degree in arts before admission to the Professional Examination, he cannot take his medical degrees until he has been admitted a B.A. At least three years of the five years' medical curriculum must be pursued at the School of Physic of the university. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final, and of course before admission to any of them he must be duly signed up as regards study in the subjects involved.

Preliminary Scientific.—This covers (a) chemistry and physics, (b) botany and zoology; the two divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (a) Anatomy, physiology, and histology; (b) applied anatomy and applied physiology. The two parts may be taken separately, but in each part all subjects must be passed at one time.

Final Examination.—*Part I:* Hygiene and medical jurisprudence, pathology, materia medica, and therapeutics. *Part II:* (a) Midwifery, gynaecology (clinical, paper, and viva voce); (b) medicine, clinical medicine, and mental diseases; (c) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the final cannot be taken before the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must read a thesis before the Regius Professor of Physic.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing, and have been engaged in practice for two years. Graduates of ten years' standing may be given a special examination.

M.A.O.—The candidate must have passed the qualifying examination in medicine, surgery, and midwifery. The examination is specially directed to obstetrics and practical gynaecology.

For the university diplomas mentioned the candidate must have completed two years in arts and five in medical studies. The examination and courses required are the same as for the degrees.

FEES.

Matriculation, 5s.; M.B., B.Ch., B.A.O., £17; M.D., £13; M.Ch., £11; M.A.O., £5; L.M., L.Ch., L.A.O., £11. Further information may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY, BELFAST.

The degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which

botany and zoology form one. The Second Examination covers anatomy and physiology, and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) Pathology, (2) materia medica, pharmacology and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the First Examination has been passed.

The Final Examination includes: (1) Medicine, (2) surgery, (3) midwifery, (4) ophthalmology, and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

THE HIGHER DEGREES.

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science. In that case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (1) Human anatomy, including embryology, (2) physiology, (3) pathology, (4) pharmacology and therapeutics, (5) sanitary science and public health, (6) forensic medicine and toxicology, (7) mental diseases. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND.

The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined thereat by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the Board of Studies of the University. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as diplomas in Public Health and in Mental Diseases.

PROFESSIONAL EXAMINATIONS.

There are four examinations. The first, which should be passed at the end of the first year, includes Part A (chemistry and physics) and Part B (botany and zoology), which parts candidates may take separately or together. At the end of the second year they should pass in anatomy and physiology; and at the end of the third year in pathology, materia medica and therapeutics, hygiene and public health, forensic medicine, and toxicology. The final examination is divided into three parts, each of which may be taken separately—namely, (a) Medicine, including mental diseases; (b) surgery, including ophthalmology and otology; (c) midwifery and gynaecology.

The higher degrees are obtainable either by examination or on presentation of an approved work, but in each case not less than three years must have elapsed since the candidate acquired the corresponding degree of Bachelor. Further information as to the constituent colleges will be found in the section relating to Irish Medical Schools.

The Irish Corporations.

There are three licensing bodies other than the Medical Faculties of Universities, and, just as in London, there are two Royal Colleges of Physicians and Surgeons and an Apothecaries' Hall. The similarity is still more complete, for in Ireland also the two colleges have formed a Conjoint Board, as in London, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall gives its Licence separately.

THE CONJOINT BOARD IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations, the first of which cannot be passed earlier than the end of the first winter session, nor the fourth before the conclusion of full five years of medical study, and before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first and second examinations deal respectively with (a) chemistry and physics, and (b) biology; and (a) anatomy, and (b) physiology and histology. All parts of these examinations, as also of the following one, which deals with (a) pathology, (b) materia medica, pharmacy, and therapeutics, (c) public health and forensic medicine, may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least four years have passed in medical studies other than those for the first examination, and five years, at least, since the beginning of the curriculum. The divisions are (a) medicine, including fevers, mental diseases, and diseases of children; (b) surgery, including ophthalmic and operative surgery; (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the divisions (a), (b), or (c), provided he has completed his curriculum as far as concerns the division in which he presents himself.

Fees.—Preliminary Examination, £2 2s.; re-examination, £1 1s. First Professional Examination, £15 15s.; Second, £10 10s.; Third, £9 9s.; Final, £6 6s.; re-examination fee is £2 2s. for each division.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, 123, St. Stephen's Green, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College, and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of Royal Colleges of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members.

Fees.—For the Licence in Medicine, 15 guineas; for the Licence in Midwifery, 5 guineas; or 16 guineas for both if they are taken within an interval of a month. Special examinations cost in each case 5 guineas extra. For the Membership, 20 guineas to a Licentiate of the College; 35 guineas to others; a special examination costing 10 guineas extra. The Fellowship £35, in addition to stamp duty, £25. Information as to special examinations and other points can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided that the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce; while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and to neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Register*; if, however, the candidate is a person whose name is on the Colonial or foreign medical *Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Licence pay 5 guineas for examination, which sum, if they pass, is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND.

A DIPLOMA is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Two periods of dissection, each not less than six months, must be included, and twenty-seven months of hospital attendance, or its equivalent. Three professional examinations have to be passed; they are held three times a year. The Primary Examination deals with biology, physics, and chemistry, practical and theoretical; the Intermediate Examination is in practical anatomy and physiology, and histology and materia medica. A candidate who has passed tests in any of the subjects of these examinations before another licensing body is exempt from further examination in such subjects. The Intermediate Examination, Part II, consists of pathology, medical jurisprudence, and hygiene. The Final Examination deals with medicine, surgery, midwifery, and pharmacy. The Hall's own examination in all these subjects must be passed. Women candidates are eligible.

Fees.—Primary Examination, £4 4s.; Intermediate Examination, £8 8s.; Final Examination, £12 12s.; Final alone, when the others have been passed elsewhere, £15. Application for other information should be made to the Registrar, 40, Mary Street, Dublin.

MEDICAL SCHOOLS AND COLLEGES.

LONDON.

APART from post-graduate and other special schools, the medical schools of London number as many as fourteen, including in the count two institutions which provide education only in the preliminary and intermediate subjects, under the title of "university centres."

Little guidance can be given in these columns as to choice of one school rather than another, for such choice must depend largely on personal factors. In a general way, however, it may be said that while to the student to-day it may, perhaps, be almost a matter of indifference to what school he belongs, there is often in after-life a certain advantage in having been an alumnus at one of the more celebrated schools. On the other hand, at the smaller schools more opportunities, perhaps, present themselves to the average man for obtaining student appointments, and especially the coveted posts of house-physician and house-surgeon.

Information as to the fees at the different schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages, and should be carefully studied by those who have no personal reason for preferring one to the other. The courses which they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the Conjoint Board or the Apothecaries' Society not less than of those who have London or other university degrees in view. At all, too, as has been said, special facilities are offered to men, who have commenced their professional education at the older universities, Oxford and Cambridge. Apart from these facts, the only point to which attention can usefully be directed is that on personal inquiry and investigation reason may perhaps be found for regarding the teaching accommodation and general arrangements for students at some schools as superior to those at others.

ST. BARTHOLOMEW'S.

THIS institution fills one side of Smithfield and Giltspur Street, sharing with the Post Office buildings a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 750 beds. Extensive new buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library and the chemical, physical, biological, and physiological laboratories, and anatomical department have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to a new and extensive *post-mortem* room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. Within the precincts of the hospital also there is a residential college for a large number of students. The Students' Union owns, moreover, grounds of some 10 acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations for the M.B., M.D. of the Universities of London, Oxford, and Cambridge, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.C.Cantab., M.S.Lond., and F.R.C.S.Eng. Special laboratory instruction for the D.P.H. of Cambridge, Oxford, Durham, and London is also given.

Appointments. Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special

departments (Ophthalmic, Orthopaedic, Gynaecological, Laryngological, Aural, Dermatological, Electrical, and Dental), and in the *post-mortem* room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical, and in the special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "Junior" house-physicians and house-surgeons, and receive a salary of £25 a year. During their second six months they become "Senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

Scholarships.—Five entrance scholarships are annually awarded after an examination held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) Two scholarships, value £75 each, in not fewer than two nor more than three of the following subjects—Chemistry, Physics, Botany, Zoology, Physiology, and Anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £50, in not fewer than three of the following subjects—Chemistry, Physics, Botany, Zoology, and Physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) The entrance scholarship in Arts, of the value of £100, will be given in Latin and mathematics, with one other language—Greek, French, or German. (4) The Jeaffreson Exhibition in Mathematics, Latin, and one other language—Greek, French, or German—and of the value of £50. The value of the scholarships and prizes is over £1,000 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical School, St. Bartholomew's Hospital.

CHARING CROSS.

THIS school, with its hospital, is situated in the very centre of London, and courses of instruction are specially designed to meet the requirements for the University of London degrees, the diplomas of the Royal Colleges, and the final studies of other universities. The hospital, with its convalescent home at Limpsfield, contains 300 beds. Between 2,500 and 3,000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for work of all classes.

The school has an arrangement whereby its students can carry out their work in the primary and intermediate portions of their studies in the laboratories of the University of London (King's College), which are situated within a few minutes' walk of the hospital. This enables its students to get the best university education from a large professional and teaching staff in their earlier studies, while still allowing them to take advantage of their own school for social and collegiate purposes.

A large laboratory, capable of accommodating up to 100 students, is available for general pathological work, demonstrations, and research, and systematic demonstrations covering the whole range of pathology are arranged daily throughout each session between 10 a.m. and 5 p.m. Good departments are also available for other final subjects of bacteriology, chemical pathology, materia medica, toxicology, public health, and operative surgery, and also for research work by post-graduates. Some of these serve King's College as its "University Laboratories of Public Health and Bacteriology."

The museum contains over 4,000 specimens, and has received a notable collection of over 800 gynaecological specimens, "The Cutlbert Lockyer Collection," from one of the members of its hospital and school staff.

The library contains the latest editions of the usual textbooks and the chief medical periodicals. The Students' Club Union includes reading and smoking rooms, cloak-room, refreshment room, and adds greatly to the social comfort of the students.

Appointments.—Demonstratorships and assistant demonstratorships are open to students of the school. Medical,

surgical, and obstetric registrars to the hospital are appointed annually. Six house-physicians, six house-surgeons, and two resident obstetric officers are appointed each year after competitive examination. They are provided with board and residence in the hospital. Clinical clerks and dressers are appointed in the general and special departments of the hospital, and every student holds in turn the post of pathological assistant and assists at the autopsies, and on the completion of his clinical appointments takes up the duty for three months of pathological clerk in the clinical laboratory. Special facilities are offered for students and post-graduates desiring to take up particular classes or work in the wards and special departments of the hospital for longer or shorter periods.

Fees.—Sessional payments of 17 guineas for the winter session and 8 guineas for the summer session for London University and other university students, and 15 guineas and 7 guineas respectively for Conjoint Board students, with an entrance fee of 10 guineas; or a total composition fee for five and a half years' tuition of 120 guineas in the case of London University students, and of 100 guineas for five years' tuition for the Conjoint Board students. The above fees are inclusive, with the exception of vaccination, dispensing, and fever hospital attendance, which have to be taken outside the school.

All information desired may be had of the Acting Dean (Dr. W. J. Fenton), the Medical School, Charing Cross Hospital, London, W.C.

ST. GEORGE'S

This school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital founded by Atkinson Morley at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centres of London University established at King's College and University College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited apartments, and a list of medical men and others willing to receive St. George's men as boarders, may be seen on application to the Dean.

Appointments.—Dresserships to the surgeons and clinical clerkships to the physicians are open without fee to all students of the hospital. There is a large number of resident appointments, which may be held for six, twelve, or eighteen months, and are open without fee to every perpetual student of the hospital, and are made strictly in accordance with the merits of the candidates. Besides this, after the student has held a house appointment, the following are, among others, open to him: Medical registrarship at £200 per annum; surgical registrarship at £200 per annum; assistant curatorship of the museum at £100 per annum; obstetric assistantship, resident, at £50 per annum; the post of resident anaesthetist at £100 per annum; the post of senior anaesthetist at £50 per annum; the posts (2) of junior anaesthetists, each at £30 per annum.

Scholarships.—Two university entrance scholarships in anatomy and physiology 70 guineas and £50 are awarded at the commencement of each winter session. The William Brown Exhibition of the value of £112 per annum (tenable for 100 years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition of £42 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees.—First year (preliminary science or first conjoint) £26 5s., or £21, according to course. Second and third years, £63 in two equal instalments. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £31 10s.

No entrance fee is payable by St. George's students who have studied at King's and University Colleges.

Further information may be obtained from the Dean of the Medical School.

GUY'S.

The hospital contains 644 beds in constant occupation, an additional 27 beds having been recently opened. Thirty-three beds are set apart for diseases of the eye, and 40 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There is a special ward of 32 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, to the orthopaedic department, and to the department for the treatment of diseases of the genito-urinary system.

The medical college fronts the east gate of the hospital, providing accommodation for 60 resident students. This contains a dining-hall, reading-rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in twenty minutes. The Gordon Museum of Pathology, the Wills Library, the newly built Departments of Chemistry, Physics, Pathology, and Pharmacology, and the school buildings in general, afford unrivalled opportunities for a liberal education and for research. Special classes are held for the First and Second Examinations for Medical Degrees of the University of London and for the first F.R.C.S. Eng. Special teaching is provided to meet the requirements of the universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are given to students without extra payment, and according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, 8 house-physicians, 20 assistant house-surgeons, 8 house-surgeons, 2 ophthalmic house-surgeons, and 9 resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, and ophthalmic house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, electricity, anaesthetics, and dentistry. More than 150 additional appointments have been added to the list of those annually open to students of the hospital, the majority of them being in the special departments.

Scholarships, Prizes, etc. The following entrance scholarships are awarded annually in the month of September: A Junior Scholarship in Arts, Classics, Mathematics, and Modern Languages and Science, of the value of £20, £10 and £50, open to candidates under 21 years of age. B. Senior or University Scholarships of the value of £75 and £35, open to candidates under 25 years of age, who have completed their study of Anatomy and Physiology. Subjects, any two of the following: Anatomy, Physiology, Pharmacology, General Pathology, Organic Chemistry. Junior prizes for general medicine and science, of the value of £20, £10 and £50. Michael Harris prize for Anatomy, £10. Banks-Cox Scholarship for Physiology, £15 for three years; Woolbridge Memorial prize for Physiology, £10; Beagney prize for Pathology, £31; Treasurer's gold medal in Medicine, Treasurer's gold medal in Surgery, and the Golding-Bird gold medal and scholarship for Veterinary £20 are awarded annually after competitive examination. The Gray Studentship in Pathology and the Beagney Scholarship in Materia Medica of the annual value of £150 and £31 10s. respectively, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durlam Travelling Scholarship of £100 is awarded triennially. The Douglas Research Studentship in Pathology, value £30 per annum, is awarded without examination.

Fees.—An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School.

KING'S COLLEGE HOSPITAL.

The medical school carried on in connexion with this institution, at Denmark Hill, deals, as do the sister institutions at Westminster and University College Hospitals,

with the advanced or final subjects of the medical curriculum. The arrangements for education in these subjects are very complete. The new and up-to-date hospital contains over 600 beds, many of which are given up to the 4th London General Hospital (T.F.). There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology, dermatology, dental surgery, etc.; pathological and vaccine departments are also included.

Appointments.—Sixteen resident medical and surgical officers are appointed yearly, as well as dressers and clerks in the wards, out-patient departments, *post-mortem* room, and special departments. Each of the special departments has several clinical assistants, and there are six registrars, most of whom receive salaries. There is also a Union Club, which combines athletics, music, and other societies connected with the school, and provides also a common room.

Fees.—The composition fee is 70 guineas if paid in one sum, or 72 guineas in two instalments (one of 40 guineas at entrance and the other of 32 guineas at the commencement of the second year).

The prospectus of the school can be obtained on application to its Secretary, S. C. Ramer, M.A.Cantab., King's College Hospital, Denmark Hill, S.E.

THE LONDON.

This hospital (which contains 922 beds) and its medical college and dental school are in the Mile End Road, Whitechapel. All the departments are modern, and adapted for the teaching of all subjects in the curriculum. Special classes for the first and second M.B.Lond., the primary and final Fellowships, and other examinations are held. A residential hostel on hospital ground has been opened for the convenience of students who wish to live near the wards and casualty departments. The athletic ground is at Highams Park, and is open to all members of the Clubs Union.

Appointments.—The salary appointments open to students are those of medical registrar (3), surgical registrar (3), obstetric registrar, registrar in the ear, nose, and throat department (2), medical, surgical, and obstetric tutors; senior dressers to out-patients; clinical assistants in the medical, surgical, ophthalmic, aurial, light and skin, orthopaedic, and electrical departments. There are 2 resident accoucheurs, 6 resident house-physicians, and 9 resident house-surgeons, 7 receiving-room officers, 2 emergency officers, 1 assistant director of Pathological Institute, and 3 pathological assistants, also paid and unpaid clinical assistants in the various special departments. In addition there are numerous assistantships, clerkships, and dresserships in the various departments.

Scholarships and Prizes.—The following is a list of scholarships and prizes: At Entrance: Price Scholarship in Science, £100; in Anatomy and Physiology, £2 10s.; Entrance Scholarship in Science, £30; Epsom Scholarship, £126; Buxton Scholarship in Arts, £31 10s. After Entrance: Anatomy and Physiology Scholarship, £25; Letheby Prizes, £25; Prizes in Clinical Medicine, Surgery, and Obstetrics, £20 each; Duckworth Nelson Prize, £10; Hutchinson Prize, £40; Sutton Prize, £20; Sir Andrew Clark Prize, £26; Anderson Prizes, £5; Dressers' Prizes, £40; Practical Anatomy Prizes, £10; Wynne Baxter Prize, £5 5s.; Harold Luk Prize in Dental Surgery, £5 5s.; Prize in Dental Microscopy, £5. The London Hospital Medical College and the Fitz Ann Alston Medical Research Funds amount to over £21,000.

Fees.—Full course, entrance fee, 15 or 20 guineas, according to examinations passed; annual fee 30 guineas. Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.

ST. MARY'S.

This school and its hospital are situated in Praed Street, in the neighbourhood of the residential districts of Paddington, Bayswater, and North Kensington, and are thus especially convenient to students who wish to reside in the immediate vicinity. A register of approved lodgings is kept in the office of the Medical School.

The athletic ground at Park Royal, Acton, is easily accessible from the Medical School. It is seven acres in area, and provides ample accommodation for the various athletic clubs; the pavilion is large and well equipped.

The hospital contains 305 beds, of which 31 are devoted to treatment by therapeutic inoculation.

The Medical School provides complete courses in the preliminary and intermediate subjects of the curriculum which are recognized by the University of London as approved courses for internal students. Students may join in October, January, or April.

The departments of biology, chemistry, anatomy, physiology, and pathology are under the direction of full-time lecturers, and special courses are provided twice yearly for the Primary F.R.C.S. In addition, special tuition is provided for the Intermediate and Final Examinations of the universities of Oxford, Cambridge, and London, and for the Final F.R.C.S.

All clinical appointments in the hospital are free to students of the school, the term of office in each case being of four months' duration, and the resident medical officers are chosen by competitive examination. Six house-physicians, six house-surgeons, four obstetric officers, and two resident medical officers to the inoculation wards are appointed each year, and receive board and residence in the hospital. A large number of salaried appointments are open annually to qualified students, including those of medical registrar, surgical registrar, casualty physician, casualty house-surgeon, resident assistant anaesthetist, assistant curator, together with several demonstratorships. In the inoculation department there are nine assistantships, the salaries of which amount to £1,600 per annum.

Scholarships.—There are Entrance Scholarships in Natural Science: one of £100, one of £50, one of £25, and two University Scholarships of £32 10s. awarded annually by competitive examination in September.

Fees.—The composition fee for students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in anatomy and physiology are admitted on payment of a composition fee of 65 guineas (£68 5s.) paid in one sum, or 70 guineas (£75 10s.) if paid in two annual instalments. A system of annual fees is also in operation for students who prefer it. Separate courses of lectures, laboratory work, or hospital practice may be taken.

The School Calendar and full information can be obtained from the Secretary, St. Mary's Hospital Medical School, Paddington, W.

THE MIDDLESEX.

The school and hospital are in Mortimer Street, W., close to Oxford Circus, Goudge Street, and Portland Road stations. There is a residential college for a limited number of students overlooking the hospital garden, a gymnasium within the precincts of the hospital, and an athletic ground within easy distance at Park Royal. The hospital contains 440 beds, including a wing containing 90 beds for patients suffering from cancer, and special cancer investigation laboratories, which offer unrivalled opportunities for the study of this disease, both in its clinical and pathological aspects. In connexion with the investigation laboratories there are several valuable scholarships awarded.

There are special wards for maternity and gynaecological cases, and for diseases of children and of the skin and eye.

The Bland-Sutton Institute of Pathology is under the charge of a director. The institute includes a pathological and anatomical museum, a lecture theatre, large pathological and public health laboratories, and smaller rooms for original investigation. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories. Senior students are eligible for clerkships in the laboratories of the institute, and every facility is given for original investigation.

In the electro-therapeutical department special attention is given to the treatment of lupus and cancer by the x ray, and opportunities are afforded to students wishing to become acquainted with the use of the apparatus employed in this method of treatment. An electro-cardiographic department has also been established.

Appointments.—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two casualty medical and two casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of

two months, after examination; six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. In the out-patient departments the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases; dresser to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and *post-mortem* clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before being eligible to hold in-patient clerkships or dresserships. No student can be appointed to any of these offices until he has passed the second examination of the Examining Board in England or its equivalent. Non-resident qualified clinical assistants are appointed in the Medical, Surgical, Skin, Neurological, Ophthalmic, Throat and Ear, Odontological, Children's, and Electro-therapeutical Out-patient departments.

Scholarships.—Three Entrance Scholarships, value £100, £50, and £25 respectively, are open to students commencing their medical studies in April or October, 1915. An annual Entrance Scholarship, of the value of £50, is open to students of the universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology. The examination for these scholarships will take place on September 20th, 21st, and 22nd. Application for admission must be made on or before September 11th. Students joining the school in the previous April are eligible. The Eraser Lucas Scholarship, value £126, is annually awarded on the nomination of the head master to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are a number of other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £50 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25; Helly Clinical Prize, value £25; Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas.

Fees.—The composition fee for students taking the University of London degree is 145 guineas, or by five equal annual instalments of £32 11s. For those who have passed the first examination for medical degrees the fee is £120 guineas, or by four equal annual instalments of £34 2s. 6d. Students taking the Conjoint Board diplomas pay 135 guineas, or by five equal annual instalments of £30 9s. Students who have passed the First Professional Examination pay 115 guineas, or by four equal annual instalments of £32 16s. 3d. For members of universities and others who have completed their anatomical and physiological studies the fee is 70 guineas, or by three equal annual instalments of £26 5s.

Further information may be obtained on application to the Dean.

ST. THOMAS'S.

This school, and the hospital in connexion with which it works, is situated in Lambeth, the joint buildings on the Thames facing the Houses of Parliament, and forming one of the well-known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and class-rooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading-room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 2 p.m. The Students' Club premises contain a dining room and smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium. Good meals are obtainable at a moderate tariff. The Terrace affords facilities for exercise and recreation. A cloak-room with lockers, and a lavatory with bath-rooms, are in the main school building. Students are thus able to spend the whole day at the school. The sports ground of more than nine acres in extent is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 604 beds, and temporary huts erected in the quadrangles afford accommodation for 336 additional patients. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that large numbers of students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room; it is arranged also for lantern demonstrations. The maternity ward, containing 20 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for supplementary instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments.—All hospital appointments are open to students without charge. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £150 each, with board and lodging. Two hospital registrars, at an annual salary of £150 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Eight resident casualty officers and anaesthetists are appointed every six months. Four house-physicians, four house-surgeons, two obstetric house-physicians, two ophthalmic house-surgeons, and eight clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Two research assistants (bacteriological and chemical) are paid £200 per annum each. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships.—There are five entrance scholarships: Two in Arts, giving one year's free tuition; one of £150 and one of £60, in Chemistry, Physics, and Biology, for students who have not received instruction in Anatomy or Physiology; one of £50 in any two of the following subjects: Anatomy, Physiology, or Chemistry, for students who have completed their examinations in Anatomy and Physiology, for a medical degree in any of the universities of the United Kingdom, and have not entered as students in any London medical school. Valuable scholarships, prizes, and medals are open for competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in Pharmacology, and the Louis Jenner Research Scholarship of the annual value of £60 for Pathological research.

Fees.—The entrance fee for second year's students is 20 guineas; for third year's students 10 guineas. The annual composition fee is 30 guineas. For Preliminary Science students the fee is 15 guineas. The fees cover all tutorial classes given by the school teachers, and there are no extra charges made for materials required in practical courses. Special courses of instruction are given for various examinations, and a register of lodgings is kept at the school. A list of medical practitioners, clergymen, and others who receive students is also available. Further information may be obtained from the Secretary of the School, St. Thomas's Hospital, Albert Embankment, S.E.

UNIVERSITY COLLEGE HOSPITAL.

The school, which forms part of the Corporation of University College Hospital, is in immediate proximity to the hospital in University Street and opposite University College. It comprises departments of medicine and clinical medicine, surgery and clinical surgery, midwifery and gynaecology, pathology including morbid anatomy, clinical pathology and bacteriology, cardiology, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear, and throat, and for instruction in anaesthetics, electro-therapeutics, and skiagraphy. The Hospital and School have acquired the National Dental Hospital and College as their Dental Departments, thus providing every facility for the study of dental subjects.

The school thus provides the final course of study for the degrees of the universities of London, Oxford, Cambridge, and Durham, and for the diplomas of the Royal Colleges of Physicians and Surgeons in Medicine and Dental Surgery, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas of public health. Each department is also equipped for more advanced work, and provides facilities for research.

A student may enter the medical school at the commencement of his career, in which case he will pursue his preliminary and intermediate studies at the University of London, University College, and his final studies in the school. He may also enter the school for the final studies after having completed his preliminary and intermediate studies at any recognized university or school.

Scholarships.—The following scholarships and prizes are open to competition: Two Entrance Exhibitions of 80 guineas each, awarded after a competitive examination in anatomy and physiology; Graham Scholarship in pathology of a sum not exceeding £200 per annum; the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £25 a year for two years for general proficiency in medical studies; Magrath Clinical Scholarship, value about £100; the Phillitt Exhibition in pathology of £30; Graham Gold Medal for research work; four Fellowes Medals in clinical medicine; Liston Medals in clinical surgery; the Bruce Medal in pathology and surgery; two Tuke Medals in pathology, and the Erichsen Prize for practical surgery.

Appointments.—All the appointments at the hospital are reserved for students of the school, the dresserships and clerkships being open, of course, to those who have still to qualify. The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, surgical registrars, obstetric registrar, casualty medical officers, casualty surgical officers, assistant in ear, nose, and throat departments, assistant in ophthalmic department, registrar in anaesthetic department, and deputy anaesthetist.

Fees.—The fee for the full course of final studies at the school is 80 guineas if paid in one sum, or 82 guineas if paid in two instalments.

WESTMINSTER.

This school, with its hospital, situated in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital, which contains upwards of 200 beds, and affords most ample facilities for instruction in all branches of medicine and surgery.

Appointments.—A medical and surgical registrar are appointed annually, each with a salary of £50. Two house-physicians, three house-surgeons, one assistant house-physician, one assistant house-surgeon, and a resident obstetric assistant are appointed after examination, and are provided with rooms and commons, except the assistant house-physician and the assistant house-surgeon, who are provided with commons only. The assistant house-physician after three months' service becomes house-physician for a further period of six months, and the assistant house-surgeon, after two months' service, becomes house-surgeon for a further period of six months. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students. Every student must perform the duties of out-patient dresser for four months, and afterwards hold the office of in-patient dresser for four months. He is also required to serve two terms of four months each as medical clinical clerk to in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every four months to assist in the *post-mortem* room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

Scholarships.—The following scholarships are offered for competition during the year 1915-16. In the summer session two natural science scholarships, £60 and £30, and one in Arts, £60. In the winter session two scholarships in anatomy and physiology, £50 each. In the spring two scholarships in anatomy and physiology, £50 each.

Fees.—The annual composition fee is 25 guineas, and an entrance fee of 15 guineas is payable by every student, including scholars. Under certain conditions 10 guineas of the entrance fee is returnable on qualification. Special terms are given to the sons of medical men. These fees include subscriptions for membership of the Clubs Union.

Further information can be obtained on application to the Dean at the Westminster Hospital Medical School, Caxton Street, Westminster, S.W.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

This school is carried on at 8, Hunter Street, Brunswick Square, in connexion with the Royal Free Hospital, and it is, like all the other London schools which have so far been mentioned, one of the constituent schools of the Medical Faculty of London University. The new school buildings, among the best of their kind, were completed in 1900 at a cost, with equipment, of over £35,000. The laboratories are large and well lighted, and are fully equipped for the first and second medical examination courses of the University of London. A large library and common room are provided for the use of the students, and sets of chambers to accommodate sixteen students. An additional block is in course of construction, which will contain extensions of the Anatomical, Physiological, Chemical, and Physical Departments, with laboratories for advanced students and research in these subjects. A Pathological Research laboratory will also be provided.

The hospital has 184 beds, all of which are available for clinical instruction. A new block has recently been completed, containing a Maternity Department, with a lying-in ward of 8 beds, new and enlarged students' quarters, a new Out-patients' Department, with special operating theatre, and departments for massage, electrical and x-ray work, dentistry, and casualty. There are also separate departments for gynaecology and obstetrics, and diseases of the eye, ear, and skin. Instruction is given in anaesthetics, bacteriology, etc., in addition to the ordinary clinical lectures and demonstrations and tutorial classes. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board, and receive special instruction in lunacy at Bethlem Hospital; they are also admitted to the practice of a number of special hospitals.

The work of the school includes preparation for the M.B., B.S. Lond., the diplomas of the Royal Colleges of England and of the Conjoint Boards of Scotland and Ireland, and the Society of Apothecaries, London; also for the greater part of the course required by the University of Durham and the other universities of England which admit women to their degrees, and the University of Glasgow; also for the medical school and general hospital course for dental students.

Appointments.—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical and medical registrars, anaesthetists, medical electrician, skinographer, curators of the school and hospital museums, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne Entrance Scholarship value £30, the St. Dunstan's Medical Exhibition value £60 a year for three years, extendible to five years, and the Mabel Sharran-Crawford Scholarship value £20 a year for four years, are offered for competition in each year. The Bostock Scholarship, value £50 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London. The holder of the scholarship must enter the London School of Medicine for Women. The Agnes Guthrie Bursary for Dental Students, value £50, is awarded each year. The Ellen Walker Bursary of £25 for two years is awarded each year to a student beginning her fourth year of study. The John Byron Bursary of £20 a year for two years, the Helen Prideman Prize of £40, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £14 10s. a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. Various missionary societies also offer scholarships on certain conditions, and assist ladies who wish to go to India and other countries as medical missionaries.

Fees.—A University of London and diplomas of Royal Colleges of England course for the first medical examination, £25; course for second and third, £135; course after the second medical examination, £90. Composition fee for course of study for other qualifications, £140. Further information can be obtained from the Secretary.

KING'S COLLEGE.

SINCE the incorporation of King's College in the University of London, the instruction given to medical students is carried out there in the classes of the Faculty of Science (Medical Division), and deals only with the subjects of the preliminary and intermediate parts of the curriculum. King's College Hospital (see p. 369) is now a separate institution, and the studies for the final examinations only are carried out there.

A special class for the Matriculation Examination is also held.

There is a large athletic ground at Wormwood Scrubs, managed by the Students' Union Society.

Scholarships.—The entrance scholarships are: 1. Two to four Warnford Scholarships, each £25 for four years; subjects—mathematics, classics, divinity. 2. One Sambrooke Exhibition of £25 for two years, open; subjects of examination—mathematics, elementary physics, inorganic chemistry, botany, and biology. The holders of the preceding awards must proceed to King's College Hospital. 3. Babbeth Scholarship, value £20, in July, for the best student of the first year. 4. Second year's scholarship, value £20, for the best student of the second year.

Fees.—Information as to fees can be obtained from the Dean of the Medical Division of the Faculty of Science at the College (Professor W. D. Halliburton, M.D., F.R.C.P., L.L.D., F.R.S.).

Information as to scholarships and subjects of examination can be obtained from the Secretary of the College.

UNIVERSITY COLLEGE.

THIS institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. The Department of Hygiene and Public Health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above-named departments, as well as in pathological chemistry, the work of which is entirely post-graduate. It undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, accordingly as whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. The general arrangements for the benefit of students include membership of the Union Society, with its gymnasium and athletic ground. There is also a collegiate residence for about forty students at Ealing.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 135 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), and two entrance exhibitions on the same subject, each of the value of 55 guineas.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and in both parts of the Second Examination, amount to 84 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England come together to 79 guineas. These fees may be divided into payments for the different courses which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Provost of University College.

THE PROVINCES.

THERE are in England and Wales, not counting London, ten medical schools, each, with one exception, supplying instruction in the full medical curriculum. Accounts of them here follow, these being placed more or less roughly in the order of their foundation. In several cases there is appended information concerning other hospitals than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

OXFORD AND CAMBRIDGE.

BOTH at Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently equipped, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them, but this is not commonly done. The local hospitals are comparatively small, so the authorities encourage the students, so soon as they have completed the earlier examinations, to join some London school, and thus spend the time of their preparation for the final examination in a city where the opportunities for gaining clinical knowledge are greater and more varied.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

THIS, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-on-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university, and their clinical work in the new *Royal Victoria Infirmary*, an institution with over 400 beds and special accommodation for the benefit of students. In a new wing of the school itself there are the departments of bacteriology and physiology. There are also in this wing a gymnasium and a set of rooms for the use of the Students' Union.

Appointments.—Assistant demonstrators of anatomy and prosectors for the professor of anatomy, assistant physiologists, pathological assistants, assistants to the dental surgeon, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected annually. Four times in the year clinical clerks and dressers are appointed for three months.

Scholarships.—A University of Durham Scholarship, value £100, for proficiency in arts, open annually at the beginning of the winter session to intending students. The Pear Scholarship, value £150, for proficiency in arts (when vacant). The Dickinson Memorial Scholarship, interest of £400, with a gold medal, for medicine, surgery, midwifery, and pathology, open to perpetual students in their fifth year. The Gilloch Scholarship, interest of £400 annually, for anatomy, physiology, and chemistry, for students at the end of their second year. The Charlton Memorial Scholarship, interest of £700 annually, open to full students entered for the class of medicine, at the end of their fourth or fifth winter. The Gibb Scholarship, interest of £500 annually, for pathology, at the end of summer session. Gibson Prize, interest of £25, for midwifery. Gaiterson Wood Prize, interest of £250, for psychological medicine. The Goyder Memorial Scholarship, proceeds of £35; subjects: Clinical medicine and clinical surgery. Luke Armstrong Memorial Scholarship, proceeds of £680, for best essay in some subject in comparative pathology. The Stephen Scott Scholarship in Surgery, interest on £1,000 annually. The Heath Scholarship in Surgery, interest on £4,000, awarded every other year. First award in 1896.

Fees.—The composition fee for lectures at the college is 80 guineas. Composition fee for hospital practice 35 guineas, plus £2 2s. yearly for three years payable to Committee of Royal Victoria Infirmary. Other information should be sought from the Secretary of the School at Newcastle.

Other Hospitals. The Hospital for Sick Children and the Infirmary for Diseases of the Eye throw open their various departments to students.

BIRMINGHAM.

THE school in this city is carried on by the Medical Faculty of the University of Birmingham, its students

having an adequate number of good laboratories, classrooms, and other necessaries devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for this purpose. Together they have upwards of 500 beds for medical, surgical, and special cases, and with an array of special departments of all kinds, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of Corporations.

Appointments.—The large number of appointments open to past or other students include the following:—At the General Hospital: 1 resident medical officer, salary £100 a year; 1 resident surgical officer, salary £100 a year; 1 resident pathologist, salary £50 a year; 2 non-resident casualty assistant physicians, salary £50 a year; 3 non-resident surgical casualty officers, salary £50 a year; 2 non-resident anaesthetists, salary £50 a year; 4 house-surgeons, office tenable for nine months, £50 a year; 1 house-surgeon to the gynaecological and 1 to the ophthalmic and aural departments, each tenable for six months, £50 a year; 3 house-physicians, post tenable for six months, £50 a year; 1 resident medical officer at the Jaffray Branch Hospital, salary £150 a year; 1 resident assistant at the Jaffray Branch Hospital, tenable for three months. At the Queen's Hospital: 3 house-physicians and 3 house-surgeons (post vacant in January and April); 1 obstetric and ophthalmic house-surgeon (post vacant in April and October). These appointments are tenable for six months. Salaries at the rate of £80 per annum, with board, lodging, and washing. One resident dresser, tenable for three months; candidates must previously have attended their lectures, etc., and need not be qualified. At the Maternity Hospital: 1 house-surgeon, salary £50 a year. At the City Work-house and Worlhouse Infirmary: 5 resident medical officers. At the Birmingham General and Branch Dispensaries: 12 resident surgeons. At the Birmingham Lunatic Asylums: 5 assistant medical officers. At the City Fever Hospitals: 3 assistant medical officers. At the Children's Hospital: 1 resident surgical officer, 1 resident medical officer. At the Birmingham and Midland Eye Hospital: 4 resident surgeons. At the Orthopaedic and Spinal Hospital: 2 clinical assistants (non-resident). At the Ear and Throat Hospital: 1 house-surgeon, £70 a year; 4 clinical assistants (non-resident). There are also 4 non-resident Poor Law appointments in the gift of the Board of Guardians.

Scholarships.—There are numerous money and other awards for students of sufficient merit, among them being the following: The Walter Myers Travelling Studentship of £150; the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on matriculation marks); four Queen's Scholarships of £100s. each, awarded annually at the first, second, third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men. The Ingleby Scholarship of £10 for proficiency in midwifery and diseases of women. There is also an entrance scholarship of £37 10s. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize, Gold Medal; Senior Surgical Prize, Gold Medal; Midwifery Prize, Gold Medal; Junior Medical Prize, Silver Medal; Junior Surgical Prize, Silver Medal.

Fees.—The composition fee for university classes is £85. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine and some other special work. The total cost for the five years' curriculum, including hospital and examination fees, is estimated at £158 2s. 6d. Other information should be sought from the Dean of the Medical Faculty.

MANCHESTER.

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature.

The clinical work of the undergraduate is done chiefly in connexion with the Royal Infirmary, an institution which itself contains about 592 beds, and has associated with it a large convalescent home and the Royal Lunatic Asylum at Cheadle. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Appointments.—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: A surgical registrar, at £75 per annum; a pathological registrar, at £100 per annum; a medical registrar, at £75 per annum; a surgical tutor, at £30 per annum; a director of the clinical laboratory, at £250 per annum, and 1 assistant director, at £75; 3 assistant medical officers and 3 assistant surgical officers, each at £35 per annum; 1 assistant surgical officer, Aural department, at £35 per annum; 5 anaesthetists, at £50 per annum each; 1 medical officer for skiagraphy and electricity, £100 per annum; 1 medical officer for home patients, one year, £150 per annum; 1 resident medical officer, one year, £150 per annum; ditto, at Cheadle, one year, £150 per annum; 1 resident surgical officer, one year, £150 per annum; 2 resident medical officers for Central Branch, £100 per annum; 1 accident room house-surgeon, six months, £100 per annum; 1 assistant medical officer at the Convalescent Hospital at Cheadle, appointed every six months, at a salary of £80 per annum; 8 senior and 8 junior house-surgeons and 10 house-physicians, appointed during the year for a term of six months. Resident officers are appointed to the Gynaecological, the Eye, and the Ear and Throat departments every six months. Four or more clinical clerks are attached to each physician and assistant physician, and 4 or more dressers to each surgeon and assistant surgeon, to the Gynaecological surgical and assistant Gynaecological surgeon, to the Ophthalmic surgeon, and to the surgeon for the Ear and Throat department, and 4 or more clerks to the Pathologist, 2 clerks to the Director of the Clinical Laboratory, and a number of clerks, not exceeding 6, are appointed to assist the medical officer for home patients. Accident-room dressers are appointed every three months, 3 senior dressers and 12 or more junior dressers.

Entrance and other Scholarships.—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum, tenable for two years. Two Dalton (entrance) Scholarships in Mathematics, tenable for two years, value £40, one being awarded annually, except in such years as a Cartwright Scholarship is awarded. Cartwright Scholarship, £35 per annum, tenable for three years. Three Hulme Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of Mechanics and Chemistry. A Dova Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially; next competition in May, 1917. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, open to the competition of scholars from Sedbergh School, Giggleswick School, and Burnley Grammar School. Subjects: Mathematics, Chemistry, and Mechanics. Dreschfeld Memorial Scholarship, value £50, tenable for one year and awarded triennially on the results of the Entrance Examination (next award in 1916). A Theodores Modern Languages Exhibition, £20, awarded annually. Two Dauntsey Medical Scholarships, value £45 and £35, tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification. Subjects: Zoology, Botany, and Chemistry. Two Entrance Scholarships in Medicine, value £100, awarded annually for proficiency in Arts or Science respectively. Two Research Fellowships in Public Health of £50 each, awarded annually. Tom Jones Exhibition in Anatomy, £25, offered annually. Robert Platt Physiological Exhibition, value £15 each, offered annually. Robert Platt Physiological Scholarship of £50, tenable for two years. A Robert Platt Zoological and Botanical Scholarship, £50. A Leech Fellowship of £100 for original research after graduation. A Graduate Scholarship in Medicine: One of £25, tenable for one year, awarded annually for proficiency shown at Final M.B., B.S. Examination. Doherty Surgical Prize, value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Scholarship, value £100, tenable for one year, awarded usually triennially; next award in September, 1916. The Turner Medical Scholarship, value £20, awarded annually for proficiency in certain subjects of the Final M.B., B.S. Examination. The John Henry Agnew Scholarship of £30, awarded annually for proficiency in the Diseases of Children. The Bradley Memorial Scholarship in Clinical Surgery of £20. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the

Diseases of Children; offered biennially; next award, 1916. Sidney Renshaw Exhibition in Physiology; One, offered annually. The details and regulations of the Dickinson Scholarships: 1 for Anatomy, 2 for Pathology, 3 Research Scholarship in Surgery, and 4 Travelling Scholarship in Medicine will be announced later.

Fees.—The composition fee for the university course in medicine is 70 guineas, payable in three instalments of 30, 20, and 20 guineas, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £25, payable in one sum. A prospectus and further information about the school and scholarships may be obtained on application to the Registrar.

Clinical Work.—The Royal Eye Hospital, the Manchester Northern Hospital for Women and Children, the well-known Hospital for Children at Peadlebury, and St. Mary's Hospital for Diseases of Women and Children all make arrangements for the instruction of students.

LIVERPOOL.

THE Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped class-rooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratories and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which an account is given below, have amalgamated to form the clinical school of the university.

Appointments.—The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

Scholarships.—The awards made each year to successful students total over £1,000. They include the following: Two Holt Fellowships, one in Pathology, the other in Physiology; a Robert Gee Fellowship in Anatomy; an Alexander Fellowship for Research in Pathology and Bacteriology; a Johnston Colonial Fellowship in Pathology, Bacteriology, and Bio-Chemistry; a John W. Garrett International Fellowship in Bacteriology; a Johnston Colonial Fellowship in Bio-Chemistry; an Ethel Boyce Fellowship in Gynaecology; and a Thelwall Thomas Fellowship in Surgical Pathology, all of the value of £100; a University Scholarship of £25, awarded on the results of the Second M.B. Examinations; a Scholarship in Mechanical Dentistry of £20; two Lyon Jones Scholarships, of the annual value of £21 each for two years, one for the junior and the other for the senior student; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Torr Gold Medal in Anatomy; the George Holt Medal in Physiology; the Kantack Medal in Pathology; the Robert Gee Prize of £5 5s. in Children's Diseases; two Robert Gee Entrance Scholarships, each of the value of £25 per annum for two years; Orthodontia Prizes, Senior £3 3s., Junior £1 1s.; Dental Operating Prizes, Senior £4 4s., Junior £2 2s.; Aclis's Prize in Dental Surgery, value £2 2s.; and other Entrance Scholarships.

Fees.—Information as to the fees paid for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School.

As many as 9 hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Infirmary for Children, the Hospital for Women, the Eye and Ear Infirmary, St. Paul's Eye Hospital, and St. George's Hospital for Diseases of the Skin. Between them they provide over 1,200 beds.

LEEDS.

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, several well-arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar class-rooms. In addition there are a library and reading room and two museums, one being devoted to pathology and the other

to anatomy. The comfort of the students is secured by common rooms and refectory in which they can take meals. It is estimated by the authorities that the approximate cost of medical education to a student in this university is £195, plus, of course, the expenses of living during the five years covered by the curriculum. The General Infirmary has over 420 beds in constant use, and includes gynaecological and ophthalmic wards and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary, has over 80 beds. The West Riding Lunatic Asylum at Wakefield is also open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary (where the practical instruction in dental subjects is also given), the City Fever Hospitals (100 beds), the Hospital for Women and Children, and the Leeds Maternity Hospital.

Appointments.—One senior anaesthetist, £50; 7 assistants, £25 each; medical and surgical tutor, at £125 each per annum; 1 resident medical and 1 surgical officer, each at £150 per annum; 1 casualty officer, at £125 per annum; 1 resident ophthalmic officer, at £100 per annum; 1 resident aural officer, at £100 per annum; 1 resident obstetric officer, at £50 (attached to the gynaecological ward and an extensive external maternity department); 1 ophthalmic house-surgeon, at £50 per annum; 3 house-physicians, each holding office for six months, and 4 house-surgeons, holding office for six months. Surgical dressers are appointed every six months; physicians' clerks, ophthalmic and aural dressers, gynaecological ward clerks, gynaecological out-patient clerks, maternity clerks, assistant physicians' clerks, dermatological clerks, and assistant surgeons' dressers, dressers in the casualty room, post-mortem clerks, and laboratory assistants every three months. A clinical pathologist (£300 per annum), together with an assistant clinical pathologist (£150), has charge of the pathological laboratory. A resident medical officer (honorary, £50) is also appointed every six months for the Ida Semi-convalescent Hospital. Appointments are also open to students at the Leeds Public Dispensary (1 senior and 4 junior resident medical officers, with salaries commencing at £80), at the Hospital for Women (2 house-surgeons, at £50 per annum, and 2 anaesthetists, £20), and at the West Riding Asylums.

Scholarships.—The university awards annually a scholarship on the results of the July Matriculation Examination in the form of a free admission to the lectures and classes given in the university, which are covered by the composition fee. The infirmary also awards a scholarship on the results of the first examination, of the value of 40 guineas, in the form of a free admission to the clinical teaching of the infirmary.

Fees.—The fee for a complete course for the First M.B. is £37 11s.; the composition fee for the course for the second and third examinations is £73 2s. 6d. (for students who have passed the second examination, £48 16s. 6d.), and for the clinical work at the infirmary, £42.

Further information can be obtained from the Dean and Clinical Subdean, School of Medicine, Leeds.

SHEFFIELD.

In this city the Medical School is one of the departments of the university, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangements and scientific equipment, on the most modern and complete lines. No expense has been spared in the matter of apparatus for teaching or research work, and the facilities for practical study in these subjects are as excellent as all the other arrangements of the school.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a museum devoted to materia medica specimens, and a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms both for men and women students. In the university buildings there is a refectory open to all students of the school, and a university journal,

Morcanus, edited by a joint committee of the staff and students, is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 500 beds for the treatment of medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the *post-mortem* examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students also have the advantage of being able to attend the practice of the Jessop Hospital for Diseases of Women, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Asylum.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) Casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. Except in the case of casualty dressers, these appointments are made for three months, commencing on the first day of October, January, April, and July. The casualty dresserships last two months, beginning on the first of any month. All students are required to hold them, and to have attended the tutorial classes for casualty dressers, before being eligible for any other of the above appointments.

Scholarships.—Entrance Medical Scholarship, value from £122 to £130, open to both sexes. Two Town Trustees' Scholarships, each of the value of £50, tenable for three years, for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees' Scholarships, value £50, for boys or girls under 19 years of age, educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Fellowship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years. Kaye Scholarship, for proficiency in anatomy and physiology, value £22 10s. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—The composition fee of £80, payable in three instalments, covers attendance on all the courses of lectures and practical classes, except pharmacy, required for a degree course in the university, or for the ordinary qualifications in medicine and surgery of the Examining Boards. It does not include hospital practice, the fee for which is £49 17s. 6d., payable in three instalments.

BRISTOL.

The school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and diplomas. The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them 470 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to arrangements for dental work and large outdoor maternity departments. At each of these institutions there are well-arranged pathological departments, comprising large pathological museums, *post-mortem* rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for *x-ray* work, both for diagnosis and treatment, the various forms of electrical treatment, including high-frequency currents, electric baths, Finson light treatment, and massage.

The students of the school have also the advantage of attending the practice of the Royal Hospital for Sick Children and Women, containing 108 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore upwards

of 600. Excellent facilities are thus afforded to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work. Each student has the opportunity of personally studying a large number of cases and acquiring practical skill in diagnosis and treatment. All classes are open to women.

Appointments.—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, and pathological clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate:—At the Bristol Royal Infirmary: Four house-surgeons, £100 each per annum; 2 house-physicians, £100; resident obstetric and ophthalmic house-surgeon, £100; throat, nose, and ear house-surgeon, £100; dental house-surgeon, £100. All these appointments are made for twelve months. From the resident officers a senior resident officer is appointed at an additional salary of £30. At the Bristol General Hospital: Senior house-surgeon, £150 per annum; casualty house-surgeon, £100 per annum, if another resident appointment has been previously held; two house-physicians, £80 per annum; house-surgeon, £80 per annum, obstetric house-surgeon, £80 per annum; dental house-surgeon, £200 per annum. All these appointments are for six months, except those of senior house-surgeon and dental house-surgeon, which are for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: Two Martin Memorial Pathological Scholarships, of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Richiardi Prize, value 7 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for general proficiency; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency.

Fees.—The fee for all the courses required for the medical curriculum, including hospital practice, is 135 guineas.

CARDIFF.

The school in this city is carried on by the University College of South Wales and Monmouthshire, and devotes itself at present principally to training students during the first three or four years of the medical curriculum, all classes being open to women students. The courses of instruction given are recognized by all licensing bodies in Great Britain, and after passing the tests corresponding to the first three years of the curriculum, the student can complete his course, for whatever degree he is aiming at, in London or elsewhere. Besides this, there is an arrangement with the Management Committee of the infirmary by which students at the school can take advantage of the opportunities for acquiring experience afforded in the wards of this large, well-ordered hospital. Hence many students, especially from Wales and Monmouthshire, find it convenient to avail themselves of the advantages of being able to pursue the earlier part of their medical curriculum near home. They can also obtain instruction in vaccination and in the administration of anaesthetics, and with a little additional work can qualify for the B.Sc. degree of the University of Wales. This degree includes the subjects which comprise the first three years of a medical student's curriculum, and it (or the B.A.) is a compulsory degree for those students who propose to sit for the M.B., Ch.B. of the University of Wales. There is also a department of public health, in which all the work for diplomas in State medicine, whether for the University of Wales or other Examining Boards, can be done. A Chair of Pathology and Bacteriology has been established. It is hoped that before long a complete Welsh National School of Medicine will be established at Cardiff, owing to the munificent offer of Sir William James Thomas to erect and present to the college a school of preventive medicine and medical school buildings, in addition to the Physiological Laboratory he has already provided.

Post-graduate vacation courses are carried on in association with the Cardiff Infirmary.

Scholarships.—There is a considerable number of scholarships connected with the college, and open to students of the School of Medicine, information as to which can be obtained on application.

Fees.—The composition fee for the three years' courses required for students proceeding to the M.B. Lond. is £63; that for the two years' courses for students proceeding to a diploma of the licensing corporations being £41 10s. The composition fee for D.P.H. classes is £30. Further information may be obtained on application to the Dean of the Faculty of Medicine.

SCOTLAND.

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of its different medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified or offer valuable opportunities for post-graduation work.

ABERDEEN.

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics, chemistry, anatomy, physiology, materia medica, pathology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in Public Health and in Tropical Medicine are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to these departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 270 patients), the Royal Lunatic Asylum (900 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (250 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (1,600 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in insanity at the Royal Asylum; in diseases of ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in diseases of the skin at the Royal Infirmary.

Bursaries.—Scholarships and Fellowships, to the number of fifty and of the annual value of £1,180, may be held by students of medicine in this university. They range from £8 to £100 per annum, and are tenable in most cases for two or three years.

Fees.—The fee for each university course is, as a general rule £4 4s.; and for a second attendance, £3 3s. An inclusive fee of 90 guineas is now payable, covering the necessary instruction within the university. Matriculation fee, both sessions, £1 1s.; summer session alone, 10s. 6d. Royal Infirmary, perpetual fee, £10; or, first year, £5 10s.; second year £5. The winter session begins on October 14th.

EDINBURGH.

THERE are three Schools of Medicine: the School of the University, the School of Medicine of the Royal Colleges, Edinburgh, and the Edinburgh School of Medicine for Women.

THE UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; Zoological Laboratory and Museum of Science and Art; Physical Laboratory; Chemical Laboratories; Dissecting Room, Bone Room, and Anatomical Museum; Physiological Laboratory; Medical Jurisprudence Laboratories; John Usher Institute of Public Health; Materia Medica Museum and Laboratory; *Post-mortem* Department of the Royal Infirmary and University Pathological and Bacteriological Laboratory; Tutorial Classes of Practice of Physic, of Clinical Medicine, and Clinical Surgery, Surgery, and Midwifery; and the practice of the hospital mentioned on the following page.

Fees.—The sessional fee for zoology, botany, chemistry, anatomy lectures, physiology, pathology, materia medica, medical jurisprudence, surgery, medicine, midwifery and gynaecology, clinical surgery (winter), clinical medicine (winter), is £4 4s. each. Second course £3 5s. Third free. A perpetual ticket taken at the beginning of the first year

is £6 6s. Physics, practical chemistry, advanced practical physiology, practical pathology, practical anatomy (winter), operative surgery, obstetric operations, practical materia medica, including pharmacy, pathological bacteriology, experimental pharmacology, vertebrate morphology and comparative embryology, are £3 3s. Clinical surgery, £2 2s. per term. Clinical medicine, first term, £3 13s. 6d.; subsequent terms, £2 2s. No perpetual ticket in these subjects. Practical botany (besides garden fee of 5s.), elementary practical zoology, practical physiology (experimental), practical physiology (histological), practical botany (advanced), practical zoology (advanced), practical anatomy (summer), anthropology, anatomy demonstrations, diseases of children, diseases of the eye, diseases of the larynx, ear, and nose; diseases of tropical climates, clinical instruction on diseases of the skin, regional anatomy, physiological chemistry, invertebrate zoology, organic chemistry, mental diseases, £2 2s. Applied anatomy (medical and surgical), £1 1s. Vaccination, £1 1s.

Scholarships.—There is a very large number of funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself. No other university is in a better, even if in as good, a position to smooth the financial path of earnest students.

THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES.—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi*; for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the Royal College of Physicians, of five members elected by the Royal College of Surgeons, and of five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management, and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street; (2) New School, Bristo Street; (3) Nicolson Square; (4) Marshall Street; and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sums payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £120. The Calendar, giving full information regarding classes and fees, can be obtained gratis on application to the Dean of the School, 11, Bristo Place, Edinburgh.

THE EDINBURGH SCHOOL OF MEDICINE FOR WOMEN.—The Edinburgh School of Medicine for Women provides all the classes required for a complete curriculum. The classes qualify for the university degree in medicine, for the diploma of the Royal Colleges, and for the triple qualification. The lecturers of the school are specially recognized by the Court of Edinburgh University for the education of women who propose taking the degree in medicine of the University of Edinburgh. Most of the classes are held in Surgeons' Hall. The office of the school and a sitting-room and other conveniences are provided in the same building for the use of the women students. The clinical instruction of the students is conducted in the wards of the Royal Infirmary specially set apart for the purpose, in the Royal Hospital for Sick Children, in the City Hospital for Infectious Diseases, at Bangour Asylum, and at the various public dispensaries. The fees and the regulations as to the course of study are the same as for pupils at the School for Male Students. Further particulars are obtainable from the Secretary of the School, Surgeons' Hall, Edinburgh.

Clinical Work.

A large number of institutions take part in the clinical instruction of students attending the Edinburgh schools, the more important of them being the Edinburgh Royal Infirmary; the Royal Victoria Hospital for Consumption; the Royal Edinburgh Hospital for Sick Children; the Edinburgh Eye, Ear, and Throat Infirmary; the Edinburgh Royal Maternity and Simpson Memorial Hospital; the Edinburgh City Hospital for Infectious Diseases at Colinton Mains; the Royal Mental Hospital, Morningside; and the District Asylum at Bangour Village. Taken together these institutions furnish some 3,000 beds.

GLASGOW.

THERE are five medical schools in this city: the two schools of the university, one of which (Queen Margaret College) is for women students; St. Mungo's College (the school of the Royal Infirmary), Anderson's College, and the Western Medical School.

THE UNIVERSITY SCHOOL FOR MEN.—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: Surgery, Pathology, Public Health, Pharmacology, Physiology, Anatomy, Chemistry, Zoology, Physics, and Botany; the Botanic Garden and the Hunterian Museum (Zoology and Pathology) are also open to students. New buildings and equipments have been provided for botany, for practical anatomy, for operative surgery, as well as for pathology; the very large additions made a few years ago to the Chemical Laboratory rendered it one of the most extensive in Scotland. The class-rooms and laboratories for the departments of Physics, Physiology, Pharmacology and Materia Medica, and Medical Jurisprudence and Public Health, are also of recent erection, and are elaborately equipped. Four additional chairs of Medicine, Surgery, Obstetrics, and Pathology have been recently established, the Professors being specially attached to the Royal Infirmary; and a number of University Lectureships in Clinical Medicine, Clinical Surgery, Venereal Diseases, Laryngology, Dermatology, Otolaryngology, and Psychological Medicine have been founded there. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduate and research work. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Regius Professors are attached; the Royal Infirmary (630 beds); and the Victoria Infirmary (260 beds); while the Royal Asylum (460 beds), the Royal Hospital for Sick Children (200 beds), the Maternity Hospital (34 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospitals at Belvidere (680 beds) and Ruchill (540 beds), and other institutions afford facilities for the practical study of special branches. During the present year (1915) special qualifying examinations in Medicine, Surgery, and Midwifery have been held, in order that candidates who had completed their full curriculum might be enabled to graduate without delay. Nearly all the successful candidates have received commissions in the R.A.M.C.

Bursaries.—Bursaries confined to the Medical Faculty amount in annual value to about £1,000, while bursaries in any faculty, amounting to about the same annual sum, may be held by students of medicine, a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in Arts. Some of the bursaries are described below.

Fees.—The matriculation fee for each year is £1 1s. In most cases the fee for each university class is £4 4s., but in some cases it is £3 3s. For hospital attendance students pay an entrance fee of £10 10s. at the Western Infirmary, with an additional fee of £3 3s. for each winter and £2 2s. for each summer clinical course; at the Royal Infirmary the fees are somewhat similar. The university fee for the four professional examinations is £23 2s. (£6 6s. each for the first and second examinations, and £5 5s. each for the third and fourth). For the whole curriculum the fees

for matriculation, class attendance, hospital attendance, and professional examinations amount to £150.

For further information apply to the Registrar, Glasgow University.

Bursaries.—The following bursaries are open to under-graduates of both sexes: The Gibson Bursary, annual value £36, tenable for four years. This is open to medical students who are preparing for service as medical missionaries in connection with the Church of Scotland, and will be awarded to the eligible candidate who has gained the highest number of marks in the First Professional Examination. One Logan Bursary, annual value £16, tenable for four years; appointment by the Senate. The Mackintosh Mental Science Bursary in medicine, of the value of £31, is awarded annually to the student of either sex attending the class of insanity who stands first in an examination in that subject; the bursar to continue the practical study of the subject to the satisfaction of the Faculty of Medicine. The Gardiner Bursary, annual value £14, tenable for two years, will be awarded after the autumn professional examination to the candidate who has passed in physiology at the Second Professional Examination, and whose aggregate of marks in that subject in chemistry and physics of the First Professional Examination is the highest. The following are tenable in any faculty: Two Pratt Bursaries (each £20 and tenable for four years); and two Taylor Bursaries (each £10, tenable for four years). Andrew and Bethia Stewart Bursaries (50 each, tenable for three years); candidates must have taken the M.A. degree of Glasgow. There is a special examination. Nine Glasgow Highland Society's Bursaries, for students of Highland descent, of the annual value of £25, and tenable for five years; two vacant each year. The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the *University Calendar*. The Dobbie Smith Gold Medal is awarded for the best essay on a prescribed subject within the science of botany. The Brunton Memorial Prize of £10 is awarded annually to the most distinguished graduate in medicine of the year. The University Commission issued an ordinance to make regulations for the admission of women to certain bursaries, scholarships, and fellowships. Scholarships and fellowships are offered by the Carnegie Trust in science and medicine for post-graduate study. There are also four McCunn Medical Research Scholarships (£100 for one year) for graduates in medicine of the Scottish universities.

QUEEN MARGARET COLLEGE.—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with class-rooms, reading-room, library, etc. They are taught in some classes apart from male students, in others together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, where wards containing 460 beds are available for their use, and in its dispensary; also in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel; the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill, and the Glasgow Royal Maternity and Women's Hospital.

Scholarship.—The Arthur Scholarship, annual value £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October each year. This scholarship is the gift of Sir Arthur, of Barshaw, and is restricted to women medical students.

Board for Students.—A house of residence for women students, Queen Margaret Hall, is situated near the college. The cost of board and residence is from 17s. 6d. to 25s. 6d. per week, according to accommodation. Full information can be obtained from the Mistress, Queen Margaret College, or from the Warden, Queen Margaret Hall, Bute Gardens, Glasgow.

ST. MUNGO'S COLLEGE.—This is the Medical School of the Royal Infirmary, which is the largest in Glasgow. The Infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the infirmary grounds.

The infirmary has (including the ophthalmic department) over 660 beds, the average number occupied in 1913 being over 600. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. In the out-patient department the attendances in 1913 numbered over 180,000. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, and year by year the latest

and most approved apparatus for diagnosis and treatment is added.

Appointments.—Five house-physicians and ten house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £2 2s. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £70. The classes are open to male and female students.

THE ANDERSON COLLEGE OF MEDICINE.—This school provides education in all subjects of the curriculum both for medical and dental students. The school buildings are situated in Dunbarton Road, immediately to the west of the entrance of the Western Infirmary, within two minutes' walk of that institution and four minutes' walk of the university. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, and also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions which are stated in the school Calendar). The courses (lectures and laboratory) in public health are also recognized by the Scottish Licensing Board, Queen's University of Belfast, the Irish Colleges, and the University of Cambridge.

Fees.—The fees for the lectures and practical work required by ordinary students range between 1 and 5 guineas a session. In the Public Health Department the fee for a six months' course is £12 12s. The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a post-card by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow W., who will forward any further information which may be desired.

GLASGOW WESTERN MEDICAL SCHOOL.—This school, which is situated in University Avenue, faces the principal entrance to the university, and is not far from the Western Infirmary. The subjects in which it affords instruction by means of lectures and demonstrations are anatomy, medicine, surgery, ophthalmology, dermatology, midwifery, gynaecology, and diseases of the ear, the throat, and the nose. Some of the classes qualify for the medical degrees of the university, and also for the diplomas of the Scottish Conjoint Board. The fee for most of the subjects is £2 2s. There is no matriculation fee. Further particulars relating to the school can be obtained from its Secretary, Mr. J. N. Morton, 58, Bath Street, Glasgow.

Clinical Work.

The opportunities for obtaining clinical instruction and experience are ample, the following institutions all making arrangements for the benefit of ordinary and post-graduate students: The Royal Infirmary, the Glasgow Western Infirmary, the Glasgow Eye Infirmary, the Royal Hospital for Sick Children, and the Glasgow Hospital for Diseases of the Ear, Nose, and Throat.

ST. ANDREWS AND DUNDEE.

The medical departments in these two teaching centres offer specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects of the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain laboratories and work-rooms for anatomy, physiology, materia medica, pathology, ophthalmology, public health, medicine, surgery, and gynaecology. The clinical work of the school is facilitated by various institutions. The class fees are 4 guineas for systematic classes, and 3 guineas for practical classes. The hospital ticket is £1 1s. for three months,

£3 3s. a year, or perpetual £10 in one sum or £10 10s. in instalments. Added up, the fees for the curriculum, exclusive of the examination fees, amount to £136 10s. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from Professor Kynoch, Dean of the Medical Faculty, Medical School, Dundee.

A special Final Examination will be held in October, 1915, in order to facilitate early graduation.

Clinical Work.

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the University of London, the University of Cambridge, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND.

THERE is a choice of six schools for those prosecuting their medical studies in Ireland, and for clinical instruction the choice is equally satisfactory and varied, though the hospitals themselves are comparatively small. Some account of the schools follows:

DUBLIN.

The School of Physic.

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians in Ireland; the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board. A three weeks' post-graduate course is given each autumn, and covers all departments of medicine and surgery. Information concerning the post-graduate course can be obtained from Dr. Alfred Parsons, 27, Lower Fitzwilliam Street, Dublin.

A special Final Examination will be held on September 13th, 1915, for students who have at least five years' credit for attendance in the school and who are volunteering for active service in connexion with the war.

The Schools of Surgery.

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the college's own school, combined with two famous old medical schools—Carmichael and Ledwich; they are attached to the college by charter. The buildings contain spacious dissecting rooms, one set apart for lady students, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the college.

Prizes.—Among the prizes annually awarded are: The Barker Anatomical Prize (£25 5s.); the Carmichael Scholarship £15; the Mayne Scholarship (£8); the Gold Medal in Surgery, and the Stoney Memorial Gold Medal in Anatomy; class prizes of £2 and £1, accompanied by silver medals, will also be given in each subject.

The next session begins October 15th. A prospectus can be obtained post free on application to Mr. Alfred Miller, Registrar, Royal College of Surgeons, Dublin.

University College.

This is one of the constituent colleges of the National University of Ireland, and at present conducts its work at buildings on St. Stephen's Green, at those formerly occupied by the Cecilia Street School of Medicine, and at the University Buildings in Earlsfort Terrace. Its permanent home is not yet ready. It possesses a good library, and the arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. The teaching staff is numerous, and through it the college is connected with many of the hospitals of the city. Students, however, are allowed to pursue their studies at any of the hospitals recognized for the purpose by the university.

Clinical Work.

There are numerous well-arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the United Kingdom. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Stevens's Hospital at Kingsbridge, with 200; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital, close to Trinity College, with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 140; the Royal Victoria Eye and Ear Hospital, with 100 beds; Sir Patrick Dun's, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Ho-pital, with an aggregate of 230 beds. As for that known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the United Kingdom. It receives nearly 3,000 patients every year, and, apart from ordinary out-patient work of a gynaecological order, annually attends approximately 2,000 women at their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to post graduates of any nationality.

BELFAST.

The Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a Students' Union which gives students the advantage of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are: The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital; the Benn Ulster Eye, Ear, and Throat Hospital; the Union Infirmary and Fever Hospital; the Fever Hospital, Purdysburn; the District Lunatic Asylum, the Samaritan Hospital, Forster Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

Scholarships.—(1) 12, of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) 16 Professional Scholarships, value from £15 to £40 each; (3) 1 Hutchinson Stewart Scholarship, £12, in mental diseases; (4) 1 Mackay Wilson Travelling Scholarship, £100, awarded triennially; (5) Isabella Tod Memorial Scholarship, tenable for three years, awarded triennially to a woman student; (6) Magrath Clinical Scholarship, awarded annually, value about £112; (7) numerous seasonal prizes. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £105. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, but not fees for the special hospitals. The course for the Conjoint Board costs about the same amount. A pamphlet containing full information can be obtained on application to the Secretary, Queen's University, Belfast.

UNIVERSITY COLLEGE, CORK.

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the new National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the new university, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to

meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmaries (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (60 beds), the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglington Lunatic Asylum. The session extends from October to June inclusive. The college contains laboratories in the departments of biology, chemistry, physiology, pathology, and materia medica and pharmacy, and there are a botanic garden and plant-houses in the grounds.

Scholarships.—Over £4,000 is available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £120. Further information can be found in the college regulations, or obtained on application to the Registrar.

UNIVERSITY COLLEGE, GALWAY.

This institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Arts, Science, Law, Engineering, Commerce, and Medicine. Candidates for degrees in medicine must reside for three years. For the remaining two years certificates from any recognized medical school are accepted. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway County Hospital, the Galway Union Hospital, and the Galway Fever Hospital. The former is a general hospital, and at the two latter students have ample opportunities of studying zymotic and chronic diseases. The Union Hospital has a special ward for diseases of children. The college entrance scholarships number twelve, and range in value from £30 to £25 each. They are open to all students, including those of the Faculty of Medicine. For students in their second, third, and fourth years, two scholarships are in each year reserved for those belonging to the Faculty of Medicine. Further information can be obtained on application to the Registrar.

CLINICAL HOSPITALS IN ENGLAND.

There are a great many hospitals in the United Kingdom which, though not connected with any medical school, open their doors either to those who have yet to become qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving what instruction opportunity offers, and at those which are situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments in the way of resident medical officerships, house-physicianships, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities, but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained both by senior and junior students, and by those already admitted to the *Medical Register*. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton;

the Royal United Hospital, Bath; the Kent and Canterbury Hospital; Derbyshire Royal Infirmary; the Royal Albert Hospital and Eye Infirmary, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Infirmary at Hartshill; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital, and the County Hospital, York. As for hospitals in the metropolis, so many of these play the part of clinical schools that it is worth while to classify them.

General Hospitals.—These include the Dreadnought Hospital at Greenwich, and its annex at the Albert Dock, which form the head quarters of the London School of Clinical Medicine and the London School of Tropical Medicine; the West London Hospital and the Prince of Wales's General Hospital, Tottenham, both of these being described in the article on post-graduate work; the Great Northern Central Hospital, Holway Road, an institution containing 185 beds; and the Temperance Hospital in Hampstead Road.

Children's Hospitals.—There are at least five of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 240 beds. There are also the East London Hospital for Children, Shadwell, with 124 cots; the Queen's Hospital for Children, Bethnal Green, with 134; the Victoria Hospital for Children, Chelsea, with 104; the Belgrave Hospital for Children, which has a considerable out-patient department, but in-patient accommodation for only 40 children; the Paddington Green Children's Hospital, an institution of about the same size; and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds.

Hospitals for Women.—These include Queen Charlotte's, which specializes in the teaching of midwifery; the Samaritan Hospital for Women, Marylebone Road; the Hospital for Women, Soho Square; the Chelsea Hospital for Women, Fulham Road; and the New Hospital for Women in Easton Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Moorfields Eye Hospital, City Road, with 138 beds and a very large out-patient department; others are the Royal Westminster Ophthalmic Hospital, near Charing Cross, the Royal Eye Hospital, Southwark, each with about 40 beds; and the Central London Ophthalmic Hospital, Judd Street, W.C., with 28.

Fever Hospitals.—The Metropolitan Asylums Board has under its control a good many institutions for the treatment of the more serious zymotic disorders, and makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board, Victoria Embankment.

Chest Hospitals.—The largest of these is the Brompton Hospital for Consumption, which has 353 beds and a large sanatorium at Frimley with 150 beds. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 175 beds, and the Royal Hospital for Diseases of the Chest, City Road, which has recently reorganized its various departments with the object of better fitting itself to act as a tuberculosis school.

Nose, Throat, and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Dean Street; the Central London Throat and Ear Hospital, Gray's Inn Road; and the Hospital for Diseases of the Throat, Golden Square—the latter, which possesses 75 beds, being the largest of the four institutions.

Miscellaneous Special Hospital.—Among these are the Bethlem Royal Hospital, Southwark, which confines its work to the treatment of mental diseases; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street,

Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; St. John's Hospital for Diseases of the Skin, in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; and the National Hospital for the Paralyzed and Epileptic, Queen Square, W.C., an institution possessing 200 beds and a world-wide reputation.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

MEDICAL EDUCATION OF WOMEN.

WOMEN are admitted to the medical examinations of the following qualifying bodies: All the universities of Great Britain, with the exception of Oxford and Cambridge; the Royal College of Physicians, London, and the Royal College of Surgeons, England; the Society of Apothecaries of London; the Conjoint Colleges of Scotland and of Ireland.

The regulations of each differ considerably, so that it is necessary for a student to decide, before beginning her course, which degree or diploma she will aim at obtaining. The ordinary regulations of the General Medical Council (see page 355) must be observed, and women can pursue their education either at certain schools only open to women, or at ordinary schools where they do their work more or less in common with men students.

The schools which admit women only are the London (Royal Free Hospital) School of Medicine for Women, which is one of the constituent schools of the Medical Faculty of the University of London; the Edinburgh School of Medicine for Women (see page 377), and Queen Margaret College, Glasgow (see page 378). Women are also admitted to the schools of medicine conducted in connexion with the Universities of Dublin, Dundee, Durham, Liverpool, Manchester, Birmingham, Leeds, Sheffield, Bristol, and Aberdeen; St. Mungo's College, Glasgow, the Schools of Surgery of the Royal College of Surgeons in Ireland and of the National University of Ireland in Dublin, Cork, and Galway. Women can also attend classes for the first three years of the medical curriculum at University College, Cardiff.

Year by year the openings for women who adopt a medical career have increased, and the field open to their energies is now wide. Women hold many appointments as resident medical officers in hospitals for women and children all over the country, and are eligible for appointments in some general hospitals, and in a large number of sanatoriums, infirmaries, fever hospitals, and asylums. Many medical women are also engaged in public health and school inspection work.

As regards the London School of Medicine for Women, particulars will be found at p. 372 in the article on London Medical Schools.

DEGREES FOR PRACTITIONERS.

At one time it was almost the universal custom for medical students educated in London not to seek a university degree, and as that custom still prevails to a considerable extent, a very large proportion of medical men in actual practice in England possess diplomas to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted that the M.D. degree of the University of Brussels is not registrable when it has been obtained subsequently to June, 1886, but this fact does not lessen its value to those who see any utility in possessing a degree as well as a registrable diploma.

UNIVERSITY OF LONDON.

Registered medical practitioners who have passed the First Examination for medical degrees and the Second Examination for medical degrees, Part I, may proceed to the Second Examination for medical degrees, Part II, and M.B., B.S. Examinations without observing the intervals prescribed by the regulations on producing certificates that they have gone through the required course of study at a school of the university; subject to the proviso that no degree of the university can in any circumstances

be granted by examination to any one in less than three years after passing the Matriculation Examination or after admission by the university of the candidate's right to exemption therefrom.

UNIVERSITY OF DURHAM.

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions without residence: The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed an examination in arts previously to the professional examination in virtue of which his name was placed on the Register, he is examined in classics and mathematics; if otherwise, he is required to translate into English passages from any one of the following Latin authors: *Cæsar, De Bello Gallico* (first three books), *Virgil, Æneid* (first three books), or *Celsus* (first three books).

Professional Examination.—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics; (ii) principles and practice of surgery; (iii) midwifery and diseases of women and children; (iv) pathology, medical and surgical; (v) anatomy, medical and surgical; (vi) medical jurisprudence and toxicology. The examination is conducted by means of printed papers, clinically, and *viva voce*, at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary, Newcastle. The classical portion of the examination may be taken separately from the professional on payment of a portion (£10 10s.) of the full fee.

Foreign and Colonial Practitioners.—Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India must produce evidence from an Indian university that they have passed within one year an examination in Latin.

Fees.—The inclusive fee is 50 guineas; if a candidate fail to pass, 20 guineas are retained, but if he present himself again, 40 guineas only are required.

Dates, etc.—The examinations are held twice a year, towards the end of March and of June. Notice, accompanied by the fee and certificates, must be sent to Professor Howden, Secretary of the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

UNIVERSITY OF BRUSSELS.

This university grants its M.D. to such foreign candidates as are already duly qualified in medicine and surgery in their own countries, provided they pass the three examinations imposed. These must be passed in due order, but if desired may be passed without any formal interlude, the time covered in the latter case being ten or twelve days. They are *viva voce* examinations, the language used being French. There is, however, an official interpreter present, whose services are at the disposition of candidates; besides this, the examiners commonly speak the English language. At their desire candidates may also undergo written tests on payment of an extra fee of £1 for each test, but such written examination does not exempt them from the *viva voce* examination. There are now over six hundred medical men holding this degree in England and the colonies.

Examinations.—Of the three examinations, the first Doctorate covers general medicine, *materia medica* and pharmacology, general surgery, and the theory of midwifery. The second covers general therapeutics, pathology and morbid anatomy (including microscopy), special and general therapeutics, the special branches of surgery, and mental diseases. The third covers public health, medical jurisprudence, clinical medicine, and surgery, operative surgery (including the performance of some of the commoner operations on the dead subject), ophthalmology, midwifery (including obstetric operations on a model), regional anatomy (with dissection), and bacteriology. The examinations commence on the first Tuesday in November, December, March, and May, and the second Tuesday in June.

Fees.—The fees aggregate to £22; they are paid in advance, but those for any examinations to which a candidate has not been admitted are returned to him.

A rejected candidate may be examined three months later on repayment of the examination fee, provided his second appearance takes place in the course of the same academic year; otherwise the matriculation fee (£8 12s.) must be paid again. Any fee paid includes the right to attend any lectures delivered in connexion with the subjects of the examination to which it relates. Other information can be obtained either from the Secretary of the University, 14, Rue des Solos, Brussels, or from Dr. Arthur Haydon, Honorary Secretary of the Brussels Medical Graduates' Association, 11, Welbeck Street, Cavendish Square.

POST-GRADUATION STUDY.

The value, and in some circumstances even the necessity, of post-graduation study is now so generally recognized that there is no occasion to dilate upon it here. The need for some means of acquiring direct knowledge of the technique of the new branches which are constantly springing up is indeed so generally felt among otherwise experienced practitioners, that several institutions designed solely for their benefit have been at work now for some years. Of these institutions some account follows. Beyond this it need merely be said that in most medical centres it is now exceptional for one or more courses for qualified men not to be held once or more often during the year; that most of the institutions mentioned in the section on Clinical Hospitals make special arrangements for the benefit of qualified men desirous of studying work of the kind undertaken within their wards; and that valuable adjuncts to post-graduation study exist in the shape of the Library of the British Medical Association—one specially rich in recent works—of the libraries of the several universities, and in those of the Royal College of Surgeons of England and the Royal Colleges of Physicians in London and in Edinburgh.

WEST LONDON POST-GRADUATE COLLEGE.

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895, and the present building was opened in 1901; it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. In the last five years the yearly entry has averaged over 220.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2.15 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments dealing with diseases of the eye, ear, throat, nose, skin, orthopaedics, x-ray work, electro-therapeutics, gynaecology, and mental diseases of children. Post-graduates are appointed to act as clinical assistants for three or six months. There is no charge to members of the college. Practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, surgical diseases of children, analysis of blood and urine, cystoscopy, venereal disease, tropical diseases, retinoscopy, ophthalmic operative surgery, and when material is available, in operative surgery. The size of the classes is limited so as to ensure that each student shall have full opportunities of gaining experience in methods of examination and treatment.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the post-graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of different anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session.

The pathological laboratory is in charge of a pathologist who attends every day. In bacteriology and microscopy special instruction is given on three mornings a week, the students working at other times under the general guidance of the pathologist.

Demonstrations are given every day in the morning by the assistant physicians, assistant surgeons, and by the

medical and surgical registrars in practical medicine and surgery. Lectures of a practical kind are given daily (except Saturday and Sunday) at 5 p.m.

The arrangements of the college may be said to be equally suited to those who are preparing themselves for examination for the higher degrees and diplomas, to the needs of officers in the different services on study leave, who attend in large numbers, and to those medical men in ordinary practice who desire to get themselves up to date in general medicine and surgery, or to make a special study of some particular branch of work. The college, it may be noted, is in a residential quarter, and there are plenty of good lodgings in its neighbourhood.

The fees are as follows: Hospital practice, including all ordinary demonstrations and lectures, £1 1s. for one week, £3 3s. for one month, £4 4s. for six weeks, £6 6s. for three months, £10 10s. for six months, £15 15s. for one year, and £30 for a life ticket. Every year in August there is a special vacation class lasting four weeks, for which the fee is £3 3s. 'Three months' instruction in the administration of anaesthetics costs £3 3s. Subscriptions for any course can be taken out from any date. The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees).

A prospectus concerning the school can be obtained on application to the Dean.

LONDON SCHOOL OF CLINICAL MEDICINE (POST-GRADUATE), DREADNOUGHT HOSPITAL, GREENWICH, S.E.

The school buildings, lecture rooms, operative surgery class-rooms, pathological laboratories, museum, library, etc., are in the Seaman's Hospital at Greenwich. The whole hospital of 250 beds, with its out-patient department, is open to students from 10 a.m. till 5 p.m.

Medical, surgical, and special department in-patient clinics are held every afternoon except Saturday by the senior members of the staff, whilst out-patients are demonstrated daily in the forenoon in the medical, surgical, and special departments by the assistant physicians and assistant surgeons. Operations are performed daily in both the in-patient and out-patient theatres. A series of lectures are delivered each session in the afternoon by specially invited lecturers, Emeritus lecturers, members of the staff of the Dreadnought Hospital, and by members of the staff of the hospitals affiliated to the school. Practical classes are arranged each session in the following subjects: The practice of medicine, diseases of the nervous system, medical diseases of women, medical diseases of children, diseases of the skin, practice of surgery, operative surgery, diseases of the eye; diseases of throat, nose, and ear; surgical diseases of women, midwifery and gynaecology, surgical diseases of children, pathology, clinical pathology, bacteriology, surgical and medical pathology, hygiene and public health; the administration of anaesthetics, skiagraphy, mental diseases.

Two sessions, of five months (October-February) and four months (April-July), are held in each year. The session's work is arranged so as to enable individual students to join the demonstrations, etc., at any time during the session.

Affiliated to the London School of Clinical Medicine for the purposes of extension of the variety of clinical material and teaching are the Royal Waterloo Hospital for Children and Women, the Miller General Hospital, Greenwich, and the Bethlem Royal Hospital for Mental Diseases. These hospitals are directly linked to the Dreadnought both by rail and by tram. The supply of material affords exceptional facilities for practical instruction in operative surgery and in pathology. There is also a wide field for the study of venereal diseases, on which special clinics are given, and there is a department with open-air wards for the treatment of tuberculosis. Every variety of disease may be studied in the wards and out-patient rooms of the Dreadnought Hospital and at the affiliated hospitals. The certificates of the school are recognized by the University of London for the higher degree, the Admiralty and the War Office, the India Office, and the Colonial Office.

Appointments. There are a medical superintendent, surgical and medical registrars, two house-physicians, and two house-surgeons at the Dreadnought Hospital, Greenwich. The pay of these officers varies from £50 to £150.

Full prospectuses, lists of special lectures, and other

particulars can be obtained on application to the Dean at the School.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.

The head quarters of this post-graduate school are situated at the Prince of Wales's General Hospital, which is in the midst of a densely populated North London neighbourhood containing about a quarter of a million inhabitants. It contains 125 beds, and its precise situation is South Tottenham, N., where it is within a few minutes' walk of South Tottenham Station on the Midland Railway, Seven Sisters Station on the Great Eastern Railway, and Tottenham Hale on the Great Eastern main line. It is also readily accessible from Finsbury Park and Hackney by electric tram passing the hospital door, and by corresponding means may be reached easily from Dalston, Edmonton, Hackney, and other parts of North London.

The college is recognized by the Admiralty and the India Office for the purposes of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its D.P.H. diploma, and there are ample arrangements for the convenience of men who are thus working, or who are general practitioners desirous of getting themselves into touch with modern methods. There is provided for their use a reading and writing room, and they can obtain afternoon tea and receive telephonic messages; similarly there is a reference and lending library for their benefit, and a museum and pathological laboratory in which they can work. The hospital as a whole certainly affords excellent facilities to qualified medical practitioners who wish to take part for a time in the work of an active general hospital, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, skiagraphy, and the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week except Saturday. Special classes are arranged in modern methods of the investigation and treatment of diseases of the lungs and heart, gynaecology, diseases of children; diseases of the throat, nose, and ear; diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, diseases of the skin, abdominal surgery, surgical anatomy, surgery of the urogenital tract, skiagraphy, anaesthetics, bacteriology, clinical pathology, vaccine therapy, pathological chemistry, and medical electricity. In all these classes the numbers are carefully limited, so as to give every member full opportunity for work.

As for fees, these are as follows: One guinea for a three months' course of study in any one department, which may be begun at any time; a fee of 3 guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may be obtained on payment of a fee of 10 guineas.

Additional information about the college and its work can be obtained on application to the Dean of the Post-Graduate College, at the hospital, or at 19A, Cavendish Square, London, W.

TROPICAL MEDICINE.

There are Schools of Tropical Medicine in London and Liverpool, and several examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees follows.

DIPLOMAS AND DEGREES.

LONDON UNIVERSITY. Tropical medicine is one of the six branches in which the M.D. degree may be obtained,

the regulations relating to the curriculum and examination corresponding to those applying to the other branches.

LONDON CONJOINT BOARD.—This body grants a diploma in tropical medicine to candidates after an examination usually held in the months of April and July. Ordinary candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in bacteriology, parasitology, medical zoology, and haematology, in a laboratory recognized for this purpose during not less than six months; (2) instruction in hygiene applicable to tropical countries; (3) the clinical practice of a hospital recognized for the study of tropical diseases during not less than six months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries deemed likely to have furnished them with the same kind of training. The fee for admission to the examination is £9 9s.

UNIVERSITY OF EDINBURGH.—This university grants a diploma in tropical medicine and hygiene after an examination which is usually held twice a year. It is open to those who are graduates of the university in medicine and surgery, and to registered practitioners who have had experience of tropical diseases in a tropical country, who may be approved by the Senatus on the recommendation of the Faculty of Medicine. In addition to this the candidates must show that they have attended approved courses of instruction in practical bacteriology (including the pathogenic micro-organisms of tropical diseases), in diseases of tropical climates (including the zoological characters and life-history of disease-carrying insects), in tropical hygiene, and in clinical study of tropical diseases. They must possess, too, certificates of efficiency in the conduct of *post-mortem* examinations. The examination is in the four subjects indicated, the fee being £4 4s.

UNIVERSITY OF LIVERPOOL.—A diploma in tropical medicine is given by this university to students who have been through the courses provided by the Liverpool School of Tropical Medicine, and have passed the examination held twice yearly by the university examiners. The examination lasts three days, and consists (1) of three papers dealing with tropical medicine, tropical pathology, and tropical sanitation and entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The results are declared as soon as possible afterwards. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF CAMBRIDGE.—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year, provided that he passes the examination of the university in this subject. Previous to admission to the examination he must produce approved evidence that he has studied pathology (including parasitology and bacteriology in relation to tropical diseases), clinical medicine, and surgery, at a hospital for tropical diseases, and hygiene and methods of sanitation applicable to tropical climates.

The examination deals with the following subjects:

1. The methods of pathological and bacteriological investigation. The examination of the blood. The characters, diagnosis, and life-history of animal and vegetable parasites. The examination, chemical and microscopic, of poisonous or contaminated foods and waters.
2. The origin, pathology, propagation, distribution, prevention, symptoms, diagnosis, and treatment of the epidemic, endemic, and other diseases of tropical climates, including malaria, blackwater fever, trypanosomiasis, relapsing fever, dengue, yellow fever, plague, tetanus, beri-beri, dysentery and hepatic abscess, cholera, enteric fever, Malta fever, and specific diarrhoeal affections of the tropics; diseases due to cestode and other worms; filariasis, bilharziasis disease; specific febrile sores, and other cutaneous affections; mycetozoa, ophthalmic affections of the tropics, affections caused by poisonous plants and animals, and by poison weapons; sunstroke.
3. The general effects on health in the tropics of seasons and climate, soil, water, and food. Personal hygiene, acclimatization. Principles of general hygiene, with special reference to food supplies and water supplies, sites, dwellings, drainage, and the disposal of refuse. The sanitation of native quarters, camps, plantations, factories, hospitals, asylums, goals, pilgrim and coole ships. Principles and methods of disinfection.

Examinations are held in January and August each year, and last four days. The fee for the examination and diploma is 9 guineas on admission or readmission. Application for further information should be made to Dr. G. S. Graham-Smith, Pathological Laboratory, Cambridge.

SCHOOLS.

LONDON SCHOOL OF TROPICAL MEDICINE.—This school is under the auspices of the Seamen's Hospital Society. Its buildings, laboratories, museum, library, etc., are within the grounds of the Branch Hospital, Royal Victoria and Albert Dock (Station, Connaught Road, Great Eastern Railway), and excellent opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. In the hospitals of the society are to be found cases of tropical disease such as may be met with in actual practice in the tropics. There are three courses in the year, each lasting three months, beginning October 1st, January 15th, and May 1st respectively. The course is so arranged as to equip men for the Cambridge and English Conjoint Board diplomas in tropical medicine. A prospectus and other information can be obtained on application to the Secretary, Seamen's Hospital, Greenwich.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—This school is affiliated with the University of Liverpool and the Royal Infirmary and Royal Southern Hospitals of Liverpool. Two full courses of instruction are given every year, commencing on January 6th and September 15th, lasting for the term of about thirteen weeks, and followed by the examination for the diploma of tropical medicine given by the University of Liverpool. Each course consists:

- (1) of a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the university; (2) of systematic lectures and demonstrations on tropical pathology, parasitology, and bacteriology by the Professor of Parasitology and the Lecturer on Parasitology at the university; (3) of similar instruction on medical entomology by the Professor of Medical Entomology and the Lecturer on Entomology at the university; and (4) of clinical lectures and demonstrations delivered at the Royal Infirmary and the Royal Southern Hospitals by the physicians in charge of the tropical ward or the professor.

The instruction given occupies six hours a day for five days a week during the term. Teaching under headings (2) and (3) above is delivered in the laboratory of the school at the university, which contains accommodation for thirty students, with all necessary apparatus, including a well-equipped museum, a class library, and access to the general departmental library. Teaching under heading (4) is given in the tropical ward and the attached clinical laboratories of the Royal Infirmary and the Royal Southern Hospitals on two or three afternoons a week.

In addition to the full courses, an advanced course of practical instruction in tropical pathology and medical entomology, lasting one month, is given every year in June; it is of such a kind as to be very useful to medical men returning from the tropics on short leave. A special course of instruction in entomology, etc., is also given three times a year to officers of the East and West African Colonial Services.

Students of the school who do not care to undertake the examination held by the university at the end of each term for its diplomas in tropical medicine are given a certificate for attendance if the latter has been satisfactory.

It is proposed to institute at an early date a course of instruction in tropical sanitation. Full particulars will be issued as soon as possible.

The new laboratories of the school adjoining the university, which are now completed, have been taken over temporarily by the War Office authorities as a hospital.

Since it was instituted the school has dispatched to the tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs, with many plates and figures, besides textbooks and numerous articles in the scientific press.

Fees.—The fee for the full course of instruction is £13 13s., with an extra charge of 10s. 6d. for the use of a

microscope if required. The fee for the Diploma Examination is £5 5s., and that for the Advanced Course is £9 4s. Further information about the school may be obtained on application to the Secretary, 10B, Exchange Buildings, Liverpool.

PSYCHOLOGICAL MEDICINE.

The study of mental diseases has long been a necessary part of the ordinary medical curriculum, and mental psychology is one of the branches of medicine which candidates for the M.D. degree of the University of London can take up. In addition diplomas in psychiatry can be obtained from the universities of Edinburgh, Leeds, and Cambridge. The Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination and encourage study of psychology and connected subjects by the offer of prizes for competition.

Those who take up psychological medicine as a career work as medical officers either of private mental hospitals, or of county or other public institutions of the same order. In all cases they are resident officers, those in the lower ranks always receiving board and lodging in addition to their salary. As a whole, they fall into three ranks—junior assistant medical officers, senior assistant medical officers, and medical superintendents. The salaries of those belonging to the junior rank have hitherto been in the neighbourhood of £150 a year, and those of senior assistants about £300 a year, but have recently shown some tendency to rise. Medical superintendents, whose pay commonly ranges between £500 and £1,500 a year, are always provided with a house in the grounds of their asylum, and usually draw various allowances.

However, asylum work as a career is by no means growing in favour, and is unlikely to do so until all the public asylums throughout the country have been linked up in such fashion that their officers can be regarded as members of one common service. At present it is quite possible for a man who does excellent work to remain in the lower rank all his life, and this fact, coupled with the desirability of minimizing as far as possible other existing drawbacks to asylum life, has recently led to the starting of a movement for reform; and in this the British Medical Association is co-operating.

PUBLIC HEALTH SERVICES.

The Public Health Service, to use the term in a strict sense, consists of medical officers of health appointed by local public health authorities and holding office under varying conditions of tenure. In addition, there are county medical officers appointed by the county councils. The latter are not, strictly speaking, public health authorities; the duties of their medical officers are somewhat similar to those of other medical officers of health, but include few executive functions. In many of the county boroughs and counties, assistant medical officers of health or assistant county medical officers are appointed, and such appointments may afford stepping stones for promotion to higher offices. The service is, however, not unified throughout the country, and there is no regular system of promotion; appointments are to be obtained only by application to some particular local authority which has advertised a vacancy.

Also upgraded are two other services which have been brought into existence by recent legislation, and whose members are charged with duties which bring them into more or less direct relation with public health authorities or county councils and their officers. The members of the one are called school medical officers, and those of the other tuberculosis officers. Appointments as school medical officer are made by education authorities, while appointments as tuberculosis officer are made in fulfilment of the duties imposed directly on the county councils and the county borough councils, and indirectly on the Insurance Committees by the scheme for the treatment and prevention of tuberculosis which was worked out by the Local Government Board for England in consultation with the Insurance Commissioners.

The Local Government Board for England, it may be noted, employs a staff of medical inspectors in connexion with the performance of its duty as the controlling department of the Government in matters of public health, and the same is true of the corresponding boards in Scotland and Ireland. The medical men forming these staffs are, however, appointed to their position directly by the head of the Local Government Board in each country, and the posts are not open to public competition.

MEDICAL OFFICERS OF HEALTH.

The office of medical officer of health in a county borough—a designation which now includes nearly all the larger towns—is in practice a permanent appointment so long as the incumbent desires to retain it, and is the same by law in administrative counties and metropolitan boroughs. The position of a medical officer of health to an urban or a rural district, or to a combination of districts which have joined together to obtain the services of a whole-time medical officer of health, is much less satisfactory, for his appointment is terminable at the will of the public health authority served by him. This fact tends to militate against the efficiency of the service, and consequently the British Medical Association, in co-operation with some other bodies, has long been endeavouring to induce Parliament to establish security of tenure of office and superannuation for medical officers of health. In view of statements recently made by the Government, security of tenure, at any rate, seems likely soon to be granted. A medical officer of health to a district or combination of districts having 50,000 inhabitants must hold a diploma in public health. The first step which must be taken by any medical man who desires to follow the career of medical officer of health must be therefore to obtain such a diploma.

SCHOOL MEDICAL OFFICERS.

School medical officers are appointed by local education authorities under schemes of medical inspection of school children which must be approved by the Board of Education. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard the education of such children, and to inform their parents of its existence. But practically their duties vary considerably in different areas. This is because most approved schemes of inspection include systems of work which aim at facilitating the task of parents in obtaining for their children the necessary treatment, at checking the results of the latter, and at keeping each defective child under skilled observation both at home and at school until it has passed altogether out of the education authorities' hands. The general object of all schemes alike is to make the inspection imposed by law of benefit not merely to the individual child, but to the community at large, by preventing conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. In short, the work is so far related to that of a medical officer of health that in most areas the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. Whole-time assistants are commonly paid salaries ranging between £250 and £300 a year, the chief attraction of the posts being that they may lead on to appointment as medical officer of health of some large area where the combined salary of medical officer of health and school medical officer will represent a fair income. In view of this consideration, if for no other reason, it is desirable for a prospective whole-time school medical officer to obtain a diploma in public health.

TUBERCULOSIS OFFICERS.

The prescribed duties of tuberculosis officers are to act as advisers to Insurance Committees in connexion with the operation of the sanatorium clauses of the National Insurance Act and to take charge of the work of the tuberculosis dispensary, which is the main unit of the Departmental Committee's scheme. A tuberculosis officer is a whole-time officer; he should have special training in tuberculosis work, and be of suitable age and attainments to command general confidence. At present the number of appointments is small, and the salary generally attached to them is in the neighbourhood of £500 a year.

SANITARY SCIENCE.

In June, 1915, the University of Cambridge issued regulations for the Examinations in Sanitary Science, conducted by the State Medical Syndicate of the University. Two examinations will be held during the year 1916—one in April and one in October. Any person possessing a registered qualification in medicine, surgery, and midwifery may be a candidate, provided that he has satisfied certain demands laid down in the regulations. The examination will consist of two parts, the first having reference to the general principles of sanitary science, the second to State medicine and the applications of pathology and sanitary science. All applications for information respecting these examinations should be addressed to Mr. J. E. Purvis, M.A., The Chemical Laboratory, Pembroke Street, Cambridge.

DIPLOMAS IN PUBLIC HEALTH.

Most of the universities and licensing corporations now grant diplomas in public health to candidates who pass the examinations imposed by them. Since all such tests must conform to the requirements of the General Medical Council, there is considerable similarity in their nature, though they differ not a little in their reputed difficulty. All of them aim at excluding any candidate who does not appear to have a thorough knowledge of his work in theory and in practice, for the regulations of the General Medical Council demand that the granting of a diploma in Sanitary Science, State Medicine, or Public Health shall be proof of the "possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health." The tests, in short, are supposed to constitute an honour and not a mere pass examination. As regards the special tuition required, it is now easy to obtain this in practically every centre of medical education, and at almost every medical school of any importance. It is desirable to note in this connexion that the chemical and bacteriological examinations for many of the health diplomas are so practical, and the time allowed so short, that unless a candidate—even though familiar with the duties of M.O.H.—has a considerable amount of the manipulative dexterity only to be acquired by ample work in a laboratory, he would not be likely to satisfy the examiners.

The regulations of the General Medical Council require that every candidate (subsequent to obtaining a registrable qualification in medicine and surgery) shall have passed through a stated curriculum in the subjects of sanitary science. This must last not less than nine calendar months, and include four months' study in a laboratory in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught, six months' practice study of the duties involved by public health administration, and attendance at least twice weekly for three months on the practice of a hospital for infectious diseases, at which instruction is given in methods of administration. These rules do not apply to practitioners registered or entitled to be registered before January 1st, 1890, while that regarding six months' practical study of public health administration is waived in the case of a candidate who has himself been in charge of a sanitary district with a population of not less than 15,000 for a period of not less than three years. The study in question must be passed under the personal supervision of a medical officer possessing certain definite facilities for affording it, these being carefully described in the regulations. The period may be reduced to three months in the case of a candidate who has undergone a corresponding period of study in the public health department of a recognized medical school, or who has been resident medical officer at a hospital for infectious diseases with accommodation for 100 patients for not less than three months. The laboratory study must include at least 240 hours' work, not more than half being devoted to practical chemistry. The examinations imposed by the diploma-granting bodies must extend over not less than four days, one at least being devoted to practical work in the laboratory, and one to practical examination in, and reporting on, subjects within the duties of a medical officer of health, including those of a school medical officer.

The steps which examining bodies take to ascertain the candidate's fitness for a diploma are in all cases much the same, though the order in which the subjects are taken is

not always identical. Every candidate, therefore, should, when he has settled what diploma or degree in State medicine he wishes to obtain, seek the schedule relating to it from the authority concerned. A certain number of the universities grant degrees in the subject as well as diplomas, but only the latter constitute a legal qualification in State medicine.

THE PUBLIC SERVICES.

THE ROYAL NAVY, THE ARMY, AND THE
INDIAN MEDICAL SERVICE.

The medical departments of the Royal Navy, the Army, and the Indian Government normally employ between them some three thousand medical men, and fill vacancies in the ranks of the services thus formed by offering commissions for competition once or more often each year. All candidates must be between the ages of 21 and 28 years, and besides possessing registrable qualifications to practise medicine and surgery in Great Britain and Ireland, must be adjudged by the Medical Boards appointed for the purpose to be physically fit for service before permission is accorded them to compete at the entrance examinations. Special attention is given to a candidate's power of vision; a moderate degree of myopia is not considered a disqualification, provided that it can be corrected by glasses so as to secure adequate vision for the performance of operations, and that no organic disease of the eye exists. Testimony has also to be furnished, or is sought by the authority concerned, with regard to the candidate's moral and general character, and the Secretary of State in each service reserves the right to refuse permission to compete to any candidate he pleases.

In the case of a candidate for the Indian Medical Service, the certificates submitted must include one showing that he has studied in an ophthalmic department for not less than three months, the work including refraction, and candidates for the other two services who have qualified in the Officers' Training Corps, or who have been employed in active service, receive an allowance of marks. In all three services the prospect of a medical officer attaining to the highest administrative grades depends to a large extent on the regulations with regard to compulsory retirement at the age of 55 (if below a certain grade at that age), so there is a distinct advantage in entering them at the earliest possible age.

In peace and apart from climatic conditions the lives of officers in these three services are of a less trying nature than those of civilian practitioners, and in the Royal Army Medical Corps, and still more in the Indian Medical Service, the opportunities for professional work of the highest kind are exceptionally great. In regard to emoluments, the pay in no rank is high, but in all it is sufficiently good to make the possession of private means not absolutely necessary. An officer in the Indian Medical Service, for instance, can retire after seventeen years' service on £300 a year, and after thirty on £700 a year with large additions should he have been employed in certain positions. In the other two services twenty years is the lowest pensionable length of service (the minimum is £365 a year, the maximum £1,125); but from either of them an officer whose record is good can retire while still under 30 years of age with a gratuity of £1,000. In the Indian Medical Service, after working for three years in a military capacity, officers are allowed as a rule to transfer, if they please, to the civil department. Therein they do work not essentially dissimilar from that performed by civilian practitioners in other warm climates, but retain their military titles and are promoted from one grade to another as their service lengthens. It should be added that during the last few years competition for admission to the Navy has been very slight, while that for admission to the Indian Medical Service has greatly fallen. The reason is that the attractions of both services set forth above are to some extent counterbalanced by removable causes of discontent among their members. The nature of these can be learnt from recent issues of the BRITISH MEDICAL JOURNAL.

Candidates for all three services have to fill in printed forms before the question of permitting them to compete

is considered, and copies of these, together with detailed information as to what each service has to offer, can be obtained on application to the Director-General of the Royal Navy, the Secretary of the War Office, and the Military Secretary of the India Office, respectively.

PRISON MEDICAL SERVICE.

Candidates for the medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is Sir Evelyn Ruggles-Brise, K.C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to give their whole time to the service.

In the case of those required to give their whole time to the service the appointment in the first instance is to the post of deputy medical officer, and from the seniors of this rank the medical officers are selected as vacancies occur. The deputy medical officers are paid £225 yearly, rising to £400, with unfurnished quarters. The whole-time medical officers are paid £450, rising to £550, with unfurnished quarters. There are twenty deputy medical officers, and nine whole-time and forty-six part-time medical officers. The number of vacancies is never large.

APPOINTMENTS UNDER THE COLONIAL OFFICE.

Medical appointments are from time to time filled up by the Colonial Office in various Crown and other Colonies, and vacancies in the West African Medical Staff are of fairly frequent occurrence. As a rule officers are required on appointment to undergo a three months' course of instruction at the London or Liverpool School of Tropical Medicine, and to obtain a certificate of proficiency before taking up their appointment. In addition to the ordinary medical appointments, vacancies also occasionally occur for which specialists are required—for example, to take charge of a lunatic asylum.

The nominal value of the appointments varies very considerably; but, as a general rule, it will be found on close examination that the rates of pay correspond in real value pretty closely when questions of climate, opportunities for private practice, the cost of living, and the actual work demanded are taken into consideration. The posts to which the lower salaries are attached commonly involve work which can be regarded as merely an adjunct to ordinary private practice, while high pay means either few opportunities for practice, an undesirable climate, or work of a special character demanding high administrative ability. Taken as a whole, all these appointments may be put down as offering their occupant the opportunity of gaining his livelihood, and possibly saving a little money, in a fashion which will test his abilities to the full. Pamphlets relating to the various appointments in its gift are published by the Colonial Office, and copies can be obtained on application by letter to the Assistant Private Secretary, the Colonial Office, Downing Street, S.W.

It may be added that, apart from the Government appointments mentioned, a large number of men find employment as medical officers of mining and other companies carrying on their operations in various parts of the tropics. Much caution should be exercised in accepting these appointments, and those to whom they are offered would find it worth while to read what was said on the subject in our issues for May 25th and August 24th, 1912.

In a pamphlet issued under the authority of the Colonial Secretary in September, 1914, it is pointed out that considerable increases have been made in the salaries and allowances attaching to posts in the different grades of the West African Medical Service. As a result of the war, the Colonial Office has found it very difficult to obtain the services of medical men for the colonies which do not possess responsible Governments and for the Protectorates. The improvements in salaries and allowances came into

effect at the beginning of the present year, and will, it is hoped, render these posts more attractive to the young and well-qualified medical men for whom they are intended.

MEDICAL MISSIONARIES.

To medical men suitably endowed the mission field seems to offer increasing opportunities for interesting work. We find that at the beginning of last year over 450 medical practitioners holding British degrees or diplomas were employed in different parts of the world by missionary societies, and the latter seem to stand in constant need of men and women to fill vacancies as they occur, and also to enable them to take advantage of fresh openings. It is not usually expected, or indeed considered desirable, that a medical missionary should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that he should be willing to take his share of definite missionary work in any hospital in which he may be placed, and that he should be adequately prepared for this purpose. As for scientific and other qualifications for the work, a medical missionary, apart from being physically capable of sustaining what may prove to be a trying life, should be a thoroughly well-trained physician and surgeon. It is very desirable that he should have held a residential appointment at a general hospital and have a good knowledge more particularly of practical surgery, tropical medicine, and the treatment of eye diseases. Societies from whom useful information on these subjects can be obtained are the London Medical Missionary Association, 49, Highbury New Park, N.W.; the Edinburgh Medical Missionary Association, 56, George Square, Edinburgh; and the Society for Promoting Christian Knowledge, Northumberland Avenue, S.W.

MEDICAL PRACTICE IN BRITISH COLONIES AND FOREIGN COUNTRIES.

Medical Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are always admissible merely on payment of a fee, provided they produce evidence that they are of good repute and eligible for registration in the United Kingdom. The only exception to this statement that need be made relates to the Dominion of Canada. Until quite recently each of its provinces acted in medical connexions as an independent State, but in 1913 a Medical Act which established a State examination and a common register for the whole country came partly into operation. It could not come into complete operation until each province had amended its existing Medical Act so as to come into line with the new Act. This step is understood to have now been taken by all of them; but it is not clear how far the reciprocity with the United Kingdom previously accorded by all but Ontario and the three Western provinces has been affected. Consequently, any medical man proposing to practise in Canada should first communicate with the Registrar of the Medical Council of Canada, 180, Cooper Street, Ottawa, stating what degrees or diplomas he holds and the length of the curriculum he has undergone, and asking for information as to the precise steps he must take in order to obtain admission to the Dominion Register.

Italy, Egypt, and the Principality of Monaco are the only foreign States which accord a right to practise in virtue of British degrees and diplomas, though the authorities in Spain occasionally issue a temporary permit in favour of British practitioners, and those of Holland and Greece sometimes exempt British practitioners from portions of the examinations imposed on ordinary candidates for registration. In all other Continental countries a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent, while each of the United States of North America has its own laws and regulations; some of them admit any holder of a degree or diploma to their Register, but the majority require a candidate for registration to submit to an examination.

Dental Surgery.

THE profession of dentistry in this country is on the same footing as that of medicine: that is to say, only those who have complied with certain stipulations laid down by the General Medical Council have a legal right to practise dental surgery. This, unfortunately, by no means implies that the practice of dentistry is confined to legally qualified practitioners, for the Dental Acts offer even less protection to dental surgeons than do the Medical Acts to doctors. An ordinary medical man is within his legal rights if he practises dental surgery, but since owing to his lack of the necessary technical training he could not do so with success, dental surgery is in effect legally practised solely by men of two classes—those who hold a qualification both in dental surgery and in medicine and those who hold a qualification in dental surgery alone or have otherwise obtained admission to the *Dentists Register*. The early stages of the education of dental and medical students cover the same subjects, and it is possible to combine the two educations so as to obtain qualification both in medicine and in dental surgery without any very great extension of the time which would be necessary to become a registered medical man alone.

In any case a prospective dental surgeon must obtain registration as a dental student (see p. 355) and thereafter pursue a curriculum which lasts a minimum of four years.

During the last two years, which must be spent at a medical school and hospital, concurrently with attendance at the dental hospital, in addition to studying anatomy and physiology, surgery and pathology, he will include in his work the more specific subjects—namely, dental anatomy and physiology, dental histology, dental surgery and pathology, and practical dental surgery, for all of which he must be "signed up" by the authorities of the dental and medical schools before entrance to the Final Examination for the Licence.

Recognized dental schools are numerous: in London there are those connected with the Royal Dental Hospital, Leicester Square; the National Dental Hospital, Great Portland Street; Guy's Hospital and the London Hospital. In the provinces and Scotland and Ireland there are those connected with the universities of Sheffield, Manchester, Liverpool, Leeds, Bristol, Durham, and Birmingham, and the Devon and Exeter Dental Hospital; the Edinburgh Incorporated Dental Hospital; the Glasgow Incorporated Dental Hospital; the Royal Infirmary, Glasgow; and the Dental Hospital of Ireland, Dublin. As for qualifications in dental surgery, these are almost equally numerous. There are considerable variations in the order in which different licensing bodies require various subjects to be taken up, and every prospective dental student should consequently study not only the regulations of the General Medical Council, but also those of the body whose licence or degree he hopes to obtain.

THE WINTER SESSION IN THE MEDICAL SCHOOLS.

INFORMATION received from the deans of the various Medical Schools in London shows that by October 1st or 4th the work of the winter session will have begun, in spite of the great difficulties created by the absence of so many members of the hospital staffs on military service. At St. Bartholomew's Hospital the opening of the winter term will be marked by no ceremony; there will be no address delivered, and the annual dinner will not be held this year. At Charing Cross Hospital, the opening of the session will be marked by the distribution of prizes and a reception in the college. At St. George's Hospital the general introductory address will not be given and the annual dinner will not be held. The same is true of Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, St. Thomas's Hospital, University College Hospital, and Westminster Hospital. At the London School of Medicine for Women and the Middlesex Hospital introductory addresses will be delivered by Mrs. Willey, M.D., M.S., and John Cameron, M.D., F.R.C.S.

In the rest of England, Scotland, and Ireland, work will have begun by the middle of October. No ceremony will mark the commencement of the term, no general intro-

ductory addresses will be delivered, and no dinner will be held in the Medical Schools at Aberdeen, Belfast, Bristol, Cardiff, Dublin, Edinburgh, Glasgow, Leeds, Liverpool, Manchester, Newcastle-on-Tyne, and Sheffield. At Leeds Sir William Osler, Bt., will deliver an address on October 1st, when term begins.

MEDICAL STUDENTS AND COMBATANT COMMISSIONS.

AT this critical time many medical students will naturally ask what is their immediate duty; should they continue their medical studies and try to qualify as soon as possible, or should they take up military service at once? So recently as last June the Under Secretary of State for War, in reply to a question from Sir Philip Magnus, stated that medical students, even in their first and second years, should be encouraged to continue their medical studies, and not to join the combatant ranks. Since then, however, the position has changed. A letter from his secretary, dated August 11th, gives it as Lord Kitchener's opinion that "it is advisable for medical students in their fourth and fifth years to continue their studies, with a view to qualifying as soon as possible. The War Office would be unwilling to suggest that junior students should be discouraged from taking combatant commissions." Sir Philip Magnus, in a letter to the *Times* of August 27th, points out the scarcity of medical men in a few years' time to which this policy will naturally lead, and he expresses the hope that the younger medical students will not be encouraged, so long as other recruits in sufficient numbers are available, to join the forces of the Crown. The position is very clearly put in the following letter received from Professor Halliburton:

To the Editor of the "British Medical Journal."

Sir,—The following are extracts from a letter I have just received from a medical student on the above subject:

I am writing on behalf of my fellow-students to thank you for all the trouble you have taken. We feel somewhat surprised at the reply you have received from the War Office; for there is a greater demand now for medical men, both military and civil, than there has ever been before, and unless the usual supply of students is kept up I fail to see how they will be obtained, for the longer the war lasts and the larger our army becomes, the more urgent will be the call for medical men. One has to bear in mind that a doctor cannot be trained under five years, so that when those who are now in their final years are qualified, there will be a scarcity for some years to come unless the supply of students is kept up.

The hospitals are now urgently in want of senior students to fill the posts of those who have just become qualified.

In the army we deal with men by the million, so surely the few hundred men who are now engaged studying in different parts of the country for the medical profession would be far more useful if they continued with their own work rather than waste two or three years of their training, for the doctor is quite as essential for the welfare of this country as the soldier or the sailor, and, like the latter, the medical profession must have recruits.

The foregoing appears to me to put the case very clearly and logically. The Government have admitted the mistake they made in the early days of the war in allowing munition workers to go to the front. To-day's papers announce that they are taking measures to prevent a repetition of this mistake in the case of skilled agricultural labourers. Surely the same applies with equal or even greater force to those who are to fill the ranks of the medical profession, the numbers of which are already disquietingly low.

I AM, SIR, YOURS FAITHFULLY,

W. D. HALLIBURTON.

King's College, London, Aug. 27th.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 22, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postage stamps on letters addressed either in initials or numbers.

OBSERVATIONS UPON ACIDOSIS IN DIABETES MELITUS.*

BY
A. P. BEDDARD, M.D., M. S. PEMBREV, M.D.,
AND
E. I. SPRIGGS, M.D.

(From the Physiological Laboratory and Wards of Guy's Hospital.)

DURING the last twelve years investigations upon the question of acidosis in diabetes have been in progress at Guy's Hospital. The chief practical result of the work has been the demonstration that analyses of the carbon dioxide in the alveolar air of the lungs afford an index of the degree of acidosis, and a guide in treatment and prognosis.

When the work began there was current the theory that in diabetes the blood is unable, owing to its diminished alkalinity, to take up the normal amount of carbon dioxide. The pressure of the gas, therefore, rises in the tissues, and the respiratory centre is stimulated to the great activity seen in the typical "air-hunger" of coma. The accumulation of carbon dioxide leads to a cessation of its production, and, according to Pavy, "death takes place when the non-removal has attained a sufficient height to reduce the occurrence of activity to a point which is no longer consistent with the continuance of life." According to this theory, diabetic coma is a condition of narcosis due to carbon dioxide.

Our first series of observations¹ was concerned with the amount of carbon dioxide in the venous blood and the alkalinity of the serum, as estimated by Wright's method. The blood required for the determination of the gases by the mercurial pump was drawn from a vein in the arm by means of an antitoxin syringe which contained a few cubic centimetres of a solution of potassium oxalate. The following tables (I, A, I B) give the results:

TABLE I.—Diabetes without Coma.

Case.	Date.	CO ₂ in Venous Blood; vols. per cent.	Alkalinity of Serum.	Urine in c.cm. per day.	Dextrose in grams.	Nitrogen in grams.	D N	Ammonia Nitrogen in grams.	Percentage Nitrogen as Ammonia.

* After administration of sodium bicarbonate. † See Table II.

Remarks on Table I a.

Case 2.—Female. December 2nd, 1902, sodium bicarbonate intravenously. Died on December 3rd.
Case 11.—C. female, aged 34. Illness began about November, 1902. Died on March 22nd, 1903; bronchopneumonia, hyperpyrexia.

The expenses of this research were defrayed by grants from the British Medical Association and the Royal Society. The work was done during the tenure of one of us (E. I. S.) of the Gull studentship.

Case 24.—T. T., male, aged 31. Wasting and thirst during previous twelve months. Coma began on February 3rd, 1905. Recovered from coma after infusion of sodium bicarbonate. Discharged from hospital July 11th, 1905. See Table IVc.

TABLE I B.—Other Diseases (for purpose of Control).

Case.	Date.	Carbon Dioxide in Venous Blood; vols. per cent.	Alkalinity of Serum.	Remarks.
8	11.ii.03	25.5	N/30	Empyema; dyspnoea on this date.
	17.ii.03	43.0	N/27	
	29.ii.03	41.8	N/27	
10	26.ii.03	51.4	N/25	Ascites, malignant.
12	30.iii.03	43.2	N/25	Pernicious anaemia.

It will be seen from the tables that in the cases of diabetes there is a relation between the alkalinity of the serum and the amount of carbon dioxide in the venous blood; the two rise and fall together without being actually parallel. In the non-diabetic cases, which were taken for the purpose of control, the alkalinity of the serum ranged from N/25 to N/30. According to Wright, the average alkalinity of the serum of healthy subjects corresponds to about N/30 NaOH. As regards the amount of carbon dioxide in healthy venous blood the usual figure is between 40 and 50 volumes per cent. In the first determination in Case 8 there was dyspnoea due to empyema, and this probably accounts for the low value of the carbon dioxide in the venous blood.

These results for diabetes confirm those obtained by Minkowski and Kraus, but they do not prove the correctness of the theory of narcosis due to carbon dioxide. The important question is the tension or partial pressure of the carbon dioxide in the blood and tissues. Attempts, therefore, were made to obtain information upon these points. The capacity of venous blood to take up carbon dioxide was determined in cases of diabetes, diabetic coma, and other diseases. Similar estimations were made for the urine, for it was assumed that the tension of carbon dioxide in the renal cells would not be raised without a corresponding increase in that gas in the urine. The results are given in the following table (No. II).

TABLE II.

Case.	Date.	CO ₂ in Venous Blood; vols. per cent.	Alkalinity of Serum.	Total CO ₂ in blood, vols. per cent.	Saturation Capacity of the Venous Blood for CO ₂ ; vols. per cent.	Saturation Capacity of the Urine for CO ₂ ; vols. per cent.	Disease.

* Sodium bicarbonate had been administered for several days before this date.

In addition, attempts² were made to estimate directly the tension of the carbon dioxide in the venous blood by exposing it in a glass sampler to atmospheres of known composition, and kept in a water bath at 37 (98.6°). After an hour or two the composition of the atmosphere and of the gaseous content of the blood was determined. For the analysis of the gases in the small amount of blood the original form of the apparatus introduced by Barcroft and Haldane was used; the difficulty of taking human blood with the ammoniacal solution rendered the results unreliable. The venous blood from a case (No. 15) of

diabetes without acidosis appeared to have a tension between 5 and 7 per cent. of an atmosphere; whereas venous blood from a case of coma with acidosis and an alveolar pressure of carbon dioxide of 2.29 per cent. absorbed carbon dioxide from an atmosphere containing 4.7 volumes per cent.

It is now necessary to consider the errors which may accompany such determinations as these already given. The serum is not the blood; it is not even a normal constituent of the blood. The alkalinity of the serum is not necessarily the same as that of the blood or the plasma. Blood is both alkaline and acid in the sense that it can combine with acids and alkalis. Physico-chemical investigations upon the relative concentrations of acid and basic ions in blood show that in health its reaction is alkaline to such a slight degree that it may be said to be neutral. The blood is a living tissue, and undergoes changes when it is removed from the body; the gases in the blood are affected, carbon dioxide increases, and oxygen decreases. If the bandage upon the arm delays the flow of the venous blood too much before the sample is withdrawn, more carbon dioxide is taken up by the blood from the tissues, and more oxygen is lost by the blood to the tissues. These sources of error will raise the percentage of carbon dioxide, and tend to make the values too high. The argument, however, based upon the low values will not be minimized by these sources of error, which are further discounted by the observations on the blood in other diseases taken for the purpose of control. The figures given in Table II show that the venous blood from patients in diabetic coma will absorb 200 to 300 volumes per cent. of carbon dioxide at the temperature of the room when pure carbon dioxide is passed through it. Although it is probable from this experiment that the blood circulating in the body of the patient has a great capacity for taking up carbon dioxide, it is necessary to prove it by actual observation. This was done in the following way; by means of a tight bandage upon the arm the flow of the venous blood was stopped for a minute or two before the sample of blood was withdrawn into the syringe. This retardation of the flow caused the blood in the small vessels to be exposed for a longer time to the action of the tissues in which the carbon dioxide is produced. The results, as shown in the following table (No. III) prove that the blood in the body of a diabetic patient has a great capacity for absorption.

Remarks on Table III.

Case 15.—T. M.; diabetes. See Tables I and IV.

Case 22.—D., male; recovering from diabetic coma; alveolar carbon dioxide = 2.7 per cent. See Table IVc.

It was desirable in the next place to determine the tension of the gases of the blood circulating in the body, for, apart from the sources of error in the exposure of blood to known atmospheres, it is not often possible to obtain samples of blood. Moreover, blood withdrawn from a vein in the arm is not a fair sample of the mass of the venous blood. The mixed venous blood from the right side of the heart contains carbon dioxide which has been taken up from the various tissues of the body, and it is probable that the pressure of the gas is below that which obtains at the seat of production. In passing through the lungs the blood gives off carbon dioxide and takes up oxygen; an analysis, therefore, of the air in the alveoli of the lungs will afford an estimate of the pressure of those gases in the arterial blood. The exact value of the estimate will depend upon the nature of this process of gaseous interchange, whether it be one of simple diffusion or whether there be an active secretion inwards of oxygen and an active excretion outwards of carbon dioxide. The

balance of evidence is in favour of diffusion. If such be the process the pressure of carbon dioxide in the alveolar air may be considered to be a little below that of the gas in the arterial blood, and the oxygen would show a reverse relationship. The alveolar air can be obtained by the method introduced by Haldane and Priestley. In these observations a slight modification was made, the last portion of an adequate expiration was collected in a vacuum sampler and, in the case of unconscious patients in coma, a small mask was placed over the face. The results are shown in the following tables (IV, IVA, IVb, IVc).

Remarks on Table II.

Case 23.—B., male, aged 25. Onset of illness about ten weeks before admission to hospital on May 27th, 1904. On July 8th he was given diabetic diet and 90 grams of starch; on the 11th diabetic diet and 50 grams of laevulose. Diabetic diet was also given on July 14th, 19th, and 20th, on the latter date 90 grams of starch being also given. The patient was discharged on July 26th, 1904, in improved condition, and with a gain of 6 lb. in body weight. See also Table V.

Case M.30.—H., female; mixed diet.

Case E.13.—Female; mixed diet.

Case M.130.—L., female.

Case A.47.—C., male. (For details of urinary examination see reference 5.) Over 100 grams of sodium bicarbonate were given on July 19th, 1915, and also on July 20th; from July 22nd to August 6th 25 grams were administered daily; and from August 9th to 19th, 46 grams daily.

* Alkaline.

Remarks on Table IVc.

Case 24.—T. T., male, aged 31. February 3rd, 1905: Onset of disease about twenty months before this date. Diabetic diet was started on January 27th, 1905. Coma began; infusion with solution of sodium bicarbonate.

February 4th: Infusion continued.

February 5th: Venous blood contains 18.9 vols. per cent. of carbon dioxide.

February 7th: Patient conscious. β -oxybutyric acid (Ryffel's method) = 9.8 grams.

February 8th: Venous blood contains 32.6 vols. per cent. of carbon dioxide. β -oxybutyric acid = 8.9 grams.

February 21st: Abscess formed at site of infusion. β -oxybutyric acid = 8.5 grams.

March 13th: β -oxybutyric acid = 11.9 grains. Sodium bicarbonate and carbolydurate given in diet.

The patient was discharged on July 11th, 1905, much improved.

Case 22.—D., male, aged 45. Illness began about October, 1905. Diabetic diet began on June 9th, 1904; coma threatening (see Table III).

June 14th, 1904: Diabetic diet.

June 15th: Diabetic diet; body weight 52 kilos.

June 17th: Diabetic diet; alveolar air after holding breath for twenty-five seconds = 3.55 per cent. CO₂ and 13.92 per cent. O₂.

June 24th: Diabetic diet.

July 27th: Diabetic diet, with 65 grams of starch and 42 grams of sodium bicarbonate. Weight of patient 54 kilos.

July 1st: Diabetic diet and 90 grams of starch.

July 7th: Fifth day of diabetic diet and 56 grams of sodium bicarbonate. Weight of patient 56.5 kilos. On this day 90 grams of starch and 25 grams of sodium bicarbonate given.

July 9th: Diabetic diet, with 50 grams of laevulose and 14 grams of sodium bicarbonate.

July 16th: Sixth day of diabetic diet. Alveolar air after holding breath for twenty-five seconds = 4.61 per cent. CO₂ and 13.4 per cent. O₂.

The patient died on August 13th, 1904, from pneumonia.

For the better understanding of the foregoing tables it is necessary to give the average values for the composition of the alveolar air of healthy subjects. The means of fifty observations upon ten men are 5.57 volumes per cent. of carbon dioxide and 14.89 of oxygen; the maxima are 6.11 and 15.59, the minima 4.87 and 13.91. In women and children the mean alveolar pressure of carbon dioxide is, according to Fitzgerald and Haldane, about 8 per cent. lower than in men.

Diabetic patients may have alveolar pressures of carbon dioxide, which are within the normal limits, although they are passing large quantities of sugar in the urine. When there is acidosis the carbon dioxide falls and in diabetic coma reaches as low a figure as 1 or 2 volumes per cent. If under treatment with sodium bicarbonate the patient recovers, the pressure of carbon dioxide may gradually rise to the normal level, as is well shown in Case No. 22. Moreover, in diabetic patients massive doses of sodium bicarbonate may raise the pressure to a height beyond the normal range; this is shown by the observations on Case A.47 in whom the highest figure was 6.99 volumes per cent.

To determine more closely the conditions as regards the carbon dioxide, observations were made upon the composition of the alveolar air before and after the patient had held his breath as long as he could.

* Healthy man. † Recovering from diabetic coma (see Table IVc). ‡ Diabetes (see Table IV).

The "breaking point" on holding the breath was determined by the discomfort, which, as observations on healthy men show, is produced by the accumulated carbon dioxide rather than by the fall in the amount of oxygen. In these patients the pressure of carbon dioxide was raised, but in no case did it reach normal figures. This result indicates that other substances, in addition to carbon dioxide, were stimulating the respiratory centre. The low values in the patient recovering from coma would suggest that it is due to the condition of acidosis. If this interpretation be correct it would be expected that the pulmonary ventilation would not correspond with the pressure of the alveolar carbon dioxide. The amount of

air breathed by a patient was determined by means of a mask provided with inspiratory and expiratory valves and connected with a meter of low resistance. The following table (VI) shows that the volume of air breathed was greatest when the pressure of the alveolar carbon dioxide was least.

TABLE VI.

Case.	Condition.	Date.	Alveolar Air.		Volume of Air Breathed per Minute in Litres at 15°.	Respirations per minute.
			Carbon Dioxide, vols. per cent.	Oxygen, vols. per cent.

	Recovering from coma	7.ii.05	3.21	17.27	3.75	18 18
	Recovered from coma	14.iii.05	4.62	15.31	5.3 5.2	20 20

* See Table IVc.

Soon after the first observation the comatose patient was given to breathe a mixture containing 3.9 volumes per cent. carbon dioxide and 18.42 volumes per cent. oxygen; the volume breathed was 8 and 10 litres with 22 and 20 respirations per minute; the pulse became more forcible, although not increased in rate, and a tendency to struggle complicated the result. Ten days later, when the patient had recovered from coma, the ordinary volume of air breathed, 5.3 litres, was increased to 7.65 and 8 litres in two consecutive minutes, when he inspired a mixture containing 5.92 volumes per cent. carbon dioxide and 20.08 volumes per cent. oxygen. The mixture made him breathe more deeply at a rate of 14 and 15 respirations per minute, and the alveolar air taken directly after contained 5.46 volumes per cent. carbon dioxide. The patient himself said that the gas caused a feeling of suffocation.

To remove any effects due to a decrease in the amount of oxygen further observations were made upon the same patient. The alveolar air contained 3.19 volumes per cent. carbon dioxide and 16.89 oxygen on February 21st, 1905; the patient then breathed in and out of a big gas-bag containing 5.78 volumes per cent. carbon dioxide and 24.45 oxygen until his breathing became much deeper. A sample of alveolar air taken directly after contained 4.83 volumes per cent. carbon dioxide, and 52.67 oxygen and the bag 5.82 carbon dioxide and 29.03 oxygen. On the same day the patient breathed in and out of a small bag of oxygen until his breathing was deeper; a sample of his alveolar air was then taken for analysis; it contained 3.96 volumes per cent. carbon dioxide and 39.58 oxygen and the bag 0.82 volumes per cent. carbon dioxide and 77.21 oxygen. The first of these observations shows that the blood in the lungs absorbed carbon dioxide from the mixture when the pressure of that gas was above that present in the patient's ordinary alveolar air (3.19 volumes per cent.). The tension of the gas in the arterial blood was probably between 3 and 4 per cent. of an atmosphere. This was confirmed by the second observation; the breathing became deeper when the alveolar carbon dioxide was raised to 3.96 per cent. by rebreathing. In both cases the oxygen was present in great excess.

A large number of observations have been made upon the composition of the urine at different stages of the disease and under various methods of treatment. Only a few of the data have been given in this paper. The total respiratory exchange was determined in only one case, and further observations are necessary before it would be possible to discuss the significance of the respiratory quotients contained in the tables. The research has been continued and extended by Dr. Poulton, who is communicating some of his results in this number of the JOURNAL.

THE SIGNIFICANCE OF ALVEOLAR CARBON DIOXIDE DETERMINATIONS IN THE TREATMENT AND PROGNOSIS OF DIABETES.*

By E. P. POULTON, M.A., M.D. OXON.,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL; BEIT MEMORIAL
RESEARCH FELLOW.

(From the Physiological Department and the wards of Guy's Hospital.)

THE study of the phenomena of respiration was put on a firm basis when Haldane and Priestley⁷ introduced a simple and accurate method of obtaining samples of air from the alveoli of the lungs. By this method Beddard, Pembrey, and Spriggs^{1,2} first showed that in diabetes the partial pressure of the carbon dioxide in the alveolar air falls with increasing acidosis, and during coma reaches a very low point, and when low can be raised by the administration of sodium bicarbonate.

The true explanation of these facts is based on the theory of neutrality regulation—that is, the power of the organism to preserve the neutral or very slightly alkaline reaction of its arterial blood at a nearly constant level. In diabetes where there is an increased production of unusual acids at least three mechanisms are brought into play to counteract their effects:

1. The acidity of the urine is increased.
2. There is an increased formation of ammonia.
3. The partial pressure of CO₂ in the alveolar air is lowered.

It is the last factor which is particularly important in the present connexion, and which has only lately been realized, owing to the work of Haldane, Barcroft, and Hasselbalch.

The venous blood gives off into the alveoli of the lungs its excess of CO₂, and this is prevented from accumulating by the respiratory ventilation. In health the latter is so adjusted that the percentage of CO₂ remains at a constant value, between 5 and 6 per cent. The arterial blood leaves the lungs saturated with CO₂, corresponding to its partial pressure in the alveoli. By the simple expedient of increasing the pulmonary ventilation the percentage of CO₂ in the alveolar air will be diminished without necessarily altering very much the actual quantity given off by the lungs, which depends on the body metabolism. Inasmuch as the alveolar CO₂ is lowered by this means, the amount contained in the arterial blood will be diminished, that is, the arterial blood will become more alkaline.

In diabetes, when the acidosis is severe, the respiratory centre is stimulated by excess of acid, so that the pulmonary respiration is increased, and the diminution of CO₂ in the arterial blood compensates for the quantities of aceto-acetic acid and β-oxybutyric acid in the circulation. Hence the amount of CO₂ in the alveolar air changes inversely as the amounts of these unusual acids present, and thus it can be taken as a measure of the acidosis.

The original observations of Beddard, Pembrey, and Spriggs were carried out on 13 patients. These included 6 fatal cases of diabetic coma, which gave very low values for the alveolar CO₂, namely, about 1 to 2 per cent. The 7 cases which were not fatal showed acidosis of varying intensity; the alveolar CO₂ pressures were normal in the 3 mild cases, that is, 5 per cent. and over. In the 4 remaining cases, the values ranged between 2 per cent. and 5 per cent., depending on the severity of the acidosis.

Porges, Leimdorfer, and Markovici¹² published results somewhat similar in 1910. The method used was that described by Plesch. The patient breathes backwards and forwards into a small rubber bag for about 30 seconds. The air in the bag is then analysed. This method certainly does not give true alveolar values; the CO₂ is too high. As a matter of fact, the results correspond to the CO₂ pressures in the venous blood; whereas the true alveolar air is the gas in equilibrium with the arterial blood.

These authors have been given the credit of being the pioneer workers in this field of inquiry.¹³ They even claim the priority for themselves,¹³ as they dispose of Beddard, Pembrey, and Spriggs's work by saying that they only investigated the carbon dioxide pressure in diabetic coma.

* The expenses of this investigation were defrayed by a grant from the British Medical Association.

They add, "In four diabetics who were not comatose they (Beddard, Pembrey, and Spriggs) obtained in opposition to our findings, absolutely normal CO₂ pressures." A true examination of Beddard, Pembrey, and Spriggs's published figures, summarized just above, shows that this statement is absolutely incorrect. These authors established all the facts concerning the behaviour of the alveolar CO₂ in diabetics, and published them before the Viennese authors started working at the subject at all.¹⁴

Straub¹⁵ and Fridericia,⁵ and Kennaway, Pembrey, and Poulton,¹¹ using the Haldane-Priestley method, quite recently published results which confirm the original observations of Beddard, Pembrey, and Spriggs.

A brief examination of all these results makes it quite obvious that the method of measuring the alveolar CO₂ should become of the greatest importance in estimating the acidosis in the severer types of diabetes, and it has been regularly employed for this purpose during the last year and a half at Guy's Hospital.

In all the results so far published the alveolar air has been analysed by means of some type of gas analysis apparatus. Such an apparatus is only suitable for the laboratory; for clinical work it is essential to have some simple method of analysis. Collingwood and Buswell⁸ have described a simple apparatus which has given satisfactory results in the hands of students.

Fridericia⁶ has introduced a modification for clinical work which makes the operation even simpler, and possesses the additional advantage that after the CO₂ has been absorbed the percentage amount can be read off, without any calculation at all being necessary.

This method of Fridericia's seemed at first sight to be the most satisfactory means of obtaining and analysing the alveolar air for clinical purposes. Experience has borne this out fully. It is an extremely simple instrument to use. The results obtained are surprisingly accurate, considering that it is purely a clinical instrument.

The object of this paper is to describe Fridericia's instrument in some detail and to bring forward observations on several diabetics which will indicate the importance of alveolar CO₂ determinations as a guide to prognosis and treatment, and to show at the same time that the instrument gives trustworthy results. The actual dimensions of the instruments used in these investigations have been chosen by the writer with a view to combining accuracy and practicability.

Fridericia's Carbon Dioxide Tensimeter.

This instrument is shown in the figure. X is the mouth-piece through which the patient blows; A is an ordinary two-way tap of wide bore;

B is a three-way tap so arranged that (1) X and Y can be put into communication with one another through a channel of wide bore, C being shut off (Position I), (2) by turning the tap through 90 degrees Y is made to communicate with C, X being shut off (Position II), or (3) by turning the tap through another 180 degrees, X communicates with C, Y being shut off (Position III). The volume of X between the taps A and B, including the wide bore of B, is 100 c.c.m., and percentages of this volume up to 7 per cent. are marked on the narrow stem of X.

The subject whose alveolar air is to be analysed must sit quietly in a chair and breathe naturally, holding the apparatus in front of him with the tap A open and B in

The subject whose alveolar air is to be analysed must sit quietly in a chair and breathe naturally, holding the apparatus in front of him with the tap A open and B in

Position I. After taking a normal inspiration he puts the mouthpiece into his mouth and blows as hard and as quickly as possible through the apparatus, thus washing out the whole apparatus and leaving it filled with alveolar air; the tap A is at once closed, and the whole apparatus is placed in a pail of water for five minutes. By this means the alveolar air in X and Y is cooled to a temperature which remains constant throughout the experiment, and the contraction in volume will cause the alveolar air in the lower part of Y to be drawn back into X, and any diffusion with the outside air at the top of Y will not reach down to the bottom of the tube owing to its length. At the end of five minutes the tap B is turned into Position II. By this means we have in X 100 c.c.m. of alveolar air at atmospheric pressure, and at the temperature of the water in the pail, which remains constant throughout the experiment.

The apparatus is now removed from the water, a rubber ball is fitted over the end of X, and the tube C is placed beneath some 10 per cent. caustic soda in a porcelain dish, and, by squeezing and releasing the rubber ball, soda is sucked up into Y; B is then turned into Position I, and the soda forced into X by squeezing the ball. During this operation the instrument is held with Y rather depressed, so as to prevent any small bubbles of air from escaping from B along the tube Y; B is at once turned back into Position II, and the remainder of the potash in Y forced out again at C. The vessel is turned up and down several times, and all the CO₂ is absorbed; half a minute is sufficient for this.

The instrument is then put back into the pail of water, which rises through C into X; B is then turned through 180 degrees into Position III. The apparatus is left in the water for five minutes to equalize the temperature. It is then raised rapidly until the level of the water in the pail is the same as that in the narrow tube X. The gas in X will now be at the same pressure and temperature as before. The reading of the bottom of the meniscus of the fluid in X is taken, and this represents without any further calculation or correction the percentage of CO₂ in the alveolar air.

Before the apparatus is put away it should be completely freed from alkali by washing out with water and dilute acid.

It has been pointed out that when any one breathes out forcibly through a tube, the expired air travels along the axis of the tube and tends to leave the air at the sides unmixed. Obviously this fact will not produce any perceptible error in this clinical instrument, as the volume of the instrument is only 100 c.c.m. and the volume of a forced expiration is 2 litres, which is sufficient to wash out the whole apparatus several times over. This fact can also be observed experimentally by filling the instrument with tobacco smoke and noticing how long it takes for the smoke to be expelled on forcibly breathing out through the tube. The smoke disappears almost instantaneously.

The accuracy of the instrument has been tested on several occasions by performing duplicate determinations with the apparatus and with the Haldane-Priestley method, or the modification of this method described by Hasselbalch and Lindhard;⁹ the latter is an excellent method for use with patients.

The following results have been obtained. The Haldane-Priestley method is so well known that it requires no description here.

Subject.	Fridericia's CO ₂ Tensimeter. Sample Obtained after Normal Inspiration.	H.-P. Method after Normal Inspiration.*
E. P. P.	5.4 5.6 5.35 average 5.15	5.50 5.20 5.10 average
A. B.	5.6 5.5 5.8 6.1 average 5.7 6.0	5.54 5.33 5.28 average 5.69

* Throughout this paper the CO₂ pressures are given in percentages of the dry alveolar air. The actual pressures of CO₂ in the lung alveolar air are a little lower because the alveolar air is saturated with moisture at 37°C. (the body temperature). For purposes of comparison in clinical work at sea level, it is unnecessary to apply this correction.

* This apparatus can be obtained from Siebe, Gorman and Co., 187, Westminster Bridge Road, London, S.E.

The results obtained by the clinical method agree quite well among themselves; but with these two subjects the mean result is slightly higher than the results obtained by the H.-P. method after a normal inspiration. They seem to approximate towards the mean alveolar CO₂ pressure, which is calculated by Haldane by taking the mean of end-inspiration and end-expiration samples. This is probably due to the fact that it takes a little longer time to breathe out through the instrument owing to the slight resistance of the taps. Hence the CO₂ has a little longer time in which to accumulate in the lung alveoli.

On many occasions the clinical method has been compared with the Hasselbalch-Lindhard modification, which is carried out as follows: The patient is told to breathe absolutely quietly into a closely-fitting mask, having inspiratory and expiratory valves attached to it. Towards the end of each expiration a minute quantity of air is withdrawn from just in front of the lips and nose of the patient. The small samples are collected together over mercury, and analyzed by a Haldane's gas analysis apparatus.

It is of course necessary to be certain that the patient is breathing sufficiently deeply to wash out all the dead space completely at each breath.

The very close agreement of the results obtained by this method can be seen from Hasselbalch's own figures.⁵ It is particularly suited to cases of diabetes, as the tidal air is larger in volume than usual in serious cases, and the results are usually very concordant. Unfortunately, the use of some form of gas analysis apparatus is essential, which at once limits its use to the laboratory.

It is the great advantage of Fridericia's instrument that the whole analysis is made as simple as the ordinary urea determination in urine. However, the instrument cannot be used when the patients are actually comatose. Under these circumstances it is best to use the Hasselbalch-Lindhard method.

Diagram I shows the effect of a rigid diabetic diet on the alveolar CO₂ of a perfectly healthy individual. It also affords a comparison between the results obtained by the

tendency to take a deep inspiration before making the forced expiration. This is the natural thing to do, and it requires some patience to get the subject to take only a normal inspiration before blowing out. The result of this error is to dilute the air in the lungs abnormally, just before the sample is obtained, and so the values are too low. In the second place the subject, after correcting the first error, is apt to hold his breath before making the forced expiration. This makes the results too high. Of course, these errors may also be present in the Haldane-Priestley method, especially when the subject has had but little practice. The magnitude of these two errors is shown by the following figures:

Subject E. P. P. (Clinical Method Used.)

	Percentage of CO ₂ .	
Normal alveolar samples	5.6	5.8
Alveolar samples immediately after taking a large inspiration	4.9	4.9
Alveolar samples after holding the breath for five seconds	6.5	6.2

Alveolar CO₂ Pressures in Diabetes.

Before considering the values of the alveolar CO₂ pressure in diabetes it is necessary to state what variations occur in normal individuals. The following figures were obtained by Fitzgerald and Haldane,⁴ using the Haldane-Priestley method, and they will serve as a standard for comparison in pathological cases.

	Number of Individuals Examined.	Maximum CO ₂ per Cent. of the Series.	Minimum CO ₂ per Cent. of the Series.	Mean CO ₂ per Cent.
Men ...	27	6.25	4.58	5.51
Women ...	32	5.76	4.26	5.10
Boys ...	16	5.92	4.30	5.21
Girls ...	11	5.62	4.37	4.94

As a contrast, the following table shows the values obtained by the writer in diabetic coma; the Hasselbalch-Lindhard method was mostly used.

	Age.	CO ₂ per Cent.	CO ₂ Pressure in mm. Hg Corrected for Pressure of Aqueous Vapor.
W. B. ... Man	35	0.86	6.9
P. S. ... Man	22	1.23	8.8
J. O. ... Man	47	2.49*	17.8
E. S. M. ... Man	24	1.01	7.3
M. N. ... Woman	47	1.51	10.8
R. S. ... Woman	61	2.13	14.1
B. K. ... Woman	40	1.66	11.7
E. H. ... Woman	61	1.14	8.1

* Shortly before death, patient not actually comatose.

Diagram I.—Dr. G. G.

Notes on Diagrams.—O denotes alveolar CO₂ determination by the Hasselbalch-Lindhard method. ● denotes alveolar CO₂ determination by Fridericia's clinical method. C denotes the onset of coma. In Diagram IV and in Diagram VII (case P. S.), and in Diagram VIII (cases L. W., W. B.), the alveolar CO₂ determinations were made by the Haldane-Priestley method, the actual samples in coma being taken by means of a mask and valves.

clinical and the H.-L. methods respectively. They agree very closely. It will be noticed that the acidosis produces a perceptible lowering of the CO₂ after thirty-two hours. This reaches a maximum in the next twenty-four hours and diminishes again towards the end of the next two days. Straub has pointed out that the alveolar CO₂ in mild diabetes behaves in a similar manner if the patient is put on a rigid carbohydrate-free diet.

On many other occasions in diabetic subjects the clinical method and the H.-L. method have been compared (see Diagram IX especially). The result is usually quite satisfactory. On the whole there is a tendency for the clinical apparatus to give the lower value, again approximating towards the mean alveolar CO₂ pressure, as it has been pointed out by Hasselbalch that his method gives results identical with end-expiration samples of the Haldane-Priestley method.

However, there are two errors in the Fridericia method that must be guarded against. In the first place there is a

The alveolar CO₂ pressures of the various cases of diabetes examined are shown in the Diagrams II to IX. Every single observation made has been plotted on these diagrams. This plan has the advantage of showing the trustworthiness of the method. It will be noticed that occasionally values were obtained which were obviously incorrect, because they lie a long way away from the curve in the particular case. In Diagram VI, for instance, two of these fallacious results are seen; one of them was proved to be incorrect by carrying out two concordant determinations by the Hasselbalch-Lindhard method at the same time. It is obviously necessary to treat the results with a certain amount of discrimination and reject those obviously wrong. It would probably be safest to do duplicate determinations in a case seen for the first time. However, these obviously erroneous results are not met with very often.

These cases of diabetes fall roughly into two groups; in

one the acidosis was mild and the alveolar CO₂ pressures were normal; in the other the alveolar CO₂ pressures were diminished and these cases usually terminated fatally.

Diagram II.—H. S., aged 44.

The mild cases (Diagrams II to IV) consisted of 5 patients, all men. In each case the amount of carbohydrate in the diet was restricted. In spite of this, in the

Diagram III.—R. E., male, aged 45.

case of H. S. the sugar excretion was roughly 8 oz. a day (227 grams), while in the case of R. E. it had practically disappeared after a fortnight. Acidosis was slight in all cases. The alveolar CO₂ was in the neighbourhood of 5 per cent. It is noteworthy that, in two cases—C. G. M. and R. E.—investigated soon after admission, the alveolar CO₂ was distinctly low—that is, 4.2 per cent. in each case (mean of two determinations), and rose subsequently. In the case of R. E., this low value was associated with a slightly raised ammonia index—namely, 7.7 per cent. It is a well-known fact that diabetics often become comatose very soon after admission into hospital, whether due to the excitement of the journey or their unusual surroundings. Probably, in these two cases, the abnormally low CO₂ values were due to the same cause, the acidosis subsequently disappearing. In the case of A. J. T. there was no obvious diminution in the CO₂ pressure on admission.

The next two cases (Diagrams V and VI) are of special interest, as the patients sometimes exhibited a mild degree of acidosis, with a normal alveolar CO₂, whereas at other times the acidosis became severe, and the

alveolar CO₂ pressure

¹⁰ It has been pointed out by Hurlley that the nitro-prusside reaction is a far more delicate test for aceto-acetic acid (diacetic acid) than for acetone. In fact, in acidosis there is probably very little acetone present if the urine is fresh. This fact has been taken into account in this paper. The strength of the nitro-prusside reaction has been used in drawing inferences as to the presence of smaller or larger amounts of aceto-acetic acid.

F. R., a boy aged 11 years, was a marked example of this kind. For about a month the alveolar CO₂ consistently gave normal values of about 5 per cent. On March 23rd a

Diagram IV.

steady decline in the CO₂ began. For ten days remarkably constant values of 3.8 per cent. were obtained, and then the patient went rapidly downhill and died in coma. This decline was associated with a very marked aceto-acetic reaction and ammonia excretion, and with a rise in the output of sugar.

The case of B. R., a woman aged 42, was of particular interest as showing the value of the method from the point of view of prognosis. When admitted she was drowsy, and had severe headache. The ammonia index was 14 per cent.—that is, distinctly raised. Coma was thought to be imminent. Alveolar determinations, however, gave values ranging from 4.4 per cent. to 5.2 per cent. A good prognosis was given, and she rapidly improved. The carbohydrate in the diet was restricted, but the acidosis remained very slight until February 26th, when she had a bilious attack, accompanied by abdominal pain and vomiting. Acetone was smelt in her breath, and she was thought to be going into coma. In fact, when the writer went to make the alveolar determination, he was told that the case was hopeless. However, the CO₂ was

Diagram V.—F. R., male, aged 11.

Diagram VI.—B. R., female, aged 42.

found to be 3.7 per cent., and again a hopeful prognosis was given. On the next day it had risen to 4.6. Undoubtedly the acidosis had been suddenly increased by the bilious attack, but, as the alveolar analysis showed, the acidosis was not sufficient in amount to indicate the immediate onset of coma. The patient was eventually discharged feeling much better.

Diagrams VII and VIII show the results obtained from analyses on patients who all died in coma.

P. S., a man of 22, is a particularly instructive case. It was one of the earliest of the series to be investigated. On admission he was not looked upon as one of the

S. S., female, aged 22. P. S., male, aged 22.*

Diagram VII.

gravest cases. Only 0.8 oz. (23 grams) of sugar was being passed, though the aceto-acetic reaction was marked. He was feeling perfectly fit. His alveolar CO₂, however, gave a value of 3.8 per cent., which is considerably below the minimal value for a healthy adult. The carbohydrate in his diet was reduced to 80 grams per diem; it was further reduced to 23 grams eight days later, and he began to get up and walk about, still feeling quite well. Three days later the alveolar CO₂ began to diminish. On July 7th

E. S. M., male, aged 24. L. W., male, aged 40. W. B., male, aged 35. M. N., female, aged 47. R. H., female, aged 24.

Diagram VIII.

the pressure was 2.5 per cent., and coma started shortly afterwards.

The other 6 cases do not require separate description, but it is noteworthy that in most of them abnormally low values were obtained several days before the onset of coma. Thus with S. S., E. S. M., and R. H. values of about 3 or 4 per cent. were obtained two days before the onset of coma, while the values just before coma were under 2 per cent.; at this stage typical air hunger was present.

The case of J. O. (Diagram IX) merits a rather fuller

Diagram IX.—J. O., male, aged 47.

description. His was a different type of case in several particulars. He was lipaemic, the blood containing fat in a finely divided state, and he retained consciousness to the end, although the breathing was obviously somewhat increased. The most noticeable thing about the CO₂ chart is its extreme irregularity; in one occasion the pressure

varied from 5 to 2.5 per cent. in the course of two days. To make sure that these variations were real, and not simply due to errors of experiment, the Hasselbalch-Lindhard modification was also used on January 22nd to 30th. The values obtained by these two methods correspond well together, the H.-L. values being usually somewhat higher for the reason already explained. The patient was given large doses of sodium bicarbonate every day, and at one time there was some temporary oedema.

Discussion of Results.

The object of alveolar CO₂ determinations is to measure severity of acidosis. Hence it is useless to apply the method when the urine, in a case of diabetes, gives a negative result with the nitro-prusside test. Under these circumstances the alveolar CO₂ pressure will always fall within normal limits. However, when the urine contains acetone bodies, it is usually impossible, from the nitro-prusside or ferric-chloride tests alone, to say how severe the acidosis is. In any of these cases the alveolar CO₂ pressure is a sure guide.

By its means cases can readily be divided into two categories: (1) *The mild cases*, where the alveolar CO₂ pressure falls within normal limits; in these cases the prognosis with regard to coma is relatively good. (2) *The severe cases*, where the alveolar CO₂ is definitely lower than normal; here the utmost care must be taken to prevent the onset of coma. All the time the CO₂ is below normal the patient is, as it were, on the edge of a precipice, and any disturbance, such as sudden excitement or worry, or the administration of too rigid a diet, may push him over the edge.

In these cases the actual CO₂ pressure observed will give the measure of the danger. A value of 2 per cent. means that coma may supervene within twenty-four hours. A value of 3 per cent. or 4 per cent. is less dangerous; in the worst event, coma will not come on for at least two or three days.

A sudden drop in the alveolar CO₂ is also of significance; it means that acidosis is increasing, and, though the immediate danger may not be great, there is always the possibility of a further increase until coma sets in. The cases E. S. M., L. W., and P. S., all of whom died in coma, illustrate this point. This sudden drop in the CO₂ pressure may be unaccompanied by symptoms, such as drowsiness, abdominal pain, or air-hunger; for these only appear when the CO₂ reaches a very low value—that is, about 2 per cent. Hence the alveolar CO₂ gives by far the earliest warning of approaching danger.

Again, it is possible to be misled if reliance is placed on symptoms alone, without determining the alveolar CO₂, because it not infrequently happens that the rapid onset of coma may be suspected from symptoms, even when the alveolar CO₂ still remains relatively high. Case B. R. illustrates this point. On two occasions—namely, December 8th and February 26th—coma was suspected from her symptoms, but the alveolar CO₂ was too high for her drowsiness, etc., to be really due to oncoming coma, and the patient improved.

Of course, it does not necessarily follow that the chance of averting coma is hopeless because a very low CO₂ pressure is obtained. It may be kept off for a considerable time by judicious treatment. In the case of J. O. death did not occur for a month, in spite of several very low CO₂ results. Boddard, Pembrey, and Spriggs have published similar cases.

There are various other methods commonly employed for measuring acidosis in diabetes, such as estimating the amount of ammonia or total acetone in the day's urine. The disadvantages of these methods are the labour involved in the determinations and the fact that it is necessary to get the patient to collect his urine for a period of twenty-four hours. However, the greatest disadvantage of all is that it is impossible to obtain the result at once. This is especially the case if the patient is being seen for the first time.

A device for overcoming this difficulty is to determine the ratio of the ammonia nitrogen to the total nitrogen in a specimen of urine. This ratio, the so-called ammonia index, is usually about 3 per cent. or 4 per cent. in health;

in severe acidosis values of about 12 per cent. to 30 per cent. are obtained. These analyses, of course, take some little time to perform, and they are essentially methods for the laboratory; but even so, the results are apt to be uncertain, because the total amount of protein consumed by the patient is unknown.

It would be possible to draw quite incorrect conclusions from this ratio in some cases. For instance, in the case of B. R., on February 26th, when she had a sharp attack of vomiting accompanied by drowsiness, the ratio was 13 per cent. This might suggest coma, but it has been pointed out from the alveolar CO₂ results that coma was not imminent. Again, in the case of R. H., on March 12th, while the ratio was only 6.4 per cent., the alveolar CO₂ on the next day was 2.7 per cent., and coma came on the day after; and even when the patient was actually comatose the ratio had only risen to 10 per cent.

The great advantage of the alveolar CO₂ pressure is that it affords a measure of the actual acidosis of the blood at the time of the observation. Its sensitiveness as an indicator depends on the sensitiveness of the respiratory centre to changes in hydrogen ion concentration of the arterial blood. This sensitiveness is very high.

On the other hand, an increase of substances excreted in the urine does not necessarily mean an increased production of these substances in the organism; it may mean increased excretion alone. The two processes, production and excretion, do not necessarily run parallel to one another. Suppose sodium bicarbonate is given to a diabetic in a state of acidosis, the excretion of acetone bodies may be increased, their production in the body remaining the same; hence the actual acidosis of the blood will be diminished, whereas, from an analysis of the urine alone, the erroneous conclusion would be drawn that the acidosis had increased.

Apart from this theoretical advantage, alveolar CO₂ determinations by the tensimeter method present many practical advantages. The apparatus is easy to use. It can be readily carried about from case to case. The method requires but little practice. The results are of a high degree of accuracy, and they are of the greatest significance in the treatment and prognosis of diabetes; in fact, to any one who has once used the method it would appear absolutely impossible to treat satisfactorily a severe case of diabetes without it.

The writer's thanks are due to his colleagues on the medical and surgical staff of Guy's Hospital for allowing him to investigate the cases under their care, and to Mr. J. H. Ryffel for letting him quote extensively the urine analyses made by him, and to Mr. J. F. Venables, who kindly undertook some of the observations when he was away.

Clinical Notes on Cases.

H. S., a porter aged 44, was admitted January 23rd, 1914, and discharged March 18th. He had been in Guy's Hospital five years previously with diabetes. He subsequently had jaundice and was operated on for gallstones. Chronic pancreatitis was diagnosed. Three months previous to admission he noticed wasting, and also that he passed a large quantity of urine. He had some bronchitis. A test meal showed hyperchlorhydria. While in hospital carbohydrate was restricted to 120 grams per diem. He was given 3 oz. olive oil per diem in addition to his diet. He passed about ½ lb. (227 gms.) of sugar daily, but put on 4 lb. in weight during his stay. Most of the time the amounts of aceto-acetic acid were present in the urine. The alveolar CO₂ remained between 5 and 6 per cent.

R. E., a postman aged 45, was admitted February 12th, 1914, and discharged March 3rd. He had a gonorrhoeal orchitis. He had had rheumatism. He became ill five weeks previous to admission, and had since lost 32 lb. in weight. Treatment while in hospital—carbohydrates 142 grams, sodium bicarbonate 6 grams per diem. His weight remained about the same as that is, 11 st. He passed about 3 oz. (85 grams) of sugar at first; this gradually diminished, and finally only traces were passed. Aceto-acetic acid disappeared after ten days. The ammonia index was 7.7 per cent. on admission. This was associated with an alveolar CO₂ of 4.2 per cent. The alveolar CO₂ subsequently rose and remained about 5 per cent.

C. G. M., a boy aged 19, was admitted March 12th. He was given a strict diabetic diet with acetone in starvation days. He had sodium bicarbonate 6 grams per diem. Aceto-acetic acid present. Sugar about 1 oz. (28 grams) per diem. Alveolar CO₂ about 5 per cent.

A. S., a man aged 30, admitted March 11th, 1913, discharged May 22nd. He had peripheral neuritis and an enlarged liver. Diet, strict diabetic. Aceto-acetic acid present. Sugar about 1 oz. (28 grams) per diem. Alveolar CO₂ 5 per cent.

A. J. T., a man aged 64, admitted January 6th, 1913, discharged February 6th. He had peripheral neuritis. Diet, etc.: Carbohydrate 57 grams, olive oil ½ oz. per diem. Traces of

aceto-acetic acid present. Sugar excreted about 4 oz. (113 grams) per diem. Alveolar CO₂ 5 per cent.

F. B., a schoolboy aged 11 years, was admitted February 2nd, 1914, and died March 20th, 1914. There was a month's history of hunger, thirst, and frequent micturition. On admission apart from his diabetes he was normal. Carbohydrates were restricted to 102 grams. Total caloric value of diet, 2,150; sodium bicarbonate 21 grams per diem. The sugar remained about 110 grams, but rose to 250 grams towards the end of February. Aceto-acetic reaction marked. Ammonia N, 1 gram per diem. Alveolar CO₂ about 5 per cent. On March 2nd carbohydrate in the diet was increased to 175 grams including a small quantity of cane sugar. Subsequently the amount of sugar in the urine increased to about 300 grams; the aceto-acetic reaction increased and the ammonia nitrogen output increased to 3.2 grams. The alveolar CO₂ remained fairly constant at 3.8 per cent. from March 5th to 14th; it then sank in three days to 2.2 per cent., and the patient subsequently died in coma. *Post mortem*: Pnecrosis small (28 grams).

B. R., a woman aged 42 years; admitted December 6th, 1913; discharged March 18th, 1914. She had neuritis in the legs. On admission she was drowsy, and had headache. Her limbs were painful and wasted; the aceto-acetic reaction was marked. The ammonia index 14 per cent.; alveolar CO₂ 4.8 per cent. Diet: Carbohydrates 88 grams, protein 126 grams, olive oil 3 oz.; total caloric value, 2,259. On February 2nd a period of restricted protein intake was begun: protein 46.3 grams, carbohydrates 40 grams per diem; caloric value, 2,502. On February 23rd the diet was relaxed. On February 26th the patient became very sick, vomiting bile-stained fluid. She had abdominal pain. Acetone was smelt in the breath. The urine contained albumin and much aceto-acetic acid; ammonia nitrogen 1.2 grams; index 13 per cent.; alveolar CO₂ 3.7 per cent. Next day she was better. Urine contained traces of albumin; ammonia nitrogen 1.9 grams; index 13.4 per cent. aceto-acetic reaction conspicuous; alveolar CO₂ 4.7 per cent. Two days later the acidosis was still less: ammonia nitrogen 0.5 gram; index 3.4 per cent. The rest of her stay in hospital was uneventful.

S. S., a woman in domestic service, aged 22. Admitted February 28th, 1914; died March 7th, 1914. Symptoms of the disease were first noticed before Christmas, 1913. On admission: Diet, light, full; no restriction of carbohydrates. Sodium bicarbonate 9 grams per diem. On March 3rd sugar excretion was 15.6 oz. (443 grams), subsequently falling. Marked aceto-acetic reaction.

	Mar. 1st.	Mar. 2nd.	Mar. 5th.	Mar. 6th.
Ammonia N (grams) ...	2.07	1.35	2.18	1.78
Ammonia index... ..	12.2%	12.9%	12.4%	24.4%

Alveolar CO₂ 3.5 per cent. two days before coma. *Post mortem*: Pnecrosis soft, smaller than usual, 37 grams.

P. S., a man aged 22; admitted June 23rd, 1913; died July 9th, 1913. Diet: Carbohydrates at first restricted to 80 grams a day; on July 2nd to 25 grams; on July 8th 102 grams were given. Sodium bicarbonate, on admission, 5.8 grams per diem; on July 8th 87 grams. Sugar excretion rather small in quantity, rising to 3.3 oz. (94 grams) on July 6th. Aceto-acetic reaction marked. Alveolar CO₂ at first 3.8 per cent.; while in coma 1.23 per cent.

E. S. M., a chauffeur aged 24; admitted January 2nd, 1914; died January 7th, 1914. Diabetes had been diagnosed four years previously. He had been dieted for three months before admission. On admission, diet light, full. Sodium bicarbonate 5 grams. He was passing 15 oz. sugar (426 grams) in the day. 7 grams. On January 6th the ammonia N was 5.8 grams, and the index 11.7 per cent. The alveolar CO₂ fell rapidly after January 5th. On January 6th, 7.20 p.m., the patient's breathing was increased, but he was perfectly sensible; alveolar CO₂ 2.2 per cent. Coma supervened the next day, and at 5 p.m. the alveolar CO₂ was 1.01 per cent.

L. W., a man aged 40, was admitted May 22nd, 1913, for a septic scalp, and died on July 2nd. On May 27th the alveolar CO₂ was 5.8 per cent. A strict diabetic diet was then begun. The alveolar CO₂ fell to 4.3 per cent. on May 30th. A guarded prognosis was given. Coma supervened three days later.

W. B., a man aged 35, was admitted March 8th, 1913, and died on March 13th, 1913. On admission an ordinary full diet was given: 110 grams sodium bicarbonate daily. On March 11th carbohydrates were restricted to 45 grams, and the index showed a strong aceto-acetic reaction. The ammonia index, 12 per cent.; sugar 241 grams; alveolar CO₂ 1.9 per cent. Coma came on the next day, the CO₂ in the alveolar air being 0.86 per cent. *Post-mortem*: Pnecrus, 35 grams, appeared normal; atheroma of aortic valves; subpleural and subpericardial atheromas.

M. N., a woman aged 47, suffering from diabetes, was admitted February 2nd, 1914, for a surgical operation. She became comatose. Alveolar CO₂ 1.5 per cent.

R. H., a woman aged 24; admitted March 6th, 1914; died March 14th. On admission, ordinary full diet; sodium bicarbonate 71 grams per diem. Marked aceto-acetic reaction. On March 12th, ammonia N was 0.9 gram, and the ratio was 6.4 per cent. On March 12th the alveolar CO₂ was 2.7 per cent. On March 13th she became comatose; ammonia nitrogen 0.34 gram; index 10 per cent.

J. O., a painter aged 47; admitted January 5th, 1914; died January 29th, 1914. He had had diabetes since March, 1913. Since then he had been on a strict diet. For the last fortnight he had complained of general lassitude. His eyesight had become bad. He had weighed 11 st. previously. On admission his weight was 8 st. 8 lb.; he was rather drowsy; his breath smelt of acetone. There was a small haemorrhage in the right retina, and some retinitis. The ferric chloride reaction was strongly positive. A diet containing 13 grams carbohydrate was given and sodium bicarbonate in large doses by the mouth and rectum (78 grams on January 7th). On January 9th ammonia N was 4.4 grams, index 13.6 per cent. He passed about 8 oz. (227 grams) sugar daily. On January 11th the urine was faintly alkaline. On January 15th ammonia N was 2.2 and the patient's legs began to be oedematous. The sodium bicarbonate was diminished to 51 grams for three days, and it was then increased again to the previous amount. The oedema disappeared in twenty-four hours. On January 26th a normal abdominal pain. He became delirious. He regained consciousness, and remained conscious right till his death, the next morning at 4 o'clock. While in hospital the alveolar CO_2 showed large variations—that is, between 2 and 5 per cent.

Post mortem.—Lipæmia, due to a finely divided suspension of fat. General wasting. Atrophied pancreas.

METHODS OF ANALYSIS EMPLOYED.

Sugar.—Benedict's method.

Ammonia.—By formol titration.

Ammonia Index (that is, the ratio between the ammonia nitrogen and total nitrogen).—The total nitrogen was calculated from the amount of urea, determined by Duprès's method, assuming that the urea nitrogen was always 95 per cent. of the total nitrogen. This is approximately the case under ordinary conditions of diet, and the results are accurate enough for clinical purposes. The Duprès method is much simpler than Kjeldahl's, and takes less time to perform.

PAROXYSMAL HAEMOGLOBINURIA.

BY

E. EMRYS-ROBERTS, M.D.,

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, UNIVERSITY OF WALES; CAPTAIN (TEMPORARY) R.A.M.C.; BACTERIOLOGIST, WELSH ARMY CORPS.

As the condition known as paroxysmal haemoglobinuria is of extreme rarity, and recorded observations may assist in its elucidation, I venture to set out some of the results obtained in an investigation of a case that has recently come under my notice.

The man, an ex-soldier, 42 years of age, who had re-enlisted for home service during the period of the war, was sent to me by the medical officer of his battalion on July 8th, in order to have his blood and urine examined, with a view to ascertaining if he was suffering from secondary anaemia and, if so, to what cause it could be assigned.

Well built and of keen intellectual capacity, he was, when I saw him, pale and bloodless, and his sclerotics were tinged yellow. He stated that he joined the army at the age of 19 years, and after six months' home service and six months at Malta was drafted to India, where he served eight years. He left India at the age of 28, and was then transferred to the army reserve. Whilst in India, at the age of 25 years, he contracted malaria—benign tertian—and also syphilis; for the latter he received oral mercurial treatment for a period of three months. After leaving the army he started work as a coal miner, and became successively a mine official and an inspector of mines. At the age of 33 he married, and six years later a girl was born, whom I have seen. She is now over 3 years of age, and appears perfectly healthy.

His general health has been excellent. Eight years ago, at the age of 34, he had an attack of what was diagnosed as influenza, with symptoms of pain in calves and thighs, and headache, but no rigors or "port-wine" urine.

In October, 1913, he formed one of an exploration party after the Seughenydd explosion. At one time, whilst returning to the base of operations, a distance of 1,000 yards, he and his companions were exposed for over two hours to smoke and gases. He himself felt great difficulty in breathing, and was unable to travel more than ten yards at a time. A fellow explorer suffered chiefly from pains in the head, calves, and thighs, with weakness of the legs—symptoms characteristic of CO poisoning.

Whether the effect of this exposure has played any part in my patient's subsequent illness it is difficult to estimate, but it is of interest to note that thereafter he complained of frequent tingling of the ears, only relieved by the application of warmth. His present illness, he told me, started eight weeks before with loss of appetite, constipation, frontal headache, lassitude, pains in the thighs and calves, some feverishness, and also some pain in the epigastrium. A fortnight later he experienced a slight "shiver," but no vomiting occurred at any time. During the last two weeks definite rigors developed, followed by profuse sweating. These rigors usually started about midday, every day, and would last from two to five hours; they were not controlled by quinine. He noticed that the first appearance of "port-wine" coloration of his urine synchronized with the first rigor. From then to the time that I first saw him he had become steadily worse. About the time that the rigors started he first noticed that an irritating rash appeared on exposing his arms and legs when getting out of bed. The rash and its attendant irritation would last from twenty to thirty minutes, and on returning to bed and keeping closely covered the skin would assume its normal condition.

The specimen of urine he brought with him (July 8th) presented the following characters: "Port-wine" colour, acid, gave strong positive reaction with tincture of guaiacum and ozonic ether; high albumin content. On centrifuging, a heavy deposit containing very many granular casts, a few granular-leucocytic casts, and much detritus, all tinged a brownish colour. A few isolated leucocytes and urinary epithelial cells were seen. Some calcium oxalate crystals were present, but these were not red blood corpuscles.

I now proceeded to obtain some blood from the tip of the right ear. This procedure was immediately followed by a rigor. It will be noted that the blood taken on this occasion represented a sample of his circulating blood during the period of his haemoglobinuria. As subsequent events proved, this was the only sample I was able to obtain while he was in this condition, as, when I next saw him, he had improved so much that his immediate symptoms had ceased.

The blood withdrawn clotted quickly, and the resultant serum was large in amount. The serum was tinged a smoky-brown colour, with the very merest trace of a reddish tint. The Wassermann reaction was positive. A differential count of 300 leucocytes, performed at the same time, gave the following result: Polymorphonuclears, 70 per cent.; large mononuclears and transitionals, 7 per cent.; lymphocytes, 9.6 per cent.; eosinophiles, 10 per cent.; mast cells, 3.3 per cent. The leucocytes appeared greatly in excess of the normal ratio to the red corpuscles. There were a few dead leucocytes, chiefly polymorphs, eosinophiles, and mast cells. Blood platelets were present in slight excess. The red corpuscles stained lightly, rouleaux formation was fair; macrocytes, microcytes, poikilocytes, and many phanтом cells present; polychromatosis abundant. No nucleated red corpuscles and no malarial parasites seen.

Four days later (July 12th), after his removal to the local military hospital, I was enabled to make continuous estimations of his urine over a period of eight days. Each time he micturated the total amount was measured, and a sample submitted to examination, in order to ascertain the question of acidity, specific gravity, general appearance and colour, and the presence or absence of haemoglobin, bilirubin, albumin and crystalline deposits. In this way it was possible to estimate the total for each successive twenty-four hours, and any changes that might occur.

The total daily amounts varied from 1,123 c.cm. to 1,746 c.cm.; the specific gravity from 1008 to 1028—even on the same day—but this variation was unusual, the average being 1016. The colour and appearance varied between a clear light amber and a cloudy deep brown; on no occasion did it show the slightest trace of a "port-wine" tint. Sometimes there would be a heavy deposit of urates, but there was never any haemoglobin present, whilst the slightest traces of bilirubin and albumin were only rarely encountered. It was surprising to find how extremely quickly the urine had approximated to the normal standard.

On July 12th I withdrew some of his blood. It again clotted quickly and produced a large resultant serum, which was, however, tinged a strong red colour. Using this serum in a fresh state I added it in varying dilutions to a 5 per cent. suspension of my own washed red corpuscles, with a suitable control, and incubated at 37° C. for one hour. No haemolysis took place in any of the preparations. The Wassermann reaction was positive.

On this day also I took 1 volume of the serum obtained on July 8th (immediately preceding a rigor), inactivated it at 60° C. for half an hour, to it added 1 volume of my own washed red corpuscles, 1 volume of my own fresh serum (complement), and 3 volumes of normal saline, incubating at 37° C. for one hour. As a result I obtained slight haemolysis of my own red corpuscles. I also, on the same occasion, took one volume of the serum obtained on July 12th (during the quiescent convalescent period), and proceeded in a precisely similar fashion, but I did not thereby obtain any haemolysis of my own corpuscles.

On July 15th I estimated his total leucocytes at 9,200 and total red corpuscles at 2,944,000 per cubic millimetre.

On July 26th I again withdrew some of his blood, the serum, as before, was strongly tinged. The Wassermann reaction was again positive.

On the same day I performed a differential count of 400 leucocytes with the following result: Polymorphs, 57.25 per cent.; large mononuclears and transitionals, 15 per cent.; lymphocytes, 20 per cent.; eosinophiles, 7.5 per cent.; mast cells, 0.25 per cent. The red corpuscles were much more uniform in size and shape, but there were still some macrocytes, microcytes, and poikilocytes, also some rosettes. The colour was better, but there was still some polychromatosis, though not so pronounced. A few shadow cells were present. Rouleaux formation was fair. There were fewer blood platelets, but many dead leucocytes, chiefly large mononuclears. There were no nucleated red corpuscles, and no malarial parasites were seen.

On July 30th I estimated his total leucocytes at 5,400 and total red corpuscles at 3,952,000 per cubic millimetre.

On this day also I made a preparation of his washed red corpuscles. To one volume of these I added one volume of his own fresh serum and one volume of normal saline, incubating at 37° C. for one hour. I further added to another volume of his own washed red corpuscles one volume of my own fresh serum and one volume of normal saline, also incubating at 37° C. for one hour. In neither preparation did haemolysis occur.

In order to ascertain if the haemolyzed state of his serum was due to free haemoglobin in the blood plasma (which seemed improbable, as his urine contained none) or to fragility of his red corpuscles, whereby the haemoglobin was expressed during the act of clotting, I withdrew on August 3rd one portion of blood, and allowed it to clot. The serum was definitely tinged with haemoglobin. Another portion of blood was received into a tube lined with paraffin wax and immediately centrifuged, thereby quickly separating the corpuscles from the plasma. The latter was seen to be entirely free from the slightest trace of tinting. In point of fact, it was perfectly normal in appearance.

A curious phenomenon was noted in the right ear. On the day following the first needle puncture the site of the puncture in the lobe, together with the upper portion of the ear, which had not been punctured, became tense and swollen with extravasated blood and tender to the touch. Thereafter the left ear was used, happily with no untoward result. The right ear assumed its normal state in the course of two to three weeks, the normal condition being hastened by keeping the ear protected and warm.

During the course of the investigation he was at first kept strictly in bed, on a milk diet. Then, when it was

found that his urine remained free from albumin, eggs were allowed; later, fish and a full diet.

Throughout he was extremely susceptible to cold. Although to the ordinary mind the temperature was distinctly warm (75° F. in the shade), he would be found with as many as nine blankets and woollen coverings, including his great coat!

During this time his temperature fluctuated between 97.4° F. and 99° F. When he began to sit up he complained of considerable pain in the thighs and calves, though this, in time, passed off. Eventually he improved sufficiently to allow his return to his billet, and his convalescence is proceeding satisfactorily. Iron and arsenic are being given to combat the anaemia. It would be inadvisable to administer neo-salvarsan intravenously until his corpuscles have regained their normal state.

In reviewing the facts disclosed, one is first of all struck with the malarial and specific history, a combination of frequent recorded occurrence in the etiology of paroxysmal haemoglobinuria, though the disease has been described when neither the one nor the other has been antecedent. The next point is that the first symptoms should have started in midsummer, as it is generally held that exposure to cold is a predisposing factor. In this case there was not even the possible exposure to the rigours of camp life, since he was billeted and his work was actuarial. I did not go the length of deliberately exposing him to cold in order to test this contention, but I understand from the medical officer of his battalion that on arrival at his billet, after a twelve-mile drive in the ambulance, he experienced a slight rigor. The vasomotor disturbances, as seen in the right ear and in the exposure rash, are of interest in connexion with the previous history of tingling in the ears, relieved by warmth, subsequent to exposure to CO fumes.

The blood counts are of interest chiefly as supporting the condition of secondary anaemia following the loss of blood indicated by the haemoglobinuria. For some reason the eosinophile count was high. The process of approximation to normal in the case of the urine was remarkably rapid and very difficult to understand.

As far as the blood serum is concerned, the suggestion is offered that the marked haemolysis present, after the period of the rigors and haemoglobinuria had passed, is evidence of the fragility of the red corpuscles, the haemoglobin being discharged from them during the act of clotting, since the plasma prepared coincidentally was normal in appearance. However, this does not quite explain why the serum of the blood taken immediately prior to a rigor, and during the period of the haemoglobinuria, should have been but barely tinged with haemoglobin; its smoky-brown colour strongly suggests reduced haemoglobin.

The presence of a haemolytic body in the serum just prior to a rigor, and coinciding with the period of haemoglobinuria, and its absence later, coincident with the cessation of haemoglobinuria, are points of some importance.

In a short note on "Psychological Medicine," published in the Educational Number last week, p. 385, it should have been stated that the University of Manchester grants a diploma in psychological medicine. We regret the oversight the more because the University of Manchester was, we believe, the first to give such diplomas.

In a paper on the experimental treatment of human beri-beri with constituents of rice polishings (*Philippine Journal of Science*, March, 1915) Williams and Saleeby come to the conclusion that allantoin has a beneficial effect in certain cases of beri-beri, although it probably never produces complete cure. Hydrolyzed extract of rice polishings has been found to benefit all the types of the disease upon which it has been tried, and unhydrolyzed extract of rice polishings is, they state, a safe and valuable remedy for infantile beri-beri, but of little use for older cases. The vitamins of rice polishings was proved to possess specific and prompt curative properties far beyond those of any other known substance, but unfortunately its cost at present prohibits its general use amongst the poorer class. As a whole the observations on the 27 cases recorded in this paper are, as regards their bearing on the etiology of beri-beri, in accord with the broad proposition that the disease, in a practical sense at least, results primarily from a poor diet, deficient more particularly in specific substances of the nature of Funk's vitamins.

CONGENITAL DISLOCATION OF RIGHT FOOT WITH ALMOST COMPLETE ABSENCE OF RIGHT FIBULA.

By E. MANSEL SYMPSON, M.D., B.C.CANTAB.,
M.R.C.S.ENG.,

MAJOR R.A.M.C.(T.F.), 4TH NORTHERN GENERAL HOSPITAL;
HONORARY SURGEON, LINCOLN COUNTY HOSPITAL.

GEORGE B., a lad aged 13, was admitted to the Lincoln County Hospital on May 29th, 1915.

History.

The malformation of foot and leg was noticed at birth. The patient walked at the usual age, resting the right foot on the right great toe; he ran well, played football, etc., became a scout when 11, and did all drills and marches without difficulty.

A year ago he began to suffer from backache after long walks, due to the tilting of the pelvis from the shortness of the right leg. Last March this deformity was noticed by the medical inspector at school, and found to be very marked.

Condition.

The right foot seemed as though it had been rotated outwards for nearly a quarter of a circle, and then turned over so that its dorsal surface looked almost directly forwards and its plantar surface backwards. The power to move the foot on the ankle existed, but backwards and forwards instead of up and down. The boy walked on

the end of the tibia, which was enlarged and made a good "stump." There was 2½ in. shortening of the right tibia (measuring from patella to inner malleolus) and, of course, owing to the absence of the foot beneath the tibia there was much more difference in the total length of each limb.

A radiograph was taken on March 11th by Captain A. L. Yates, now on active service "somewhere in France or Flanders." As will be seen from the sketch of the radiograph here reproduced the hinge of the joint was between the upper and posterior portion of the articular surface of the astragalus with the outer edge of the lower end of the tibia. This bone is also seen to be much enlarged and curved, with the convexity inwards. The inner malleolus is large and turned outwards. A small piece of the lower end of the shaft of the fibula appears in the plate between the tibia and the tibia.

Amputation.

On June 5th, 1915, a flap was formed from the dorsum of the foot, the tendons and ligaments were divided, the incision carried upwards and downwards over the os calcis, the tendo Achillis cut, the flap turned upwards and outward, making the wound like an inverted U. This healed by first intention, and the scar is well out of the way of any vertical pressure.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SOAMIN TREATMENT OF CEREBRO-SPINAL MENINGITIS.

CASE I (under the care of A. M. B.).—E. G. C., aged 29, had an attack of influenza in February. On March 10th, 1915, had acute symptoms of influenza, with vomiting and symptoms of meningitis. On March 12th the head was very retracted, pulse 48, and temperature 99°; the legs were drawn up and slightly rigid; the patient was very irritable but quite conscious and had no rash; Kernig's sign was well marked. He was given 5 grains of soamin by injection into the glutens maximus muscle, together with an injection of morphine ½ grain and atropin ⅛ grain. On March 13th he had well marked *tache cerebrale*; Kernig's sign was less marked than the day before. A peculiar patch of herpes was noticed on the right ankle, which was like a burn from a hot water bottle. This, however, did not prove to be the case, for it happened in a similar way to several other patients, and was clearly due to conglomeration of herpes; this patch, like similar ones, took six weeks to heal. Another injection of soamin (5 grains) was given; the pulse was 56 and temperature about 100°. His irritability required injections of morphine twice a day until March 17th. He required frequent catheterization. On March 16th a lumbar puncture was performed for headache and pressure signs and an injection of meningococcal serum given. On March 14th there were papules on the chest; the temperature was then 102° and pulse 108. From March 16th Kernig's sign became less marked, headaches ceased, and he made an uneventful recovery, and was discharged on March 20th quite cured and without any symptoms whatever.

CASE II (under the care of J. F. R.).—R. Y., aged 14, was quite well on March 31st, and working till 4 or 5 p.m. He felt slightly ill towards evening, and at 11 p.m. I was called to see him. His temperature was then 105.4°, the pulse 140, the face was flushed, and he was drowsy, but complained of pain in the left side of the chest in the axillary line. The blood count showed 23,700 leucocytes per cubic centimetre; 72 per cent. multinuclear; Kernig's sign was present, and also *tache cerebrale*, and stiffness and rigidity of the neck muscles; the pupils were dilated. There was a peculiar patch on the left ankle, looking like a recent bug-bite, 3 to 4 cm. in extent. Meningococci were cultivated from the posterior nares. An injection of 3 grains of soamin had a somewhat marked effect. His temperature came down shortly afterwards to 100°, and the pulse to 80, while Kernig's sign was less pronounced. After one day's interval, as the temperature again reached 103°, another 3 grains were injected, and again on the fifth day 2 more grains were injected in the gluteal region; drowsiness decreased, headaches became less, and the pulse much better. Apart from a sudden rise of temperature to 104.2° on the sixteenth day, he made steady and uneventful progress. On the fourth day there was a peculiar rash on the left hip, and herpes of two square inches over the left eye, nose, and anus, and one or two rose spots on the trunk. The patch noticed on the ankle within twenty-four hours became bullous, and looked like a scald; then the scab dropped off, and left an ulcer half an inch in diameter, which took over six weeks to heal. At the end of three weeks he appeared fully recovered, and swabs taken were negative. In the fifth week, after resuming normal life, he had a sudden rise of temperature to 104°, pulse 130, coupled with violent headache and pains down spine. Bromides relieved this, and, apart from another attack a week later, he has been quite well in every way.

SURGICAL TUBERCULOSIS.

WE are glad to draw the attention of the profession to a new book dealing with the disease which, above all others, is the source of worry to hospital surgeon and general practitioner alike. DR. JOHN FRASER has been well known for some years as the author of papers recounting the results of original investigation in tuberculosis. He has collected these papers on pathology and etiology, added clinical studies, and, finally, has built up the whole into a most excellent treatise on *Tuberculosis of the Bones and Joints in Children*.¹ The work has been carried out in the Royal Hospital for Sick Children in Edinburgh, and the author makes acknowledgement of his indebtedness to that distinguished surgeon Mr. H. J. Stiles, an inspiring and encouraging guide. The book falls naturally into two divisions—general and special; in the latter tuberculous disease of each individual joint and of many bones is considered in detail. This method is apt to lead to repetition, but the tendency is kept well in check, and the story of each joint unfolds itself complete and self-contained.

The first part of the volume is devoted to the general discussion of the subject; the pathological development and minute structure of the lesion, from the earliest deposit of a bacilli-laden embolus and endarteritis obliterans to the formation of abscess and sequestrum, are very fully set forth. The illustrations of this portion are all exceedingly beautiful original photomicrographs; they form quite the most perfect series of the kind known to us. If they have a fault, it is that the description attached to each is too meagre; the practitioner who is not accustomed to inspecting microscopic sections would appreciate them more if the various details of the picture were pointed out by lettered lines or arrows.

The growth of bone on the external surface of bones infected with tubercle is quite frankly credited to the osteogenetic function of the periosteum. It seems to us that Macewen's theory as to the periosteum being merely a limiting membrane is too airily dismissed in a two-line footnote. The theory has gained very wide acceptance, and, so far as we know, the accuracy of the experiments proving it has not been contested. In this connexion it is of interest to note that Dr. Fraser cannot explain the fact that "in tuberculosis of the vertebrae the periosteum rarely forms any degree of new bone."

There is only one other minor criticism which we desire to make: it is in connexion with the clinical evidences of the second stage of hip disease. In this work the attitude of the limb is said to be flexion, abduction, and eversion. In most books the limb in the second stage is said to be in a state of flexion, adduction, and inversion, with apparent shortening. Of course, it is obvious that in such a disease stages are arbitrary divisions with indefinite limits, but for teaching purposes it is convenient to regard the stages of the disease as three, and uniformity of description of each stage is desirable.

We do not think that any more useful or practical work on the subject of tuberculosis of bones and joints in children has been placed in the hands of the profession. It is admirably arranged, most fully and beautifully illustrated throughout, and written in free, graceful style. A most commendable feature is the oft-repeated insistence on conservatism in treatment. Young practitioners and surgeons will find here that even tuberculous abscesses may diminish in size and their contents become dry and calcareous if left alone, provided recumbency and general treatment be carried out, and that the treatment of joint tuberculosis is a matter of infinite patience lasting sometimes for years. There is no department of these diseases, etiology, pathology, clinical manifestations or treatment, in which the anxious family doctor or the enterprising surgeon to a children's hospital will not find the information he seeks, and generally he will find far more than ever he thought of.

Bibliographically the volume is handsome, its whole

¹ *Tuberculosis of the Bones and Joints in Children*. By J. FRASER, M.D., F.R.C.S.E., Ch.B. The Edinburgh Medical Series. London: A. and C. Black, 1914. (Sup. roy. 8vo, pp. 368; 51 plates; 164 figures. 15s. net.)

arrangement reflecting credit on the publishers. We have found only one proof-reading slip; on page 80 "Michael's" should be "Michel's."

ANTITYPHOID INOCULATION.

DR. H. MÉRY of Paris has written a brief and admirable account of the history, principles, and practice of inoculation or vaccination against typhoid fever.² It was first employed in France by Chantemesse and Widal in 1888, experimentally and on mice; it was not employed to protect man by Chantemesse till 1899, three years after Wright in England and others in Germany had used it for that purpose. Besredka employed his sensitized vaccine in 1902. At the present time antityphoid vaccines fall into three main classes, according as the cultures are injected dead, alive, or in the form of autolysates (extracts). The chief vaccines of the first class are those of Wright, Wright and Leishman, Chantemesse, Pfeiffer and Kollé, and Russel, in which the typhoid bacilli had been killed by heat; in other instances they are killed by antiseptic drugs, as is the case with Vincent's polyvalent antityphoid vaccine now being employed extensively in the French army. The second class is represented by Castellani's vaccine, Besredka's living sensitized vaccine, and others; all are used much less freely than the vaccines containing only dead typhoid bacilli. The same is true of the autolysate antityphoid vaccines of Wassermann, Conradi, Vincent, Rowland, and others, which contain only extracts of the bacterial bodies.

Practical considerations lead to the use of antityphoid vaccines containing killed bacteria for choice. The vaccine should be injected, according to Vincent, in the region of the left shoulder, behind the border of the deltoid muscle and two or three fingerbreadths below the spine of the scapula. Intravenous injections are not free from danger. Antityphoid inoculation should not be practised on phthisical persons or patients with disease of the heart or kidneys.

Discussing the vaccine treatment of patients with enteric fever, Méry notes that it was first tried in 1893 by Fränkel; Netter in 1913 collected 1,318 cases of its use, with a mortality of 5 per cent.; and Gauchery 2,256 cases, with a mortality of 5.7 per cent. The vaccines employed here are the same as those described above for prophylactic use; the doses are much smaller, from 5 to 30 or 60 million of the dead microbes being injected and from two to four injections being given, as a rule. The treatment is not free from dangers—high fever, cardiac failure, aggravation of the disease, even rupture of the spleen; Méry notes the fact, and is unable to give any definite rules or indications whereby the practitioner may foretell the cases in which the vaccine treatment is contra-indicated. This is an excellent little book, well and temperately written. It should be in the hands of all medical men who have to deal with the prophylaxis and treatment of enteric fever.

NOTES ON BOOKS.

YEAR BOOKS.

THE Charity Organisation Society has recently issued the twenty-fourth edition of its *Annual Register and Digest*.³ This gives a classified register of all the more important charities in or available for the metropolis, together with a digest of information respecting legal and voluntary means for the prevention and relief of distress, and the improvement of the condition of the poor. It begins with an introduction of nearly 400 pages, in which the modes in which the benefits of these charities ought to be turned to account is given. In other words, this supplies the reader with an outline of the principles of charitable work. The bulk of the volume is occupied by details of the societies, institutions, agencies, and leagues actively concerned in the relief of sickness and poverty. There is an excellent index, to which, indeed, the reader will naturally turn first when making use of this annual. The book has grown vastly since it was first brought into

² *La Vaccination Antityphoïdique*. Vaccination préventive et Vaccino-thérapie. Les Actualités Médicales. Par le Dr. H. Méry, Paris: J. B. Baillière et Fils, 1915. (Cr. 8vo, pp. 95; 6 figures. Fr. 1.50.)

³ *The Annual Charities Register and Digest*, with an introduction on How to Help Cases of Distress. By C. S. Loch. Twenty-fourth edition. London: Longmans, Green, and Co. For Charity Organisation Society, London, 1915. (Demy 8vo, pp. 1071. 5s. net.)

existence in 1879. It is not too much to say that it is quite indispensable to all who are concerned in charitable work in London and most useful to those so concerned elsewhere in this country.

The new edition, that for 1915, of *Low's Handbook to the Charities of London*⁴ is the eightieth; it gives particulars of the objects, funds, and offices of over 1,200 charitable institutions. The classified table of contents not only facilitates reference but shows the great variety of objects with which such institutions in, or for, the metropolis exist. The editor makes a special appeal for the support of the benevolent public at this time. It is recognized that this will be a very critical year for all institutions dependent for maintenance on incomes from subscriptions, and there is a real danger that their resources may be crippled unless those whose generosity has rendered it possible to build up the magnificent fabric of the voluntary system continue the help so ungrudgingly given in the past.

The *Girls' School Year Book*,⁵ which is the official book of reference of the Association of Head Mistresses, has reached its tenth year of publication. Its object is to provide a record of all matters of interest to parents, school mistresses, and girls in connexion with secondary education, so far as concerns public secondary schools for girls with governing bodies, and to the exclusion of private schools. In addition, it contains information about universities and colleges for women. The last 200 pages are given to information and advice about professions and employments for educated women—teaching, the civil service, secretarial, clerical, and librarian work, journalism, medicine, nursing, social work, music, art, agriculture, horticulture, the drapery trade, and other such things. The book should be of great service to those for whom it has been compiled, and seems well up to date.

There are over eighty universities and university colleges in the British Empire, ranging from Aberdeen and Acadia to Western Australia. The *Year Book of the Universities of the Empire*⁶ gives in summary form the information contained in their respective calendars, so far as it may be of service to those responsible for university organization and to advanced students who are looking out for opportunities of study and research. Ten appendices on kindred institutions are added and sixty-five pages of war rolls; forty pages at the end give a list of the names of those teaching at the various universities and colleges included in the volume. This year-book is now in its second year; it appeals to only a small audience, but should be of great utility to those for whom it caters.

For those who are taking holidays this year, *The Holidays*,⁷ issued by six of the large railway companies in England and Scotland, contains a vast amount of useful information. It gives lists of hotels, boarding houses, apartments, and all the other information required by holiday seekers in Great Britain and Ireland.

HIGHLANDS AND ISLANDS MEDICAL SERVICE BOARD.

(From our Correspondent in Edinburgh.)

In July, 1912, a Committee was appointed by the Treasury, under the chairmanship of Sir John Dewar, Bt., M.P., "to consider at an early date how far the provision of medical attendance in districts situated in the Highlands and Islands of Scotland is adequate, and to advise as to the best method of securing a satisfactory medical service therein, regard being had to the duties and responsibilities of the several public authorities operating in such districts." This Committee, under the guidance of its secretary, Mr. (now Captain) Malcolm Beaton, was able to visit the Highlands and Islands (including the Outer Hebrides, the Orkneys and Shetlands, and the Fair Isle), to examine a large number of witnesses, and, speaking generally, to look into local requirements and difficulties in a conspicuously thorough manner.

The result was a report presented in the end of December of the same year, out of which grew the Highlands and Islands Medical Service Act of 1913, with its annual grant of £42,000 for the improvement of medical service, including nursing. The next step was the coming into being of the Highlands and Islands Medical Service Board, which, according to the first report of the Highlands and Islands Medical Service Board for the period ended December 31st, 1914, is constituted as follows:

- Sir John A. Dewar, Bt., M.P., Chairman;
- The Lady Susan Gilmour;
- Sir Donald MacAlister, K.C.B., Principal and Vice-Chancellor of Glasgow University, and President of the General Medical Council;
- Dr. W. Leslie Mackenzie, Medical Member of the Local Government Board for Scotland;
- Dr. John Macpherson, Senior Medical Commissioner in Lunacy for Scotland;
- Dr. John C. McVail, Deputy Chairman of the Scottish Insurance Commission;
- Dr. J. L. Robertson, Senior Chief Inspector of Schools in Scotland;
- Dr. Norman Walker, Direct Representative for Scotland on the General Medical Council; with
- Mr. Lewis McQuibban, of the Scotch Education Department, as secretary.

This Board, which is appointed for four years, commenced its work in November, 1913, but did not report until May 31st of the present year, and then only concerning preliminary and emergency matters; now, however, it has issued, after approval by the Secretary for Scotland and the Treasury, a very far-reaching series of schemes for the improvement of the medical service (including nursing) in these outlying regions of Great Britain.

It cannot be doubted that the fact of the British Empire's participation in the greatest war of history was known to the Board, along with the additional facts that the former Committee's secretary (Captain Beaton) was at the front, and that many of the medical practitioners vitally affected by these schemes were serving in Flanders or at the Dardanelles, having left their work in the Highlands and Islands at their country's insistent call. No hint of these is contained in the schemes put before the doctors of the north and west of Scotland and less directly of the medical profession in general; one is tempted to ask if, after all, there is not a perfect peace and an overflowing supply of medical men available in the Highlands, or, alternatively, if the Board has not succeeded in demonstrating that the Government Departments exist and do their work in absolutely water-tight and non-communicating compartments. Such suppositions are certainly strengthened by the instructions given to the medical men in the north to whom the Board has addressed a letter, dated August 16th, transmitting a copy of Scheme A providing for the general conditions under which medical practitioners will be eligible to participate in grants from the Board, published in the SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL of August 21st (pp. 93-98). The Board enclosed a draft form of agreement between the Board and medical practitioners, and a "form to be filled up by all medical practitioners who desire to make a claim for a grant from the fund" (see Appendix).

The papers were sent out on August 16th, and the medical practitioners who received them were informed that their claims must be completed and submitted to the Board before August 31st. It is probable that some of the

The Philippine Journal of Science (vol. X, Sec. B, No. 1) contains papers on cholera, the treatment of infantile beri-beri, new compounds of emetine, the preparation of tetanus antitoxin, and the development of the eggs of *Ascaris lumbricoides*. Of these, perhaps the most interesting to tropical medicine is the paper on the new compounds of emetine by Du Mez, who has produced an emetine mercuric iodide and an emetine bismuthous iodide. He hopes that these new compounds will simplify the emetine treatment and increase its efficiency; he thinks that he has obtained a remedy which can be administered frequently in fairly large doses, with a minimum amount of trouble, and that it brings emetine into contact with the entamoeba for a longer time than the form in which it is administered at present. Clinical tests alone will show whether this hope is warranted or not.

medical men who have gone to the front may be receiving the papers by the latter date. One is inclined to agree with Dr. Encas K. Mackenzie of Tain when he says (in a letter to the *Scotsman* of August 23rd), "the scheme outlined is revolutionary, and it seems extraordinary that it should be issued at this time, when the national crisis is uppermost in the minds of the profession and the public, and when the majority of medical men in the Highlands and Islands are either fully occupied performing civil and military duties at home or are actually serving with His Majesty's forces abroad."

Not only is the date chosen for the issue of the schemes inopportune and the time given for consideration of and compliance with them far too short, but the proposals contained in them are radical, sweeping, and subversive, and are marred by many of the same faults as made the Insurance Act so unwelcome to many of the medical profession two or three years ago.

Yet it will be generally agreed that the objects aimed at in the schemes are admirable, and likely, if attained with smoothness and ease, to be most beneficial. The financial aid to be given to district nursing associations, and the linking up of medical and nursing work in private practice, in connexion with schools, with infectious disease, with tuberculosis, and with maternity cases, and in the general medical and surgical work, and in the care of the sick poor and old age pensioners, are both steps in the right direction. The district nursing associations will, we do not doubt, scan most carefully the conditions they are asked to fulfil before they can participate in any grants-in-aid. Admiration may also be freely expressed for the scheme which deals with hospitals and ambulance services, for any means which can bring serious cases requiring specialist skill quickly and safely into hospitals where such skill is available must be good both for the patients affected and for the hard-worked doctors who have to travel many miles to look after them; but, again, the managers of hospitals will be well advised to look closely at the responsibilities they are asked to accept in order to receive the proffered aid. The grants towards the provision or improvement of houses for doctors and nurses, admirable in their object, are again seemingly overburdened with irritating restrictions and minute details providing against almost unimaginable contingencies.

One would like to see one-half of the many desirable things accomplished which are placed before the profession in the scheme which is occupied with grants towards specialized services. There are three directions in which such grants are intended to exert their beneficial effects. The first is to bring medical consultations, assistance at operations, and the supply of surgical appliances within the reach of all patients everywhere within the areas included in the Highlands and Islands. Obviously, this is a great thing to accomplish, but it is hedged around with many difficulties, and the wording of the scheme itself suggests obstacles when it says, "The remuneration of a specialist for services rendered is a matter that will call for very careful consideration"; the reference to retaining fees, modified charges, and supplementary fees from the Board does not sound too hopeful, although the goodwill of the specialists and their desire to "do their bit" may possibly facilitate and simplify matters. Specialized services in connexion with dentistry, the medical treatment of school children, and school clinics form the second group under this heading, and at first sight at least do not seem so beset with difficulties as some of the others; the provision of laboratory facilities, which is the third direction in which grants can flow, may seem as yet almost visionary, but such facilities are very essential, for it can hardly be expected that doctors working under this Board and undertaking the extra clerical labour which that work will involve will be able "to maintain small pathological laboratories and provide vaccines of various kinds." Nothing respecting the grants towards the extension of telegraph and telephone facilities need be said, save that great good may be expected to flow therefrom unless all the money is expended before they are reached.

Something, however, must be said regarding the regulations which are laid down, and which must be complied with before medical practitioners can begin to receive grants from the Highlands and Islands (Medical Service) Fund, or can continue to participate in them. It is this

scheme—and it is indeed the leading and most vital one, for upon it the success of all else depends—which seems to have produced a feeling almost bordering upon dismay in some parts at least of the Highlands and Islands. Dr. Mackenzie's letter makes this feeling vocal, and his views have been adopted as their own, in large measure, by a number of medical men engaged in practice in the Highland district of Perthshire, who held a meeting on August 23rd to consider the scheme. These practitioners, after pointing out how inopportune the launching of the scheme is, say, "We cannot see how a Board which have taken two years to draw up their scheme can expect us to make up our minds in as many weeks to accept or reject their proposals." They continue, in words which indicate some irritation, not very surprising in the circumstances and with the clauses of the schedules before them, "We are told in the agreement which we are supposed to accept that we are to keep motor cars or motor cycles, and motor boats if necessary, to get expeditiously to see our patients, but there is not a word about what we are to receive in return for all this. We are apparently to sign the agreement, and trust everything in the way of fees to the generosity of the Board. According to the scheme the doctor is to be a sort of machine under the Board; he is to go to certain places on certain days; he is not to think for himself; he is to keep a different set of books and registers; and he is to be regularly visited by an official of the Board, who is to see that he is doing his duty, who is to examine his books and registers, and generally to pry as much as possible into his private affairs."

At a meeting of the members of the Inverness Division of the British Medical Association held in Inverness on August 28th, a resolution was unanimously passed to the effect that, owing to the anxiety felt amongst medical practitioners on the mainland of the county of Inverness as to the working of the proposals of the Highlands and Islands Medical Service Board and their bearing upon future medical practice, and the numerous difficulties in the way of clearly understanding the proposals which arose during the discussion, the Board be respectfully asked to send a representative to a meeting of medical men in Inverness at a date to be arranged by the Board, and that in the meantime the medical men of the county of Inverness should delay completing their form. The attendance at the meeting, the *Scotsman* reports, was not large on account of so many Highland doctors being away on military duty.

A clause which can hardly be regarded as helpful to a medical man anxious to work under the Board is that in which it is stated that "for the current year no payments will be made by the Insurance Committees in respect of mileage for attendance on insured persons, but the subsidy payable to the doctor will be arranged on a footing that will cover the travelling expenses involved in attendance on insured persons, as well as on all others entitled to receive medical attention under any arrangement between the doctor and the Board." Why, the year is two-thirds over, and, moreover, what, it may be asked, do the words mean, and how can the Board step in between the medical men and the Insurance Committees in respect of work already done? Dr. Encas Mackenzie points out that for a grant of uncertain amount and duration the medical man is to act as medical officer of health, as parish doctor, and as medical officer of schools; he is to treat school children, to attend patients at fixed fees no matter how far they are away or what difficulties are to be met with in getting to them; he is to give personal attention to midwifery cases, attend at fixed hours and days at different parts of his district, and to provide his own locomotion. Even the Board will, perhaps, excuse Dr. Mackenzie's caustic inquiry whether he has not also "to bath the children and assist at the weekly washing."

Six cardinal objections to the scheme are stated by Dr. Mackenzie, and may be given here as summarizing the criticism which has thus far emerged. He trusts it will be opposed:

1. Because it has been devised by the Board without taking the medical men into their confidence as a whole, but deals with them in their individual capacity.
2. Because no time is given to the medical men, many of whom are away from home serving their country, to consider the scheme properly.
3. Because remuneration is not based upon work done, and

because mediocrity and inefficiency are to be encouraged at the expense of ability and attention to duties.

4. Because clerical work is made of greater importance than medical services.

5. Because there is no discrimination made between Highland and Lowland areas.

6. Because there is intolerable interference with the liberties and rights of individual medical men and scrutiny of their private affairs by public officials.

Dr. A. C. Miller, of Fort William, who was a member of the Treasury Committee of 1912, has endeavoured in the *Scotsman* for August 28th to meet some of the objections tabled by Dr. Mackenzie and the medical men of Inverness and the Highlands of Perthshire, and it is only just to consider carefully what he has to say, for he has knowledge. For instance, in respect of the objection that the Board has not taken the medical men into their confidence as a whole, Dr. Miller says that the Treasury Committee, which preceded the Board, invited (with few exceptions) all medical men practising in the Highlands and Islands to assist them in their investigations either through written information or by oral evidence; and adds that of 102 query schedules issued to practitioners, no fewer than 87 were replied to, while altogether 93 medical men belonging to the area proffered their views. It is, however, a different thing to give opinions regarding facts and to be allowed to criticize the proposed measures to be adopted to correct the defects revealed by the facts, and it scarcely appears that the medical men have had any opportunity of pursuing this latter line of comment or criticism.

Dr. Miller is on surer ground when he points out that the Committee presented a unanimous report in January, 1913, and that three of the members were medical men; and he is also right in claiming that their investigations made them to some extent acquainted with the hardships and perils which doctors in the north and west have to face in the prosecution of their calling. It may be added that surely with this experience in mind the Board will view sympathetically any protests these same doctors may now be making, and see whether, after all, there may not be cause for some complaint; for, as Dr. Miller himself writes, there are "complicated and delicate problems" to be dealt with by the Board.

It is a little difficult to follow Dr. Miller's arguments in connexion with the mileage grant when he maintains that it will not, in effect, be diminished under the scheme of the Board. Possibly he is right, subject to considerations such as the fact that the scheme will throw the whole £42,000 into hotch-potch, to be allotted as the Board may think fit after taking into account the private and confidential information in Form 2 inserted below. One must not forget that £10,000 was voted by Parliament for mileage in the Highlands and Islands for the financial year 1913-14, and £42,000 for the purposes of improving medical service in the Highlands and Islands, "and for other purposes connected therewith," but nothing for mileage specifically. Dr. Miller thinks *evolution* is a better term for the Board's schemes than *revolution*, the word which the critics have applied to them; but he is hardly happy when he passes the objections to clerical worries, officious interference, and official supervision lightly by with the reflection that apprehensions regarding these things under the Insurance Act have turned out to be to a great extent unfounded. Many will say "Question" to that. The suggestion that "the profession is strong enough to get an objectionable official disposed of at any time" is not, perhaps, very helpful, and seems to foreshadow troublesome times. Further, Dr. Miller's letter cannot be said to answer the second, third, fifth, and sixth objections lodged by Dr. Mackenzie and the others at all; but at the same time all will unite with him in hoping that measures and arrangements may yet be evolved which will prove a charter of emancipation for practitioners resident in the Highlands and Islands.

Even an entirely disinterested survey and study of the schemes, and especially of the first (that concerning grants to medical practitioners), reveals many regulations which are sure to be irksome if no worse, as well as matters of principle, which it is essential should be fully considered by a full gathering of the medical men involved. Such a gathering is impossible until the war is over. It seems not unreasonable to ask for delay until that desirable termination has been reached, unless the Board is

prepared to struggle with the same sort of difficulties as the Insurance Commissioners had to meet, and to overcome them by means which will leave a bitterness in the hearts of the medical men who sometimes at the risk of their lives, and often with great personal inconvenience, try their hardest to supply the comforts and assuagements of modern medical and surgical means to the dwellers in the outlying districts of our land known as the "Highlands and Islands."

LETTER TO MEDICAL PRACTITIONERS.

Highlands and Islands Medical Service Board,
4A, St. Andrew Square, Edinburgh,
August 16th, 1915.

HIGHLANDS AND ISLANDS (MEDICAL SERVICE) FUND.

SIR,—I beg to inform you that the general consent of the Secretary for Scotland and Treasury has now been obtained to the proposals submitted by the Board for the administration of the Highlands and Islands (Medical Service) Fund, and the Board now propose to proceed forthwith to make arrangements with practitioners in regard to the terms and conditions under which grants may be payable to them.

2. I am directed to enclose for your information a copy of a Scheme (A) setting forth the general conditions on which grants may be made to medical practitioners.

3. If, on consideration, you desire to enter into an agreement with the Board, I am to ask you to be good enough to submit to the Board at your earliest convenience, and not later than August 31st, the statement of information asked for on the accompanying form. The information supplied in the form filled up by you will be regarded as *strictly confidential*.

4. It is intended that the Board's grants shall be payable half-yearly—namely, about 45 per cent. of the approved claim at the end of June and the balance at the end of December in each year, or as soon thereafter as may be found to be practicable.

5. I also enclose draft form of agreement with practitioners which the Board propose to adopt, *subject to adjustment according to the circumstances in each individual case*.

6. I also enclose for your information copies of the following documents:

Scheme (B), in regard to the general conditions under which district nursing associations will be eligible to participate in grants from the fund.

Scheme (C), in regard to grants to central hospitals and in regard to ambulance services in connexion therewith.

Scheme (D), in regard to the provision and improvement of houses for doctors and for nurses.

Preliminary scheme (E), as to the general conditions under which grants will be made towards specialized services.

Scheme (F), in regard to telegraph and telephone extension in connexion with the medical and nursing services.

I am, Sir,

Your obedient Servant,

L. MCQUEBBAN,
Secretary.

To Dr.

Form 2 (Claim).

Private and Confidential.

HIGHLANDS AND ISLANDS (MEDICAL SERVICE) FUND.

Form to be filled up by all Medical Practitioners who desire to make a claim for a grant from the fund.

The particulars asked for in certain sections of the form may be omitted by practitioners whose net professional income is over £300 a year (see footnotes on page 405).

N.B.—By "net professional income" is meant the gross income from all professional sources (including appointments, private practice, fees for special services and medicines supplied to patients), less travelling expenses incurred in attending patients, drugs purchased, and payment for rent of house and rates and taxes thereon.

1. Two copies of this form are supplied. One copy should be filled up and returned to the Board, the other should be kept by the doctor for reference.

2. It is to be understood that the information given in this form is *strictly confidential* and that it is supplied solely for the information of the Board and such of their officers as may be required to deal with it.

Draft Agreement.

HIGHLANDS AND ISLANDS (MEDICAL SERVICE) GRANT ACT, 1913.

DRAFT FORM OF AGREEMENT BETWEEN THE HIGHLANDS AND ISLANDS MEDICAL SERVICE BOARD AND MEDICAL PRACTITIONERS.

N.B.—This Draft Form of Agreement is sent as a general indication of the undertaking which the Board propose to ask practitioners to enter into as a condition of the payment to them of any subsidy. The Agreement will be subject to adjustment according to the circumstances in each individual case.

AGREEMENT between the Highlands and Islands Medical Service Board (hereinafter called "the Board") of the one part and Dr. of (hereinafter called "the practitioner") of the other part, whereby it is agreed as follows:

1. The practitioner shall, as from the date on which this Agreement shall be deemed to have commenced, visit systematically and when asked to do so, all persons within the area of his ordinary practice in need of medical attention.

2. For the purposes of this Agreement the area of the practitioner's ordinary practice shall be—

(Specify the parishes or parts of parishes.)

3. Subject to the provisions of Article 13 hereof, the fees chargeable by the practitioner for medical attendance and treatment provided under this Agreement shall not exceed those specified in the following Table, and no addition shall be made to such fees in respect of the distance from the practitioner's residence to the place of residence of the patient attended.

(Specify fees as arranged with the doctor—for example, fees per visit, per contract, or otherwise, and midwifery fees.)

In the event of any dispute as to whether any patient resident within the aforesaid area as specified in Article 2 hereof comes within the scope of the arrangements for medical attendance and treatment at the foregoing rates, the matter shall be decided by the Board, and the practitioner shall give attendance in accordance with the decision of the Board. But nothing herein contained shall infer any liability on the Board for said fees.

4. The practitioner undertakes that he shall not do anything to terminate or to involve the termination during the currency of this Agreement, of any Agreement or arrangement entered into by him with any Parish Council or Parish Councils and Insurance Committee or Insurance Committees and Public Health Authorities with reference to providing medical attendance and treatment or medicines, drugs, and appliances to paupers, old age pensioners, insured persons, and others respectively within the area of his ordinary practice.

5. The practitioner shall make regular and systematic visits to the outlying districts within his practice, and for that purpose shall attend for the purpose of providing medical attendance and treatment under this agreement at the places and at the times following.

(For example, at A on each Monday between 2 p.m. and 4 p.m.)

6. The practitioner shall, where requested, and so far as practicable, give personal attendance in midwifery cases.

7. The practitioner shall give regular attendance at schools or elsewhere within the area of his ordinary practice on such terms as, with the approval of the Board, may be agreed upon between him and any School Board or School Boards or Secondary Education Committee or Committees concerned for the treatment of diseases of school children, including attending to the defects disclosed by the medical inspection of school children.

8. The practitioner shall, so far as not already done, provide himself with suitable means of conveyance to enable him to attend patients at their place of residence as expeditiously as possible, having regard to the circumstances of his area, and, in particular, but without prejudice, to the said generality he shall provide himself with—

(Specify motor car, cycle, etc., as may be agreed upon.)

9. The practitioner shall keep a classified Register, to be supplied by the Board, of all persons attended by him under this Agreement, including paupers, old age pensioners, and insured persons, showing in each case the number of visits paid, the distance of the patient from the practitioner's residence, and the fees collected in respect of attendance, which Register shall be open to the inspection of any accredited Officer of the Board.

10. Subject to the provisions of Article 13 hereof, the practitioner, where the circumstances so require, shall supply to all persons attended by him under this Agreement such medicines, dressings, and appliances as may be necessary and that at strictly moderate prices, being as nearly as possible such as to recompense him for his outlays in respect of such medicines, dressings, and appliances; but nothing herein contained shall infer

any liability on the Board for said medicines, dressings, or appliances.

[Where the fees specified in Article 3 of this Agreement cover medicines, dressings, and appliances, this article will have to provide that these are to be supplied to the patient free of any additional charge.]

11. Notwithstanding the date hereof this Agreement shall be deemed to have commenced as on the first day of January, 1915, and shall continue in force until the thirty-first day of December, 1915, and from year to year thereafter, provided always that either party may at any time terminate this Agreement on giving three months' previous notice in writing to the other party.

Note.—In the event of the practitioner ceasing to practise within the area, the Board may accept less than three months' notice, but in that case the practitioner shall provide during the unexpired period of the three months a duly qualified medical practitioner approved by the Board as a substitute.

12. The Board shall, provided the practitioner has implemented his part of this Agreement to their satisfaction, pay to the practitioner a sum at the rate of pounds per annum, which sum shall be payable in each year by two instalments, the first, amounting to 45 per cent. of the sum for the year, being payable as at the thirtieth day of June, and the second, representing the balance of 55 per cent., being payable at thirty-first December, or as soon after said respective dates as is practicable; and in the event of this Agreement being terminated prior to 31st December in any year, the payment for that year so far as then remaining due shall be made as soon after such termination as is practicable. In the event of the practitioner not having implemented his part of this Agreement to the satisfaction of the Board, the Board may withhold and cancel the right to such portion, or even the whole of the sum payable to the practitioner, as they think proper.

13. Nothing herein contained shall prejudice or affect any Agreement or Agreements or other arrangements made between the practitioner and any Parish Council or Parish Councils or Insurance Committee or Insurance Committees or Public Health Authorities with reference to providing medical attendance and treatment, or medicines, drugs, or appliances to paupers, old age pensioners, or insured persons, or others, and nothing herein contained shall entitle the practitioner to any payment from such paupers, old age pensioners, and insured persons in respect of medical attendance and treatment, medicines, drugs, or appliances, provided by him under such Agreements or arrangements; but except in so far as such medical attendance and treatment, medicines, drugs, and appliances are provided under such agreements or arrangements these presents shall apply to paupers, old age pensioners, and insured persons.

14. Any notice to be given by, or on behalf of, the Board shall be sufficient if signed by any member of the Board, or the Secretary thereof, and a certificate or letter signed by any member of the Board, or the Secretary thereof, shall be final and conclusive evidence as to the decision of the Board as to any sum due under this Agreement or as to the satisfaction or non-satisfaction of the Board and the extent to which the Board have resolved to withhold or cancel the right to any payment under this Agreement.

IN WITNESS WHEREOF, the parties hereto have executed this Agreement as follows:

Signed for and on behalf of the Highlands and Islands Medical Service Board at.....

on the.....day of.....One Thousand Nine Hundred and.....in the presence of—

MILEAGE.

Paragraph 4 of the Memorandum A on grants to medical practitioners (SUPPLEMENT, August 21st) is so unfortunately worded that its meaning is very far from clear. Some light

is thrown on the matter by a paragraph dealing with the subject in the first report of the Medical Service Board issued last June.

(1) Mileage Scheme.

The annual grant-in-aid voted by Parliament is £42,000. The grant of £10,000 previously voted in aid of mileage and other special charges connected with attendance on insured persons in the Highlands and Islands is, however, included in the annual grant-in-aid, and the additional grant provided by the Act of 1913 is therefore £32,000.

The "mileage" grant of £10,000 in respect of the year 1913 was distributed amongst the practitioners entitled to a share thereof by the various Insurance Committees under a scheme prepared by the Scottish Insurance Commissioners and approved by the Treasury. . . . The organisation of the work of the Board was not sufficiently advanced in the early part of 1914 to enable them to undertake the distribution of the corresponding grants in that year. Accordingly they sought and obtained the consent of the Secretary for Scotland and Treasury to a temporary scheme in respect of the year 1914, whereby grants from the Fund equivalent to those allocated in the previous year to the various Insurance Committees under the Commissioners' Scheme would be payable to the various Committees for distribution amongst the practitioners under the same terms and conditions as in 1913. The first two instalments of the grant have been paid to the various Committees, and the third and final instalment will be paid on the certificate of the Scottish Insurance Commissioners that they are satisfied that the principles laid down in their Scheme of 1913 have been duly observed by the Committees concerned during the current year.

For 1915 no payment will be made by the Insurance Committees in respect of mileage for attendance on insured persons, but the sum formerly set aside for that purpose will be paid on the subsidies payable to the practitioners by the Board in respect of travelling expenses involved in attendance on all persons entitled to receive medical attention under any arrangement between the practitioners and the Board.

THE BRITISH ASSOCIATION.

ANNUAL MEETING AT MANCHESTER.

This week Manchester has been giving a hearty welcome to the eighty-fifth annual meeting of the British Association. Since Sir David Brewster, in 1831, called together at York a preliminary meeting of men who were willing to join with him in a scheme for the assistance of scientific discovery and the public diffusion of the result of research, the association has never abandoned its primary object—"the advancement of science." The chief business of the preliminary meeting at York was to draw up a constitution for the society and to outline a list of subjects on which reports were to be prepared for the first actual meeting of the association at Oxford in 1832. Since that time the conception of what is included in the term "science" has been gradually widened, and, in spite of some opposition, educational matters and a wide range of economical questions have been included within the purview of the association, while some of the original sections have had to be divided up into two or more, notably physiology, which became a section apart from anthropology in 1894. A very substantial part of the income of the association is devoted to the assistance of scientific research where extended observations have to be made or particular apparatus purchased, and at the close of each annual meeting the town to be visited two years later is fixed in advance, and a president-elect is named.

The present occasion is the fourth on which the association has met in Manchester, the first being in 1842, when Lord Francis Egerton was president, the next in 1861, with Sir William Fairbairn as president, and the last occasion in Jubilee Year, 1887, when Sir Henry Roscoe was president. The Manchester meeting in 1887 was one of the best attended of the whole series, no fewer than 3,838 persons being present, including an unusual number of eminent foreign scientists. On the present occasion, owing to the war, it was hardly to be expected that the attendance would even nearly equal that of previous meetings, as not only must a large number of foreign scientists be unavoidably absent, but even many of the leading British scientists, who take the greatest interest in the meetings, have had to announce that Government duties in connexion with the war will prevent their attendance. At one time, indeed, the question was seriously considered whether the meeting should not be altogether abandoned this year, but it was felt that there were so many connecting links between the advance of science and the conduct

of modern warfare that the meeting might prove of even unusual value; practically the only deviation from the usual programme has been that most of the social functions have been abandoned and the meeting has been more than ever for what may be called business science.

President's Address.

The inaugural meeting was held in the Manchester Free Trade Hall on Tuesday evening, September 7th, when Professor ARTHUR SCHUSTER took over the presidency from Professor William Bateson, and delivered his presidential address on "The common aims of science and humanity." There were not wanting many members who would have preferred that Professor Schuster should have dealt with some of the more strictly scientific questions on which he is the highest living authority, but the reception he received was in no way lessened on that account. In the course of his address, he said: Under the influence of the diversity of pursuits imposed upon us by the conditions of modern life, different groups of the community—men of business, men of science, philosophers, or artists—have acquired detached and sometimes opposing interests. Each group, impressed by the importance of its own domain in the life of the nation, and focussing its vision on small differences and temporary rivalries, was in danger of losing the sense of mutual dependence. But in the shadow of a great catastrophe it has been brought home to us that the clash of interests is superficial. As we eliminate the superficial, and regard only the deep-seated emotions which control our thoughts and actions, the differences vanish, and the unity of purpose and sentiment emerges more and more strongly. Were it otherwise, the British Association could not perform one of its most important functions. Our records show that while not avoiding controversy and even inflammatory subjects, we have been able to exercise a powerful influence on the progress of science. Nevertheless, it may be admitted that our efforts have been spasmodic, and the time has arrived to consider whether it may be possible to secure not only a greater continuity in our work but also its better co-ordination with that of other scientific organizations. Dealing with the qualities of intellect and temperament characteristic of different occupations or pursuits, Professor Schuster showed how Poincaré concluded that the characteristic of the mathematician is a peculiar type of memory. It is not a better memory, for some mathematicians are very forgetful, and many of them cannot add a column of figures correctly; but it is a memory which fixes the order in which the successive steps of reasoning follow each other without necessarily retaining the details of the individual steps. Applying the same reasoning to other occupations, the same conclusion is inevitable. The commercial man, the politician, and the artist must all possess the type of memory best suited to concentrate in the field of mental vision their own experiences as well as what they have learnt from the experience of others; and, further, they must have the power of selecting out of a multitude of possible lines of action the one that leads to success; it is this power which Poincaré calls the inventive faculty. The most fatal distinction that can be made is the one which brings men of theory into opposition to men of practice, without regard to the obvious truth that nothing of value is ever done which does not involve both theory and practice. In his presidential address, delivered to the association in 1899, Sir Michael Foster arrives at the same result which I have tried to place before you: that there are no special peculiarities inherent in the scientific mind. But if we must avoid assuming special intellectual qualities when we speak of groups of men within one country, we ought to be doubly careful not to do so without good reason in comparing different nations. So-called national characteristics are in many cases matters of education and training; and, if I select one as an example, it is because it figures so largely in public discussions at the present moment. I refer to that expedient for combining individual efforts which goes by the name of "organization." The cry for organization, justifiable as it no doubt often is, resolves itself into a cry for increased discipline. This discipline is not an inborn quality which belongs more to one nation than to another; it is acquired by education and training. In an emergency it is essential to success, but if it be made the guiding principle of a nation's

activity, it carries dangers with it which are greater than the benefits conferred by the increased facility for advance in some directions. Why does a scientific man find satisfaction in studying Nature? Let me once more quote Poincaré:

The student does not study Nature because that study is useful but because it gives him pleasure, and it gives him pleasure because Nature is beautiful; if it were not beautiful it would not be worth knowing and life would not be worth living. I am not speaking, he it understood, of the beauty of its outward appearance—not that I despise it, far from it—but it has nothing to do with science. I mean that more intimate beauty which depends on the harmony in the order of the component parts of Nature.

It might easily be shown that what has been said of science equally applies to other studies, such as history or literature. We may even go further, and say that any occupation whatever from which we can derive an intellectual pleasure must possess to a greater or smaller degree the elements of combining the useful with the beautiful. There is only one feature in the operation of the intelligence by means of which a sharp division may possibly be drawn between brain workers showing special capabilities in different subjects. In some persons thought attaches itself mainly to language, in others to visualized images, and herein lies, perhaps, the distinction between the literary and scientific gift. Those who, owing to external circumstances, have resided in different countries, are sometimes asked in what language they think. Speaking for myself, I have always been obliged to answer that, so far as I can tell, thought is not connected with any language at all. The planning of an experiment, or even the critical examination of a theory, is to me entirely a matter of mental imagery, and hence the experience, which I think many scientific men must have shared, that the conversion of thought into language, which is necessary when we wish to communicate its results to others, presents not only the ordinary difficulties of translation, but reveals faults in the perfection or sequence of the images. Only when the logic of words finally coincides with the logic of images do we attain that feeling of confidence which makes us certain that our results are correct. According to Poincaré, the pleasure which the study of science confers consists in its power of uniting the beautiful with the useful; but it would be wrong to adopt this formula as a definition of the object of science, because it applies with equal force to all human studies. I go further, and say that the combination of the search for the beautiful with the achievement of the useful is the common interest of science and humanity. Some of us may tend more in one direction, some in another, but there must always remain a feeling of imperfection and only partial satisfaction unless we can unite the two fundamental desires of human nature. I have warned you at the beginning of this discourse not to beat the utilitarian drum too loudly, and I have laid stress throughout on the idealistic side, though the most compelling events of the moment seem to drive us in the other direction. Should I not have found a surer ground for the claims of science in its daily increasing necessity for the success of our manufactures and commerce? I have said nothing to indicate that I do not put the highest value on this important function of science, which finds its noblest task in surrendering the richness of its achievements to the use of humanity. But I must ask you to reflect whether the achievement of wealth and power, to the exclusion of higher aims, can lead to more than a superficial prosperity which passes away, because it carries the virus of its own doom within it. Do we not find in the worship of material success the seed of the pernicious ambition which has maddened a nation, and plunged Europe into war? Is this contempt for all idealistic purposes not responsible for the mischievous doctrine that the power to possess confers the right to possess, and that possession is desirable in itself without regard to the use which is made of it? I must therefore insist that if we delight in enlisting the wealth accumulated in the earth, and all the power stored in the orbs of heaven, or in the orbits of atomic structure, it should not be because we place material wealth above intellectual enjoyment, but rather because we experience a double pleasure if the efforts of the mind contribute to the welfare of the nation. Happy were the times when it could be said with truth

that the strife of politics counted as nothing before the silent display of the heavens. Mightier issues are at stake to-day: in the struggle which convulses the world all intellectual pursuits are vitally affected, and Science gladly gives all the power she wields to the service of the State. Sorrowfully she covers her face because that power, accumulated through the peaceful efforts of the sons of all nations, was never meant for death and destruction; gladly she helps, because a war wantonly provoked threatens civilization, and only through victory shall we achieve a peace in which once more Science can hold up her head, proud of her strength to preserve the intellectual freedom which is worth more than material prosperity, to defeat the spirit of evil that destroyed the sense of brotherhood among nations, and to spread the love of truth.

The Sections began their meetings on Wednesday, mostly at the university, and continued to meet for the reading of papers and discussion on Thursday and Friday. It is proposed to give some account next week of subjects that arose of medical interest.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received during the past fortnight have been as follows:

	£ s. d.		£ s. d.
Mr. C. E. S. Watson	5 0 0	Dr. Fred Hazell	1 1 0
Cape of Good Hope		Dr. Bolger	2 2 0
Branch (Western Division), B.M.A.		Dr. Reynolds	1 1 0
Dr. E. B. Fuller	5 5 0	Dr. Guillemand	1 1 0
Dr. McGowan Kitching	2 2 0	Dr. S. F. Silberbauer	1 1 0
Dr. Chas. Anderson	5 5 0	Guernsey and Alderney Division, B.M.A.	
Dr. G. W. B. Daniell	1 1 0	Dr. H. D. Bishop (Hon. Sec.)	
Dr. Simpson Wells	1 1 0	Dr. Carothers	0 5 0
Dr. Benjamin Cohen	0 10 6	Dr. Hugh Smith	0 10 0
Dr. Hugh Smith	5 0 0	Dr. Bishop	0 10 0
Dr. C. C. Elliott	5 0 0	Dr. Wallace	0 10 0
Dr. Verduhaer	0 10 6	Dr. Baitlee	0 5 0
Dr. Darley Hartley	1 1 0	Dr. Gibson	0 10 0
Dr. A. W. Carden	2 2 0	Dr. Bisson	0 5 0
Dr. C. J. Hill Aitkin	1 1 0	Dr. Bostock	0 5 0
Dr. E. F. W. Moon	1 1 0	Dr. R. W. Winstanley	1 1 0
Dr. W. Thomas	5 0 0	Leicester Pharmaceutical Association (per Mr. C. J. Avery)	15 7 6
Dr. Gerecke	1 1 0	Mr. A. Chapman	0 11 8
Dr. J. Conroy	1 1 0	Mr. E. A. Williamson	0 7 6
Dr. F. Waldron	2 2 0	Anonymous	1 0 0
Dr. H. Syrett	2 2 0		
Dr. H. Kramer	2 2 0		

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and would be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

We have received from Copenhagen a leaflet stating that a society has been formed to study the "social consequences of the war." The head quarters of this society—"Selskabet for Social Forsken at Krigens Følger"—are at Østerbrogade 56 C, Copenhagen, and its aims are: (1) The foundation of a collection of the whole war literature appearing in all European languages. (2) The classification of the materials to facilitate a scientific elaboration of the same. (3) The elaboration of the materials. Apparently the society already possesses "a special library of social war literature. . . . A special room is placed at the disposal of anybody who wishes to work on a scientific basis. It purposes to publish bulletins about the collections and progress of work of the society." We are not given any details as to the origin of this society; the names of the members of its executive committee—if such exists—are not supplied us, and the only name that appears is that of D. Lewin. Over his signature we are told that the aims of this society are purely scientific, and that it remains absolutely neutral in all political questions. It is to be hoped that the society's self-appointed task of "preparing scientifically the new social formation to come by elucidating the scientific, financial, social, and political consequences of the war" will be successfully carried out. It will not be easy.

British Medical Journal.

SATURDAY, SEPTEMBER 11TH, 1915.

THE WAR EMERGENCY.

THE campaign for the recruiting of commissioned officers for the R.A.M.C. is in full swing. Medical men of suitable age and physical condition in England and Wales are urged by the War Emergency Committee, which is sitting at 429, Strand, London, W.C., to take immediate service where possible, or to undertake to do so at some specified date. The scheme of enrolment is now worked out. All men of military age are earnestly requested to enroll themselves with the Committee as willing to take service in case of special emergency. Forms have been prepared which can be had on application. These forms provide spaces in which the doctor can enter the particular difficulty which prevents his volunteering forthwith. These difficulties will be taken into consideration by the Committee; men on this roll will only be called upon in case of special necessity, and each case will be considered on its merits according to the statements made by the signatory of the form. It is particularly requested that medical officers of municipal authorities who have medical men of military age on their staff will encourage these members of their staff to fill up these enrolment forms. By so doing they will render considerable service, enabling the Committee to have knowledge of all the available material; the statements made on the form of enrolment indicating the particular difficulty which prevents immediate volunteering will ensure that they do not lose these members of their staff, except in case of special necessity.

The Committee has this week received a communication from the War Office concerning the age limits for medical officers; it shows that the somewhat varied statements of the several commands have now taken definite and identical form. Medical officers for home service only will not be commissioned over the age of 55 years. Medical men for foreign service will now be accepted up to the age of 45 provided they are in every way fit. One important point arises out of the limitation of the age for commissions for home service to 55 years. It means that men over this age who are fit for additional work or for some form of medical practice differing from that which they are doing at present can best serve their country by doing the work of some younger man and releasing him for foreign service.

As has previously been reported, the Committee resolved to represent to the Director-General A.M.S. that it was not desirable that medical men of age for foreign service should fill home military posts. It has now been informed by the Medical Department of the War Office "that the question of men of military age doing military work at home is under our serious consideration, and steps have already been taken to prevent men who are under 40 being continuously employed in regular military hospitals in this country. The question is also being taken up with regard to Territorial Force General Hospitals and Voluntary Aid Hospitals, and it is hoped that a satisfactory arrangement will be arrived at. We

are in every way discouraging younger men who are physically fit for active service from engaging for home service only."

Medical men desiring information on any of the points here mentioned should, if resident in England or Wales, apply to the Secretaries of the War Emergency Committee, 429, Strand; if resident in Scotland, to the Convener of the Scottish War Emergency Committee at the Royal College of Physicians, Edinburgh; if resident in Ireland application may for the present be made to the Medical Secretary in Ireland of the British Medical Association, Dr. Hennessy, 16, South Frederick Street, Dublin.

THE HIGHLANDS AND ISLANDS MEDICAL SERVICE.

THE schemes of the Highlands and Islands Medical Service Board for the amelioration of conditions in respect of medical attendance and treatment in those remoter parts of Scotland were published in the SUPPLEMENT to the JOURNAL of August 21st, and this week we are enabled by the courtesy of the Board to publish (p. 404) for the information of the profession generally the documents it sent on August 16th to the medical practitioners resident in the areas concerned.

It will be worth while in the first place to trace the brief history of the Board. Representations as to the difficulty of securing a satisfactory medical service for the Highlands and Islands were made to the Treasury by the Scottish Insurance Commission soon after it was formed, and in July, 1912, a Committee was appointed, with Sir John Dewar, M.P. for Inverness, as Chairman, to consider "how far the provision of medical attendance in districts situated in the Highlands and Islands of Scotland is inadequate, and to advise as to the best method of securing a satisfactory medical service therein, regard being had to the duties and responsibilities of the several public authorities operating in such districts." The members of the Committee made a tour of the Highlands, encountering discomforts by land and sea which must have impressed on them the perils of practice in these districts; they heard many witnesses as reported in our columns at the time, and after they got home drew up a report which was made the basis of the Highlands and Islands (Medical Service) Grant Act of 1913. This Act provided that for the four years ending December, 1917, on which date the Act itself will expire, there shall be paid to the Board set up by the Act the sum of £42,000 a year "for the purpose of improving medical service, including nursing, in the Highlands and Islands of Scotland, and otherwise providing and improving means for the prevention, treatment, and alleviation of illness and suffering therein."

The Board got to work in November, 1913, but before issuing its first annual report in June last gave no overt signs of life until, on August 16th, it launched upon the practitioners in the Highlands and Islands a series of documents of a voluminous and complicated character, and demanded much information and the acceptance of a draft agreement on or before August 31st. When it is remembered that at the best of times the post to not a few of the places takes several days, and moreover that at this particular time fully a third of the medical practitioners concerned are serving in the Army and Navy, many of them in Flanders or the Dardanelles, it is difficult to understand how the blunder of allowing so short a time for consideration could have been made. That

it was no more than a blunder we have no doubt, but it would not have needed very much imagination to picture the perplexity such an avalanche of documents must produce in the mind of an isolated man not perhaps very well acquainted with legal terminology, and the suspicion which the short time allowed for their consideration, a time so short as to render consultation among the men affected practically impossible, would naturally arouse.

We must credit a Board appointed for a purpose so benevolent and containing so large a proportion of medical members with the best intentions, and it will be proper first of all to attempt to realize the objects the Board may be supposed to have had in view. We take it that they were somewhat as follows: The grant is intended to benefit the population of the Highlands by making available for them medical attendance and nursing on reasonable terms. The money is not to be devoted wholly to doctors and nurses; it is to include the cost of such facilities as improved telegraph and telephone communication and aid in the provision of hospitals and of suitable houses for doctors and nurses; but increased income and increased travelling facilities for doctors and nurses are important features of the proposals. Before the Insurance Act relieved the situation the plight of many doctors was lamentable, and there is still much room for improvement, especially in remote and thinly-populated areas, where many of the people have very little command of money.

The medical problem is divided pretty sharply into two parts, though they overlap each other—namely, single practice areas and multiple practice areas. In the former the doctor has no competitor. The local sources of income are very small, and the legislature intended in every such case to make life at least tolerable for the doctor. The Committee's idea, as suggested in questions to medical witnesses, would seem to have been an income of £300 a year after paying travelling outlays, and house rent and rates and taxes, excepting income tax. The Board appears to have adopted the principle that every local source of medical income should be utilized to provide a living for the doctor of the single practice area. If there is to be any treatment of school children, the doctor is to be prepared to undertake it and the salary will be taken into account. If there is a lighthouse the Lighthouse Commissioners' payment for medical attendance should, it is considered, go to the same man and not to some one from a distance. The parish council appointment is commonly the most important; next comes the income under the Insurance Acts; and all these also should, it is held, be in the hands of the same man. The request that the amount received from appointments under the Poor Law and Lunacy and Public Health and Education and Insurance Acts, as well as from private practice and from medicines, should be set out in the statement of income (Form 2) is doubtless due to considerations of this order. As we understand the matter, the idea of the Board is that when it is in possession of these details, and also the details of expenditure, it will be in a position to confer with the doctor as to the amount of subsidy appropriate to the case. With regard to private practice, it would appear that the Board desires, not merely that a doctor should be obtainable throughout the whole area of the practice, but that he should be obtainable at moderate terms—that is to say, that there should be for people of the crofter and cottar classes a fixed uniform fee, independent of distance, so that a crofter twenty miles away would pay the same charge for a visit as a crofter next door. Any reduction due to this cause in the income from

existing private practice will have to be estimated in fixing the amount of the subsidy.

In multiple practice areas the position is in some respects different. A small town or populous village is usually the centre of a multiple practice area, and from the centre doctors go out in various directions to attend the strictly rural population. Sometimes many miles have to be travelled. It is equally important that in these areas also poor people should be assured of medical attendance at a rate within their means, but we gather that the Board does not propose to attain this end by making arrangements with the doctors in such a centre to secure for them a minimum net income. Their net income may already be in excess of anything that the Board would be able to offer, but the Board would appear to desire that the town or village doctors should receive under the grant such remuneration as will enable them to attend distant crofters and cottars at a fee commensurate with the means of the crofter or cottar. It is for this reason no doubt that Form 2 does not require from such doctors any information as to the income from private practice or the expenditure on travelling or on house rent, etc., and that the Board does not seek to know the net professional income.

Having, as we hope, done full justice to the intentions of the Board, we feel at liberty to say that the manner of their presentation has been most unfortunate. No attempt whatever was made by way of a memorandum to explain the objects the Board had in view or its, no doubt, excellent intentions. The covering letter issued on August 16th was of the driest official sort, and it certainly seemed to require the immediate signature of an agreement to cover the whole of 1915, including the eight months already expired, "and from year to year thereafter." The covering letter said that it was a draft form of agreement with practitioners which the Board proposed to adopt, "subject to adjustments according to the circumstances in each individual case," but not a word was said about how these adjustments were to be made. On the contrary, it appeared on the face of it that the form was to be duly witnessed and signed by the doctor over a 6d. stamp; Jeddart justice, in fact: hang him first and try him afterwards. The provision that the agreement may be terminated by three months' notice does not really relieve the situation and no appeal seems to have been provided in respect either to the amount of remuneration or the terms of service. At the hastily summoned meetings so far held in the Highlands it has been asked that any agreements now signed shall be considered provisional, and we have been given to understand that this is the Board's intention, but, if so, it has failed in the most singular manner to make it plain, and the further request made at these meetings for explanation is fully justified.

The reference in Scheme A, paragraph 4, to the matter of mileage has excited much apprehension: this is, we believe, really due to the unfortunate turbidity of the paragraph in question. The matter is made rather more clear in the paragraph quoted at p. 407 from the annual report of the Board. Before the Medical Service Act was passed a grant of £10,000 a year was voted by Parliament for mileage under the Insurance Act; later, Parliament voted £42,000 a year for all the purposes of the Board, among which was to be the making of arrangements for the payment of mileage for attendance not only on the insured under the Insurance Act, but also on the uninsured of the crofter and cottar class. It is, we think, clear that there is no intention to diminish the mileage grant, but there is equally no assurance that it will be maintained, or, as it ought to be, increased.

There are many other points which need to be cleared up. How, for instance, is a doctor to visit "systematically and when asked to do so" all persons in need of medical attention (all persons, let it be observed, from the shooting tenant to the cottar); how is he also to give personal attendance in mid-wifery cases, and to do these things while undertaking to make regular and systematic visits to certain localities on fixed days? How, again, is he to obtain and maintain his motor car or cycle, or motor boat? Is the capital expenditure to fall upon him, and when the motor cycle is smashed or the motor boat wrecked, is he to bear the cost of replacing it?

In this state of obscurity we are glad to know that the Scottish Committee of the British Medical Association has been summoned to meet at Perth on September 10th to discuss the whole matter in all its aspects.

THE UNIVERSITIES OF LANCASHIRE AND YORKSHIRE.

The Vice-Chancellors of the Universities of Manchester, Liverpool, Leeds, and Sheffield addressed a letter on August 26th to the Committee on Public Retrenchment, expressing the desire of the authorities of these universities to do whatever is wise and possible to secure such economies in the expenditure of public and private moneys as will be found consistent with the needs of the country in the present national emergency. The letter expresses the opinion that it will be found on inquiry expedient in the economic interests of the nation somewhat to increase the public grants to the universities, even at the present time of financial difficulty. The four universities concerned have the intention of reducing their expenditure during the period of the war to the lowest point consistent with efficiency; they have already effected drastic economies and have others in view. The income of the universities is derived from the annual grant made by the Treasury to university institutions which, being without ancient endowment, need public subsidy in the discharge of their national work; from grants from the Board of Education for the encouragement of technological and professional training; from grants from the Board of Agriculture for the training of men and women as agriculturalists, horticulturists, and dairy farmers, and grants from the Development Commission for scientific experiments on a commercial scale for the resuscitation of the flax industry, and for the improvement of cereals and other crops. Their other source of income—students' fees—amounts in some instances to a quarter, and in others to two-fifths, of the total. The universities by their charters are open equally to women and men, and it is admitted that the number of women students may be maintained, possibly increased, especially in the faculties of arts and medicine. It is, however, submitted that the most important part of the work of these universities lies in the field of pure and applied science, in the training of chemists, physicists, doctors, dentists, public health officers, steel experts, civil, mechanical, and electrical engineers; architects, farmers, colliery managers, textile managers, metallurgists, gas engineers, dyers, and leather trade experts. The universities concerned have in consequence been able to render very important service, in some respects vital, to the State during the war, and they have further in a specifically military sense rendered important service, especially in the training of officers. "The various departments of a university," the letter continues, "are interdependent. The intellectual life of one department gains from intimate association with the intellectual life of another. For example, you could not curtail or close down the departments of inorganic and organic chemistry without paralysing the departments of chemistry applied to dye-stuffs, leather, or fuel consumption. Again, some of the researches in the physics de-

partment have a close bearing on the work of the department of textile industries, which at first sight seems remote. And the departments of applied science gain stimulus and range of vision from association with scholars who are engaged in economic, historical, and other studies. A university which is actively contributing to the life of the nation is a unity, and would be lamed by partial closure. Moreover, it takes years to form a staff of researchers and teachers imbued with the spirit of scientific co-operation. Such a staff is a delicate organization, and, if 'scrapped,' could not be started again at pleasure." The universities receive about one-fifth of their income from local authorities out of rates, but this support is to some extent measured by the Government grants; if the Government subsidy were cut down the local grant would probably be reduced, and the result to the universities would be very serious. The Vice-Chancellors insist upon the need of looking to the future; the universities, they say, were created to supply the educational needs of the great industrial populations of the north. They are slowly, and not without a struggle, winning the confidence and respect of the communities in which they are set, and are inculcating upon the business world the advantages of scientific education. If, they conclude, it be true "that one of the most obvious lessons to be drawn from the war is the need of an increased application of scientific method to industry, we feel that the northern universities have a great part to play in the direction of such a movement, and that it would be unwise and unthrifty to starve those of their energies which are devoted to that end." The force and truth of the appeal put forward by these four universities, which are bound together by a statute for the purpose of conducting a joint matriculation, and still more by the similarity of the duties which fall upon them in the great industrial communities which have called them into existence, will appeal to all those who appreciate the perilous position of British industries in competition with the enterprise of Germany and the United States, in both of which countries the leaders of industry seem to have a better understanding of the need for scientific investigation and scientific methods. From the point of view of the medical faculties, which, perhaps, more particularly concern us, it has now become a truism to say that they cannot be efficiently carried on without adequate endowments, or, failing them, adequate subsidies from the State and from municipalities; the time has long passed when students' fees, ekeed out by the utmost self-sacrifice of the teachers, could suffice. Medical education has become costly, and is certain to become yet more costly in the future.

FLIES AT THE FRONT.

It was foreseen that a plague of flies was to be expected both in Flanders and Gallipoli, owing to the conditions inevitably associated with military operations, especially, perhaps, when the forces engaged are more or less stationary. Apart from the discomfort which the troops would suffer by the presence of flies of various kinds in large numbers, the danger of the dissemination of disease was, of course, recognized, and the need of instituting effective practical methods of keeping down the plague to the smallest dimensions possible fully understood. In Flanders the precautions taken have been of an elaborate kind, and date back to April last—that is, before the commencement of the house-fly season, when a circular memorandum on *The Abolition of Flies in Camps, Bilets, and Hospitals* was issued by the Director-General of Medical Services, British Forces in the Field. Sir Arthur Sloggett pointed out that within the area occupied by the British forces in the field there were concentrated enormous numbers of men and horses, with the result that abnormal quantities of stable manure and other waste organic matter were produced, and he added that in places along the line of the actual front there were many unburied

bodies. He anticipated that in consequence flies in unparalleled numbers would make their appearance in the course of the summer and autumn unless adequate measures were taken to prevent the insects from breeding. The memorandum, which was widely circulated to medical officers, contained full practical instructions for the prevention of the fly plague, and among other fly poisons enumerated was the solution of sodium arsenite, which, as was noted in the JOURNAL a short time ago, has recently been employed with success and, under proper precautions, without risk in South Africa. Very shortly after the issue of this circular, a special entomological commission for service in the field was appointed; it consisted of three well-known entomologists—Mr. Robert Newstead, F.R.S., Professor of Medical Entomology, Liverpool University; Mr. R. W. Jack, Government Entomologist, Southern Rhodesia; and Captain E. E. Anstey (Artists' Rifles), British Museum (Natural History). The commission was instructed to study the question on the spot and to inquire into the efficacy of the measures for the suppression of flies already adopted or projected. After a preliminary investigation of the conditions in a part of the front area, visits were paid to the lines of communication and the various bases. An extensive series of experiments were made with a view to ascertaining the best method of dealing with fly-breeding places which it might be impossible to destroy by fire. As a result of this work, further recommendations were issued by the commission in an interim report. Since then the commission has been continuously engaged in visiting all parts of the front in turn with a view to giving advice to sanitary officers and others on the spot. In this way visits have been paid to a large number of casualty clearing stations, field ambulances, and advanced dressing stations, to the town of Ypres, to the trenches, and to farms and other billets within range of the enemy's guns. The flies to be dealt with have been house-flies, blue-bottle flies and green-bottle flies, and the places where the insects were found to be breeding, and the best practical means for checking them were indicated. In the trenches themselves house-flies have been less numerous than blue-bottle and green-bottle flies; although in certain places in the war zone in France and Belgium house-flies have been more numerous than could be wished, yet a great deal has been done, and but for the preventive measures adopted and the attention paid to the subject by those responsible the plague would undoubtedly have been much worse than it is. The blow-flies, blue and green, have presented greater difficulties. Dr. Shipley, in the account he published last year of the habits and life-history of both the blue-bottle fly and the green-bottle fly,¹ pointed out that two species of blue-bottle or blow-flies had to be considered, *Calliphora erythrocephala* and *C. vomitoria*. He spoke of them as outdoor flies which entered houses in search of a suitable place to deposit their eggs, by preference on fresh or decaying meat, but even on wounds. The habits of the green-bottle fly, *Lucilia caesar*, are very similar, but it is said to prefer fish when it can find it. The eggs of the blue-bottle hatch out in from ten to twenty hours in normal British temperatures; the larval life in its three stages lasts from seven to eight and a half days; the pupa state lasts a fortnight, so that the total development extends a day or two over three weeks. Though no practical means for destroying these flies in the trenches on a wholesale scale have been devised, it has been found possible to drive them away by periodic spraying with a suitable fluid. Fortunately, though perhaps more annoying than house-flies, the blow-flies are far less dangerous to man as disseminators of disease.

THE ALCOHOL QUESTION IN FRANCE.

M. RIBOT, the French Minister of Finance, has drafted a bill to regulate the manufacture and sale of alcoholic beverages in France, which embodies many of the recom-

mendations of the Académie de Médecine enumerated in the JOURNAL of August 21st, p. 299, and those of the Académie des Sciences, which were almost identical. The discussion on the question of permitting wine as part of the regular ration issued to French soldiers was concluded by the Académie de Médecine on August 24th, but not before the views expressed by M. Gautier and others,¹ who advised a litre of wine a day to replace part of the meat, had been severely criticized by Professor Chauffard and Professor Richet. The former disputed the assertion that the food ration was insufficient, and denied that wine should be considered an aliment, holding that the Académie would come much nearer the truth if it described wine as an agreeable condiment. The issue of wine had been suggested as a means of fighting alcoholism, but he expressed the opinion that unless the soldier could be prevented from going to wine shops to supplement the ration the remedy would be worse than the disease. Professor Richet's criticism was directed mainly against the pedantic use of the doctrine of calories. A poisonous substance might be burnt up in the body and yield a certain number of calories, but it remained a poison, and it was not a contradiction in terms to say that alcohol both yielded calories and was a poison. He held that the use of wine, even in a small quantity, was an evil, that it slowed gastric digestion, and that if it produced some passing stimulation this was paid for by depression later on. At the same time, he thought that the habit of drinking wine was too deeply rooted to be eradicated, and that it would be better to issue wine in strictly limited quantities rather than to leave the soldier to obtain it clandestinely. Finally, the Académie determined to define a moderate quantity of wine as half a litre, the quantity issued daily in the French navy. After adopting the following aphorism: "*Apéritifs* never, wine with food and in moderate quantity, a liqueur occasionally, but only after a meal," it passed a resolution in these terms: "That naturally wine in moderate quantity—namely, in the same amount as in the navy—be included in the official ration of the soldier, and that precautions be taken to ensure that if the administration supplies wine to the soldiers they shall not be allowed to consume it elsewhere."

A LONG SHOT.

EARLY in 1886 Dr. Byrom Bramwell saw a man of 45 with complete loss of peripheral vision and very marked reduction of macular vision, the result of an attack of what appeared to be uraemic convulsions twenty months previously. Dr. Bramwell diagnosed the condition as probably due to a simultaneous bilateral lesion of the two occipital lobes of the brain, in the region of the half-vision centre. In October, 1910, the patient died of crumpons pneumonia, and his brain was sent to Dr. J. S. Bolton, who completed his elaborate examination in May, 1915; it entirely confirmed the brilliant diagnosis made by Dr. Bramwell twenty-four and a half years before the patient's death; during that period the condition had remained practically unaltered, while sensory and motor paralyses were absent. Without going into detail, the following points from Dr. Bramwell's preliminary report² on the case may be noted. Originally the patient had an attack of acute general dropsy, probably due to acute nephritis, with epileptiform convulsions, permanent loss of peripheral vision, normal fundi, and no mind-blindness or word-blindness. During the next quarter of a century the patient remained in fair health, speaking generally, able to get about by himself and to read large type and to write; his mental condition was not abnormal; the pupils reacted normally to light and to accommodation. In 1905 the optic discs were described as having a somewhat leaden-grey atrophic

¹ BRITISH MEDICAL JOURNAL, AUGUST 7th, p. 251.

² Edinburgh Medical Journal, July, 1915.

appearance, with extensive shallow cupping, and a well developed scleral ring round each. The retinal arteries had a hard "silver-wire" appearance. After examining the brain, which contained a large lesion in each occipital lobe, Dr. Bolton makes the preliminary report that "the histological investigation of this case may thus claim not only to have explained the clinical features present during life, but to have added to our knowledge of the part played by the visuo-sensory area in macular and in non-macular or panoramic vision. It may, in fact, be stated that the anatomical basis of the former is the cortex of the calcarine core of the pear-shaped visuo-sensory area, and that the anatomical basis of the latter lies in the surrounding and remaining visuo-sensory cortex." Questions as to the cortical localization of the centres for the special senses in man can only be determined, as Dr. Bramwell points out, by the combined observations of the clinician and the pathologist in man, for the results obtained by experiments upon the lower animals cannot be transferred directly to human beings. In the present instance Dr. Bramwell's skill and his success in following up the patient have added materially to our knowledge of the functions of the visuo-sensory cortex.

GERMAN ORGANIZATION.

For a generation at least before the war the Germans made bold, if not always very skilful, use of bluff to establish a belief in their pre-eminence in various spheres of activity—as for instance, in science. They are pursuing the same policy in the war to-day. A year ago they were proclaiming loudly that the number, high training, and bravery of their soldiers, and the strategical genius of their generals would bring them early victory. Now, when these boasts would sound hollow, they proclaim that their confidence in ultimate success rests on the efficiency of their organization, civil as well as military. "The Germanic race," says Professor Ostwald, "has discovered the factor of organization." That its organization is very carefully thought out, and that when subjected to the maximum strain for which it is calculated it works very efficiently, no one doubts. When the strain on an organization is much greater than that calculated defects are bound to be disclosed, and a breakdown can only be avoided if there are skilled experts possessed of initiative in positions of sufficient authority to enable them to make good defects as they are detected. A year ago the cruelties to which British wounded were subjected by their captors were partly excused on account of the sudden stress produced by the rapid advance into France, which ought, of course, to have been foreseen, and partly explained by the ostentatious hatred with which fear of this country had inspired the German people. But the very interesting article by an "Exchanged Officer" in *Blackwood* for this month shows that even four months later, in January, 1915, the machine had not been repaired. At that late date a large number of wounded men, Germans and prisoners, were crowded into third-class carriages for the long journey from Flanders to southern Germany. No distinction was maintained—among the wounded prisoners, at any rate—between sitting-up and lying-down cases, the forwarding of the trains by the railway officers was about as bad as could be, the arrangements for feeding and supplies generally totally broke down, and the policing of the stations seems in many places to have been left to chance. A fact mentioned incidentally, and quoted as an example of good organization, is that dressing rooms and pharmacies had been established at railway stations in Belgium. This looks well until we learn that wounds were not dressed during the long journey, and that, in fact, there were no trained orderlies or nurses to make any attempt in that direction. The whole story of muddle and callousness takes us back to pre-Criméan days, with some added horrors, due to mere spite and cowardice, thrown in.

A SCHOLARLY PARANOIAC.

AMONG the minor benefits conferred upon us by the war is immunity from medical conversation at the mixed dinner table. Those ladies who were accustomed to dogmatize on diet and drugs now talk tactics and strategy. However, the attention given in various lay publications to a case which we will refer to as that of Dr. X., warns us that the interest in medical topics is only in abeyance, and is ready to become active again as soon as the interest in temporarily more absorbing matters has subsided. Dr. X., apart from his scholarship, which was not ordinary, was an ordinary paranoiac, with the ordinary proclivity of the paranoiac to take the life of his imaginary persecutor whenever opportunity presents and exasperation reaches the boiling point, from which it is never far distant. The double event occurred in the early hours of a winter's morning in 1872, and the unfortunate paranoiac, who ought not to have been allowed at large, shot and killed in the street an unoffending passer-by. It is not mentioned in the reports now published, but the fact was that on waking in the night Dr. X. had seen at the foot of his bed an imaginary figure which he took to be that of his persecutor. He bounded out of bed, seized his revolver, and followed the figure downstairs and into the street, where he saw a real man, whom he identified with the imaginary man that he was pursuing, and shot him dead. At the trial he was found "Not guilty, on the ground of insanity," and was detained at Broadmoor for many years. He was a man of education and literary tastes, and was, of course, allowed every alleviation possible, which in his case took the form of an abundant supply of books. The single rooms at Broadmoor are not spacious, nor elastic, and Dr. X.'s room was crammed with piles of books as high as a man, which left but the narrowest of passages between them; and here for many years he worked for Dr. Murray in the production of the wonderful Oxford *Dictionary*. The public gapes with wonder at the conjunction of madness with scholarship and unusually high intellectual attainments, but to those who are familiar with insanity there is nothing unusual in the combination, and to those who understand what insanity is there is nothing to wonder at in the combination. A highly intellectual and learned man is no more immune from insanity than a yokel or a boor, and in paranoia, as in many other mental disorders, the disorder affects but a small region, though unluckily a very important region, of mind, and leaves the remainder completely normal. *Pope* Mr. Pope, a little knowledge is not necessarily a dangerous thing. It is not dangerous if it is a sound knowledge of a true principle, and this resurrection of the case of the unfortunate Dr. X. would be of great value if it were used, not as an occasion for stupid wonderment, but as an opportunity of inculcating the maxim, which is generally true, that every paranoiac is a potential homicide, and that no paranoiac ought to be allowed at large. Unfortunately there are many paranoiacs at large. There are many who are so clever that their relatives and acquaintances cannot believe that they are mad, although they are well known to cherish delusions of persecution. Such persons are a grave danger to the community in which they live. Some years ago one of them, at Ramsgate, shot down seven unoffending wayfarers in the street, three of them fatally; and scarcely an assize goes by without one or more paranoiacs in some county or other being indicted for murder or some crime of violence.

THE Governor of Hong Kong announces that in the two weeks ending September 6th four cases of plague occurred; all died.

DR. JAMES DONELAN desires to state that, having resigned his appointment as medical referee to the London Committee of the French Red Cross, he has no further responsibility in regard to appointments in French auxiliary military hospitals.

THE WAR.

THE PROPORTION OF RECOVERIES AMONG THE WOUNDED.

Ugeskrift for Læger, the journal of the Danish Medical Society, published in its issue for July 29th, the following table, furnished to it by Louis Fraenkel, showing the relative number of deaths, recoveries and partial recoveries among all the German soldiers treated in the military hospitals in Germany during the first nine months of the war. The results, he states, are in reality better than would appear from the table, as a number of the rejected recovered sufficiently to again offer their services for military work at a later date.

Results of Treatment in German Military Hospitals.

	Fitted for Service.	Died.	Rejected.
1914.			
August	84.3 per cent.	3.0 per cent.	12.2 per cent.
September	88.1 ..	2.7 ..	9.1 ..
October	89.9 ..	2.4 ..	8.7 ..
November	87.3 ..	2.1 ..	10.6 ..
December	87.8 ..	1.7 ..	10.5 ..
1915.			
January	88.7 ..	1.4 ..	9.9 ..
February	86.6 ..	1.3 ..	10.0 ..
March	88.9 ..	1.6 ..	9.5 ..
April	91.2 ..	1.4 ..	7.4 ..

Comparable figures have not been published in this country, and it is not probable that their compilation will at present be undertaken. We believe, however, from information in our possession, that the following percentages, based on the experience of the first year of war, will prove to be approximately correct:

Results of Treatment in British Military Hospitals in Great Britain and Ireland.

Discharged to duty, on furlough, or sent to convalescent homes	95.00 per cent.
Died	0.86 ..
Permanently unfit	4.14 ..

Such statistics possess a certain interest, but it is not possible to draw from them any conclusions as to the ratio of men who have died of wounds to those who have recovered more or less completely. A large but unstated number of men treated in the most advanced medical units and on the lines of communication must have died before they reached the hospitals in Germany or the United Kingdom.

In connexion with this subject reference may be made to the following statement published by Geheurnat Dr. W. Exner in the *Wiener medicinische Wochenschrift* for June 12th, 1915: "Dr. Biesalsky, an authority in Germany on cripples, has reported that out of 800 wounded under his care, he has found 235 severe cases. But only in 10 of these cases were the patients completely crippled. This would be about 1 per cent. of all the wounded. But even if the proportion of cripples is only 1 per cent. and is smaller than was first anticipated, the responsibility towards the individual is not lessened."

ABERDEEN WAR DRESSINGS DEPOT.

The Aberdeen War Dressings Depot was opened on May 19th, 1915, in a house kindly lent for the purpose in a central part of the city. A General Committee was formed under the presidency of the Marchioness of Aberdeen and Temair, and the management placed in the hands of a small Executive Committee, consisting of a doctor, three trained nurses, and a secretary. Before the undertaking was started a certain monthly income had been guaranteed by voluntary subscription.

The object of the depot is to save time and labour in hospitals abroad by providing them with dressings and other requisites ready for use. Since all the work is done

voluntarily, the articles are produced at a very low rate. They are sterilized and packed in assortments ready for immediate use.

The house in which the work is carried on has been utilized from floor to roof, while the outhouses have been turned into store-rooms and workshop, and even the garden is used for the drying of sphagnum moss for dressings. On the top floor are store-rooms for materials and work-rooms in which moss and pine sawdust dressings are made. On the next floor there are rooms for the padding of splints and the making of swabs, an additional store-room, and a tea-room, where tea is served at 9d. a head, the profits being devoted to the general fund. On the ground floor a large room is given up to the making of bandages; here also are sewing machines for making the muslin bags for the moss and pine sawdust dressings. On this floor also is the office and a room where the finished articles are collected and examined before packing. The basement is used for the packing and export department and for the storage of packing cases, wood for splints, dried sawdust, etc. By the kindness of the directors all the necessary sterilizing is done at the Aberdeen Royal Infirmary.

The number of workers on the books is over 300; they work in relays from 10.30 a.m. to 1 p.m., and from 2.30 p.m. to 5.30 p.m. From May 19th to August 26th the number of articles made and dispatched was over 72,000, consisting, in round numbers, of 55,000 swabs, 6,000 moss dressings, 4,000 pine dressings, 4,000 roller bandages, 1,000 padded splints, 600 many-tailed bandages, 200 "T" bandages, 300 wood-wool fomentation pads, 400 slings, 100 pillows, 300 pillow-cases, 100 rolls of plugging, 100 face-cloths. The following notes, founded on the experience, may be of use to others:

The moss must be thoroughly cleaned and all pine needles, grasses, twigs, etc., carefully removed. It must not be artificially dried, as this makes it very brittle and dusty. The most satisfactory plan is to expose it in coarse muslin bags to the action of the sun and air. Pine sawdust is sifted twice, first through a No. 8 sieve, to exclude the coarse particles, secondly through a No. 36 sieve to remove the fine dust, which otherwise passes through the muslin. The sawdust is well dried before use in the drying-room of a steam laundry which has kindly offered its services for the purpose. For the finished dressings the moss and sawdust are put into muslin bags, which are made in four sizes, 6 in., 8 in., 10 in., and 12 in. square. The muslin must be of a fine quality, and the bags are filled about half full. These are packed in flannelette bags, each holding twenty assorted sizes, and are then sterilized.

Round and flat swabs are made of gauze and absorbent wool; they are packed in lots of 25 and 50, in sealed grease-proof paper bags. Eight bags containing 25 swabs each, or four bags containing 50 swabs each, are packed in pillow cases and sterilized. A small number of ear, nose, and throat swabs are sent with each consignment.

Straight splints are made in the following sizes—9 in. and 12 in. long, 3 in. wide by $\frac{1}{2}$ in. thick; and 20 in. and 29 in. long, $\frac{3}{4}$ in. wide by $\frac{1}{2}$ in. thick. Long Liston splints are made 52 in. and 55 in. in length by $\frac{3}{4}$ in. wide by $\frac{1}{2}$ in. thick, and are finished with perineal counter-extension bands. Long Liston splints and back splints with footpieces are moulded. All splints are padded in the recognized manner, the pads being made of old linen filled with well-tensed tow, and are held in place by strong tacking across and across the backs of the splints. This method has been objected to on the ground that the pad may easily become soiled by discharges, and the time devoted to the making consequently wasted, but if the splint is protected by a piece of lacoon, this accident can usually be avoided. A properly padded splint is much more efficient and comfortable than one extended with wool and bandage, moreover it is cheaper.

Roller bandages are made in the following sizes: 1 in., 3 in., 4 in., and 6 in. wide. A very thin flannelette has been found to be an excellent substitute for doelette, and is considerably cheaper. It is also used for making "T" bandages, and many-tailed bandages, which are in two sizes, abdominal and limb.

Packing for export is done as far as possible in light tea-chests, but splints and sawdust dressings are sewn into bales. Both boxes and bales are lined with waterproof sheeting for use in hospitals, and bales are provided with corner tags for doghooks.

The cost of materials is unfortunately increasing, but up to the end of July the cost price of some of the articles was as follows: Swabs, 7d. per 100; many-tailed and "T" bandages, each 4 $\frac{1}{2}$ d.; 3 in. bandages, about 1d. each; 4 in. bandages, 1 $\frac{1}{2}$ d. each; 6 in. flannelette bandages, 8 $\frac{1}{2}$ d. each; moss and sawdust dressings, size 6 in., about 30 for 5d.; 8 in., about 16 for 5d.; 10 in., about 12 for 5d.; 12 in., about 8 for 5d.; slings, each 2d.; wood-wool fomentation pads, each under $\frac{1}{2}$ d.

The cost of the depot is met by monthly subscriptions and donations, and, in addition, numberless gifts of

material of all kinds have been received. Many willing workers in outlying districts collect and forward sphagnum moss and pine sawdust, of which large supplies have to be stored before the approach of winter makes the work of collection impossible. Other gifts include empty cases for packing, hessian, rope, wood for splints, sacks, ticking, fetters, etc.; while much help has been received in the form of work done by joiners and others in making splints, putting up shelving, sifting sawdust, closing packing cases, mending machines, and in various other ways.

GERMAN EXPERIENCES OF WAR SURGERY.

THE TREATMENT OF BULLET AND SHELL WOUNDS.
DR. W. ISRAEL, Oberarzt of the 11th Field Hospital of the Guards, in summarizing his experiences in the treatment of wounds, states that at the outbreak of the war conservative treatment of bullet wounds, including shrapnel wounds, was generally adopted, and subsequent experience confirmed the wisdom of this course. It was found that the fate of men thus wounded depended on the first aseptic dressing, and that from a clinical, though not a bacteriological point of view, the wound inflicted by a bullet was primarily aseptic. On this account it was advisable not to probe such a wound nor to attempt to remove the bullet.

Conservative treatment of shell wounds was frequently practised early in the war, and they were often left to themselves, the dressings being seldom changed. A more frequent change of dressings, and more active treatment, including free incisions and amputations, would, he thinks, undoubtedly have saved many lives. Every shell wound was septic from the outset, and in the majority of cases anaerobic gas-forming organisms, producing an offensive smell, were present. Among these anaerobic organisms only the *Bacillus emphysematousus* of Fraenkel was really pathogenic. As it was impossible to detect the nature of the infection of a recent shell wound it was not possible to anticipate the course of the infection. It might be strictly limited, and give rise to a necrotic or purulent inflammation with circumscribed gas phlegmon, or it might develop into a rapidly progressive galloping gas phlegmon or gas gangrene, terminating fatally within forty-eight hours. On account of this uncertainty of the course of the infection, and in order to save not only the patient's limb but his life, it was imperative to operate as early and as radically as possible. It was necessary to remove all the dirt, grass, straw, and particles of clothing which fragments of shell had carried into a wound, as well as metallic fragments and clotted blood. The small scab or crust which, when covering a bullet wound, was interpreted as a sign of healing without infection, was, in the case of shell wounds, a treacherous mask, the removal of which disclosed a brown, stinking, gaseous discharge. This was the case even with quite small shell wounds, and it was therefore necessary to remove all such crusts.

While dry dressings were excellent for bullet wounds, and were necessary for all wounds during transport, the ideal dressings for shell wounds were wet. After the wounds had become relatively clean, the wet dressings were replaced by ointments; by this treatment change of dressings was painless, and there was no hæmorrhage. In the early stages of the wound, and when there was a profuse stinking discharge, it was found advisable to change the dressing at least once a day in order that any spread of infection might be detected early. In many cases the track of a fragment of shell was overlooked, and only a small superficial wound was detected. In such cases the persistence of suppuration led to a more careful examination of the wound, and to its exploration with a thick blunt probe, a procedure harmless in the case of wide septic shell wounds; it often led to the discovery of a channel through the tissues, at the end of which a fragment of shell was found. Such a channel was always freely opened, and the fragment of shell removed at all costs. Dr. Israel never regretted freely opening all shell wounds at the earliest possible opportunity, and he often found the removal of hidden fragments of shell and other foreign bodies followed by the disappearance of suppuration and offensive smell, by a fall in the temperature, and by improvement in the patient's general well-being, noticeable within a few hours of the operation. When

the presence of large vessels and nerves in the neighbourhood of a shell wound prevented free incisions, small incisions and a liberal use of drainage tubes were indicated. Early incision and drainage were so essential in the case of shell wounds that they should be undertaken by surgeons in the first line ("Sanitätskompanie") and not deferred until the man was admitted to a hospital. This course, however, was practicable only when the number of wounded at a given time was limited and the fighting of a stationary character, as in trench warfare. Daily change of the dressings of shell wounds and the careful examination for signs of extension of infection were too often neglected; many a limb had been lost because a free incision of a localized gas phlegmon was made too late. However clean and well applied the dressings of a shell wound might be when the patient was admitted to hospital, they should at once be taken off and the wound thoroughly examined, in order that the development of a pocket of pus might be detected early. While the first dressing usually determined the course of a bullet wound, the course of a shell wound was principally determined by the degree of care devoted to the case throughout its course and by the timely intervention of the surgeon when complications arose. When wounds of the limbs were complicated by fractures, even early surgical interference was often attended by failure.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed.

SURGEON FREDERICK JAMES HUMPHREYS, R.N., died of wounds in the Dardanelles. He was educated at St. Thomas's, and took the diplomas of M.R.C.S. and L.R.C.P. Lond., and also the degrees of M.B. and B.S. Lond. in 1912. After qualifying he filled the posts of house-physician, casualty officer, resident anaesthetist, and obstetric house-physician at St. Thomas's. He joined the navy as a temporary surgeon on August 4th, 1914, and was attached to the Armoured Car Division when killed.

ARMY.

Killed.

Lieutenant Peyton Tollemache Warren, R.A.M.C. (T.F.), who, as already noted, was reported on August 20th as killed in the Dardanelles, was educated at Dublin, where he took the diplomas of L.R.C.P.I. and L.R.C.S.I. in 1909. He was medical officer and public vaccinator at Bryn, Port Talbot, Glamorgan, where he was a prominent member of the Bryn golf and rifle clubs. He received a commission as lieutenant in the third Welsh Field Ambulance on June 9th, 1913.

Captain James Noble Armstrong, R.A.M.C., killed in France on August 22nd, was the only son of Mr. J. M. Armstrong, J.P. of Dundalk. He was educated at Ipswich and at Trinity College, Dublin, where he gained a senior moderatorship in science, with gold medal. He took the M.B., B.Ch., and B.A.O. at Trinity College in 1914, got a temporary commission as lieutenant R.A.M.C. on August 15th, 1914, became captain in April, 1915, and was attached to the 2nd Battalion Durham Light Infantry when he was killed at the age of 25.

Lieutenant-Colonel Charles Ernest Thomas, V.D., of the New Zealand Army Medical Corps, was killed in action in the Gallipoli peninsula on August 28th, 1915. He was the son of Mr. H. S. Thomas, formerly of the Madras Medical Service, a member of the Madras Council, now of Parkside, Tiverton, and was educated at Cheltenham College and at the Middlesex Hospital. He took the diplomas of L.S.A. and L.R.C.S. Edin. in 1888, and after acting as house-surgeon and house-physician at Middlesex Hospital went out to New Zealand. There he filled the post of resident surgeon of the Timaru Hospital, and afterwards settled in practice at Timaru, where he was port health officer and public vaccinator. He was surgeon-captain in the 5th New Zealand Regiment, the South Canterbury Infantry, and served with the New Zealand contingent in South Africa in 1900-1, receiving the Queen's medal with three clasps. When the New Zealand force was raised for the present war, he was appointed to the Medical Corps, with the rank of lieutenant-colonel.

Died of Wounds.

Lieutenant T. A. Peel, R.A.M.C., was wounded on August 19th in the Dardanelles, and succumbed to wounds

on August 24th. He was the youngest son of Mr. J. E. Peel, solicitor, Armagh, a very well-known name in the North of Ireland. He received his education at the Armagh Royal School and then entered the medical school of the Royal College of Surgeons in Ireland, after about a year there he went to Newcastle-on-Tyne, and finally graduated M.B., B.S., 1911, in the University of Durham. He had a very successful and distinguished career in the University and earned for himself the good opinion and affection of his seniors and fellow students. T. A. P., as he was known to his intimates, was an all-round man and had very distinct literary tastes; his strongest inclinations in this respect were towards poetry, and on his own account could jingle a string of verses which were both tuneful and pleasing. He had an affection for the works of Francis Thompson, and the writer treasures a copy of *The Hound of Heaven* given to him by his dead friend. Peel's literary tastes had some outlet when as a student he was on the staff of the *Students' Journal* at Newcastle, and he was particularly gratified that during his term of office he was instrumental in issuing a print of Henry Gray, the anatomist. After leaving the university he became a house-surgeon at the Royal (Gwent) Hospital, Newport, and he is well remembered there as a courteous and efficient officer. After leaving Newport he went to the Stafford General Infirmary, where he remained for some months, and then passed on to the larger institution—the North Stafford Infirmary at Stoke; he was a very popular officer there, and gained the very good will of the staff. He was gazetted temporary lieutenant R.A.M.C. on October 10th, 1914, and was for a considerable time in training with the 5th Dorset Regiment; he went out with the 11th Division Mediterranean Force. Peel was not untravelled: he was particularly interested in the clinics of Lambotte at Antwerp, and Tuffier in Paris. There is no doubt that he would have rapidly attained eminence in his own profession, and men of his charming temperament and conspicuous ability are a sad loss to our much stricken profession. Peel is survived by his father, two sisters, and two brothers, one of whom, a solicitor, is serving in the forces. He would say, in the words of his beloved Francis Thompson:

My mangled youth lies dead beneath the heap,
My days have cracked and gone up in smoke.

Lost in Transport "Royal Edward."

The list of officers lost in the transport *Royal Edward*, torpedoed and sunk in the Aegean Sea on August 14th, with the loss of about a thousand lives, was published on September 7th. Out of thirty-two officers on board, thirteen were lost, including four medical officers—Lieutenant-Colonel J. H. Dauber, Major J. Mowat, Captain C. B. Marshall, and Lieutenant T. Hayhurst. Obituary notices of the first two have already been published in the JOURNAL.

Major James Mowat, R.A.M.C., who was lost in the *Royal Edward* transport when she was torpedoed in the Aegean Sea, with great loss of life, on August 14th, was an ex-naval officer. He was educated at Gordon's College, Aberdeen, and at the university in that city, where he took the degrees of M.B. and C.M. in 1891. Entering the navy as surgeon, he attained the rank of fleet surgeon on May 10th, 1910, and retired at twenty years' service. He rejoined at the beginning of the war, and was medical officer on board H.M.S. *Hermes* when she was torpedoed and sunk near Dover last autumn. He then had to take sick leave, and was subsequently discharged on account of ill health, receiving the thanks of the Admiralty for his services. Having recovered, he applied for employment in the R.A.M.C., and was appointed major in the 54th Casualty Clearing Station from April 29th, 1915. "An Old Shipmate" writes: "When H.M.S. *Hermes* was torpedoed Mowat rendered gallant service. Owing to the force of the explosion the ship's carpenter had both his legs broken. Mowat rendered first aid, and gave up his own lifebelt and placed it around this man. Having attended those he could, he helped the wounded to reach the destroyers around, and by lucky chance survived himself. Some months later he retired a second time and took up private practice, but later, when there was a shortage of R.A.M.C. officers, he volunteered, and joined as a major (T.F.), and met his fate in H.M.S. *Royal Edward*. A most capable officer, beloved by all who knew him."

Captain Charles Bertram Marshall, R.A.M.C.(T.F.), was educated at Manchester, where he took the M.B. and Ch.B. Vict. in 1909, the D.P.H. in 1911, and the M.D. in 1913. After acting as resident medical officer to the Manchester Children's Hospital and resident surgical officer to the Ancoats Hospital, Manchester, he went into practice at Bramhall Park, Cheshire, Hulme, Cheshire. He joined the 3rd East Lancashire Field Ambulance (head quarters, Manchester) as lieutenant on September 5th, 1914, and became captain on February 27th, 1915.

Lieutenant Thomas Hayhurst, R.A.M.C.(T.F.), took the M.B. and Ch.B. at Edinburgh in 1911. He filled the posts of junior and senior house-surgeon to the Victoria Hospital, Burnley, in 1911 and 1912, and then went into practice at Fulwood, Preston. He joined the 1st East Lancashire Field Ambulance (head quarters, Manchester) as lieutenant on September 5th, 1914.

Died.

Major J. L. Duval, of the Canadian Army Medical Corps was reported in the casualty list of September 1st as having died in Flanders. He was an officer of the 1st Canadian Field Ambulance, to which he was appointed as captain on September 22nd, 1914, becoming major on April 17th, 1915.

Wounded.

Dardanelles.

Lieutenant-Colonel A. R. Wilson, R.A.M.C.(T.F.)

Major L. P. Brassey, I.M.S.

Captain C. V. Baigent, M.D., Otage Infantry.

Lieutenant T. C. Clarke, R.A.M.C.(T.F.).

Lieutenant C. H. K. Smith, R.A.M.C.(T.F.).

Lieutenant R. G. M. Ladell, R.A.M.C.(T.F.).

Lieutenant J. C. Young, R.A.M.C. (Special Reserve).

Lieutenant J. D. Jones, R.A.M.C. (temporary).

Lieutenant W. Magner, R.A.M.C. (temporary).

Lieutenant H. H. Elliott, R.A.M.C. (temporary).

Lieutenant H. E. McWall, R.A.M.C. (temporary).

Lieutenant N. Matthews, R.A.M.C. (temporary).

Lieutenant Quartermaster J. F. E. Godman, R.A.M.C.

Flanders.

Lieutenant R. J. Batty, R.A.M.C.

Missing.

Captain A. P. Smith, R.A.M.C., Dardanelles.

DEATHS AMONG SONS OF MEDICAL MEN.

The following cases have been reported during the past two weeks, chiefly from the Gallipoli peninsula: Campbell, George Edward Forman, Lieutenant 2nd Battalion 10th Gurkhas, wounded and last surviving son of Colonel Robert Neil Campbell, C.B., I.M.S. (retired), Senior Medical Officer, Pavilion and York Place Indian Hospitals, Brighton, killed in the Dardanelles, between August 6th and 10th, aged 21. He was born on August 27th, 1893, educated at Edinburgh Academy, where he was in the school eleven and fifteen, was a King's Cadet at Sandhurst, and entered the army on August 24th, 1912.

Chapman, Philip E., Private 8th Battalion Hampshire Regiment, eldest son of Dr. Paul Chapman, of Carfax, Hereford, died at Malta, September 4th, of wounds received in the Dardanelles.

Harries, Eric Guy, Captain 7th (Merioneth and Montgomery) Battalion Royal Welsh Fusiliers, younger son of Dr. Harries, of Grosvenor House, Aberystwith, died on August 16th from wounds received in action in the Dardanelles on August 10th, aged 22. He was an engineer by profession, and was employed in the Cambrian railway works at Oswestry, till he got a commission as lieutenant on September 2nd, 1914, becoming captain on March 6th, 1915.

Hoffmeister, H. A. N., Captain King's Shropshire Light Infantry, second son of Mr. John Hoffmeister, of Cowes, Isle of Wight. He reached the rank of captain on December 31st, 1914.

Humphreys, R. M., Second Lieutenant 7th (Merioneth and Montgomery) Battalion Royal Welsh Fusiliers, eldest son of Major C. E. Humphreys, R.A.M.C.(T.F.), District Sanitary Officer, 68th (Welsh) Division, and County Medical Officer of Merionethshire, killed in the Dardanelles. His commission is dated September 2nd, 1914.

Hunt, C. H., Second Lieutenant 5th Battalion Lancashire Fusiliers, son of Dr. T. Hunt, of Heywood, Manchester. He received his commission on March 1st, 1912.

Key, Douglas, Second Lieutenant 78th Field Company R.E., elder son of the late Dr. James M. Key, of South Africa, died of wounds in France. He was educated at Montrose Academy and Dulwich College, and received his commission on July 2nd, 1914.

O'Duffy, Kevin Emmanuel, Second Lieutenant 7th Battalion Royal Munster Fusiliers, second son of Mr. Kevin O'Duffy, L.D.S., Surgeon Dentist to His Excellency the Lord Lieutenant

of Ireland, killed in the Dardanelles on August 15th, aged 20. He was educated at Belvedere College, Dublin, and at Stouyhurst, and got his commission on January 28th, 1915.

Proctor, Charles Edgcombe, Lieutenant 7th Battalion Norfolk Regiment, son of the late H. C. Proctor, M.D., of Southport, and of Lady Smith, Natal, killed in France on August 2nd, aged 23. He was born in Lady Smith, in the siege of which town his father served, and educated at Lindisfarne College, Epsom College, and Middlesex Hospital, and had passed the medical missionary. He received his commission on January 1st, 1915.

Roberts, E., Lieutenant 7th Battalion West Yorkshire Regiment, son of Dr. E. Roberts of Leeds, died of wounds in Flanders. His commission is dated August 23rd, 1913.

Scott-Skiving, A. W., Captain 5th Battalion Royal Irish Fusiliers, son of Dr. Robert Scott-Skiving of Sydney, died at sea on August 7th of wounds received in the Dardanelles. He formerly held the rank of Lieutenant in the Australian Commonwealth Forces, and became Captain on December 2nd, 1914.

Southern, Gerald Cameron, Lieutenant 53rd Sikhs, second son of Mr. F. G. Southern, M.R.C.S., of Clifton, Bristol, and of Llandebe, Carmarthen, killed in action at Sheikh Otman, Aden, while leading his men, in the range of July 21st. He was born on March 7th, 1892, entered the army on August 24th, 1912, and became Lieutenant on November 24th, 1914.

Thompson, E. H. B., Lieutenant 9th Battalion Somerset Light Infantry, eldest son of Dr. E. T. Thompson, of Southfield, Belgate Road, Bath, died at sea, on the way to the Dardanelles, aged 35. He was formerly in the 3rd Royal Irish Regiment, and had served in the South African war, when he gained the Queen's medal with three clasps.

Tobin, Richard Patrick, Lieutenant 7th Battalion Royal Dublin Fusiliers, only son of R. F. Tobin, F.R.C.S.I., of Angharagh, Dublin, killed in the Dardanelles on August 15th, aged 21. He was a medical student at Trinity College, Dublin, and a member of the O.T.C. when the war began, and received his commission on March 6th, 1915.

Tomes, Geoffrey, Captain 53rd Sikhs, second son of Lieutenant-Colonel A. Tomes, I.M.S.(ret.), killed in the Dardanelles, while attached to the 1st Battalion 5th Gurkhas, between August 6th and 12th, aged 30. He was born on October 6th, 1884, and joined the Queen's West Surrey Regiment from August 5th, 1902. He entered the Indian army on October 23rd, 1906, and was posted to the 1st Sikh, with that regiment he served in the Zalka Khal and in the campaigns on the North-West frontier of India in 1908, receiving the Queen's medal with a clasp. With it also he went to Egypt, took part in the repulse of the Turks on the Suez Canal. In July he was sent to join the 15th Gurkhas, with which he was serving when killed in the Gallipoli peninsula.

Treves, Harold Thomas, Lieutenant Nelson Battalion Royal Naval Division, younger son of the late W. K. Treves, F.R.C.S., of 32, Dalby Square, Margate, died at sea on May 25th, from wounds received at the Dardanelles on May 22nd. He was a barrister-at-law of the Middle Temple.

Turnbull, Percy D., Private 1st Battalion King's Own Scottish Borderers, son of Surgeon-General P. S. Turnbull, I.M.S.(ret.), of 4, Churchhill, Edinburgh, lost in the *Royal Edward*, torpedoed in the Aegean Sea on August 14th.

Weston, Captain John Theodore Spencer, killed in action in France on August 20th, was the younger son of Dr. Darby of Weston of Handsworth, Birmingham, and was in the last year of his medical course in the university of that city when war broke out. He was a Colour-Sergeant in the University Officers' Training Corps, and at once volunteered. He received a commission as Lieutenant in the 1st Royal Warwickshire Regiment, but was transferred to the 1st Berks in the Regiment, with which he was serving at the time of his death. He was mentioned recently in dispatches and received the Military Cross for conspicuous service in the field. He was promoted Captain a few weeks ago. He was 23 years of age.

Whitaker, Owen, Second Lieutenant Royal Garrison Artillery, eldest son of Dr. J. Smith Whitaker, of the Insurance Commission, was killed in Flanders on August 29th. He was born at Great Yarmouth on May 6th, 1895, educated at University College School, and had entered at University College, London, with a view to beginning medical studies. He was for four years a member of the O.T.C. on the Training Corps, and received a commission in the R.G.A. on September 29th, 1914, when he was posted to Plymouth Honorary Force in Flanders, where he was serving in the Expeditionary Force. His name appeared as killed in the casualty lists of September 14th, and on the same day in a list of officers on whom the Military Cross had been bestowed for gallantry in action, as follows: "Tenants, Lieut. Owen Whitaker, 34th Trench Howitzer Battery, R.G.A., for conspicuous gallantry on the Yser Canal on August 14th, 1915, when a portion of our trenches was under fire for over three hours from several of the enemy's trench mortars and aerial torpedoes. Sec. Lieut. Whitaker's detachment were all killed or wounded, but with his soldierly servant (Gunner Raynor) he took placed two bombs in the enemy's trenches before expending all the ammunition on the spot. They were under very heavy fire from the enemy's trench mortars all this time."

Young-James, A. Y., Lieutenant 8th (Lancs of Wight) Battalion Hampshire Regiment, son of Dr. Young-James of Bournemouth,

wounded and missing, believed killed, in the Dardanelles. He was by profession a solicitor, in practice at Newport, Isle of Wight.

MEDICAL STUDENTS.

Auchinachie, George, Lance-Corporal Gordon Highlanders, son of the late Provost Auchinachie of Aberchirder, killed by a shell in Flanders. He was a medical student at Aberdeen, who had enlisted for the war, and had been twice previously wounded.

MacAdam, John, Lieutenant 4th Battalion Essex Regiment, died of wounds at the Dardanelles, August 18th. He was the son of Mr. H. MacAdam, of Messrs. MacLaren and Sons, Ltd., the publishers, London, and was educated at the City of London School and at St. Bartholomew's Hospital. He got a commission as Second Lieutenant in 1912, becoming Lieutenant on August 5th, 1914, and went to the front in July. Another brother holds a commission in the same battalion.

NOTES.

HONOURS.

On September 6th the War Office published a list of twelve appointments to the Distinguished Service Order, and thirty Military Crosses, bestowed for gallantry in the field. One medical officer, Captain K. W. Jones, R.A.M.C., Special Reserve, received the D.S.O., and one, temporarily Lieutenant T. L. Ingram, R.A.M.C., the Military Cross, for the following services:

Captain Kingsmill Williams Jones, M.D., R.A.M.C.(S.R.), attached to 1st Battalion East Kent Regiment. For conspicuous gallantry and devotion to duty at Hooge. During the entire night of August 9th-10th, 1915, and the whole of the following day and night, he was attending to and evacuating himself to shell and rifle fire. He was twice slightly wounded, but stuck to his work with unflinching energy. It was entirely owing to wounded. Before the crater was successfully evacuated of Manchester, and was a member of the City Council.

Temporary Lieutenant Thomas Lewis Ingram, R.A.M.C., attached 1st Battalion Shropshire Light Infantry. For conspicuous devotion to duty and energy at Hooge. He was evacuating wounded from the front trenches almost without intermission on the entire nights of August 9th and 10th, 1915, and his lives of many severely wounded officers and men. He has previously done consistently good work. Before the war Lieutenant Ingram practised at Rugby.

The award of the Military Cross to the late Lieutenant Owen Whitaker is noted above.

At the same time the Distinguished Conduct Medal was bestowed upon 144 non-commissioned officers and men, including the following nine men of the medical services:

Sergeant J. W. Broome, R.A.M.C., 1st East Anglian Field Ambulance.

Private H. T. Cameron, No. 3 Field Ambulance, 1st Canadian Division.

Private J. Comrie, New Zealand F.A.

Lance-Corporal G. C. Farnham, 3rd F.A., Australian Imperial Force.

Private W. J. Hendy, New Zealand F.A.

Private E. P. Hitchcock, Australian A.M.C.

Private J. V. F. Gregg-Macgregor, 1st F.A., Australian Imperial Force.

Private A. A. Morath, Australian A.M.C.

Private L. Crawford-Watson, New Zealand A.M.C.

RUSSIAN DECORATIONS.

Among the recipients of honours conferred by the Emperor of Russia for distinguished service in the field, as announced on August 25th, appears the name of Lieutenant John Downie, M.B., Yorkshire Mounted Brigade Field Ambulance R.A.M.C.(T.F.), who receives the Order of St. Anne, Fourth Class, inscribed "For Valour in War." The list also contained the names of the following non-commissioned officers and men of the medical services:

Cross of the Order of St. George.

Third Class.—Sergeant-Major T. Crawley.

Fourth Class.—Assistant Surgeon K. P. Elloy, Staff Sergeant E. Dymond; Sergeants A. W. Brown, T. M. Brown, T. B. Carter, and R. H. Davies; Privates M. Johns, A. Kester, W. A. Last, H. C. Sell, and D. Wolfe.

Medal of St. George.

First Class.—Sergeant C. Ingram.

Second Class.—Sub-Assistant Surgeon Gopinath Agarwall, Staff Sergeant W. Lankin, Sergeant J. H. Faveley, and Corporal F. M. Harris.

Third Class.—Corporal A. Burns, Private F. Turner, Driver J. N. Gibbs.

Fourth Class.—Privates W. Hanson, W. Malone, T. Markes, H. Stapleton, P. M. Stephens, C. B. Tomkins, H. Wilkinson, and A. B. Wood.

ANGLO-RUSSIAN RED CROSS HOSPITAL.

A committee has been formed in England for the purpose of organizing a hospital unit of 200 beds to be offered to the Russian Red Cross for work in Russia. It is known that the offer will be appreciated, and when the staff and equipment have been completed the medical superintendent and some members of the committee propose to go to Russia to make final arrangements; the hospital could be adapted for work at a base or on the lines of communication, but the manner in which it can best be employed must be determined entirely by the Russian military authorities. The committee has already made considerable progress towards providing the personnel of the unit. It is proposed that the medical staff shall consist of a senior operating surgeon, a physician, a radiographer, a bacteriologist, and two assistant surgeons, and the nursing staff of a matron, twenty-two qualified nurses and eight probationers. There will also be a small clerical and subordinate staff, consisting of a store keeper, clerk, and two or more artificers; it is expected that orderlies will be procured when the hospital gets to Russia. The hospital will be equipped in every detail, and it will be ready to start work, it is hoped, almost as soon as it arrives in Russia. It is anticipated that in addition a convoy of motor ambulances and accessories will be attached to the hospital. The scheme of the committee has the approval of the British Ambassador in Petrograd, and Queen Alexandra is its patron. Its president is Lord Cremer, Lord Chylesmore is the chairman of the Executive Committee; Sir Starr Jameson vice-chairman, Sir Owen Phillips treasurer, and Lady Muriel Paget honorary secretary. From Professor Pares, who has been working with the Russian Red Cross for nearly a year, the committee has received the assurance that the help thus proffered will be highly appreciated, particularly at the present time. The offices of the Anglo-Russian Hospital Committee are at 116, Victoria Street.

SCOTTISH AMBULANCE TRAIN FOR FRANCE.

The ambulance train which has been constructed by the Caledonian Railway Company for service in France, at the cost of £20,000, is of the kind known as the permanent hospital train, and consists of sixteen long carriages, some of which are ambulance coaches fitted with tiers of cots, others are coaches for the medical officers, nursing sisters, and remaining personnel, whilst yet others constitute the treatment room, operating theatre, kitchen, and the dispensary. Sir Charles Eric Renshaw, the chairman of the Caledonian Railway Company, in some remarks at the opening ceremony on September 2nd, referred to the increasing means of dealing death in modern warfare, and said that he was thankful to think that the surgical and medical possibilities of the present day were also enormously greater. There was first aid on the field of battle, a swift motor service to and from the field hospitals, and splendid ambulance trains going from the field hospitals to the base hospitals. All these agencies were helped by the devoted labours of the medical profession, the value of whose efforts during the present war it would be impossible to exaggerate. The whole empire owed them a great debt of gratitude. The Duchess of Montrose, in performing the opening ceremony, made use of the appropriate expression "veritable train de luxe" for the work of the Caledonian company's yards. The train was on show during the remainder of the week at Glasgow, the proceeds from the visitors going to the funds of the Scottish branch of the Red Cross Society; it was then viewed in Edinburgh on Monday, Tuesday, and Wednesday (September 6th to 8th), and was afterwards taken to Dundee, Aberdeen, and other centres.

THE FRENCH RED CROSS.

In a paragraph published in the JOURNAL of April 24th, p. 740, it was stated that a system had been started in conjunction with the London Committee of the Croix Rouge Française for supplying voluntary service by British surgeons for short periods. We are disposed to think that in existing circumstances British surgeons wishing to give their services for limited periods would be well advised to consider in the first place the claims of their own country and the needs of the British Red Cross and the St. John Ambulance Association. The call on the profession in this country is very urgent, and the War Emergency Committee appointed at the Representative Meeting of the British

Medical Association is prepared to advise British medical men as to the best course they should take. Communications may be addressed to the Honorary Secretaries, War Emergency Committee, British Medical Association, 429, Strand. It is satisfactory to be able to add that, as was shown during the recent debate in the French Chamber, the French organization for dealing with wounded from the French army has been, during the last few months, very greatly improved.

THE STAR AND GARTER HOSTEL.

The acquisition of the Star and Garter Hotel at Richmond for the purpose of a home for paralysed and disabled soldiers and sailors was referred to in our issue of August 21st, and an outline of the scheme, so far as it had then proceeded, was given. Many of the details were still then under consideration a fortnight ago, and even now much remains to be decided. The original Star and Garter, erected in 1738, and subsequently greatly improved and extended, was totally destroyed by fire in 1870. The present hotel was built a few years before the destruction of the old building, and on a neighbouring site. The actual site of the old Star and Garter is occupied by the present pavilion, which was built in 1872. The first part of the plan now to be proceeded with relates, not to the larger building, but to this comparatively low-roofed annex, which comprises two very large apartments, the pavilion dining room and the Prince's Hall. This part of the building is being converted so as to accommodate sixty-four paralysed men, and will be opened in two months. Meanwhile the work upon the main structure will be proceeded with so soon as the architect's plans for remodelling have been finally worked out and approved. The garden village scheme also is in the tentative stage at present, and the question of opening up the big colonnade is still under discussion. There will be a resident medical officer, but the institution will not be a hospital. The cases received will be those of paralysed men who have been discharged from the services as incurable. Should an inmate show signs of improvement, he will be sent at once to a hospital proper. The institution when completed will, it is hoped, be not only an expression of national gratitude to those who have been so peculiarly stricken, but also an important national memorial to the work of the British Red Cross Society in the time of the great war.

MONTENEGRO.

The following is an extract from a letter written by Dr. Strong to Miss Mabel T. Boardman, chairman of the American Red Cross Relief Committee. It describes a visit to a hospital to Pech in Montenegro:

On entering the hospital I saw in the first room² through which we had to pass many piles of clothing which had been removed from the typhus cases. These lay on the floor, and crawling over these and upon the floor in the vicinity were literally thousands of lice. I had never seen so many before, even in Serbia. The hospital had about 250 cases of typhus. They were all badly neglected. The wards themselves were in a dreadful condition. There were no disinfectants, and means of bathing the patients, and no clean clothes or bed-covers for them. The condition of the latrines was beyond description. Unless strenuous measures are immediately taken, here an epidemic may spread and another general typhus will probably rapidly spread and another general epidemic result, as happened in Serbia. I have arranged to disinfect the hospitals here, the patients, and their clothes.

YPRES, OCTOBER, 1914.

Mrs. Pumphrey (Stocksfield-on-Tyne) has inserted an advertisement in this issue of the JOURNAL, in the hope of being brought into communication with a medical officer of the army or navy who, on October 24th, was working at a hospital in Ypres station; the building had apparently been a convent, and may have been a French or Belgian hospital.

MEDICAL OFFICERS WANTED.

2/1st Highland Mounted Brigade Field Ambulance, R.A.M.C. Two medical officers are urgently required to complete the establishment of the 2/1st Highland Mounted Brigade Field Ambulance, now sending drafts of officers and men overseas. Full particulars of pay and duties from Captain Mount, Officer Commanding 2/1st H.M.B.F.A., R.A.M.C., Highland Mounted Brigade Camp, Thetford, Norfolk.

Recruits for Sanitary Section Wanted.

Captain C. B. Moss-Blundell, R.A.M.C., Officer Commanding Sanitary Section, Hillsborough Barracks, Sheffield, is anxious to obtain recruits for the section. The duties performed by men of a sanitary section are analogous to those performed by civil sanitary inspectors in time of peace, and men who have already had experience in sanitary work would be preferred.

24th Cameron Highlanders.

A medical officer is wanted for the 24th Battalion the Queen's Own Cameron Highlanders. Pay as in regular army. Promotion to captain after six months' service. Apply the S.M.O., 191st Infantry Brigade, The Camp, Blair Atholl.

31st H.C.F.A., R.A.M.C.(T).

Wanted for the 31st H.C. Field Ambulance, R.A.M.C., one medical officer to complete establishment; he must undertake the foreign service obligation. Applications should be made to the C.O., Smiths Lawn Camp, Windsor.

2nd Line Welsh Border Mounted Brigade.

Two medical officers, willing to undertake the Imperial Service obligation, are urgently required for service with the 2nd Line Shropshire Royal Horse Artillery and Cheshire Yeomanry. Pay and allowances as in the regular army, also outfit and camp kit grants. Full particulars on application to Lieutenant-Colonel D. C. Leyland Orton, Senior Medical Officer, 2nd Line Welsh Border Mounted Brigade, The Camp, Morpeth, Northumberland.

England and Wales.

THE EDGAR ALLEN INSTITUTE FOR MEDICO-MECHANICAL TREATMENT AT SHEFFIELD.

MR. EDGAR ALLEN, who died in the early part of the present year, was one of Sheffield's industrial princes, who, observing the number of casualties sustained by Sheffield workmen in the ordinary course of their employment, equipped, maintained, and to some extent endowed an institute where, under medical direction, they could be helped to regain muscular movement and nervous equilibrium. On the outbreak of war, the institute, then three years old, rose to the new occasion, and down to the date of a report recently issued had dealt with some 600 invalided soldiers. The treatment is founded on the Swedish system of physical exercises applied to apparatus for remobilizing injured joints and groups of muscles; capable masseurs assist by early passive movements. A scheme of enlargement is now going forward, the result of which will be to double the accommodation for the disabled men, and the public is being asked to support what is now a national and no longer a strictly local project. The report, which can be obtained (price 3d.) from the Secretary of the institute, at Gell Street, Sheffield, contains numerous photographs which give an excellent idea of the machinery employed, as well as of the nature of the exercises, and the manner in which, by an elaborate system of measured resistances for meeting the requirements of the injured part, any given case can be dealt with progressively, and the gradual improvement recorded.

RECRUITING FOR THE R.A.M.C. IN MANCHESTER.

It is a matter for regret that the recruiting for the Manchester "City" Battalions has recently fallen off very considerably, only 400 men having enlisted in Manchester in the week ending September 4th. The two brigades of the "City" battalions, forming part of the 30th Division, representing about 10,000 men, will certainly be disappointed if the County Palatine Brigade, which were at first so rapidly recruited, should be unable to develop into a County Palatine Division without the addition of outside units. At least 1,500 men are needed as early as possible. At the same time there is urgent need for more rapid recruiting for the medical units of the R.A.M.C. and the Royal Naval Division, and Lord Derby has been authorized to state that unless more men come forward for the R.A.M.C. very soon they will not be able to receive sufficient training in time for them to go out with the City Battalions of the 30th Division. For home service men are required to be between the ages of 17 and 50, and for service abroad between 17 and 40. Preference is given to those holding the certificates of the St. John Ambulance Association, the British Red Cross Society, or other bodies recognized by the War Office. During the last week a fair number of recruits presented themselves, and batches have been, or will shortly be, sent to Aldershot or Blandford or one or more of the London hospitals.

PRESENTATION OF MOTOR AMBULANCE FOR ANCOATS HOSPITAL.

At the close of a performance last week at the Gaiety Theatre, Manchester, the proprietor of the theatre, Miss

Horniman, formally handed over to the Ancoats Hospital a motor ambulance which had been provided by the Gaiety Theatre Motor Ambulance Fund. The fund was started by the staff of the theatre, and was assisted by the staff of Lloyd's Bank, Manchester; much of its success is due to Miss Horniman herself. Trustees of the fund were appointed and a trust deed was drawn up, by which the ambulance was handed over to the trustees of the hospital to be used by them for the duration of the war. The trustees have further promised money for the erection of a garage in the hospital grounds and to provide for upkeep so long as the war lasts.

MANCHESTER ROYAL EYE HOSPITAL.

It is reported that the number of new cases treated at the out-patient department of the Royal Eye Hospital during the eight months ending August was 27,533, which is nearly 1,500 in excess of the number treated in the same period last year. Much of the increase is undoubtedly due to the war, as treatment has been given to a large number of soldiers from neighbouring military hospitals, to men referred to the hospital by recruiting officers, or men in training at the camps. About 40 beds in the hospital have also been allocated to the military authorities for wounds or diseases affecting the eye, and during the same eight months 241 soldiers have been treated as in-patients. In recognition of the treatment given by the hospital to wounded soldiers several special donations have been received from various war relief funds.

Scotland.

ANNUAL CONGRESS OF THE INCORPORATED SANITARY ASSOCIATION OF SCOTLAND AT GLASGOW.

At the forty-first annual Congress of the Incorporated Sanitary Association of Scotland, held in Glasgow on the first three days of September, several of the addresses and discussions had a direct bearing on medical matters. The annual general meeting was held on the evening of September 1st, when the retiring president, Mr. Francis Braid (Kirkcaldy), was succeeded by Mr. Robert Lambie, Convener of the Public Health Committee, Lanarkshire County Council, and when Dr. Alex. Robb (County Medical Officer, Midlothian, Linton, and Peebles), and Mr. F. G. Holmes, C.E. (Office of Public Works, Govan), were elected vice-presidents. Dr. Robb was also nominated president-elect. The president (Mr. Lambie) took for the subject of his address (which was delivered on September 2nd) "Twenty-five years of Local Government," beginning his survey with the Local Government (Scotland) Act of 1889, which opened the way to a more progressive and comprehensive policy and set up a machinery which had proved wonderfully successful. The death-rate had fallen, and infantile mortality had also gone down; deaths from phtisis had decreased, whilst comfort and convenience had been added to the everyday life of the community. There had been and there still were anomalies in rating; but the Legislature should not permit a system to exist which was capable of allowing a local authority to neglect in any way its public health and sanitary duties because of the fear of high rating. He made a plea for a broader basis of rating all round, with an adequate recognition from the imperial funds.

Insects and Disease.

On the evening of September 1st Dr. R. M. Buchanan, bacteriologist to the Corporation of Glasgow, gave the customary popular lecture, taking as his subject insects in relation to disease. It was, he said, a remarkable fact that the sinister influence of a relatively small number of insects in spreading some of the most deadly diseases had only come to light in the past ten or fifteen years. It was now known that a few species (for example, mosquitos, tsetse flies) had controlled the destinies of nations and made parts of the world wellnigh uninhabitable. By spreading both malaria and yellow fever, mosquitos had for a time held up that stupendous engineering scheme, the Panama Canal. The common house-fly, too, was credited with a share in the transmission of the intestinal diseases, typhoid fever, infantile diarrhoea, dysentery, and cholera. It had a prodigious progeny, but fortunately it had also many powerful enemies, including man the

common fowl, and a parasitic fungus (*Empusa muscae*). The last-named enemy caused the only serious disease to which the fly was subject, and attempts had been made to use it for the extermination of the insect. A crusade against flies must aim at prevention rather than at destruction, and must be applied against them at the earliest stages of their existence. The injunction "kill that fly" implied a confession of failure in sanitation. Intelligent scavenging could be counted on to do much, along with the timely collection and destruction of domestic refuse and garbage and the stringent enforcement of measures dealing with stable manure. Since the shortest period necessary for the development of the fly from the egg was ten days, the removal of all temporary collections of fermenting matter should be undertaken at intervals of not more than seven days.

The Care of the Health of the Child.

One of the most important matters dealt with at the Congress was that of the care of the health of the child, the discussion upon which took place on September 2nd. Dr. A. Campbell Munro, County Medical Officer, Renfrewshire, divided his address into four parts—the prenatal care of the child, care in infancy, in the period between infancy and school age, and during school age. He hoped that in the coming years there would be a compensatory increase in the birth-rate to make up for the wastage of the most virile manhood of the nation in the war. It was satisfactory that notification of births was now compulsory, and he should like to see a roll—not of honour—of the local authorities in Scotland who had not adopted the system voluntarily. But even this compulsory notification did not lead far, and it was essential that official health visitors should be appointed, and provision for this was contained in the Notification of Births (Extension) Act. It ought to be made penal to sell or buy long-tube feeding bottles. There was also a wide sphere of usefulness for voluntary infant health visitors' associations, and between these and the local authority and its officials there should be the most intimate touch. There should be infant consultations and consultations for expectant and nursing mothers, prematurity homes, and post-natal homes. Child welfare committees would be a better name than infant health associations. There was great need for the passing of a Midwives (Scotland) Bill, and when the Act was in existence the Medical Officer of Health should be the "supervising medical officer" over the practising midwives. Maternity benefit, under the National Insurance Act, required revision; the money should be payable only on the certificate of the medical adviser to the Insurance Committee that the mother had received proper attention in connexion with her confinement. Dr. Campbell Munro moved that the Congress should resolve that measles and whooping-cough be made compulsorily notifiable; but the motion was lost on a vote being taken.

Dr. J. W. Ballantyne, of Edinburgh, spoke specially on the prenatal care of the infant. He said he would not go back beyond the marriage of the parents, being content to leave to the eugenists the directing and perfecting of matrimony among the "fit." He recommended, however, that newly married couples should make an immediate choice of their medical attendant, and not wait till the emergency conditions of a threatened miscarriage sent them to the nearest practitioner. He recommended, also, that the wife should put herself under medical supervision and care as soon as she suspected herself to be with child; to wait until the pains of labour were upon her was certainly the very reverse of prenatal provision. Medical men and women should likewise be ready to accept the responsibility for the care and supervision of the expectant mother during the whole time of her expectancy, and be ready to treat any of the complications of pregnancy which might arise, and so save many infantile lives. In all large towns prematurity homes for unmarried girls and rest-homes for married women should be provided where pregnancies could be watched over medically and where tired women could rest in the later weeks of their term of expectancy. Financial aid should be forthcoming in the four weeks preceding labour as well as in the month following it, as was being done in France. If this aid were given, it would send women earlier to their doctors, and it might, along with the discovery of a reliable blood

within reach. Prematernity wards, prenatal nurses (to visit and advise expectant mothers among the poor), and antenatal clinics and consultations at maternity hospitals, were other most desirable things, and should not be outside the range of authorities in large cities. He instanced a case of a woman who gave way to drink in the last month of her pregnancies who had recently been under his care in the prematernity ward of the Edinburgh Royal Maternity Hospital, and had been preserved from temptation during her critical month, had been safely delivered of a healthy child, and had been sent safely home again. Dr. Ballantyne concluded by seconding a motion made by Dr. Campbell Munro, "That in the opinion of this Congress it is important that the Midwives (Scotland) Bill should be passed into law without further delay." The motion was put to the meeting and carried unanimously.

Milk, Town Planning, Dietary, and other Subjects.

Another interesting discussion took place on the essentials of a pure milk supply and suggestions for regulations under the new Act; this was introduced by Mr. John Frew, County Sanitary Inspector, Linlithgowshire, and in it Dr. Fred Dittmar, Edinburgh, Mr. John Finlay, and others took part. Other subjects dealt with were methods of treating vermin in buildings, refuse bins on fire, sanitary provisions in Scottish town-planning schemes, economic dietary in time of war (opened by Dr. A. K. Chalmers), the effect of the war on the duties and responsibilities of local authorities in Scotland, and the training of nurses in local authority and Poor Law hospitals and their relation to the general supply of nurses (introduced by Dr. Walter F. Brown of Ayr).

MILITARY APPOINTMENT OF EDINBURGH PHYSICIAN.

Dr. G. Lovell Gulland, Professor of Practice of Medicine in the University of Edinburgh, has been appointed a Consulting Physician to the Forces in the Mediterranean, with the temporary rank of Colonel.

Ireland.

DUBLIN HOSPITALS: COST OF FEEDING WOUNDED SOLDIERS.

THE Board of Superintendence of the City of Dublin Hospitals announces in its fifty-seventh annual report, covering the year ended March 31st last, that it had visited all the hospitals and found everything most satisfactory. Reference is made in the report to the hospitals opened for the reception of wounded soldiers, and it is stated that the officer in charge of King George V Hospital, who had these institutions under his supervision, informed the board that the way in which the wounded and sick were treated in them was, without exception, highly satisfactory. The board points out that the financial aspect of the treatment of wounded soldiers in hospitals set apart for the use of the poor is a subject that demands its special consideration, for its chief duty is to see that the hospitals under its control "fulfil in an economical and thorough way the objects for which they were instituted." The report attempts to arrive at an estimate of the payments that would reimburse the out-of-pocket expenses of the general hospitals under its supervision. The calculations are exclusive of the cost of buildings and the furnishing and equipping of such buildings. For the last year the daily cost of each bed in the several hospitals was as follows:

	Richmond.	Stevens's.	Meth.
An occupied bed ...	3s. 5½d.	4s. 2½d.	4s. 1½d.
An unoccupied bed...	2s. 5½d.	2s. 10½d.	2s. 7½d.

From these figures, and bearing in mind that the maintenance of wounded soldiers is more costly than that of fever patients and of children—classes of cases proving a considerable part of the hospital patients—it is held that the amount paid by the Treasury—3s. for occupied bed up to December 13th, 1914, and on and after that date 4s. per occupied bed, and nothing at all for unoccupied beds—is too small, so that all hospitals working on these terms are incurring a loss each day that passes. In November, 1914,

authorities, pointing out the insufficiencies of the payments. As a result the payment for occupied beds was raised to 4s., but payment of any kind for unoccupied beds was not granted.

ST. JOHN AMBULANCE ASSOCIATION.

Sir John Moore, who presided at the distribution of certificates gained by the lady members of the staff of the Insurance Commission at the St. John Ambulance Society's examination in first aid and home nursing, paid a tribute to the excellent work done by Mrs. Dickie in connexion with the classes.

On the motion of Dr. Lumsden, a vote of thanks was passed to Lady Glynn, who attended the meeting and distributed the certificates. Dr. Lumsden said some men might be accused of slacking, but that could not be said of the women, as the work done by them was one of the outstanding features of the war.

THE LATE DR. JEREMIAH COTTER OF CORK.

Many former students of the old Queen's College, Cork, will lament the death of Dr. Jeremiah Cotter, F.R.C.S.I. An obituary notice appeared in the JOURNAL of August 28th, p. 351. That Dr. Cotter was held in high esteem not alone by the members of his own profession in the South of Ireland, but also by various public bodies, is manifested by the many votes of condolence which, within the last few weeks, have been conveyed to his wife and family in their bereavement. The North Infirmary, the South Infirmary, the County Council, the Cork Corporation, the Cork Union, the Cork Borough Insurance Committee, the Eglinton Asylum Committee, and last, but by no means least, the members of the Cork Medical and Surgical Society, of which he had been the honoured President, have all recorded their sorrow. The following resolution was passed at a special meeting of the profession:

We, the members of the Cork medical profession, desire to express our deepest regret at the lamented death of our President, Dr. Jeremiah Cotter, F.R.C.S.I., and to record our unanimous opinion that his loss to the profession and to the public cannot be adequately estimated.

As a member of the medical profession Dr. Cotter occupied a leading position, which, through his sound knowledge, eminent ability, skill and judgement, he richly deserved.

As a friend and colleague he at all times proved himself true and honourable, while his invariable amiability endeared him to all those with whom he came in contact.

His love for the Cork Medical School led him to devote a very large amount of his time, energy, and ability to teaching, while he took a deep and permanent interest in the success of his graduates. We desire to convey our expression of heartfelt condolence and deepest sympathy to his sorrowing widow and children, and all those who mourn his loss.

Correspondence.

MEDICAL STUDENTS AND COMBATANT COMMISSIONS.

Sir.—I have read with much interest the answer of Lord Kitchener's private secretary to Professor Halliburton's letter of August 16th, 1915, and while the wishes of the War Office, contained in the reply with regard to fourth and fifth year students, are quite unambiguous, I regret I am unable to say the same as to their statement about the position of the junior students. I know many who were most anxious at the beginning of the war to take combatant commissions, but reluctantly continued their studies at the suggestion of the War Office and the request of the authorities of the hospitals to which they were attached, and now we have a statement which, if it means anything, appears to favour the view that they ought to take combatant commissions.

From conversations I have had with the students and their parents, it seems to me that both would much prefer a decided expression of opinion one way or other, since medical students are not the type of young men who desire to wait until they are forced to join the army.

There is another way out of the difficulty, and that would be for the War Office to form a special corps under the R.A.M.C. in which junior students could serve as privates and non-commissioned officers. In this way their services would not be lost to the medical profession and

they would gain an insight into the medical and administrative aspect of the army, which would be most valuable to them in after life.—I am, etc.,

R. KING BROWN,

Medical Officer of Health, Bermuda; Lecturer on Public Health, Guy's Hospital, London, S.E., Sept. 1st

THE SUPPLY OF MEDICAL OFFICERS.

Sir.—The recent appeal made to the medical profession must have caused many of us to consider whether we are doing the whole of our duty. To men working country practices, much of the work with troops would not come strangely. Most of us can ride, we have been accustomed to do the greater part of our own surgery, and to treat accidents on the spot, with extemporized appliances and without aid from hospitals. Yet, anxious as we are to do our duty, there are many difficulties in the way. When a man's nearest medical neighbour is eight miles or more away, it is not possible that his neighbour should carry on the two practices if the one leaves. Locumtenents are hard to get, their fees are high, and it does not seem right that a country doctor should pay a man younger than himself to look after patients to whom he must be a stranger.

Yet there must be many men who, while their health is not good enough for active service, are still able to do work at home. There must, too, be many men whose health or whose nerves have suffered from the strain of work abroad, and who might recover health and strength while working a country practice. We in the country have no means of getting in touch with such men. I suggest, then, that the British Medical Association should take steps to furnish a list of such men who would be willing to do country work at a fee that we could pay, and who, themselves incapacitated for further foreign service, could do work at home, and so free men who, anxious to do their duty, have so far been unable to leave home.—I am, etc.,

CHAS. W. SMERTON, M.R.C.S., L.R.C.P.

Hovingham, Malton, Aug. 23rd.

A NOTE ON THE TESTING OF DISINFECTANTS.

Sir.—In view of the fact that the International Committee on the Standardization of Disinfectants, appointed at the last meeting of the International Congress of Applied Chemistry, cannot meet this year owing to the war, and that this may entail a further delay of three years, we desire to call attention to one or two points which have arisen since the publication of our paper on "Approved technique of the Rideal-Walker test,"¹ and to submit the following suggestions as addenda to the paper referred to.

First, in view of the difficulty experienced by some workers not familiar with the technique of the chemical laboratory, we suggest that a burette, such as that described by Hermann W. Mahr, of the Board of Estimate and Appointment, New York,² can be adopted in place of the dropping pipette. On the other hand, we know many workers who have a decided preference for the dropping pipette originally used by ourselves, and who do not see the necessity for changing this detail of the technique.

The second suggestion deals with the well-known variations in resistance offered by the standard broth culture of *B. typhosus*. To obtain the desired result in the phenol column—life in two and a half minutes and in five minutes, and no life thereafter—dilutions ranging anywhere between 1 in 80 and 1 in 140 may be required. We feel that this range is too great, and suggest therefore that the culture be rejected if it calls for a phenol dilution higher than 1 in 110 or lower than 1 in 90. Where the culture becomes so attenuated as to call for dilutions higher than 1 in 110, it can be strengthened by passage through any suitable animal. By restricting this range in dilution the only rational objection to the Rideal-Walker test is at once removed.

A new difficulty has been introduced through the war: it is impossible now to obtain supplies of Witte's standard peptone. We understand this matter has been taken up by an American committee, representing four prominent laboratories, with Dr. Conn as umpire, and that this committee is about to report in favour of a brand which is said to be equal to Witte's in every respect. In the mean-

¹ American Journal of Public Health, vol. vii, No. 6.

² New York Medical Journal, March 7th, 1914.

time it would be interesting to have the views of other workers. We therefore invite discussion on this point.—We are, etc.,

SAMUEL RIDEAL,
London, Aug. 10th.
J. T. AINSLIE WALKER,
New York, Aug. 23rd.

USE OF A SLEEVE OF VEIN IN NERVE SUTURE.

SIR,—Under the above heading Mr. Fullarton of Belfast describes a method of treating nerve unions which I can cordially recommend, as I have used the same method for many years. I demonstrated the method at a meeting of the Glasgow Medico-Chirurgical Society on April 18th, 1913; the method was again illustrated in the *Clinical Journal* for November, 1913, in an article entitled "A Few Examples of Grafting."—I am, etc.,

ALEX. MACLENNAN.

A. NOCI ASSOCIATION.

SIR,—It ought to be unnecessary to remind your readers that the adjectival stem from the root of *nocere* is not *noci-* but *noxi-*; indeed, "Innocuus" by his pseudonym (p. 346) admits this, though he does not follow it to its logical conclusion.

The proper form of the word in dispute is "innocuousness," and as this is also the most obvious and most euphonious form, it is strange that any other should have found acceptance.

Can we venture to hope that the profession will adopt the right word? The clumsy words "chemo-taxis" and "ptomaine" (for "chemio-taxis" and "ptomine") persist in spite of protests.—I am, etc.,

F. J. ALLEN.

Obituary.

DAVID BRIDGE LEES, M.D. CANTAB. AND DURH., F.R.C.P.

CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL, THE HOSPITAL FOR SICK CHILDREN, AND ST. JOHN'S HOSPITAL, TWICKENHAM.

Not one month had elapsed after the tragically sudden death of one distinguished member of the consulting staff of St. Mary's Hospital—Mr. Edmund Owen—when another member, on this occasion a distinguished physician, Dr. D. B. Lees, also expired suddenly. Both, like Nicanor and Sivadard the Strong, died in harness—in fact, Dr. Lees had a fatal seizure when actually at work in his consulting-room on August 16th.

David Bridge Lees was born in 1846; after leaving the Owens College in Manchester, his native town, he studied at Trinity College, Cambridge. He distinguished himself both in classics and mathematics. He was Carns prizeman, and took the B.A. in 1869, coming out fifth in the Natural Science Tripos, received the degree of M.B. in 1874, and as he had gone through the usual curriculum at Guy's Hospital, he was able to qualify as M.R.C.S. in the same year. Dr. Lees had also studied for a time in the medical schools at Vienna. After qualification he returned to the Owens College, of which he was an Associate. He took the degree of M.D. at Cambridge in 1875, and in the same year became M.R.C.P. (London); in 1881 he was elected F.R.C.P. In 1879 Dr. Lees was elected assistant physician to the Hospital for Sick Children, Great Ormond Street, becoming full physician in 1890. He was placed on the consulting staff in 1905. In 1880 Dr. Lees became associated physician to a London medical school, being elected assistant physician to St. Mary's Hospital. In 1887 he was appointed full physician, holding that post until he retired and was made consulting physician in 1907. Thus Dr. Lees was an active member on the staff of a general hospital with a medical school for no less than twenty-seven years, and was attached for nearly as long a period to one of the most celebrated of all hospitals devoted to the treatment of children's diseases.

David Bridge Lees, settling down to work as physician to a general hospital, soon proved himself to be an excellent clinical observer. His writings, which must be well known to every one bringing the notification, are of a high order. He was elected senior Registrar of the Royal College of Physicians of London last July. At the funeral at Finchley the College was represented by the President (Dr. Frederick Taylor), Dr. Newton Pitt (Censor), and Dr. Ormerod (Registrar); the Hospital for Sick Children by Sir James Goodhart and Dr. W. S. Colman; and St. Mary's Hospital by Dr. Luff, Dr. William Hill, and Mr. Kenneth Lees, Dr. Lees's son, who is at present surgical registrar to the hospital.

of bronchopneumonia treated with bleeding and ice." He considered that the true indication for bleeding in pneumonia was the approach of failure of the right heart to overcome the greatly increased pressure in the pulmonary artery, due either to extensive consolidation of lung or to overwhelming engorgement. Failure was imminent in both the cases, which he reported at full length, but he insisted that the relief which followed the abstraction of blood would have been but temporary but for the beneficial influence of cold applications. Venesection, tepid sponging, and the ice-bag were made use of for the first patient, a maidservant aged 15; and tepid bathing, leeching, and the ice-bag for the second, a female infant 6 months old. Both cases recovered, although very severe, indeed the second was complicated by internal otitis resulting in posterior basic meningitis.

Dr. D. B. Lees contributed other important articles to our pages. Our readers may remember his paper on "The effective treatment of acute and subacute rheumatism," read at a meeting of the Therapeutical Section of the Royal Society of Medicine, and published in the *Journal*, January 16th, 1909. The profession, noting the subject of this contribution, may profitably pause and reflect how well it is that a leading doctor should in his teachings dwell for a time not on "rare and interesting" maladies, blood counts, and bacteriology, but rather on very common diseases most interesting to the general public yet, though known to the ancients, not so easy to overcome even by the newest resources of medical and therapeutic science. The author was not above supporting an already popular remedy—sodium salicylate—and pointing out that some of the organic compounds of salicylic acid were hardly, if at all, preferable to the alkaline salt, and he specially expressed, on the strength of personal experience, his distrust of aspirin. He in fact lay great trust in sodium salicylate, especially on its alkalinity, recommending that a large proportion of sodium bicarbonate be prescribed and administered with it. This teaching, including certain precautions which Dr. Lees published along with his advocacy of the salicylate, was valuable reading for many, especially the younger of us who may think too much of cerebral and abdominal surgery. Dr. Lees found that the strong doses of two salts, combined with the application of ice to the heart, was most satisfactory in the treatment of cardiac rheumatism, endocarditis as well as pericarditis. The photographs of rheumatic nodules accompanying this useful and excellent paper were, our readers must admit, highly instructive. Dr. Lees favoured us in the same year with an important contribution on the physical signs of incipient pulmonary tuberculosis and its treatment by continuous antiseptic inhalations, published on December 11th, 1909. He advocated the continuous use of an oro-nasal respirator charged with a solution composed of carbolic acid, creosote, tincture of iodine, and spirits of chloroform. He had employed that therapeutic measure in about thirty cases with good results, and in order to convince his readers he published the abstracts of all of them in our pages. Dr. Lees's reputation as a physician skilled in the clinical as well as the pathological features of phthisis doubtless caused him to be selected as Bradshaw Lecturer at the Royal College of Physicians in 1912, where he discoursed on incipient phthisis. Much other work of interest appeared in other publications, the *Lancet* publishing in 1893 an article entitled, "Is there a dextero-cardiac respiratory reflex?" whilst Dr. Lees's views and experience on rheumatism, above referred to, were conveniently summarized in Sir W. Allchin's *Manual of Medicine*, which included a special article by the deceased physician on acute and subacute rheumatism as a whole.

Dr. David Bridge Lees was a man of a very retiring disposition. He mixed but little with his colleagues, who, on the other hand, from first to last recognized him as a deeply conscientious and religious man, the soul of honour in professional matters as well as in every-day life.

Dr. Lees was elected senior Registrar of the Royal College of Physicians of London last July. At the funeral at Finchley the College was represented by the President (Dr. Frederick Taylor), Dr. Newton Pitt (Censor), and Dr. Ormerod (Registrar); the Hospital for Sick Children by Sir James Goodhart and Dr. W. S. Colman; and St. Mary's Hospital by Dr. Luff, Dr. William Hill, and Mr. Kenneth Lees, Dr. Lees's son, who is at present surgical registrar to the hospital.

Dr. R. H. STEEN (Medical Superintendent, City of London Mental Hospital, Dartford) writes: The news of the sudden passing of Dr. Lees will come as a great shock and sorrow to all his old pupils. Dr. Lees was most careful in all his work, and spared neither time nor trouble to do his best for his patients. He was keenly alive to all progress, and was ever willing to impart his knowledge to those who worked under him. His tone through the wards of St. Mary's was always popular with the students, and among the circle of those listening to his remarks by the bedside were frequently to be found some of his old house-physicians who had returned to brush up their work. In the days when I was his house-physician he was especially enthusiastic upon the use of the ice-bag for pneumonia. At the beginning of our six months' residence few of his house-physicians were so sanguine in this direction as our master, but when our time of office had expired most of us were converted to his views. He used to insist that the first thing to be done was to place hot-water bottles to the feet of the patient, and then to apply ice-bags, not only to the dull area but to the entire lung affected. There is no doubt that under this treatment the area of dullness receded sometimes in a remarkable manner, and if one could not state with certainty that it aborted the disease (though at times it appeared to do so), it gave great relief to the patient. Dr. Lees was perhaps best seen in his systematic lectures, which always gave evidence of careful preparation and attracted large attendances. His sterling and upright character will always remain as a bright example to those who were associated with him.

GEORGE ALFRED EDSSELL, M.D.,

LIEUTENANT-COLONEL, R.A.M.C. (T.F.).

LIEUTENANT-COLONEL GEORGE ALFRED EDSSELL, R.A.M.C. (T.F.), commanding the 3rd Home Counties Field Ambulance, died on August 16th, aged 56, at his residence, Cedar House, Surbiton, of pleurisy, contracted at the front from which he had recently been invalided. Born at Aberdovey on January 18th, 1859, Lieutenant-Colonel Edsell was educated at St. Bartholomew's Hospital and at University College, and took the M.R.C.S., the L.R.C.P.Lond., and the L.S.A., in 1886, the M.D.Durb. in 1902, and the D.P.H. of Cambridge and also that of the London Colleges in 1905. After qualifying, he acted as resident obstetric assistant and as clinical assistant in some special departments at St. Bartholomew's and as clinical assistant in the Royal Eye Hospital, Southwark. Subsequently he became clinical assistant to the Samaritan Hospital for Women, and honorary surgeon to the Cripples' Home, Surbiton. In 1904 he contributed to the JOURNAL (vol. i, 1904, p. 131) a case in which a severed finger was successfully replaced; the patient was a man aged 60; when killing a pig, the animal bit off his right index finger through the middle phalanx. It was replaced after the patient had walked six miles, and a few years later, though the distal joint was stiff, the finger was useful for work. Dr. Edsell was examiner and honorary life member to the St. John Ambulance Association, surveyor to the medical department of the Admiralty, and a member of the British Medical Association.

Dr. FRANK B. NORRIS of Surbiton writes: When the history of the present war comes to be written Edsell's name will deservedly be entitled to a place in the list of heroes who have sacrificed their lives in the cause of their country, for the illness which has terminated fatally was contracted at the front in the course of the arduous work of attending to sick and wounded soldiers, on which he had been engaged for some months. He removed from Thame, near Oxford, to Surbiton about twelve years ago. He quickly won great esteem, not only for his professional attainments, but also because he was a thorough sportsman in the field with gun, and likewise at tennis, at cricket, and at hockey. Many a day have I spent with him and badly shall I miss him. For a few years he was on the Surbiton District Council, but resigned his seat soon after becoming a member of the Surrey County Territorial Force Association. He always manifested keen interest in military work, especially in its medical branch. In 1889 he joined the Oxfordshire Light Infantry as surgeon. Subsequently, after settling in Surbiton, he joined the 3rd Home Counties

Field Ambulance, R.A.M.C., as captain, was rapidly promoted to the rank of major, and eventually assumed command of the unit, his promotion to the rank of lieutenant-colonel having taken place on October 22nd, 1911. Largely owing to his enthusiasm, recruits were obtained to bring the unit up to its full establishment. When the Territorial Force was mobilized the 3rd Home Counties Field Ambulance was called out, and after undergoing a period of training at Surbiton, Sittingbourne, and Winchester, it proceeded to France, where since last December it has been doing yeoman service in the firing line. It has worked mainly in the neighbourhood of Ypres, Hill 60, and St. Eloi. "A Private" who has served under him abroad writes to emphasize Colonel Edsell's sterling qualities as a gentleman and a commander. He was, he says, loved by all who served under him, both at home and in Flanders. The men speak in high appreciation of his thought at all times for their comfort and safety. "We all loved and admired him."

The funeral took place on August 18th with the full military honours of his rank. The arrangements were in the hands of the War Office, and a large body of troops attended under the command of Lieutenant-Colonel H. P. Treby, D.S.O. The coffin was draped with a Union Jack, upon which were placed the deceased's sword and helmet.

ARCHIBALD ROBERTSON DOUGLAS,

L.R.C.P. AND S.E., L.F.P.S., GLASGOW.

We regret to record the death on August 26th, after a few days' illness, of Dr. A. R. Douglas, the esteemed medical superintendent of the Royal Albert Institution for Mental Defectives at Lancaster.

Born in 1868 at Newcastle-on-Tyne, he was educated successively at Madras College, St. Andrews, the Newcastle College of Medicine, and in Edinburgh, where he took the triple qualification. His first appointment was that of resident surgical assistant at the Royal Infirmary, Newcastle, and he was subsequently registrar and clinical assistant at the Throat and Ear Hospital in that city. Later he took up the practical study of psychological medicine, and after serving as clinical assistant at Dunston Lodge Asylum, Gateshead, he became assistant medical officer to the East Riding Asylum, Beverley. He had also some years' experience in the prison service, acting temporarily as medical officer to H.M. Prison, Durham, and subsequently as deputy medical officer to H.M. Prison, Portland.

He was appointed assistant medical officer to the Royal Albert Institution in 1893, and succeeded Dr. Telford-Smith as chief medical officer in 1899. As medical superintendent he displayed conspicuous ability in the administration of the large institution under his charge during a difficult period of transition consequent upon the passing of the Mental Deficiency Act. He was most eager to extend in various directions its utility as a training institution, quite regardless of the increased responsibilities such extension would entail upon himself. The Central Committee lose by his death the services of an energetic and devoted officer, and his colleagues a considerate and sympathetic chief. His fellow workers in his special department of psychiatry have reason to lament the premature loss of one whose help had been invaluable in unravelling the intricate problems of legislation for the feeble-minded, as evidenced by his practical statements before the Royal Commission and his various contributions to medical literature. His labours at Lancaster have enhanced the high reputation enjoyed by the Royal Albert amongst similar institutions; and the esteem in which he was universally held was shown by the large attendance at his obsequies at Scotforth Cemetery, not only of the committee, officers, and inmates of the institution, but of numerous members of the local medical profession, of the Masonic lodges, and of the Mayor and Corporation of Lancaster. He leaves a widow and two sons to lament his loss.

We are permitted to subjoin the following extract from a letter written to Mrs. Douglas by Sir James Crichton-Browne: "I am shocked and grieved by the announcement of your good husband's death. He seemed so full of life, and health and energy, and had so much useful work before him, that it is inscrutably sad to see him thus cut down in the very heyday of his career. I have long since

friendship, and held him in the highest esteem. He is an irreparable loss to our department, for he brought to his work clear insight and sound judgement, ripened by unique experience. I hoped that one of these days he would be called to high public office, as he has done admirable work, and conferred signal benefit on a grievously afflicted class."

The Services.

TERRITORIAL FORCE. EXCHANGE DESIRED.

CAPTAIN, R.A.M.C.(T.), at present with Field Ambulance (T.) in France, wishes to exchange to Territorial General or Casualty Clearing Hospital, either at home or in France. Captain's pay and allowances.—B. W., c/o. Editor, BRITISH MEDICAL JOURNAL.

Lieutenant A. E. Huxtable, 23rd London Field Ambulance (T.F.), desires to exchange with a Territorial medical officer serving in, or anywhere south of, London. Ordinary pay with full billeting and ration allowances. His present address is 7, Brunswick Road, Norwich.

Medical News.

THE Scottish Committee of the British Medical Association has been summoned to meet at Perth on September 10th to consider questions arising in connexion with the schemes and form of agreement issued by the Highlands and Islands Medical Service Board.

DR. LOCKHART STEPHENS, of the White House, Emswote, has been appointed a Deputy Lieutenant for the county of Hampshire.

In the list of names which have recently been inserted in the Commission of the Peace for the County Palatine of Lancaster appears that of John Kendall, L.R.C.P. and S., of Oaklands, Coniston.

WITH the concurrence of the Director-General of the Army Medical Service, an exhibition of the various forms of apparatus that have been found most useful in the treatment of fractures met with in the war will be held in the house of the Royal Society of Medicine, 1, Wimpole Street, W., from October 7th to 11th, both days included. The apparatus will be shown by officers of the R.A.M.C. serving in France, as well as by those attached to the base hospitals at home. The bulk of the apparatus will be brought over for the purpose from Boulogne. In addition, Colonel Sir Almonst Wright, C.B., F.R.S., will demonstrate his most recent researches in the drainage of wounds. Invitations to exhibit will be issued to the consulting surgeons of the various commands, and officers desiring to send exhibits should communicate with the consulting surgeon for the command in which they are serving.

THE Royal Sanitary Institute held its annual meeting at Brighton on September 3rd and 4th. It assembled in the Permanent Fine Art Gallery, where it was welcomed by the Mayor and the chairman of the Brighton Health Committee. The first paper read was by Major S. P. James, I.M.S., who, in discussing some sanitary problems in hospitals for Indian troops in England, gave a description of the Kitchener Indian Hospital in Brighton. Afterwards Major C. C. Munson, I.M.S., staff officer of the hospital, dealt with the use of storm-water drains, and Professor H. B. Kenwood urged the importance of establishing, wherever practicable, a complete water carriage system for the semi-permanent hatted camps of which there are now so many in this country. Afterwards visits were paid to the Kitchener and to the Royal Pavilion Hospitals. On the second day of the meeting a discussion on maternity and child welfare and infant mortality was opened by Dr. Boothby, M.O.H. Nottingham, and Dr. Duncan Forbes, M.O.H. Brighton. The latter said that when the infant mortality from all causes in the first week of life was investigated very little difference was found between the richer and the poorer classes. If this were proved generally to be the case, it seemed an argument against the view that the better feeding and housing of the mother, and freeing her from manual labour and anxiety, had an effect upon the health of the child at birth. A discussion also took place on the final report of the Royal Commission on Sewage

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Artillery, Westward, London*; telephone, 2634, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertising, etc.), *Artillery, Westward, London*; telephone, 2639, Gerrard, etc. (3) MEDICAL SECRETARY, *Medicines, Westward, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

QUERIES.

INCOME TAX.

RETIRED PRACTITIONER'S EMBODIES ceased in November last, but small sums have since been received. Is he liable to pay income tax on these sums, and if so, does the three years' average rule apply?

* The assessments made in the past have year by year covered the full profits of the practice, and liability to income tax ceased as from the date the practice was relinquished. If, as is doubtless the case, "Retired Practitioner's" returns in the past have been computed on the basis of cash receipts only, this statement still holds good. That basis of return is accepted by the authorities only on the ground that in a practice of some years' standing the year's cash receipts are equivalent to the value of the year's bookings, and the cessation of liability immediately on retirement is a natural corollary of that proposition. We understand from our correspondent that his successor has been charged in respect of the period from November, 1914, to April, 1915, by the local authorities. This is in accordance with the fourth rule applying to the first and second cases of Schedule D, but the tax collected from the retiring practitioner should have been restricted to the proportion applying to the period from April to November, 1914. If it is clear that this has not been done, our correspondent should communicate with the surveyor of taxes on the matter.

C. T. calls attention to the fact that in an article on the general practitioner's income tax returns, which appeared in our issue of April 18th, 1914, no mention is made of deductions to be made for the cost of drugs, chemicals, bottles, etc.

* The expenses in question are certainly deductible for tax purposes. The expenses quoted in the article should be regarded as the usual, but not necessarily the only, forms of professional expense.

ANSWERS.

G. W. R. (Bieldside) is referred to an article on "Officer's Income Tax" published in the JOURNAL of March 20th, 1915, page 510.

A. G. P.—Gonorrhoea and syphilis can both be treated successfully in a pregnant woman. The risk of infection of the child's eyes by gonorrhoea during delivery must of course be borne in mind. Our correspondent should inform the husband that he cannot share with a chemist the responsibility of treating him.

SCOPOLAMINE-MORPHINE IN LABOUR.

J. G. M. M.—We may refer our correspondent to the article published in the JOURNAL of June 19th, 1915, p. 1052, where he will find the principle discussed, together with references to papers contributed to the Section of Obstetrics and Gynaecology of the annual meeting of the British Medical Association in 1908 (BRITISH MEDICAL JOURNAL, vol. ii, pages 805-8) by Professor Krönig, of Freiburg, and Dr. R. C. Buist. Mention is there made also of the popular work by Mrs. Hanna Riou. We are not aware of any clinic in this country where the method can be seen in routine use or according to the Freiburg ritual. Cases are usually individualized.

LETTERS, NOTES, ETC.

WE have received a communication from a director of a Church Army hospital in France suggesting that the credentials of any person representing himself to be a captain of the Indian Medical Service and F.R.C.S. Eng., who may apply for an appointment in Great Britain, should be carefully investigated.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 8 0
A whole column	10 0 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, no later than the first post on Wednesday morning preceding publication, and if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post *restante* letters addressed either in initials or numbers.

THE TREATMENT OF CHOLERA BY HYPERTONIC SALINE SOLUTIONS

DURING AN EPIDEMIC AT SWATOW, SOUTH CHINA.

BY

G. DUNCAN WHYTE, M.D. ED., D.T.M. & H. CANTAB.,
SWATOW.

The ideal method of treating a bacterial disease is to destroy the causal bacillus *in situ*. Attempts have been made to achieve this end in cholera by the use of such antiseptics as calomel,¹ carbolic acid,² chlorine,³ cresote,⁴ mercury cyanide,⁵ iodoform,⁶ salol,⁷ and more recently, creolin;⁸ but all these methods are passing into disuse (save perhaps the use of calomel) since the good results reported in one epidemic are rarely obtained—even by the same doctor—in subsequent epidemics.

At the Bombay Medical Congress in 1909 Pant⁹ mentioned that he used solutions of potassium permanganate in the treatment of cholera, and Rogers,¹⁰ having satisfied himself—both by laboratory experiments and at the bedside—of the value of permanganates in destroying the toxins formed by the bacilli, has regularly used them since either in the form of a solution of the calcium salt, or as pills of potassium permanganate. Unfortunately this line of treatment did not prove acceptable to the Chinese patients; the unpleasant astringent taste, when given in solution, frequently brought on exhausting vomiting, and the same result followed the administration of permanganate pills. Rogers does not make any reference to the use of these salts in his account of "The treatment of cholera at Palermo,"¹¹ and it may be that this permanganate treatment is unsuitable for those with more sensitive stomachs than his Indian patients.

According to Liebermeister,¹² the patient's vitality is diminished by (1) "the loss of water from the blood and tissues," (2) "the absorption of . . . poisons," and (3) "the severe disease of the intestinal membrane may cause . . . heart failure." Presuming that the above poisons exert their most serious action on the heart, these three factors may be resolved into two, namely, the degree of concentration of the blood, and the failure of the heart. Treatment by the intravenous injection of saline solution exactly meets these conditions, for on the one hand large quantities of fluid are supplied to diminish the concentration of the blood (and incidentally to dilute the toxins), and on the other hand the heart is powerfully stimulated. The value of intravenous infusion in combating shock due to surgical causes is too well known to require further reference, but it is only rarely employed to overcome collapse in medical cases. A case described by Bradley and Smith¹³ shows the great value of intravenous infusion in overcoming very severe prostration following a sudden fall of temperature.

It is interesting to note that this method of treatment was introduced (in the pandemic of 1831-2) by two British physicians, one of whom confesses that his "first idea was to return into the system the alvine dejections by injecting them into the venous system . . . but as the dejections are seldom preserved, it occurred to me to make an artificial serum."¹⁴

The extraordinary effect of intravenous infusion in the collapse stage of cholera must be seen in order to be realized. Unfortunately, however, the improvement that follows infusion with normal saline is generally transient, the diarrhoea and vomiting recommence, or become more severe, and in a few hours the patients again collapse, and often fail to rally.

So the practice of intravenous infusion fell largely into disuse till Leonard Rogers overcame the fundamental difficulty—the rapid passage of the saline from the circulatory system into the alimentary canal, and its subsequent loss by vomiting and diarrhoea—by the use of saline solution double the normal strength, and so established intravenous saline infusion as the most successful as well as the most scientific method of treating cholera. It may be said that no real advance had been made in the treatment of cholera from the time of Latta (1832)¹⁵ till Rogers made this discovery.

Mild cases of cholera occur during an epidemic which it would be absurd—and might even be dangerous—to treat with intravenous infusion, while in other cases the

progress of the disease is so rapid that only immediate intravenous injection can save the patient's life. The line of treatment to be carried out in each particular case can only be determined by the accurate measurement of the degree of concentration of the blood and of the amount of cardiac failure.

The greater the degree of concentration of the blood the higher will be its specific gravity, and O'Meara, in reporting the treatment of a cholera epidemic in 1908, recommended that the specific gravity of the blood should be taken at the bedside;¹⁷ this important advance was a feature of the line of treatment carried out in Swatow.

The most rapid method of taking the specific gravity of the blood at the bedside is by means of solutions of definite specific gravity, with which the blood can be readily compared. The most convenient standard solutions are composed of oils in which the blood does not diffuse itself (as in a mixture of glycerine and water), but retains a definite globular outline. If a blood drop is placed in such a solution it will rise to the top and float on the surface if the blood is lighter than the oils, and will sink to the bottom if it is heavier. Mixtures of oil of wintergreen with either castor oil or olive oil were used throughout the epidemic.

Rogers has shown that two specific gravity figures stand out as of special importance in cholera—namely, 1.062 and 1.066; if the specific gravity of the blood is below 1.062, the injection of saline is not required, whereas, if it is over 1.066, 120 oz. must be administered at once; between these two figures 80 oz. of saline should prove a sufficient amount. In treating this cholera epidemic I found these two figures of incalculable value, for, in place of measuring the specific gravity of the blood exactly, it is only necessary to determine its relation to these two standards.

But the proper line of treatment to be adopted cannot be learnt from a study of the specific gravity of the blood alone; the condition of the heart must also be examined. The sphygmomanometer enables the degree of cardiac failure to be measured accurately, so that, instead of depending upon one's estimation of the strength of the pulse, as made out by digital pressure, one obtains an exact figure representing the number of millimetres of mercury required to obliterate the pulse. Here, again, Rogers has established a standard figure for the guidance of those engaged in the treatment of cholera. He writes:

As a result of prolonged experience, I have come to regard a blood pressure below 70 mm. of mercury as an indication of the presence of a dangerous degree of collapse necessitating an intravenous saline injection. . . . I have several times had occasion to regret having postponed transfusion in cases with a pressure a little below 70 mm.¹⁶

After treating the Italians at Palermo, he advised that the standard for Europeans should be 100 mm.¹⁴

Although in healthy Indians "the blood pressure is often on a much lower scale than is the case in Europeans,"¹⁸ yet this does not apply to Chinese,²⁰ and in treating cholera amongst Chinese intravenous injection is often required while the blood pressure is between 70 mm. and 100 mm. of mercury. It sometimes happens that in a patient with quite a good blood pressure (for example, over 100 mm. of mercury) the blood is so concentrated as to demand the administration of saline solution. In such a case the injection should not be given intravenously, but may be administered under the skin or by the rectum.

The sphygmomanometric estimation of the blood pressure yields more reliable information as to the strength of the heart than any other method, but if only the systolic pressure is estimated one will occasionally be led to wrong conclusions in patients in whom there is an abnormal difference between the diastolic and systolic blood pressures.

Although it may be more difficult to determine exactly the diastolic pressure—that is, the sustained pressure between the beats—yet it is upon this, rather than upon the systolic pressure, that the carrying on of vital functions depends. As a rule, the difference between the systolic and diastolic pressures is about 30 mm., but in various abnormal conditions it may be either greater or less. The difference is, for instance, much greater in aortic incompetence; and in the case of a cholera patient aged 35, who

was also suffering from aortic incompetence, his high systolic pressure led to the postponement until too late of the intravenous infusion that might have saved his life. On the other hand, when the difference between the systolic and diastolic pressures is less than usual, the patient may make a good recovery without intravenous infusion, although the low systolic pressure may have suggested that this was necessary. This was exemplified in the case of woman, aged 27, an opium smoker who was menstruating.² She was admitted with a blood pressure of 70 mm. of mercury. The pressure remained between this figure and 90 mm. for the five days she was under observation, although after the first twenty-four hours the blood was not unduly concentrated and a reasonable amount of urine was being secreted each day. It is important that one should be on the watch for these cases in which the cause of the misleading systolic pressure can only be discovered by a thorough and careful examination of the patient's general condition.

Those who have treated epidemics of cholera in the past, without the guidance afforded by the accurate determination of the concentration of the blood and the degree of cardiac failure, will remember the anxiety with which they often had to consider the question of the necessity or otherwise of saline infusion—an anxiety which is now done away with.

The solution (sodii chloridi 1 oz., potassii chloridi 24 grains, calcii chloridi 16 grains, aquam destill. ad 80 oz.) was filtered into glass flasks holding 20 to 30 oz. each, and these were plugged with sterile wool and boiled for ten minutes. The infusion was administered by means of Horrocks's apparatus, which consists of a simple glass funnel into which the saline is poured, and a rubber tube through which it makes its way to a cannula inserted into the vein. It was found advisable to interrupt this tube a few inches from the vein by the insertion of a simple piece of apparatus which not only acted as a trap for air bubbles, but also enabled the temperature of the saline to be measured as it was about to enter the patient's body.

The apparatus consisted of the body of a common glass syringe from which the piston had been removed; to the nozzle of the syringe was attached an india-rubber tube leading to the glass funnel. The other end of the syringe was closed by a cork with two holes. In one hole was a short glass tube which communicated with the interior of the syringe, and to which at the other end was attached an india-rubber tube communicating with the cannula to be inserted into the vein; through the other hole in the cork passed the tube and bulb of a common domestic thermometer, bearing on its stem two marks to indicate the position of the mercury at temperatures of 95 and 100° respectively. It is desirable (1) that the syringe be about four-fifths filled with saline before the infusion is commenced—it is not easy to estimate the flow if the syringe is quite full; and (2) that the "inflow" end be elevated, so that if by any mischance an air bubble should find its way into the apparatus it will not enter the vein.

Apart from the use of saline solution very little was done in the way of routine treatment. If the blood pressure was low and the blood was not unduly concentrated, vaso-constrictors were given, either infundibular extract or adrenalin chloride hypodermically, or, when all vomiting and nausea had ceased, the fluid extract of *apocynum cannabinum* by the mouth. The use of the sphygmomanometer showed that the use of these drugs was almost always followed by a rise in blood pressure and an increase in the flow of urine.

After the acute stage of the illness has passed, some patients are troubled with persistence of the vomiting or of the diarrhoea. For the former, cocaine,³ menthol,⁴ and iodine²² have been recommended; but in cases treated with large saline infusions the vomiting is rarely so persistent as to require such special treatment. Throughout this epidemic no patient was troubled with long-continued nausea and vomiting—a result that may be attributed, in part at least, to the almost routine use of calomel in doses of one-sixth of a grain every hour. In the few patients who were troubled with frequent small stools so late as the third or fourth day after the onset, immediate relief followed the use of a small starch enema containing one

or two drachms of bismuth subnitrate and half a drachm of tincture of opium.

A difficult problem in the treatment of cholera is the question of how to sustain the patient's strength. The persistent vomiting and diarrhoea prevent the giving of nourishment either by the mouth or in the form of nutrient enemata, and even after the vomiting is relieved the patient has but little appetite and only feeble digestive power. The administration of dextrose dissolved in the saline solution is advisable in very severe cases, for, although it may increase the tendency to hyperpyrexia, it certainly helps to sustain the patient's strength while he is in a very critical condition. The most important point that was insisted upon was that the patients must remain in a recumbent position. The attendants soon learnt that any infringement of this rule was likely to be followed by fatal results.

It was on these lines that the Swatow epidemic was treated, and the results varied according to the age, sex, and habits of the patients.

Table showing the Influence of Age in Determining the Result of Treatment.

Age Period.	Number Treated.	Number of Recoveries.	Percentage of Recoveries.
1-10 years	15	6	40
11-20 years	34	27	80
21-30 years	53	45	85
31-40 years	53	40	75
41-50 years	30	19	63
51-60 years	19	14	73
Over 60 years	8	3	37

Sex.

The results among the women were not so good as amongst the men, for death ensued in one-third of the female and only one-fourth of the male cases.

Opium Smoking.

In chronic opium smokers the results were unsatisfactory, for not only was their vitality diminished by long-continued indulgence in this habit, but it was found that they were especially liable to develop hyperpyrexia, and if that danger were surmounted there was considerable risk of their succumbing to *uraemia*. Taking the epidemic as a whole, of the 212⁺ patients who were treated with intravenous saline injections 154 recovered—that is, 72 per cent.

It would be unreasonable to contrast this eminently satisfactory figure with the percentage of recoveries obtained in the days before Rogers had published the

Table compiled from Recently Published Reports of Cholera Epidemics.

Date.	Place.	Number Treated.	Number of Recoveries.	Percentage of Recoveries.	Physician in charge.
1910	Puglia	14	3	21	Casharrini ²³
1911	Tunis	688	229	33.2	Conseil ²⁴
1911	Toulon	466	241	51.7	See ref. ²⁵
1911	Palermo	67*	40	58.2	Rogers ²⁶
1911	Calcutta	94†	59	62.8	Megaw ²⁷
1911	Madeira	319	206	64.6	Stevens ²⁸
1911	Toulon Fleet	18	12	66.6	See ref. ²⁷

These figures only include those cases which were so severely ill as to require the intravenous injection of saline.

* This number, as has already been stated, does not include the large number of cholera cases in which, though the concentration of the blood may have required the use of saline, the state of the heart was such that it was not necessary to administer this intravenously; these cases all recovered. Fourteen patients were taken home before their treatment had been completed. Some of them are known to have recovered, but as in other cases the final result could not be ascertained, none of these fourteen is included in the total of 212 cases. On the other hand, this figure does include the cases that were brought to the hospital in a moribund condition, or no case was considered too ill to receive treatment, so that there were no deaths in those who remained under our treatment that are not included in these statistics.

² Delmaboy Allen has found that the blood pressure usually falls at the commencement of the menstrual period and does not reach the normal again till the period is over. (From a private letter.)

results of treatment carried out with hypertonic—that is, "double strength"—saline solution; but comparison may fairly be made with the results obtained in epidemics treated since that date.

CAUSES OF DEATH: PRECAUTIONS.

In the course of the Swatow epidemic 58 patients died; the main causes of these deaths were collapse, hyperpyrexia, uraemia, and asthenia.

Table showing the Causes of Death in the Swatow Epidemic compared with the Causes of Death in other Epidemics.

Swatow Patients.	Collapse.	Hyperpyrexia.	Uraemia.	Asthenia.	Other causes.
Age 1-15 ...	3	8	0	0	1
Age 16-40 ...	6	10	2	3	4
Age over 40 ...	4	7	5	2	4
Total at Swatow	13	25	7	5	9
Palermo ...	15	2	7	1	2
Madeira ...	104	0	2	3	4

These causes must now be carefully examined, so as to learn how to anticipate and, if possible, avert the tendency to death.

Collapse.

Collapse accounted for death in 6 per cent. of the cases treated. In anticipating the probability or otherwise of a patient becoming collapsed great assistance is derived from a reliable history of the duration of the illness. The more rapid the onset, the more likelihood there is of the patient becoming suddenly collapsed.

Two members of the same family were seen at 9.30 one morning; one had been ill since the previous evening and had a blood pressure just below 70 mm., the other had a blood pressure just above 70 mm., but had only been ill since sunrise. Although the blood pressures differed but little, the history showed that the latter patient was more acutely ill and would require closer attention. The subsequent course of the cases showed the accuracy of this judgement, for although both alike received 80 oz. of saline into a vein, six hours later the former patient had a blood pressure of 86, while the latter was still in a semicollapsed condition and the blood pressure remained as before. A second infusion was then administered, raising the blood pressure to 86, and the patient made an uneventful recovery.

This shows that in a patient with a history of rapid onset the blood pressure requires to be estimated at short intervals till the acute stage has drawn to a close, and in dealing with cases in which no history can be obtained equally frequent observations are required until the rate of progress of the disease has been estimated.

Table showing the Rapidity with which the Blood Pressure may Fall, and the Consequent Importance of taking Frequent Readings with the Sphygmomanometer.

Sex.	Age.	Hour.	Specific Gravity.*	Blood Pressure.	Treatment.
M.	49	9 a.m. 12 noon	- +	110 mm. 88 mm.	Intravenous.
M.	40	6 p.m. 9.30 p.m.	+ +	102 mm. 84 mm.	Rectal. Intravenous.
F.	30	2.30 p.m. 6.30 p.m.	- +	120 mm. 84 mm.	Intravenous.
M.	42	7 a.m. 11 a.m. 1 p.m.	- + +	110 mm. 84 mm. 74 mm.	Rectal. Intravenous.

*The negative sign in this column indicates that the specific gravity of the blood was less than 1.062; the positive sign that that figure was exceeded.

But it is not enough to determine the blood pressure before commencing treatment with a view to deciding whether intravenous infusion is or is not required. After such an injection has been given, within even so short a period as six hours, the blood pressure may again fall so low as to make a second intravenous injection necessary. During the first six weeks of the epidemic in more than a quarter of the patients the blood pressure had fallen

within eight hours so low as to necessitate another injection. The patients therefore should be visited twice daily for four or five days. The two charts here reproduced show the need for those repeated visits.

It will be seen that it was only by constant attention and repeated treatments that the patients were brought through the dangers that threatened them. If death from collapse is to be avoided frequent estimation of the systolic blood pressure must be made, and intravenous injections of saline must be administered as often as the pressure falls to a dangerous level.

CHART 1.—Showing daily variations in blood pressure and specific gravity of blood. I, Intravenous infusion of 80 oz. of "double strength" saline solution. II, Rectal administration of 30 oz. of "normal" saline solution. Male, aged 26.

Hyperpyrexia.

The second great cause of death was hyperpyrexia, which accounted for death in 11.5 per cent. of the cases treated. This figure, though high, is a marked improvement on the death-rate from hyperpyrexia (23 per cent.) which obtained amongst the Europeans treated in Calcutta from 1895 to 1906 before the use of hypertonic saline solution had been introduced.

Composition and Amount of Saline Solution.

If deaths from this cause are to be avoided, careful attention must be given to the composition and amount of the saline solution to be injected and to the temperature at which the injection is to be made.

Composition.

McIntosh and others²⁶ have shown that the infusion of saline solution, which has been sterilized but from which the dead bodies of the bacilli have not been filtered, is sure to be followed by the development of pyrexia. They suggest that if these bodies are got rid of, little or no fever will result. More recently, however, Hort and Penfold²⁷ have shown that there may be present, even in bacillus-free water a substance, "pyrogen," the injection of which into a patient's circulation will assuredly be followed by the development of fever; this substance can neither be removed by filtration nor destroyed by heat.²⁸ A further point is that the saline solution must not be unduly concentrated. Rogers has shown that as a result of raising the saline content of the blood by the use of hypertonic solutions, the tendency of the osmotic currents is to carry fluid from the intestines into the blood stream. Consequently, if the saline solution injected is too concentrated, the salt content of the blood will be raised so high that a dangerously large amount of toxic fluid will be absorbed

from the intestines.²⁹ Repeated sterilization of the saline solution by boiling may render it so concentrated as to be dangerous; sterilized distilled water should, therefore, be added after each boiling in order to restore the saline solution to its original volume.

Chart 2.—Showing daily variations in blood pressure and in the specific gravity of the blood. *a*, Intravenous infusion (as in Chart 1). *b*, Rectal saline (as in Chart 1). *c*, Dry cupping over the kidneys. *s*, Subcutaneous injection of 40 oz. of "normal" saline solution. Male, aged 50.

Amount of Saline Solution Injected.

It has been shown experimentally²⁹ that the greater the volume of fluid injected the greater will be the degree of fever produced, so it is obvious that in order to prevent an undue degree of fever the amount of saline solution injected must not exceed the limit approximate to each case. Some light is thrown on this question by Table III, which shows that hyperpyrexia was the cause of a larger proportion of the deaths under the age of 16 than of those at the other age periods. In dealing with children it must be borne in mind that the normal blood pressure is low (in a child of 3 it is only 70 mm. of mercury) and varies with each year of age, so that Rogers's standard figure here becomes inapplicable. In view of this variation in the normal, one may sometimes be led to administer saline solution to children by the intravenous route when a saline enema would have met the requirements of the case. In such a case even a very small amount of saline may prove to have been too large and hyperpyrexia may ensue. Further, in those cases in which an intravenous infusion is really necessary sufficient

allowance must be made for the much less body weight and much smaller circulatory system of children, and a correspondingly small infusion must be given.

Temperature.

In regard to the temperature at which the saline is administered, Rogers¹⁰ has shown that, in the case of patients who are febrile in the collapse stage hyperpyrexia will almost certainly develop if saline is administered at the ordinary temperature (98° to 100° F.), whereas if the temperature of the saline is reduced to 70° to 80° F. the fever will in all probability not increase to any dangerous extent.

But in spite of every precaution the temperature may rise too high, and if it remains above 105° F. for any length of time, it is probable that all efforts to reduce the fever will prove useless and the patient will die.

If these deaths are to be avoided, therapeutic measures must be energetically carried out as soon as the rectal temperature reaches 104° F. It is true that many of these cases might recover without treatment, but as it is impossible to tell in which cases the temperature will subside if left to itself, and in which it will rise to uncontrollable heights above 106° F., it would be unjustifiable to withhold treatment from a patient who might benefit thereby. Cold sponging, the application of ice to the head, and the administration of iced saline enemas will probably prove the most effective means of reducing the temperature.

Uraemia.

The third main cause of death was uraemia. Seven patients died from this cause—that is, 3 per cent. of those treated; only two of these were under 40 years of age, and most were over 50. To avoid death from uraemia one must secure and maintain a copious flow of urine, and treatment directed to this end must embrace three distinct lines—the blood pressure must be raised, the concentration of the blood must be diminished, and congestion of the kidneys must be relieved.

The importance of a high blood pressure has been shown by Rogers,¹⁰ who found by experiment on kidneys obtained at *post-mortem* examinations that whereas in normal organs a pressure of 20 to 30 mm. of mercury sufficed to run a good stream through the renal circulation, yet in the case of kidneys obtained from patients after death due to the uraemic complications of cholera a pressure of 80 to 100 mm. of mercury was required for the same purpose. Theoretically the blood pressure can be raised by intravenous saline infusion, but often the patient seemed too well for such severe treatment, so a drug was prescribed for this purpose. The preparation which yielded the best results as a vaso-constrictor was the liquid extract of *apocynum cannabinum*, in doses of 2 minims every three or four hours.

For diminishing the concentration of the blood, water must be given—into the vein or under the skin, into the mouth or into the rectum. When one is dealing with a case of threatening suppression of urine, the less salt introduced into the body the better, so that once the initial collapse stage has been passed, the amount of salt added to the water to be administered should be reduced to its lowest possible limits. If the fluid is for intravenous or subcutaneous use then "normal saline"—that is, one drachm of salt to the pint—should be employed, while if it is proposed to give the fluid per rectum no salt at all need be added to sterile tap water.

The third line of treatment in uraemia is to relieve the congestion of the kidneys, and this is best secured by cupping. In many cases this was practised twice daily, and although it occasioned some discomfort to the patient, the passage of urine, which so frequently followed the cupping, more than compensated him for the discomfort he had undergone. In cases that proved fatal it would have been well if as a last resort the capsules had been stripped off the kidneys, but neither the patients nor their friends would consent to this operation.

Unfortunately, however, the battle with uraemia is not won when the kidneys have begun to secrete a little urine; if the secretion is not maintained, deaths will occur from delayed uraemia. The following may represent the history of a case in which this threatens: A patient has got over the stage of collapse and has not developed hyper-

²⁹ The pyrogenetic power of cholera toxins may be gathered from the frequency with which fever used to be brought about by the reabsorption of the bowel contents consequent upon the sudden checking of the diarrhoea in cholera by large doses of opium.

pyrexia; he has passed urine, the vomiting and diarrhoea have practically stopped, and no anxiety is felt either by the friends or the physician, but the patient has little desire for food and his friends do not insist on his taking it; and so day by day less nourishment is taken. The patient does not complain of any discomfort, and he still gives a prompt and cheery response to inquiries for his welfare. After a few days a certain delay is noticed in the response; the patient is far from being comatose, he is only a little lethargic. Once the doctor's attention is aroused, inquiry reveals the fact that only little fluid is being ingested and that still less, if any, is being excreted. Prompt treatment will probably save the patient, but if this earliest symptom—the delayed response—is neglected, the results may be fatal. Treatment must be directed to the cupping of the kidneys and to getting plenty of fluid into body; fluid foods at frequent intervals and enemata must be insisted upon.

I cannot close without expressing my indebtedness both to my senior colleague, Dr. Alexander Lyall, and to Dr. Chalmers of Swabue—to Dr. Lyall for his invaluable help and advice in the treatment of the more serious cases and for his kindness in setting me free from the routine work of the hospital throughout the epidemic, and to Dr. Chalmers for carrying on the treatment during my temporary absence from Swatow.

somewhat similar collation of evidence is embodied in an annual report by the Medical Officer of Aberdeen. In reply to his inquiries none of the medical officers of districts where measles was notifiable were able to adduce convincing evidence of gain, but in some instances the feeling was nevertheless strongly in its favour.

Experiments in the notification of measles have probably been carried out on a larger scale in Scotland than elsewhere. For Aberdeen the records are more than usually detailed. Measles was notifiable in Edinburgh also from 1880-1902, at the end of which period the medical officer was reluctantly compelled to admit practical failure. The more elaborate investigations of Aberdeen, carried out by Hay and Wilson, ended in the same conclusion.

Notification of measles has been in force since 1892 in Renfrewshire. All the conditions of success laid down by Thomson, except hospital treatment, have been rigorously observed. There has been no evidence that more cases of measles than of other infectious diseases have been missed. The information thus acquired has been for some time the subject of study (the results of which are as yet unpublished) by the writer. It may be appropriate here to mention briefly some of the points which have emerged in relation to the value of notification.

At the outset it is obvious that the absence of notification in other comparable areas deprives us of the very information required as a control to the Renfrewshire figures. Moreover, since the introduction of notification was practically synchronous with the commencement of county public health administration in Scotland, statistics for comparison with the past are not available. We are confined to a comparison of death returns in Renfrewshire and adjacent counties where measles is not notifiable. The mean annual death-rates from measles per 100,000 of the population in the Western Lowland Counties of Scotland, 1893-1912, are as follows:

Renfrew	21.04
Stirling	30.56
Dumbarton	30.50
Ayr	25.04

A chart of the biennial death-rates from measles in these counties since 1891 demonstrates that a decline has occurred in every case. The rate for Renfrewshire in 1891-2 was by far the highest, and that for Ayrshire least. In Renfrewshire a very sudden drop occurred in 1893-4, and continued in 1895-6, since when the curve has run at a lower level than the others. In Stirlingshire and Dumbartonshire a sharp rise took place in 1893-4, followed by a steep fall in 1895-6. Since that time the curves have been more or less parallel with that of Renfrewshire, but always at a higher level. The curve for Ayrshire runs a course more nearly horizontal.

Of the uniformly notifiable diseases, scarlet fever is less different from measles in its characteristics than any of the others. The proportions of deaths from measles per 100 deaths from scarlet fever in the four counties, 1893-1912, are as follows:

Renfrew	176
Stirling	225
Dumbarton	398
Ayr	222

Port Glasgow is an industrial town in Renfrewshire. Measles had been compulsorily notifiable there since October, 1898, and the campaign has been conducted on the same energetic lines as in the county. Port Glasgow is continuous with one end of the larger town of Greenock, where compulsory notification is not in force. A chart of the mean biennial death-rates from measles in these towns from 1891-2 to 1903-10 reveals a great and practically continuous decline of the measles death rate in Port Glasgow since 1893-4, and a similar descent for Greenock since 1897-8. The trend of the curve is somewhat steeper in Port Glasgow, and, from being almost uniformly higher in the first three biennia, it has run consistently at a lower level in the last three. It will be noted that the fall commenced in Port Glasgow before measles became notifiable. In Port Glasgow the mean of the annual death-rates in the second decennium is 60.9 per cent. lower than that for the first. The corresponding percentage for Greenock is 49.2.

None of these sets of figures afford fit basis for conclusive arguments, but, taken altogether, they show some

THE ADMINISTRATIVE CONTROL OF MEASLES.

BY

RALPH M. F. PICKEN, M.B., Ch.B., B.Sc.GLAS.,
D.H.P.CAMB.,

ASSISTANT TO THE MEDICAL OFFICER OF HEALTH, GLASGOW.

DISCUSSION at a recent meeting of the Central Council for District Nursing in London, and the circular letter of the Local Government Board issued on March 31st, 1915, are signs that measles as a potent cause of death in the young is again the subject of official and unofficial concern. It may be interesting to review briefly some past experiences in the effort to control its ravages. For many years public health officials have been fully alive to the problem, as official reports and the proceedings of various medical and sanitary societies testify. No doubt these records will be carefully considered in the formulation of new schemes for dealing with the measles.

Perhaps the earliest systematic effort to compile and sift the methods of control adopted by various local authorities was made by Thomson in 1894-5. The practice in 33 districts where measles had been notifiable was made the subject of minute inquiry, which resulted in the advocacy of notification. But he admitted the futility of notification unless it was supported by an adequate epidemic staff, rigorous search for unnotified cases, hospital treatment, judicious employment of school closure and other machinery for bringing the health department into the closest touch with measles at every point. The result of a

evidence in favour of the notification of measles both in a county area and in an industrial town.

It has been strongly urged by Campbell Munro that one of the great advantages of notification is the early information it affords on which to base school closure. He has adduced numerous instances from his experience in Renfrewshire, Port Glasgow, and Jarrow-on-Tyne, of the efficacy of notification and school closure, both in his annual reports and elsewhere. Körösy, Kingsford, and others have discussed the influence of the normal holiday closure, the former regarding the effect as important, Kingsford rather inclining to scepticism. According to Gilmour, the value of school closure depends largely on the better social class of the scholars. The statistical investigations of Brownlee on the inherent tendency of epidemics to end themselves, and on rhythmic variability in the power of the virus to infect, require to be considered in drawing conclusions from all such experiments on the controlling of epidemics. He emphasizes the importance of these two factors, the former having been indicated originally by Farr and discussed, along with influences of season and susceptible population, by Ransome.

Considered over a number of years effectual school closure should reduce the case-rate; delay the age of attack, and so reduce the case-mortality; and diminish the volume of biennial epidemics. As a matter of fact, comparing the decennia 1893-1902 and 1903-1912 in Renfrewshire, one finds a fall in the mean annual case-rate of only 7.6 per cent., whereas the case-mortality has dropped by 32.0 per cent. That the lower case-mortality is not due to protection of young children from infection is shown by the fact that the mean annual case-rate under 3 years of age has fallen only 5.6 per cent., while the case-mortality at these ages has declined by 30.3 per cent. The mean age of all cases under 20 years of age has actually fallen from 5.56 years to 5.41 years. No doubt part of the disproportion is the result of imperfect notification in the early years. Again, if the years considered are periods of twelve months from September to August, the biennial fluctuation of cases is more pronounced in the six years 1907-1912 than ever previously. It would appear that some factor has come into play which has tended to reduce the fatality more than the incidence of the disease. Whether it has been the educative campaign associated with notification, or improved social conditions, or increasing immunity by selection, or a natural variation of the disease, it is not possible to decide in the absence of mortality statistics elsewhere.

In order to delay the age of attack Sykes made a strong plea for raising the age of school entrance. This might save a certain number of children, but it is difficult to see how it would materially affect the children at ages when measles is most fatal—that is, under 3 years.

Hospital treatment has been advocated in many quarters, notably in Glasgow and Kensington, and by Thomson. The difficulty of treating in hospital any serious proportion of cases of a disease like measles, which flares out in epidemics, has been generally recognized. In Glasgow hospital treatment has been adopted on a large scale for many years. And yet the curves of death-rates from 1893 to 1912 in Glasgow and in Lanarkshire, which encircle the city and has never offered hospital treatment to any extent, are remarkably similar in their trend. The influence of hospital treatment on chronic sequelae can hardly be measured, but it is probably important. On the other hand, the risk of infectious bronchopneumonia is increased.

Home visitation by trained nurses is now receiving official countenance. The educative effect and the prevention of sequelae may be valuable. It cannot have much influence on the spread of infection, and probably little upon the immediate fatality of the disease. Indeed, it is highly improbable that any measure short of the production of artificial immunity will have much influence on measles. The work of Anderson and Goldberger holds out hope that the discovery of the organism may yet lead to its administration in some attenuated form. Meanwhile, any advance in the administrative measures for dealing with measles is a move in the right direction, and must be based on accurate information, such as compulsory notification affords.

UNIVERSAL SUSPENSION APPARATUS FOR ARM AND LEG.

By M. SINCLAIR, M.B., CH.B. EDIN.,
CAPTAIN R.A.M.C.

ARM.

This is composed of a movable wooden top and a fixed wooden perpendicular (Figs. 1 and 2).

The lower perpendicular pole, L.P. (2 in. by 2½ in.), 5 ft. in length, is fastened to the top of the bed by means of a flat bit of timber, F (4 in. by 1 in.) 2 ft. 4 in. long, bolted with two bolts to the pole, with bed head rail between them, on the extreme right or left of bed.

Fig. 1 (from a photograph).—Showing arm suspension applied.

This pole, L.P., has two sets of hinges, anterior and posterior, to enable it to be used for right or left arm— anterior for left, and posterior for right. These hinges are set at 15 in. apart, the upper hinge being 4 in. from the top of pole L.P. They also allow the top to swing 180 degrees.

The hinges are composed of two parts (Fig. 3), thus allowing the top to be easily moved when the suspension is required for right or left arm, as the case may be.

By this method two male parts are fixed to the upper perpendicular, U.P., and four female parts to the lower perpendicular, L.P. In alternate suspensions male and female parts are reversed.

The top has a perpendicular cap, U.P., and carries two

fixed horizontals, L H and U H, and a movable arm, M A, which is hinged to the upper perpendicular, U P.

Fig. 2 (from a photograph).—Arm suspension, showing details.

This top can be completely removed from the pole by pushing the top upwards and thus separating the male from the female hinges. This renders it applicable to right or left arm. The upper perpendicular, U P, is made of the same material as the lower fixed perpendicular, L P (namely, 2½ in. by 2 in.), and is 3 ft. 2 in. in length. The two fixed horizontals L H and U H are set at right angles one above the other. They are 2 ft. 8 in. in length, the material is 3 in. by 1 in. They extend 2 ft. in one direction and 8 in. in the other.

The upper, U H, rests on the horizontal L H, which in turn rests on a block of wood X, all three being screwed to the upper perpendicular, U P. From the end of the shorter pieces of these two horizontals two stays, S S (2 in. by 1 in.), are fixed to the top of the upper perpendicular to counteract the weight that has to be applied to the longer ends. No dovetailing is done so as to avoid any weakening of the superstructure.

The ends of the longer pieces of the two horizontals are joined by a piece of wood, T S (3 in. by 1 in.), and, in order to keep this level, it is let in at the end which is in contact with the higher of the two horizontals, and rests on the top of the other horizontal. At each end of this transverse stay T S is a flat iron upright (¾ in. by 1 in. by ¼ in.) projecting upwards to act as a check, K, to the movable arm, and at the same time give more strength to these joints.

The movable arm, M A (3 ft. by 1 in.), is hinged to the upper perpendicular, and the upper edge 4 in. from the top of U P moves through an angle of 90 degrees. It is for the attachment of a block when the arm is extended, as in an arm Thomas splint. When the arm is extended (as in Fig. 1) in an arm Thomas splint, there are three eyes of wire fixed to the splint, two at the ring (one on each side of the iron bars of the splint), and the third at the middle of the transverse bar at the hand end.

Three cords, C 1, 2, 3, are attached to these eyes—watch-chain hooks are very convenient—and each passes through its respective two blocks, and a suitable weight is attached to the other end.

For the right arm the cord C 1 from the hand end passes through block B 4 which is attached to the end of the M A, then passes to block B 1, which is fixed to horizontal L H, and a weight (sandbag) of about 2 lb. is attached at the other end.

The cord C 2 is attached to the outer eye at the ring end of the splint, passes through block B 5, which is fixed at the junction of T S and U H, then through block B 2 on L H, and carries a weight of about 4 lb.

Cord C 3 passes from the inner eye of the splint through the other block, B 6, fixed at the junction of T S and U H, thence to block B 3 on L H, and carries a weight of about 6 lb.

The blocks B 1, 2, 3, should be so placed on L H as to allow free play of the weights without touching.

In the accompanying drawings from photographs the irrigator rubber tube and two cords supporting the tubing which is leading to a wound that is being treated by continuous irrigation, are not lettered, to avoid confusion.

A gutter of perforated zinc is fixed to the sides of the Thomas splint, and holes are burned in the zinc opposite any drainage tubes. To prevent tissues herniating through these exits, the holes should not be too large. The whole is sterilized by flaming, and the arm with wounds is laid directly on this bed of zinc.

Fig. 4.—(i) Three cords with suitable weights are arranged as follows: Fix a block with about 4 in. of cord to a hook at (a). Fix cords at (b) (c) (d). Thread cord (b) through block (a), and suspend (b) (c) (d) to three blocks about 2 in. apart at the extremity of U H. Arrange blocks, cords, and weights so that they do not touch. Approximate weights: (b) 5 lb., (c) 4 lb., (d) 3 lb. (ii) Approximate weights: (a) and (c) 3 lb., (b) and (d) 2 lb.

This form of suspension of the splint conforms to all permissible movements of the limb, and is a great comfort to the patient, who is free to move at his will, or to sit up by his bedside if he wishes. Wounds so treated, drained freely, are readily dressed, and are open to inspection at all times.

By redistribution of the weights and blocks, this suspension can be adapted to a rectangular wire splint or a square wire frame, both of which are filled in with perforated zinc, for use with the flexed elbow.

LEG.

The suspension consists of a fixed frame carrying a travelling cradle, from which the limb in its splint is suspended by a system of weights and pulleys.

Fig. 5.—Diagram of suspension.

Frame.—The material is 3 in. by 2 in. A length of T-section iron rail is screwed to the upper surface of an 8-ft. wooden bar for a distance 5 ft. 6 in. from the foot

end. Two such bars are supported at their extremities by 6-ft. uprights placed so that the rails are 3 ft. 3 in. apart and parallel to each other. The uprights are firmly fixed

Fig. 6 (from a photograph).—Leg suspension applied. F Z, Perforated zinc.

to the floor by suitable stays, and the pair at the head end is joined by a transverse bar.

Cradle.—The material is 3 in. by 1 in. (all dimensions are outside measurements). The travelling cradle is rectangular with sides (F 1 and F 3) 4 ft. in length, carrying two window-sash pulleys, each let in 4 in. from the extremity R 1, 2, 3, 4. The ends F 2 and 4 are 3 ft. 4 in. in length. This rectangle is divided by a transverse stay, T, at 1 ft. 5 in., and the two smaller rectangles thus formed have diagonal stays, D 1 and 2, to prevent racking and give rigidity. On F 2 and T iron checks, X 2 and 1 (6 in. by 1 in. by $\frac{1}{2}$ in.), project vertically downwards, just clearing the horizontals B H 1 and 2. Strong 2-in. screws are fixed half in into the inner sides of B H 1 and 2 to engage with these checks. These are best adjusted experimentally. Sixteen round-headed

Fig. 7.—The same, showing patient raising pelvis unaided four days after injury. F Z, Perforated zinc.

2-in. screws are fixed half in into the upper edges of F 2, T and F 4 in the following way (Fig. 5): On F 2 four screws at the 6th and 15th inch from each side. On

T four screws at the 2nd and 11th inch from each side. On F 4 eight screws at the 4th, 9th, 14th, 19th, 21st, 26th, 31st, and 36th inch.

There are now sufficient for a right and left leg, and are for the attachment of the single blocks of the Hodgen's splint ($1\frac{1}{2}$ in. block is the best size).

In slinging a right fractured femur in a Wallace's splint, blocks are attached to screw S 1, 2, 5, 6, 13, 14, 15, 16.

There are four eyes of wire fixed to the splint, two on the ring (one on each side below the bars of the splint), and the other two to the transverse bar carrying the foot-piece.

Four cords—C 1, 2, 3, 4—are attached to these eyes; watch-chain hooks are very convenient, and each passes through its respective two blocks, while a suitable weight is attached to the other end.

Cord C 1 from outer foot attachment passes through block B 1, which is attached to screw S 5 on T, then through block B 5, which is attached to screw S 13, and carries a weight of about 7 lb.

Cord C 2, from inner foot attachment, passes through block B 2, which is attached to screw S 6 on T, then through block B 6, which is attached to screw S 14, and carries a weight of about 7 lb.

Cord C 3 from outer ring attachment, passes through block B 3, which is attached to screw S 1, then through block B 7, which is attached to screw S 15, and carries a weight of about 14 lb.

Cord C 4, from inner ring attachment, passes through block B 4, which is attached to screw S 2, then through block B 8, which is attached to S 16, and carries a weight of about 14 lb.

This suspension allows the patient very free movement, is a great comfort to him, and nursing is made comparatively simple. Fig. 7 (from a photograph) shows the patient, who has a fractured femur and ulna, raising his pelvis unaided four days after injury.

AN OPERATION FOR THE OBLITERATION OF THE CAVITY IN THE TIBIA REMAINING AFTER SEQUESTROTOMY.

By WILLIAM GEMMILL, F.R.C.S.,

KILMARNOCK.

The operation described is after the osteoplastic method recommended by M. W. af Schulten.¹ The patient was a man aged 61 whose left leg had been crushed nineteen years previously. At that time he was for four months in hospital; according to his own statement some dead bone came away from the lower part of the leg, and the wound healed. About a year afterwards the upper part of the leg, which had remained swollen, became very painful, was laid open, and part of the bone was removed. The wound produced at this operation had never healed, but the patient for sixteen years pursued his occupation with frequent intervals of incapacity due to the discharge becoming more profuse and foul. During this period he had four operations, which, he said, consisted in "scraping the bone," and one in which an unsuccessful attempt had been made to obliterate the cavity by filling it with wax.

The condition of the limb before operation was as follows: The whole of the shaft of the left tibia was much thickened and rounded, and scars of old sinuses were present over the lower part. The upper third of the shaft presented a cavity with overhanging edges about an inch apart at the outlet. The depth was one inch and a quarter, and the length three inches and three-quarters. The upper limit of the cavity reached to within one inch and a quarter of the knee-joint. The epithelium had grown well down into the cavity, leaving the posterior wall, however, covered with weak exuberant granulation tissue. There was some sero-purulent discharge.

Under a general anæsthetic, the limb having been rendered bloodless by means of a tourniquet, the cavity was thoroughly swabbed with pure carbolic acid. An incision down to the bone was made round the opening of the cavity just outside the margin. The epithelium

within the incision and the granulation tissue in the cavity were thoroughly removed with a sharp spoon till healthy hard bone was reached all round. From the upper and lower extremities of the wound vertical incisions were made, terminating at the levels of the roof and floor of the cavity, and what remained of the bony part of the anterior wall of the cavity was removed. A transverse incision was now made at the upper, and a corresponding one at the lower, end of the wound reaching down to the bone, care being taken at the same time to avoid injury to the tibialis anticus muscle. Each incision was $\frac{3}{4}$ in. in length, and reached on either side to the junction of the lateral with the posterior wall of the cavity. Through these incisions the attachments of the lateral walls to the roof and floor were now severed by means of a small saw. The lateral walls, consisting of skin, subcutaneous tissue and bone, now remained attached only to the posterior wall, and the next step consisted in severing the bony attachments. This was done by means of a chisel and mallet, working from the inside of the cavity, the last part of the separation being completed by using the chisel as a lever and breaking through the outer shell, in order to preserve the periosteum intact. The lateral walls could thus be turned outwards as two flaps. Sufficient bone had now to be chiselled away from them and from the posterior wall to allow the flaps to lie against the posterior wall and their edges to be brought together. Unfortunately, before this step was quite finished the condition of

Diagram of transverse section through cavity in tibia. Shaded part represents bone removed to allow flaps a and b to come together; c = periosteum, d = tibia.

was again dressed on the seventh day, when the stitches were removed.

The wound healed partly by first but mainly by second intention, and with the exception of two small sinuses, one at either end, which admitted a probe and led down to small points of bare bone, had entirely healed by the seventh week. Three weeks later the sinuses had disappeared, the bony flaps had joined solidly to the shaft, and the patient was walking about. The resulting scar consisted of a vertical part with a transverse piece at either end.

Two points worthy of note arose during the operation. The first was that the amount of bone which had to be removed before the flaps could be brought into apposition was much greater than I had anticipated, and the other that before the edges of the transverse incisions could be brought together it was necessary to bevel down the edges of the overhanging bone at the roof and floor of the obliterated cavity.

Had the condition of the patient under the anaesthetic permitted of sufficient bone being removed to bring the flaps accurately together recovery should have been more rapid.

THE TREATMENT OF SEPTIC WOUNDS BY THE ELECTROLYTIC BATH.

BY

FRANK FOWLER, M.D.,

MEDICAL OFFICER IN CHARGE OF ELECTRICAL DEPARTMENT, ROYAL VICTORIA AND WEST HANTS HOSPITAL, Bournemouth.

THERE has lately been much discussion of the possibility of sterilizing wounds by antiseptic lotions. A weak solution will not kill the septic organisms, and a strong solution will kill those it can reach, but produces a slough, which provides excellent culture material for those deeper in the tissues. The question asked was: "How can we attack those germs which remain in the tissues?" Bacteriologists have had some success in this direction with vaccines and serums, utilizing and fortifying the natural resistance of the body to the infection.

It did not occur to any one to ask, How can these germs be induced to leave the deep parts? The idea that a Pied Piper should arise to call them from their fastnesses to be destroyed seems fantastic; yet it appears that this is not only possible but in many cases easy. The credit for the discovery belongs to Dr. Charles Russ,¹ who found that nearly all germs are carried towards the positive pole of an electric current passing through a solution of sodium chloride, and that the small current required is lethal to the bacteria without the need for any aid from the ionization of various drugs, such as the salts of zinc and copper, which have been much used for the purpose of introducing an antiseptic into the cell's.

The practical results of treatment seem to support Dr. Russ's observations. I have been much impressed by the success obtained in every case that I have treated. I will only describe one, a perforating gunshot wound of the foot, with a crater on the dorsum leading to a tunnel through which the little finger could be passed and which opened on the sole of the foot. The whole wound was welling with pus and it seemed doubtful whether the man's leg could be saved; five days later granulation tissue was level with the skin at both wounds, which were surrounded by a healthy looking ring of new skin.

The action of the current is not confined to carrying bacteria from the wound, but also stimulates the formation of granulation tissue and epithelial growth.

The treatment opens up a wide field for further research in the treatment of many intractable conditions. Dr. Russ reports some cases of chronic cystitis in which it has produced very satisfactory results.

Apparatus.

The only apparatus required is a battery of 20 to 30 dry cells with a current collector and a good milliamperemeter reading to 25 m.a. with a shunt to 250 m.a.

Bath.—A Schnee four-celled bath is very convenient, but any vessel will do if it is long enough to immerse the forearm and hand, or deep enough to cover a wound of the foot or leg, wounds of the other parts can have a local bath applied, such as a glass cylinder made water-tight with plasticine, as suggested by Dr. Russ, and filled with a warm saline solution.

Electrodes.—Two electrodes are necessary—the carbon of a Leclanché cell serves admirably, or they can be cut from sheet zinc. One is immersed in the bath with the wounded limb, and this must be connected with the positive pole of the battery, marked +. The negative pole has to be connected to some (indifferent) part of the body, either in another bath, or the electrode may be placed under the back of the patient, separated from the skin by sixteen thicknesses of lint well soaked in warm salt solution—this pad should be 12 in. square, and must be well washed after use to remove any trace of caustic soda produced by the current.

Method of Treatment.

The wounded limb being placed in the bath and covered with warm normal saline solution, the negative pole connected to some other part of the body, the current should be slowly turned on from zero until the meter registers 20 to 30 milliamperes. This current, which the patient will barely feel, is sufficient for an average bullet wound; for larger wounds the current must be increased proportionately. The patient must be warned not to take the

THE Prefect of Police in Berlin has notified the German medical profession that the authorities are disquieted by the great fall in the number of pathological specimens sent to the laboratories for investigation. He points out that this slackness on the part of medical men greatly increases the chances of epidemics. However much the ranks of the medical men may be depleted by the demands of the army, the authorities, he declares, cannot allow practitioners to neglect one of the most important measures for the early detection and localization of infectious diseases.

limb out of the bath until the current is quite turned off, or he will get a shock; for the same reason the turning off of the current at the close of the treatment must be gradual.

Treatment should be given daily, for half an hour on each occasion.

My experience of the method leads me to recommend it as giving excellent results in all septic wounds and ulcers; it needs no expensive outfit and is painless.

A CASE OF HYSTERICAL AMBLYOPIA.

BY

KENNETH CAMPBELL, M.B., F.R.C.S.,

SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL.

AN acquaintance with a few elementary principles of psychology is necessary for the proper understanding of the modern views concerning hysteria. Up to the time of Locke (1632-1704) the belief was generally held that all ideas are innate—that is, that the mind has the power of spontaneously drawing from its own depths conceptions and ideas which are quite independent of all experience. It was this philosopher who first taught the now generally accepted doctrine that impressions received from without must precede any ideas in the mind, that no ideas exist antecedently to experience. Locke likened the mind at birth to a sheet of white paper upon which the environment prints its messages.

There are reasons for thinking that each of us possesses a dual mental life—(a) the ordinary life of normal conscious thought, and (b) a subconscious mental life (the "subliminal consciousness"). This in effect means that there are two main planes of consciousness—a higher and a lower—and that impulses flowing into the lower plane are not of such degree of intensity as to excite immediate attention, but, being stored up in the mind as memory images, can, under the influence of certain stimuli, enter the higher plane of conscious thought, and thus be presented to the ego. According to Freud, there is no such thing as chance in the determination of a thought, for he postulates that for every psychic phenomenon there has been an antecedent experience in the life-history of the individual. He illustrates this thesis by the following history of a case: A certain young woman complained of the constant presence of the odour of burnt pudding, concerning which she herself could offer no explanation. By applying his method of psycho-analysis Freud eventually was able to trace the hallucination to its source; at a time of great emotional crisis in her life (a repressed love affair) she had been occupied with a burnt pudding.

Alice K., aged 21, exhibits all the classical symptoms of hysteria. She is highly emotional, self-conscious, of defective will power, keenly desirous of sympathy, and speaks in a whisper (hysterical aphonia). Her life has no satisfactory aims.

Visual acuity varies within wide limits. Sometimes it is as low as $\frac{2}{300}$; at other times, particularly when her attention is distracted, it is as high as $\frac{5}{5}$. Retinoscopy shows +2 D. of correction. That there is no element of malingering is proved by the fact that she will unintentionally hurt herself by stumbling over a chair or knocking against a post. Just as visual acuity varies, so does the visual field vary, at times being reduced to a small area around the fixing point. On ophthalmoscopic examination the media are found to be transparent and the fundus normal. There are no signs of disease in any of the viscera. The blood pressure is not raised and the urine is free from albumin. The condition of the kidneys is very important, inasmuch as many cases of amblyopia are uramic in origin.

Following Freud's method of endeavouring to trace every particular symptom to its source—some antecedent experience in the life-history of the individual—it was revealed that a short time prior to the onset of the visual defect the eyesight of the patient's father had begun to fail. This preyed considerably on her mind, and from then dates the beginning of the amblyopia. Having now traced the condition to its source, the next thing was to

get the patient frankly to acknowledge its nature, to face it bravely, and to bring the entire circumstances of it under the criticism of the mind. This line of treatment, combined with measures adopted to improve the general health, effected a cure by the end of nine months.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HYPOCHLORITE SOLUTIONS IN THE TREATMENT OF WOUNDS.

SINCE reading the experimental observations of Professor Lorrain Smith and others on the use of hypochlorous acid as an antiseptic I have used a solution of hypochlorous acid, made by diluting the liquor sodæ chlorinatæ B.P. with water (one to four of water), extensively in the treatment of industrial injuries in the casualty department of the Bradford Royal Infirmary (at present under my charge). It has exceeded my expectations in every way, although, like many others, I have used it for many years in septic throat conditions with great advantage.

The liquor sodæ chlorinatæ has the advantage over "eupad" in that it is much more stable, and does not lose its gaseous contents so readily. It is also much more convenient—in civil hospitals, at all events—than the solid "eupad," and its solution is less troublesome to prepare than "eusol"; also its hypochlorous acid content as demonstrated by its power of liberating iodine from a solution of potassium iodide, is greater than that of "eusol." After over twenty years' experience of various antiseptics, I have no hesitation in saying that it is better than any other I know. It is cheaper even than mercury perchloride; it is non-poisonous, is non-irritating to the deep tissues and skin, being almost a neutral solution or only slightly alkaline; it does not either discolour or irritate the surgeon's hands, or destroy his instruments. I have done a number of amputations in badly lacerated hands, where there was every chance of sepsis arising, and even when the full strength of the liquor sodæ chlorinatæ was used primary union of the flaps was obtained. I have not worked out the lowest effective strength of dilution, but in all probability it can be used effectively in much weaker solution than I have employed. In several cases of previously septic wounds I have used the full strength with most gratifying results. My apology for writing this is that probably many medical men do not realize that they have at hand an old preparation which gives them the benefits of the most recent researches on the antiseptic treatment of wounds when the conditions are such that aseptic methods cannot be applied.

Bradford.

WILLIAM MITCHELL.

LOCALIZATION OF FOREIGN BODIES.

I HAVE been asked if my "ladder" localizer, described in the BRITISH MEDICAL JOURNAL of July 3rd, could not be adapted for the localization of foreign bodies by the fluorescent screen. The following method is quite simple and accurate: With the usual arrangement, the screen above the patient and the tube below, the latter is first set so that the vertical ray is in the plane of the ladder. The shadows of the wire rungs are thus superposed, forming one black line on the screen. This line is marked conveniently by placing over it on the lead glass of the screen a thin knitting needle, with a small piece of adhesive strapping at each end. The shadow of the chosen point of the foreign body is also marked by the point of an ordinary pin, similarly furnished with a bit of strapping. The tube is then moved so that the vertical ray passes through the chosen point of the foreign body. The ladder shadow is now, of course, spread out, the rungs appearing separately. The dividers are next brought into play, one point set on the former shadow of the foreign body (the pin point) and the other on the present shadow. The dividers are then moved to the ladder shadow (the line joining their points being kept parallel to its original direction) and moved along with one point kept lightly pressed against the knitting needle until the second point of the compasses falls on the shadow of a rung, let us say a quarter of the

way along the fourth rung. The foreign body is at the depth thus indicated—that is, 3.25 cm. below the screen. The tip of a second knitting needle pressed lightly on the skin, so that its shadow coincides with that of the foreign body in the second position of the tube, can, if necessary, be localized similarly, to allow for the distance of the plate above the skin of the patient. In any case, the knitting needle should be set in place and the position of its tip marked on the skin, recording the spot which is vertically over the foreign body.

Reports

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

MANCHESTER CHILDREN'S HOSPITAL.

A CASE OF STUPOROUS INSANITY CURED BY THYROID EXTRACT.

(By G. H. HICKLING, M.D., D.P.H., B.Sc.)

M. B., aged 12, was brought to the dispensary in March last. She was assisted to a chair, being apparently unable to walk alone. She did not speak nor take the slightest notice of what was said to her, but remained during the entire consultation in a condition of complete apathy, staring blankly before her.

History of Onset.

During the past six months from being a pleasant, good natured girl she became increasingly bad tempered and sulky. Then dirty habits developed. Incontinence of urine and faeces occurred by day and by night. She lost all interest in her surroundings and became more and more morose. The only thing which roused her was the sight of food. She was ravenous and greedy, eating all that was placed before her, even stealing the portion of the younger children. She would sit in one position for hours, never uttering a word. Occasionally, however, if disturbed she would give vent to loud inarticulate cries. There was no history of shock before the onset, nor had the child suffered from any previous ailments other than the minor maladies of childhood. She was the third child of a family of seven, and all the others were healthy.

Condition when First Examined.

She was a pale, thin child, small for her age; her face was devoid of expression. The tongue was furred, the bowels constipated; the hands and feet were cold, the pulse slow and feeble; no heart lesion was detected; respiration was shallow, but the lungs appeared normal; the urine was not examined owing to difficulty in obtaining a specimen; there was no indication of the approach of puberty; the knee-jerks were present but response was slow. During the examination the child remained passive, offering neither resistance nor assistance. She never turned her head when spoken to, but continued to gaze stolidly before her. At the conclusion of the interview she had to be dragged from the seat and more or less carried out of the room.

Treatment.

The case was duly labelled "mental" and a poor prognosis given. An aperient mixture together with bromides were prescribed. A fortnight later the bowels were acting freely but the mental condition was unchanged. Treatment with thyroid extract, 1 gr. daily, was then started. Two weeks later there was a slight but distinct improvement, with an attempt at speech, and after another fortnight she replied intelligently when questioned. From that time on she progressed rapidly. After two months of thyroid treatment she had regained control over bladder and rectum, and her appetite was normal. A month later her demeanour suggested no mental abnormality; she looked bright and amiable though somewhat frail. She has now been sent into the country for a month, and given a tonic of iron, arsenic, and strychnine. It is proposed to keep her under observation for some time longer until puberty is established.

Rebicus.

DELORME'S "WAR SURGERY."

VERY large numbers of surgeons have been discovering during the past eventful months that the surgery of war was not quite the same thing as the surgery of peace. The lessons learnt by the surgeons of a generation or more ago had to be relearned by the men of to-day. Very early in the war Inspector-General DELORME, of the French Army Medical Service, published a volume of advice to surgeons, and with the object of preserving "unity of doctrine" and uniformity of practice. That volume has now been supplemented by *War Surgery*, a translation of which has been made by Dr. H. DE MÉRIC. The work is a small, compact volume, not overburdened with detail, rather synoptical in its form. Reference to any subject is easy, and the reader finds quickly the information on the matter in hand. The author confines himself strictly to the point of view of injuries and their direct results as they are produced in war.

The preliminary chapters on weapons and projectiles are interesting for the authors remarks on the so-called "humanitarian" bullets. "It is truly pushing the love of paradox very far to call humanitarian a bullet that goes through several men when fired from a short distance, and that is capable of causing great slaughter in a zone of more than 3,000 metres." Bullets which on meeting the slightest obstacle turn on their axis, strike obliquely or transversely, and so give rise to wounds of large size, are, he considers, outside the borders of "humanitarian." The mortality in short-distance rifle firing is, he says, very great, and he does not accept the idea that men are simply placed *hors de combat* for a short time and not killed. With equal fearlessness he dismisses the notion of the employment of explosive bullets so often alleged against the Germans. In these terrible injuries the "explosive shots are due to projectiles of very high velocity becoming more or less broken up in their course through the tissues." The ricochet accounts for very many of these explosive effects. Ricochet occurs in about one-third of all rifle bullets fired. The so-called explosive bullet does not ricochet.

In the treatment of wounds of arteries Delorme's experience suggests the adoption of this formula, which we quote in full: "In wounds of large vessels, ligature after compression should remain an operation of emergency for cases in which the haemorrhage continues; if it stops, the patient should be immobilized on the spot and closely watched. Supervision would be better carried out in the first line than in halting places on the road or on the railway. When the surgeon considers the proper time has arrived he will send the wounded man on to the nearest hospital."

In dealing with metallic foreign bodies he maintains that the asepticity or otherwise of the wound is of more importance than the tolerance of these bodies in the tissues, or their nature, size, and form. But if a foreign body in an aseptic wound gives rise to no pain or uneasiness by coming into contact with vessels and nerves, it should be left. No attempts have hitherto been made, so far as we know, to classify the effects on bone of rifle-bullet fire in relation to velocity—that is, distance from which the shot has been fired. M. Delorme states that as a general rule the higher the velocity of the projectile the more limited in length is the fracture, but the greater is the comminution; and he makes a classification, fully illustrated with diagrams, which we commend to surgeons dealing with these injuries in any of their stages.

Conservatism is the leading note of the chapter on abdominal injuries. The treatment of such is summed up in two sentences: First, narrow wounds made by bullets fired point blank should be left alone, the patient kept at rest and starved; secondly, extensive wounds of both skin and bowel made by bullets which have turned, or by shrapnel, certain to be accompanied by peritoneal infection, should be treated by absolute rest, starving, Murphy's small incision in the lower abdomen to drain the pelvis, rectal salines, and Fowler position.

This little book is very systematically arranged and reference is facilitated by a good index, and the translator

¹ *War Surgery*, by E. Delorme. Translated by H. de Méric. London: H. K. Lewis and Co., Ltd. 1915. (Cr. 8vo, pp. 256; 14 figures, 5s. net.)

has done his work well. The volume, as has been said, is small, and might well be added to the kit of every young surgeon attached to our forces. On the way out to the Dardanelles or in the preparatory months at home, time would be well spent in mastering the concentrated expression of M. Delorme's experience.

TEXTBOOKS OF MIDWIFERY.

The appearance of a fourth edition of Dr. EDEB'S *Manual of Midwifery*¹ forms abundant evidence that the popularity into which it immediately sprang on its first publication less than a decade ago was well founded. As a student's textbook particularly it has in these years held one of the foremost places. The present edition differs from its predecessors in one important point only—namely, its increased size. The author explains that he has had to include descriptions of the advances in the science and art of obstetrics which have taken place during the last three years, and certainly every justice has been done to these matters. Several of them, however, involve questions upon which the final judgment has yet to be pronounced, and it is a moot-point whether in a book which presumably is primarily designed for students, they deserve an increase of close upon seventy pages. If this process continues, we venture to think that the whole character of the book will change. Amongst the new subjects introduced, a prominent place is given to the rare form of obstruction in labour due to the formation in the uterus of a contraction ring, and the author has made an interesting classification of the various forms of spasm of the uterine muscle met with during labour. The condition is incisively explained, and the classification will be distinctly helpful to the student. The whole question of the serum reactions in pregnancy is touched upon, and a description given of Abderhalden's reaction. The question of its ultimate value is judiciously left open. The section upon the physiology of pregnancy has been rewritten and expanded in other directions also, and reference made to the functions and correlation of the endocrine glands. The treatment of placenta prævia has been revised, and due consideration has been given to Caesarean section as an operation suitable for certain cases. Recent work on the etiology of eclampsia has received ample recognition, but in regard to its treatment mention might have been made of veratrine, as distinct from other preparations of veratrum viride, in view of the encouraging results that have followed its use in the hands of several authorities. The new edition unquestionably maintains the book at a high level of excellence. Its general production is first-rate, and the addition of four good coloured plates adds to its attractiveness.

The work on obstetrics² by Professor LEOPOLD MEYER, of Copenhagen, possesses many of the characteristics of the ideal textbook. Each volume is light and handy, the print is large, and the convenient device of using small print for the discussion of matters of secondary importance is of inestimable value to the student, who thus gets a book combining the advantage of an epitome with that of a detailed review. There are many signs that the author is indebted to the German schools, and a certain number of the illustrations are taken from Bumm's book, but many of the best illustrations are original, and the author's style is in marked contrast to the ponderous and tedious composition of many German scientific publications. Professor Meyer's book reads as easily as a novel, but is not verbose, and it would be impossible to condense his book appreciably without serious loss of valuable matter. This combination of brevity with style and lucidity is so rare a feature of textbooks that the restriction of this work to the readers of Danish, which is little read outside the Scandinavian countries, is all the more regrettable. Probably much of the charm of Professor Meyer's style would be lost in translation. His many years of teaching have no doubt impressed on Professor Meyer the importance of avoiding side-issues and qualifications of general statements, and he is blameless of Gladstone's *per se* pursuit

of successive digressions. But the virtue of keeping to the main point and to generalities exposes the author to the critic armed with the exceptional case; and when the author gives catheterization of the bladder as the only cause of cystitis after labour he is probably overlooking other factors. Thus, on page 310, he says: "Cystitis may occur during pregnancy, but it is rare; it is more common in the puerperium, when it is due to catheterization-infection during labour or the puerperium. It occurs readily when frequent catheterization is necessary at this stage, but it can be avoided, as under other conditions, with practical certainty, by the use of prophylactic irrigation with 1 in 200 silver nitrate." In the matter of anaesthesia Professor Meyer does not run after strange gods, but cleaves to the time-honoured use of chloroform under certain conditions and in small quantities. The Freiburg method of inducing "twilight sleep" with small, frequent injections of scopolamine and morphine is damned with the faint praise implied by the use of small print. The author says: "But the method appears to be far from safe, at any rate for the child; its technique is very complicated, and necessitates, among other things, the constant presence of the physician; and it has been adopted but little outside the place of its birth." Hypnotism as an analgesic during labour is discussed by the author with even less respect, and in the two lines he devotes to this topic he dismisses it as a failure.

POST-MORTEM METHODS.

DR. J. M. BEATTIE has written an account of the *Post-Mortem Methods*³ he has found to be of practical service, and his book is meant to be used in conjunction with textbooks of pathology and bacteriology by students or medical practitioners called upon to perform obductions. Dr. Beattie lays great stress on the employment of a regular routine in the making of *post-mortem* examinations, if important points are not to be missed. Still more important is it that the pathologist should know as much as possible about the case before he examines it, in order that he may know what special points to look for and not overlook details that may turn out later to be of cardinal importance.

Dr. Beattie gives few details of morbid anatomy or morbid histology. After describing the general examination of the body and the modes of removing the separate viscera, he gives accounts of their examination in greater detail organ by organ. The second half of the book is devoted to medico-legal considerations, an outline of the bacteriological and histological examinations most generally useful, and a long chapter on the investigation of special cases, in which the reader is told the special points to be looked for at autopsies on cases of the commoner diseases. Dr. Beattie makes a number of quotations from Dr. Shennan's recent textbook for pathologists. He writes clearly and to the point; though he has succeeded in compressing a large amount of information into the volume, one may question whether it would not gain by expansion. The text contains a number of misprints; thus on p. 52, par. 2, line 1, "auricular" should be "ventricular"; "carnae," on p. 54, should be "carnea"; on p. 58 "diphtheria" should be "diphtheriae"; on p. 82 "pubis" should be "pubes"; "influenza," on p. 175, should be "influenzae"; on p. 195 "*Bilharzia haematobium*" represents an unhappy hybrid doubtless obtained by crossing *Bilharzia haematobia* with its homonym "*Schistosomum haematobium*." Throughout the text the word "aneurysm" is spelt "aneurism." The book should be of service to those for whom it has been written.

THE SEAMY SIDE.

NOWADAYS there is a great boom in what may be called biographical novels, in which the material and spiritual progress of the hero is traced from his infancy to his final marriage or grave, as the case may be. We say "final marriage" because so many of these heroes have preliminary experience of brief and irregular unions, or of the divorce court, or of both, before their creator, the author, thinks fit to draw his novel to an end. In

³ *Post-Mortem Methods*. By J. Martin Beattie, M.A., M.D., Cambridge Public Health Series, under the editorship of G. S. Graham-Smith, M.D., and J. E. Purvis, M.A. Cambridge: The University Press. 1915. (Demy 8vo. pp. 239; 8 plates, 3 figures. 10s. 6d. net.)

addition, novels of this type run to great length. Their most notable exemplar, *Jean Christophe*, written by that brilliant French musical critic and man of letters, Romain Rolland, extends to ten volumes; yet the reader's interest is maintained to the end, for the hero has a character full of interest that goes on developing to the last, and the author's literary skill enables him to hold the reader's attention throughout. The ten volumes are not too many for their theme. The well-known playwright, Dr. W. SOMERSET MAUGHAM, has recently published a novel² composed on these lines, in which he traces the school-days and early career of Philip Carey, crippled with a clubfoot, who first fails in life as an artist and finally qualifies for medical practice. Dr. Maugham is to be congratulated on the skill with which he has reproduced the squalid gloom and tedium in which Philip and his friends seem habitually to have lived. His purple patches, such as they were, consisted in brief passages of passion with various women, presented by Dr. Maugham in unattractive lights to the reader. Other strong and abiding interests than these Philip did not apparently possess; his friends, when not actually vicious, were aural, and with one or two exceptions were selfish friends who failed him in moments of emergency. Philip himself did no less to those dependent on him, it is only fair to say. A most unpleasing description is given of the anxiety with which he waited to step into the shoes of his dying uncle, an anxiety which drove him to the undertaker before his uncle had died; and even when 30 years of age he was so lacking in self-control and in respect for others as to abuse the confidence of the young girl he himself intended to marry. The gloom lightens at the end of the book, for Philip is left on the hands of this sensible and competent young woman, who seems to be capable of making him marry her and keeping him straight afterwards; whether he is a valuable acquisition to the medical profession is a matter for the reader to decide. Many of the characters in the book leave one, as does Philip himself, with a slight feeling of nausea. No doubt such people exist, but was it necessary to bring them all together in the pages of a single volume to the exclusion of honest folk? An author has a right to choose his own atmosphere and setting for his tale, but does life consist of nothing but nastiness, envy, hatred, malice, and all uncharitableness, to the exclusion of such simple and common virtues as truth, honour, and natural affection? Dr. Maugham gives a vast amount of biographical detail in his closely-written account of the unfortunate Philip Carey. But the unwholesome Philip remains an uninteresting and unattractive figure that vividly recalls a stanza by a recent Cambridge writer of verse:

For your dull little vices we don't care a fig |
It is this that we deeply deplore,
You were cast for the common or usual pig,
But you play the invincible bore.

NOTES ON BOOKS.

BOOKS FOR THE LAYMAN.

THE public is always interested in its nerves. This interest exhibits itself in the large number of books on the mind and its disorders written for consumption by the lay public. These books have many characteristics in common. They deal largely in generalities and optimism; they often have some system of mental or physical therapeutics to boast; not a few of them are written by medical men. JAMES ALEXANDER'S book on the *Requirements of Blushing*³ has been written to meet the requirements of blushing fifteen. It contains an account of the origin and treatment of bashfulness, blushing, nervousness, shyness, stammering, stuttering, timidity, and adolescent fears. The line of treatment may be fairly summed up in the single word, "Don't."

In his book, *Nerve Control*,⁴ on the cure of nervousness and stage-fright, written for artists and performers, H. E. HUNT develops the method in which suggestion, itself the cause of nervousness, may also be used as its cure; man,

as he says, is the master of his fate. Accordingly, if any one determines not to be frightened on the stage, platform, or pulpit, he will not be frightened when he finds himself there. The book is full of general advice and suggestions which should prove harmful to nobody.

A small manual on *Making the Most of Life*⁵ has been published by MESSRS. O'SHEA and KELLOGG. It is an American work, meant for the instruction of the public at large. It sets out in popular language the benefits of exercise, the importance of a proper diet, and the dangers of unhealthy modes of life. It is highly didactic, and contains enough popular science thoroughly to confuse and impress the mind of the man in the street. It is well illustrated, and at the end of each chapter contains a number of questions which the reader should be able to answer if he has mastered what he has read.

Dr. CHARLES REINHARDT'S volume on *Mental Therapeutics*⁶ is an attempt to offer rational explanations of faith healing, hypnotism, somnambulism, telepathy, auto-suggestion, and the workings of the mind in general. Half the book is occupied by auto-biographical reminiscences of Dr. Reinhardt's experiences in these various phenomena. The second half of the book contains generalities on what Dr. Reinhardt calls the scientific aspect of his subject. The whole book is written for the general reader; it contains an uncritical survey of the statements taken to establish the truth of occultism, clairvoyance, telepathy, and faith healing. Sir Oliver Lodge has furnished an introduction to the volume.

In his racy volume on *The Secret of Human Power*⁷ Dr. HAYDN BROWN, writing *de omnibus rebus et quibusdam aliis*, gives us his thoughts about modern life in general. In the world in which he moves he sees much, alas! to give him pain. The education of children, the rising generation, the war, vicious circles in disease—these and many other subjects give him cause for sad reflection. He hopes, however, that the truth will survive; with Tennyson, he holds that

Self reverence, self knowledge, self control,

These three alone lead life to sovereign power |
or so, at any rate, we interpret his volume after perusing it.

⁵ *Making the Most of Life*. The Health Series of Physiology and Hygiene. By Professor M. V. O'Shea and J. H. Kellogg. New York: The Macmillan Co., 1915. (Post 8vo, pp. 306; illustrated, 3s. 6d.)

⁶ *Mental Therapeutics; or, Faith Medicine and the Mind*. By Charles Reinhardt, M.D.; with an introduction by Sir Oliver Lodge, F.R.S. Third edition. London: The London Publicity Co., Ltd. (Cr. 8vo, pp. 287.)

⁷ *The Secret of Human Power*. By Dr. Haydn Brown. London: G. Allen and Unwin, Ltd., 1915. Cr. 8vo, pp. 328; illustrated. 6s. net.

MILITARY PENSIONS AND GRANTS.

REPORT OF SELECT COMMITTEE.

THE Select Committee on Naval and Military Services (Pensions and Grants) appointed by the House of Commons on November 18th, 1914, issued its third report on September 10th.⁸

This report, which deals with pensions and grants to disabled officers, and officers' widows, orphans, and dependants, makes the following recommendations; they, however, apply primarily to combatant officers only.

Under existing regulations, the pensions paid to widows and children of naval and military officers are on three scales, which differ according to the circumstances under which an officer meets his death. In cases in Class I (killed in action) a gratuity is paid in addition to pension. The Committee considers that the regulations should be more elastic, and recommends the following classification for cases arising out of the present war:

Navy.	Army.
Class I.—Killed in action or died from wounds received in action, whether afloat or ashore, or by destruction of ship, drowning, or other violent death due directly and wholly to war service.	Killed in action or died from wounds received in action or from other violent death due directly and wholly to war service.

⁸ The price of the report is 1d. (net and not post free). It may be purchased, either directly or through any bookseller, from Messrs. Eyre and Spottiswoode, East Harding Street, E.C.; or Messrs. Wyman and Sons, Limited, 29, Breems Buildings, Fetter Lane, E.C.; and 54, St. Mary Street, Cardiff; or His Majesty's Stationery Office (Scottish Branch), 23, Forth Street, Edinburgh; or E. Ponsbury, Limited, 116, Grafton Street, Dublin; or from the agencies in the British Colonies and Dependencies, the United States of America, the Continent of Europe, and abroad, of T. Fisher Unwin, London, W.C.

² *Human Bondage*. By W. Somerset Maugham. London: W. Heinemann, 1915. (Post 8vo, pp. 648. 6s.)

³ *The Cure of Self-Consciousness*. By J. Alexander. Newcastle-on-Tyne: A. Heil and Co., Ltd. London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd., 1915. (Died. 8vo, pp. 154. 3s. 6d. net.)

⁴ *Nerve Control*. The Cure of Nervousness and Stage-fright. By H. E. Hunt. London: W. Rider and Son, Ltd., 1915. (Cr. 8vo, pp. 127. 1s. net.)

Navy.

Class II.—Death from disease due to exposure or exertion on service or from injuries received in and by service so far as not covered by Class I.

Class III.—Died from disease, injury, or accident not coming under Class I or II.

The Committee recommends that the rates for lieutenants and sub-lieutenants in the navy and lieutenants and second lieutenants in the army be raised to the existing rates for the widows of captains in the army—namely, Class I, £100 a year; Class II, £75 a year; Class III, £50 a year; the additional gratuity in Class I being paid at existing rates.

In Class III an officer's widow is not, under existing regulations, entitled to pension unless he has served for a certain period, in the army ten years. The Committee recommends that, for the present war, this restriction should be waived, and that, where a deceased officer has not served long enough to qualify his widow for a pension, a gratuity of from one to three years' pay should be given, either in a lump sum or in instalments.

It is recommended that rates for children of all officers, up to and including captain in the navy and colonel in the army, be fixed at the rates now given to children of a colonel in the army, namely, Class I, £24; Class II, £20; Class III, £16.

Paragraph 5 of the report recommends that in cases of pecuniary need the Admiralty or Army Council should have power to give a further education allowance of £35 a year for a boy, £25 for a girl, from the ages of 13 to 18, with possible extension up to the age of 21. The present regulations for grants of pensions to officers' relatives (other than widows and orphans) the Committee considers are too rigid and should be revised.

The paragraph dealing with disablement is of great importance. Under existing regulations an officer, disabled by injuries received on service, is entitled to a wound pension in addition to the retired pay of his rank. The regulations in navy and army differ in detail; both are complicated. The rates vary from a maximum of £200 to a minimum of £54 15s. a year in the army and £46 in the navy. The existing rates do not vary according to the degree of disability. The Committee is of opinion that present rates of disability pensions for junior officers should be increased, and that the amount of pension given should, especially in the case of junior officers, vary with the degree of disability.

The scales of disability pensions recommended are given at length, for permanent and for temporary officers separately. The rates recommended for officers holding permanent commissions vary with rank, length of service, and amount of disability, the lowest rate recommended, in cases of serious disablement, being £100 a year, the highest £350.

As regards officers holding commissions in the Special Reserve and Territorial Force and those holding temporary commissions, it is recognized that few, if any, can have sufficient length of service to qualify for service addition to pension. In the case of such officers, therefore, the following recommendations are made:

Earning Capacity.	Sub-Lieut.		Lieut.	Lieut.-Commander.	
	NAVY. Midshipman. Cadet.			Major.	Commander.
	ARMY. Subaltern.			Lieut. Col.	
Totally destroyed ...	£150	£150	£200	£225	
Seriously affected ...	£100	£128	£175	£201	
Impaired ...	£75	£100	£125	£150	
Slightly impaired ...	In all cases a gratuity not exceeding £500.				

The Committee recommends that pensions and gratuities for wounds and injuries should be at the rate given under present regulations to army captains—for example, for each limb or eye lost by wounds, gratuity of £250 for the first year, with a pension of £100 in following years. Such pensions to be in addition to any other pension to which an officer may be entitled under existing regulations, but

Army.

Died from disease due to active operations in the field or otherwise directly attributable to military service, or from injuries received in and by service so far as not covered by Class I.

Died from disease, injury, or accident not coming under Class I or II.

not in addition to the new disability rates recommended in the report. No officer who, as the result of injuries received in action, loses the sight of both eyes, should receive less than £300 a year in all. The children of disabled officers should be eligible for the education allowances proposed in paragraph 5.

In concluding its report the Committee states that "the above proposals relate primarily to officers holding combatant commissions in the navy and army. The cases of other officers (including quartermasters and commissioned warrant officers in the navy), should be reviewed departmentally where necessary on similar lines," and paragraph 11 states that the new scales and conditions recommended should be applicable to cases arising out of the present war only. Cases which have already so arisen should be reassessed as from March 1st last.

MEDICAL SERVICES.

As it is distinctly stated, in the paragraph quoted, that the proposals relate primarily to officers holding combatant commissions, it would appear that the recommendations of the Committee do not directly affect the medical profession, except in the comparatively few cases in which doctors have taken combatant commissions, and the much larger number in which medical men are concerned through their sons serving as combatants.

These proposals, however, though not immediately applicable, concern by analogy the very large number of medical men who are now serving as officers of the Special Reserve, of the Territorial Force, and as holders of temporary commissions in the R.A.M.C.

Presumably the rates of disablement pension, widows' pension, etc., given to medical officers serving in this war will be not less than those recommended by the Committee for combatant officers of the same rank. But it is to be hoped that definite rates will be sanctioned for medical officers, and that orders to this effect will before long be published. The number of medical officers now serving must be very large; at the end of May Mr. Tennant gave it as over 7,000, of whom less than 2,000 were regulars; and it must be remembered that a large proportion of the medical officers of the Territorial Force and Special Reserve and not a few of those holding temporary commissions are older, many much older, than men of equivalent rank in the regular medical services. This consideration also applies, though to a less degree, to combatant officers. Among the officers of the R.A.M.C. and I.M.S. the great majority of the lieutenants and a large number of the captains are, as a rule, unmarried. But while many of the Territorial and temporary medical officers now serving are young newly-qualified men, probably unmarried, there are also a very large number of men of middle age, or thereabouts, who have left their usual work and responded to their country's call from patriotic motives. Many—probably most of them—are already heavy losers by their patriotism.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received during the week have been as follows:

	£ s. d.	Salisbury Division.	£ s. d.
North of England Branch of Fund (per Dr. Fran. Don and Mr. A. S. Percival, Hon. Secs.)		B.M.A. (per Dr. L. S. Luckham) (third donation, total £15 15s. 7d.)	
(twentyish donation, total £775 7s. 6d.)		Dr. Westrup ...	0 5 0
Dr. Arnison ...	3 3 0	Mr. R. B. Besty ...	0 10 6
Dr. Bays, collected by—		Mr. J. W. Catford ...	0 5 0
Dr. Telling ...	3 3 0		

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vocux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C. The Master acknowledges gifts from—

Dr. G. T. Schofield, Widnes.	The Canadian Red Cross Society.
Dr. Major Greenwood, London.	per Lieut.-Colonel Hodgkiss.
Lady Horne Drummond, per Dr. Dods Brown, Perth.	Canadian Red Cross Commissioner.

THE BRITISH ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

THE first act of Professor A. SCHUSTER, before delivering his presidential address to the British Association (reported in our issue of last week), was to propose a loyal address to the King assuring His Majesty that the association as a whole and every individual member thereof are wholeheartedly anxious to devote all their energies to assisting His Majesty's Government in the task of bringing the war to a victorious conclusion. In reply to this, a telegram was received from the King, gratefully accepting the resolution and "recognizing with deep appreciation the valuable services which are being rendered by men of science to bring the war to a final victory."

The effect of the war on the meetings last week in Manchester is shown by the fact that, while the number of tickets issued to members and associates in 1887, when last the association met in Manchester, was 3,833, this year the number did not reach 1,500, and the attendance at many of the more technical sections dwindled down after the first day very considerably, though the Sections of Economics and Educational Science, dealing with more general questions of immediate social interest, continued to be well attended to the end. Though most of the usual social functions were abandoned, the members had numerous opportunities during the week, of which large numbers took advantage, of visiting many of the works and public institutions in the district. The Section of Education organized a visit to the Sandlebridge Home for the Care of the Feeble-minded, and the Section of Anthropology visited the Roman Camp at Ribchester, where a meeting was held to open the newly built "Roman Museum." On Wednesday evening there was a reception by the Lord Mayor and Lady Mayoress at the Municipal School of Technology. It may be noted that in previous years it had been the custom for the president's banner to show the coat of arms of the town in which the meeting was held, with the name of the president, but on the present occasion the banner, hanging with its predecessors in the Reception Hall at the University, depicted a woman standing with one hand covering her eyes and the other stretching upwards. Surrounding her were cypress trees, a serpent writhing between, and in the background cypress trees, symbolic of mourning and death, the whole representing Science as weeping because of the war.

During the week a series of "citizens' lectures" were delivered at various places in and about Manchester. They were evidently highly appreciated and, on the whole, well attended, especially those which were more or less connected with the war. The subjects dealt with were: Evolution and war, by Professor F. W. Gamble; The strategic geography of the war, by Dr. Vaughan Cornish; The making of a big gun, by Dr. W. Rosenham; Daily uses of astronomy, by Mr. A. R. Hinks; Health conditions in the modern workshop, by Professor B. Moore; Formation of the sun and stars, by the Rev. A. L. Cortie; Some lessons from astronomy, by Professor H. H. Turner; and on Curiosities and defects of sight, by Dr. W. Stirling, Professor of Physiology in the University of Manchester. Professor Stirling's lecture, which was illustrated by lantern slides of experiments projected on the screen and by cinematograph films, dealt first with the structure of the organs of sight in the lower animals, then with the evolution of the eye, and next with the structure of the eyeball in man and the higher animals. After describing the mechanism of vision and defects of refraction, Professor Stirling dwelt on the importance of the care of eyesight during infancy and school life, and went on to consider the nature of colour vision and the importance of colour blindness in relation to railway signalling and at sea.

SECTIONS OF ECONOMICS AND EDUCATIONAL SCIENCE.

It is impossible in the short space at our disposal to give more than a brief survey of comparatively few of the numerous papers and discussions in the sectional meetings. As might almost have been expected under the circumstances of the war, the Sections of Economics, presided over by Professor W. R. Scott, and the Section of Educational Science, presided over by Mrs. Henry Sidgwick,

were perhaps the best attended. In the former section special interest was taken in the discussion on the promotion of industrial harmony, where two employers and two representatives of the Trades Union Congress and two economists addressed the section. It was significant that the meeting was totally unable to arrive at anything like agreement as to the means to be adopted to promote the desired harmony. There was also a large attendance at the discussion on the effects of the war on credit, currency, and finance, which arose on the consideration of a report prepared by a conference; the chief interest centred round the questions as to the ability of the country to meet the cost of the war, the methods of raising the money for the war, especially the proportion between the amount of money to be borrowed and the amount to be raised by taxation, and the question of paper currency. Professor Scott made the remarkable statement that if the cost of the war did not exceed a thousand million pounds a year, this country would be able to finance the war indefinitely if it put its back into it. In the Education Section an animated discussion arose on the subject of military training in schools, in which Professor BOYD DAWKINS and the Rev. A. A. DAVID, strongly dissented from the attitude taken by Mr. PATON, head master of the Manchester Grammar School, who thought that military training in schools would tend to produce in this country that very militarism which we are now fighting against in Prussia. Perhaps the most numerously attended of all the meetings of the week was the Friday meeting of this section. The audience consisted largely of women, and the subject of interest was the education of girls with reference to their future careers, the discussion being opened by Miss HALDANE, sister of Lord Haldane.

ENGINEERING SECTION.

In his opening address the President of the Engineering Section, Dr. HILL-SUAW, dealt at length with the organization of labour and the relations of employers and workmen, and various papers were read dealing with the drainage, gas, electricity, and water undertakings of Manchester, as well as numerous technical engineering questions. In the course of some notes on the Manchester Gas Works, Mr. NEWBIGGER said that coal-tar had hitherto been the chief source of toluene, but the great demand for the purpose of making the high explosive trinitrotoluene, T.N.T., had drawn attention to the fact that most of the toluene produced in the carbonization of coal to make gas remained in the gaseous form. Simple methods had now been devised for washing toluene out of the gas without unduly reducing the calorific value, and Manchester was now doing its share in producing this important munition of war.

SECTION OF AGRICULTURE.

In this section the President, Mr. R. H. REW, gave an address on farming and food supplies as affected by the war. In the course of his remarks he said that though a few cargoes of foodstuffs had been sunk by the enemy, the effect of the war on our food supply from abroad had, thanks to our navy, been practically negligible. At the same time British farmers had quietly added 25 per cent. to the acreage of wheat, 7 per cent. to the acreage of oats, had maintained the large area of potatoes of the previous year, and had largely increased the stock of cattle and sheep.

SECTION OF GEOGRAPHY.

In the Section of Geography several papers were read on geographical questions arising out of the visit of the association to Australia last year, and, in conjunction with the Section of Anthropology, there was an interesting discussion on the distribution of races in the Balkans. It was opened by Professor G. ELLIOT SMITH, who, after giving a detailed account of the successive intrusions of peoples and the grouping and regrouping of the various races in the Balkan peninsula, concluded that the most desirable solution of the difficult problems now presenting themselves would be the reconstitution of the Balkan League, and a confederation of Balkan States, so that peoples who had a common origin, but were separated in development and religion, could unite for their common interests. At the same time he recognized that though organization on ethnographical lines might be possible, it might not be advisable politically, and that a racial blending might be best.

SECTION OF ASTRONOMY AND PHYSICS.

In this section Sir F. W. DYSON, Astronomer Royal, who presided, gave an account of the manner in which, by the aid of the telescope and spectroscope, conclusions had been reached as to the construction of the heavens. Accurate measures of the light of the stars had been made by the application of the photometer to the telescope, and within the last few years photography had been used to determine stellar magnitudes, while the velocities of stars in the line of sight and their physical characteristics had been determined by the spectroscope. Now that the direction and the amount of the sun's motion were known, and more proper motions became known, it was reasonable to hope that better knowledge would be obtained of the streaming and distances of stars. At present little was known of the more distant portions of the stellar depths; for example, little more than guesses could be made at the distance of the Milky Way or its movements. At the same time the methods employed in the last few years seemed competent to produce a fairly good model, showing the co-ordinates, velocities, and effective temperatures of the stars, and the amount of light they radiated; with industry in the collection of accurate data, the material for the dynamical and physical study of the history and evolution of the stellar system would be greatly improved.

Professor A. FOWLER opened a discussion on the spectral classification of stars and the order of stellar evolution. The first classification made by Secchi, fifty years ago, divided the stars into four groups distinguished by their colour, the white being the youngest and the red the oldest; in this way the great majority of the stars could be classified. This classification, together with the later Draper system, was regarded as representing the actual stages of temperature and evolution, the temperature varying from about 10,000° C. for the earliest and hottest down to about 3,000° C. for the latest. Sir Norman Lockyer and others maintained, however, that the history of a star began with an actual nebulous mass which condensed into a red star, and for a time there was a rise of temperature with the condensation, so that there must be stars that were getting hotter as well as stars that were getting cooler. Thus the order of evolution might be very different from that suggested by the Draper classification.

In conjunction with the Chemistry section, a valuable but highly technical discussion was opened by Professor SODDY on radio-active elements and the periodic law, at which numerous experiments were described tending very largely to modify some of the current theories as to the constitution of the elements.

SECTION OF CHEMISTRY.

In this section the President, Professor W. A. BONE, was in the difficult position of having to take the place at the last moment of Professor Baker, who was unable to attend. Professor Bone dealt at some length with the importance of a more adequate scientific control of coal supply and coal consumption. The United Kingdom, he said, consumed on an average each year about four tons of coal per head of population, but strangely little was done by scientists to impress on the Government and the public the need for some systematic control. He believed that with proper public supervision it would be possible to save many millions of pounds in the annual coal bill—a saving that would redeem a large amount of the war loan. He suggested that a memorial should be addressed to the Government asking it to establish a central organization for the supervision of fuel consumption, to include a systematic chemical survey of the British coal-fields and experimental trial of new inventions for fuel economy.

A large number of papers were read dealing with the smoke nuisance, Manchester and Salford receiving special attention.

Mr. E. D. SIMON (chairman of the Manchester Smoke Abatement League) said that a reasonable estimate of the damage done in Manchester and Salford by smoke was that it amounted to nearly £1,000,000 a year. Something had been done by the pressure of public authorities to reduce the smoke from factories, but a large field remained for research with regard to domestic smoke. The most hopeful line was in securing that bituminous coal should not be burnt as such, but that it should be converted into products which could be burnt

smokelessly, and he suggested that the British Association should form a central committee to act in co-operation with town councils to deal with the problem.

Professor F. RANZEY (University of Louvain) spoke of the damage done to vegetation by smoke and vapours, especially sulphur dioxide, given out by factories, and he suggested methods by which the damage thus done could be discriminated from the damage that arose from faulty cultivation and sour or poor soil. Professor KNECHT exhibited and described some constituents of Manchester soot, and Mr. A. G. RUSTON showed by means of a series of lantern slides the effects of smoke on flowers, plants, and trees.

An address with a number of somewhat startling experiments, given by Professor DIXON on explosions of gases, attracted a large audience. Papers were also read by Dr. H. F. COWARD on the dilution elements of inflammability of mixed inflammable gases with air; and by Professor BONE on gaseous combustion at high pressures. Experimental demonstrations were given of a new cadmium vapour electric arc lamp by Dr. H. J. SAND and by Dr. J. W. POPE on liquid crystals.

SECTION OF GEOLOGY.

The presidential address of Professor COLE dealt mainly with problems of the earth's crust and its movements. He said that in spite of the tragedy of Messina about seven years ago, there was a feeling that Europe was a settled continent, but the vast interior of the earth was unseen and but little known, and in spite of the present superficial quiet, the inconceivable might happen any time. The more that was learnt of the causes now in action on the earth, the greater the mystery seemed. For example, the greatest change that ever came upon the globe, the moment when living matter first appeared on its surface, could not be realized. Matter was either dead or living—there was no intermediate state—but, he asked, was this life a surface concentration, a specialization of something that had previously permeated all matter, but had remained powerless because it was infinitely diffuse? In all such questions the geologist had to confess that he was very much beyond his depth.

The Age of the Earth.

One of the most important discussions in the section took place on Friday on radio-active problems in geology, with special reference to the age of the earth. The discussion was opened by Professor Sir E. RUTHERFORD, who mentioned some of the earlier methods put forward to determine the age of the earth, the estimates varying from twenty million years upwards, but he said that no geologist would think of accepting less than from forty to sixty million years. Kelvin's method was quite uncertain, while estimates from the rate of deposit of sedimentary rocks or the amount of sodium in the ocean could only give unreliable results. The most recent method followed on the discovery of the radio-active bodies, such as radium and thorium, and Sir E. Rutherford explained how from the presence of these bodies in the oldest rocks the age of the earth might be calculated. In the other direction, he said it would be safe to predict that the sun would continue to shine for more than nine million years, and possibly even for several hundred million years. In a paper on the same subject Mr. A. HOLMES said that time periods had been calculated on the assumption that the radio-active constants of uranium and its daughter-elements had not varied, and on this assumption it might be said that some period like fifteen hundred million years had elapsed since the crystallization of the oldest plutonic rocks in the earth's crust. The actual age of the earth would be much greater than this, for the oldest plutonic rocks were found to be intrusive into the pre-existing sedimentary or volcanic series. The most important problem for the geologist was now to determine the possible dependance of the rate of decay of uranium on time, pressure, and temperature. It is necessary to add that some of the members present, especially Professor Joly of Dublin, expressed their disagreement with some of the theories founded on the consideration of the radio-active bodies.

Antiquity of Man in Britain.

In the same section Professor Boyd Dawkins dealt with the geological evidence as to the antiquity of man in

Britain. The only proof offered of the Pliocene age of man in East Anglia was, he said, the roughly chipped flints found in the basal Pliocene strata, but he thought it had been proved that similar flints could be made, without the intervention of man, by the action of ice or torrents or rivers or the waves of the sea. The presence of man in East Anglia during the glacial period rested on even worse evidence. The evidence of the discovery on Pitdown of *Eoanthropus dawsoni*, which might be called the missing link between man and the higher apes, was, he believed, more reliable, and after examining the whole group of the remains he agreed that the find belonged to the early Pleistocene period. Thus man appeared in Britain at a period when he might have been expected to appear from the study of the evolution of the tertiary mammalia—namely, at the beginning of the Pleistocene age. In older strata he could only be represented by an ancestry of intermediate forms.

The geology of Manchester and district furnished material for an interesting address by Dr. G. HICKLING, who also read a paper on the micro-structure of coal. There was a well sustained discussion in conjunction with the Section of Geography on the classification of land forms.

SECTION OF PHYSIOLOGY.

The Physiological Importance of Phase Boundaries.

On Wednesday, September 8th, Professor W. M. BATLISS, in an opening address on this subject, said that a consideration of the arrangements present in living cells showed that the physical and chemical systems concerned operated under conditions very different from those reactions taking place between substances in true solution. The cell system, in other words, was one of many phases. Whilst parts of this system appeared homogeneous, yet they might be heterogeneous, and were in what was known as the colloidal state. Considering one phase only, the molecules at a surface were exposed at one side to the influence of similar molecules, but on another to the influence of molecules of a nature chemically unlike their own, and such phase boundaries were the seats of various forms of energy. Surface tension was the most obvious form. In relation to the contractile force of muscle it was found that surface tension decreased with rise of temperature—a fact which was not surprising when they remembered that the interface between a liquid and its vapour disappeared when the temperature rose to the critical point. It was significant to note this close association between surface tension and the contractile stress, for it was found that this property alone of muscle had a similar negative temperature coefficient; and within the limits of temperature between which the muscle could be regarded as normal, the contractile stress was greater the lower the temperature; and the same held good for the heat developed during the contractile stage. It was familiar, too, that tonus of smooth muscle increased with fall of temperature. Other facts probably explainable by these facts about surface tension had relation to the heart muscle, for all the phenomena connected with the output of blood by the heart could be satisfactorily explained by the hypothesis that the energy of the contraction was regulated by the length of the ventricular fibres during the period of development of the contractile stress. Surface tension, or phase boundaries, must necessarily be intimately related to the cell substances and molecular constitution. The phenomena of adsorption, electrolytic and chemical changes were also touched upon in this address. Certain aspects of enzyme action, too, were, it was said, suggestively explained by these views. On the whole, it might be concluded that more study of the phenomena at phase boundaries would throw light on many problems still obscure. It would probably not be going too far to say that the peculiarities of the phenomena called vital were due to the fact that they were manifestations of interchange of energy between the phases of heterogeneous systems. Life was incessant change or transfer of energy, and a system in static equilibrium was dead.

The Motor Area.

Dr. GRAHAM BROWN (Manchester) illustrated by the lantern the effects observed in a chimpanzee after operative removal of first the right, then the left post-central gyrus, and lastly, the right motor area. Paralysis lasted for six days, but within fourteen days the animal's actions had

become apparently again normal, and it could with much ingenuity execute even the fine movements associated with the opening of a door with a key. Such operations, therefore, had not caused loss of power for fine movements.

Thyroid and Adrenals.

Professor P. T. HERRING (St. Andrews) recorded the effects of thyroidectomy and thyroid feeding on the adrenin content of the suprarenals. The thyroidectomized cat gave suprarenal content which had little action; in the thyroid-fed, however, the content was relatively active. Much significance attached to the manner of collecting the gland substance, as also to the emotional state of the animal, since operative procedure itself altered the quantity, and excitement of any kind acted similarly. For testing the effect of the adrenin the glands were rapidly removed, minced, Ringer's solution added, and filtered whilst still hot; 2 c.cm. of this fluid were injected into the circulation of an animal and the effect on the blood pressure noted. Folin's method also was used as a test. Testing by gland weight relative to body weight showed little change in the cat. Rabbits were tried in a similar way. In this animal no effect followed thyroidectomy. This operation seemed to have little effect on the adrenin content, but in the thyroid-fed animal there was a more noticeable increase in the gland content. In these general results the possible influence of the posterior lobe of the pituitary gland must be borne in mind.

The Electro-cardiograph and Auricular Fibrillation.

Dr. C. E. LEA (Manchester), after illustrating with the lantern various curves gained by electrical methods, recorded their value as a means of diagnosis in a particular case, one of ordinary auricular fibrillation in a woman who had been under observation for over two years. All this time the pulse had been characteristically irregular, but could be readily controlled in rate by digitalis. Electrical curves verified the diagnosis previously made. On one occasion, however, though the pulse was just as irregular as ever, the electrical curved showed that the auricles had resumed activity, and were for the time not in fibrillation, though the rhythm was still markedly irregular. The patient was taking pilocarpine at the time. On no other occasion, before or since this observation, was a similar resumption of auricular activity shown. This case illustrated the fact that even though the pulse-rate and rhythm might show no apparent change, yet the auricles might resume their normal action, and possibly fibrillation was not so permanent and persistent as was commonly believed. Great variations in vagal tone could be demonstrated in these cases, and the question of vagotonia offered a fruitful field for investigation.

The Pathology of Diabetic Coma.

Dr. E. B. POULTON (London) recorded observations to show that the cause of diabetic coma was not essentially due to an acid quality of the blood—was not, in fact, a true acidosis. The blood in uraemia, for example, was more acid than was that of diabetes, as was also the blood during moderate exercise. The active poison in coma was not known. In this condition, however, there was a definite lowering in value of the alveolar CO_2 , and this condition itself could induce symptoms similar to those of coma. The estimation of the alveolar CO_2 formed a reliable guide to the onset of coma, and the latter could, with some definiteness, be predicted in this way.

The Physics of Phagocytosis.

Dr. J. TAIT (Edinburgh) observed that when the behaviour of invertebrate blood cells removed from the vessel and placed on a slide was studied, it was noted that many of them flowed outwards upon the glass surface so as to be reduced to a very thin and greatly expanded sheet. The fact that the movement was progressive and irreversible, and the further fact that on a greasy surface the same cells underwent no deformation, suggested that the expansive force was a capillary phenomenon, the cell substance spreading in the same way as a drop of water spread on a clean surface of stone or glass. For cells thus unstable on a non-greasy surface of foreign material the author suggested the name "thigamoocytes." Simple physical reasoning showed (1) that if a fluid were unstable on a slab of a given substance it would flow around or ingest a small particle

of that substance; (2) if it refused to ingest a particle of any given substance it would be stable on a slab of that substance. Experiments on thigmocytes showed that they conformed to both these results. The phenomenon of phagocytosis in the case of these cells at least appeared to be physical. Thigmocytes were non-amoeboid; consequently, power of amoeboid movement was not essential for phagocytosis. Many phagocytic cells—for example, mammalian polymorphonuclears—were stable on non-greasy foreign bodies and yet ingested non-greasy particles. It was shown, however, that on physical grounds stability of the cell on a slab of a given material was quite consistent with ingestion of a particle of that material. In other words, there was no *a priori* evidence against the extension to stable (amoeboid) leucocytes of the physical hypothesis regarding phagocytosis. Following out similar principles to these, new light might be thrown on a number of problems, such as the mechanism of amoeboid movement, the relation between opsonins and agglutinin, emigration of leucocytes, amitotic cell division, and blood coagulation.

Some Laws of Fat Absorption.

Dr. F. W. LAMB (Manchester) illustrated facts ascertainable by suitable staining methods, which showed that different fats varied in their reactions, and could, indeed, be recognized just by their particular staining qualities. It was shown that there was considerable fat absorption from the stomach, especially its cardiac end. In any given animal it was generally found that where there was evidence of fat absorption in the stomach, there was little similar evidence in the intestine, and vice versa; this was probably due to time factors.

Copper in Tissues.

Dr. POWELL WHITE (Manchester) stated that he found considerable quantities of copper in most tissues, the amount varying within rather wide limits in different tissues and in different animals, or such objects as seeds and oysters. Much interest was shown in the delicate test for copper. It was curious that this colour test, of extreme delicacy for this metal, was gained by an exactly similar manner for morphine (Oliver's test). Such a test, however, did not lend itself to quantitative methods, and for this purpose, in these estimations, the ferrocyanide method was used.

SUBSECTION OF PSYCHOLOGY.

Some interesting papers were read in this subsection; recent legislation in connexion with feeble-mindedness had evidently stimulated observation in this direction. From the family histories of fifty mentally defective children studied by Miss Agnes Kelley it appeared that the greater number of the fathers were casuals and hawkers. In only about half a dozen could the home conditions be described as good. Insanity was present in the family histories of 15 of the children. Other cases of mental deficiency were found in 30 of the histories, and epilepsy in 9. In a large proportion of cases the parents were such heavy drinkers that the mental defect was probably inherited. Throughout the whole of the pedigrees it was noticeable that, both physically and mentally, the general standard was below par. A visit was paid by many members to the Homes for Feeble-minded at Sandbridge, organized by the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded. The home had its origin in 1898, the outcome of a scheme formulated by Miss Dendy and the late Dr. Henry Ashby. Children under and over 16 are admitted, and there are now 267 inmates of both sexes. Under 16, day school work is the chief occupation; over 16, the boys work on the farms, and the girls help in the laundry, etc. The practical lessons learnt at this institution certainly facilitated the passing of the Mental Deficiency Act of 1913. Closely bound up with this work is that directed to the study of the child mind. Dr. Kimmings, who has examined the special interests of children in the war at different ages, found a distinct bellicose attitude in the girls of 10, depression at 11, and normal interests at 12. Boys were more warlike at 11, and showed less of the depression noted in girls. It was remarked how mature the ideas on such a subject as the war were at the age of 13, especially in girls, who in this respect were at least a year ahead of the boys.

SECTION OF ANTHROPOLOGY.

In the Section of Anthropology the presidential address by Professor C. G. SELIGMAN dealt with the early ethnological history of the Anglo-Egyptian Sudan, tracing, from a close examination of materials recently discovered and the beliefs and customs of the peoples, the various influences that have been at work in the past in Equatoria.

Egyptian Civilization and World Culture.

One of the most important discussions was that on the influence of ancient Egyptian civilization on the world's culture, opened by Professor G. ELLIOT SMITH, who gave numerous reasons for believing that the essential elements of the ancient civilization of India, Further Asia, Oceania and America were taken to these places by mariners trading from the Eastern Mediterranean from 800 B.C. and for several centuries afterwards. The highly complex and artificial culture thus spread abroad was largely from Egypt, with many accretions and modifications from the Phoenicians, East Africa, Arabia, and Babylonia; the final stream, with many additions from China, Japan, and elsewhere, continued for many centuries to play on the Pacific littoral of America. As proofs of these ideas were mentioned a large number of extraordinary practices and beliefs, such as mummification, the building of megalithic monuments, sun worship, making of idols, tattooing, wearing of linen, special metallurgical methods, intensive agriculture, phallic ideas and practices, the use of the boomerang, the use of precious stones and metals, and curiously arbitrary features in boat-building. The knowledge and practice of all these had evidently been spread by the ancient mariners along a well-defined route from the Eastern Mediterranean to America, where in this way had been planted the germs of the remarkable pre-Columbian civilization.

Environment and Chest Disease.

A paper was contributed by Dr. G. W. HAMBLETON on the influence of environment and occupation on diseases of the chest; he claimed to have shown at a previous meeting that chest types were not inherited as a rule but acquired owing to post-natal conditions. A large part of the male population was living, he said, under conditions that tended to retard chest development, and many otherwise good recruits for the army had been rejected through deficient chest measurements. Such persons could, by the application of proper scientific methods, without interfering with military training, be brought up to standard. Dr. Hambleton then went on to give his remarks about the chest a more general application; he expressed the belief that it should be possible to ascertain the conditions that brought changes in types of men, and a knowledge of these once placed on a scientific basis might make it possible to produce such types of men as were best fitted for various occupations, and thereby prevent the great loss of life that occurs from want of adjustment between constitution and occupation or environment.

Other papers were read on the origin of the alphabet, by Sir A. J. EVANS; on hereditary syndactylism and polydactylism, by Dr. J. MANSON (with skiagraph exhibit), and by Professor FLINDERS PETRIE, who gave a specially interesting account of ancient Egyptian jewellery, illustrated with coloured lantern slides. Among the reports presented were those of committees on Roman sites in Britain, the age of stone circles, the lake villages near Glastonbury, and the physical characteristics of the ancient Egyptians.

SECTION OF BOTANY.

In the Section of Botany the President, Professor W. H. LANG, gave an address on some aspects in the study of the form, structure, and development of the plant. The development of most plant individuals, he said, started in a single cell, but it had always been difficult to apply to plants the biogenetic law, originally founded on animal development, that "the ontogeny is a concise and compressed recapitulation of the phylogeny," and the characters of the embryos of plants had given little if any help on doubtful questions of phylogeny. He dwelt at some length on the initial development and morphology of the shoot and the problem of alternation of generations as seen specially in the fern. Taking the prothallus and the fern-plant as in a sense two individuals, it seemed almost necessary to assume that the specific substance of fern

could exist in two allotropic modifications. After discussing problems of the seed and its embryo, Professor Lang concluded: "We have to think of the plant as at once a physico-chemical mechanism and as a living being; to avoid either treating it as something essentially different from non-living matter or forcibly explaining it by the physics and chemistry of to-day. It is an advantage of the study of causal morphology that it requires us to keep the line between these two crudities—a line that may some day lead us to a causal explanation of the developing plant and the beginnings of a single science of botany."

A contribution which was regarded as of special interest to Manchester was a paper on the application of science to the cotton industry, by Mr. W. LAWRENCE BALLS, who has held the post of Botanist to the Agricultural Department of Egypt, and experimented largely in cotton-growing. He showed that before cotton-growing could be placed on a scientific basis it was necessary that the cotton spinner should be able to express in scientific terms the properties he desired in cotton, and that the grower should then know how to alter cotton in any desired direction. With the progress and application of research different cottons could be grown for different purposes and pure strains could be produced, and in this way cotton-growing might be made into an exact science. He suggested that the Manchester University should form a special department in order to link together scientists, growers, and spinners. The Vice-Chancellor, Professor WEISS, said he had no doubt the university would do everything it could if the growers and others in the cotton industry would find the necessary money, which he thought could be easily raised.

A valuable paper was read by Professor BOTTOMLEY on the formation of auxinones. He said that for the complete nourishment of plants there must be in the soil organic matter known as humus, and the substances in humus which really promoted growth had been named auxinones. Experiments had been going on for the last six years, and as a result of treating peat with certain bacteria a manure fifty times more valuable than two-year-old farmyard manure had been produced. Four potato sets, weighing altogether a few ounces, placed in a small box of moss-litter, and watered once a week with the extract from bacterized peat, produced 3 lb. of potatoes in eight weeks; and eighteen cucumber plants grown in nine parts ordinary soil with one part bacterized peat gave 5 cwt. 3 qrs. of fruit, while eighteen plants treated with well-rotted dung and bone meal only yielded 4 cwt. 1 qr. of fruit. The bacterized peat would soon be placed on the market, and could be produced for a few pounds a ton.

On Thursday afternoon an interesting series of demonstrations of various botanical specimens was given by a number of the members in the Botanical Laboratories of the university.

SECTION OF ZOOLOGY.

In the Section of Zoology, the President, Professor E. A. MINCHIN, took as the subject of his address the evolution of the cell, and put forward some original ideas which will be of the greatest interest to biologists. Hitherto, he said, the evolution of the cell had received slight attention, and study had been directed mainly to the most perfect form of cell as it occurs in the metazoa and higher plants. But the study of the protista revealed the fact that the cell, as seen in the higher animals and plants, with its complicated nucleus and cytoplasm, and its extraordinary changes as seen in the process of karyokinesis, could no longer be regarded as the starting-point for organic evolution. He believed that the evolution of the cell could best be studied in the protista, which showed much simpler forms of cells. He then explained at length the terms in ordinary use applied to the complete cell as seen in the higher animals, and proceeded to show that among the protista cells of gradually decreasing complexity were found, until bodies were reached which hardly deserved the name of cell. These living bodies consisted apparently of nothing but a minute particle of chromatin. The staining properties of chromatin, useful though they might be, could not be depended on as a criterion as to what was and what was

not chromatin, and no chemical tests were sufficient; the only test was the behaviour of the particle in the life-history of the organism. Careful study of the life-history of the lowest forms of protista had led Professor Minchin to a view diametrically opposed to that of Haeckel and others who held that the earliest forms of life were composed of a substance of the nature of cytoplasm, and that the nuclear substance or chromatin arrived later in evolution as a product of the cytoplasm. On the contrary, Professor Minchin gave many reasons for believing that the chromatin substance was the primitive constituent of the earliest living organism, the cytoplasm being a later structural complication. On this theory the earliest living body might be only an ultramicroscopic particle of chromatin. After alluding to the ingenious speculations of Mereshkowsky, who assumed a double origin for living beings from two sorts of protoplasm, Professor Minchin said that he regarded the chromatin as of primary importance, though in using the term "chromatin" he postulated no fixity of chemical nature for it. For the hypothetical primitive organism, consisting solely of a free-living particle of the nature of chromatin, he suggested the name "biococcus." The first step up from this would be possibly the acquirement of an envelope such as was seen in the simple forms of micrococcus, though the advance might equally take the form of an enveloping matrix of periplasm surrounding one or perhaps a colony of biococci. The next step might be the organization of the chromatin grains (biococci) into a definite nucleus giving for the first time a true cell for which the term "protocyte" was proposed. This became the starting-point for an infinite number of further complications in structure, together with a gradual development of the complicated processes of karyokinesis, until at last the typical cell as described in the books was reached. Professor Minchin agreed with those who derive bacteria—as primitive truly non-cellular organisms—directly from the biococci through ancestral forms, and not at all with those who regarded bacteria as degenerate cells, and claimed that his scheme co-ordinated a large number of isolated phenomena into an orderly sequence.

Several other papers dealt with special points in the life of the cell. Professor McBRIDE opened an interesting discussion on chromosomes and heredity, and was followed by Professor MARCUS HOGG on chromosomes and micro-kinetism. Reports were presented from various zoological stations, and a number of papers dealt with special points of interest to zoologists, a demonstration of specimens being given in the zoological laboratories.

CONCLUDING MEETINGS.

The concluding general meeting of the association was held in the Free Trade Hall on Friday, September 10th, when Professor R. A. SAMPMSON, Astronomer Royal for Scotland, delivered an address on the census of the sky, illustrating his remarks with many remarkable photographs of star groups, mainly from negatives taken by the late Mr. Franklin Evans. The lecturer showed that it was quite impossible to state the number of the stars except within the widest limits, but the calculation up to the present was between one and two millions. On the motion of Sir J. LAEMOR, M.P., the thanks of the meeting were given to Professor Sampson.

The meeting closed by votes of thanks being proposed by the President, Professor SCHESTER, to the Lord Mayor, the authorities of the university and other institutions, and the officials who had made the various arrangements for the meetings.

At the meetings of the general committee held during the week sums amounting to £968 were granted to the various sections for the purpose of research in selected subjects. It was officially stated that the number of members attending this year's meeting was 1,438, which under the special circumstances was considered very good. It was decided that the next meeting of the association should be held at Newcastle-on-Tyne on a date to be fixed later, and that Sir Arthur Evans should be the president. The president-elect is a Fellow of Brasenose College, Oxford, and has been Keeper of the Ashmolean Museum for many years; he is well known for his historical and archaeological researches. In response to a deputation from Bournemouth it was decided that the meeting of 1917 should be held at Bournemouth.

British Medical Journal.

SATURDAY, SEPTEMBER 18TH, 1915.

THE RUSSIAN VODKA MONOPOLY.

THE suppression of the sale of vodka in Russia was an event the dramatic quality of which appealed to the popular imagination, and the press was flooded with articles and letters more conspicuous for enthusiasm than accuracy. In our issue of January 23rd (p. 171) we drew attention to the clear account of the facts published in a Russian Supplement by the *Times*. That account should have helped to remove prevalent misconceptions, but since its appearance there has been no lack of proof that erroneous ideas are still entertained in many quarters, and the Temperance Legislation League has now caused to be published a pamphlet by Mr. Arthur Sherwell, M.P.,¹ which seems well calculated to enable a reader to grasp the essentials of the situation.

Mr. Sherwell begins by showing that although the ultimate responsibility for the re-establishment of a State monopoly of the sale of vodka rested on the late Tsar Alexander III, the execution of the project was the work of the late Count Witte, who carried it out when Minister of Finance in 1894. The motives actuating Count Witte were no doubt various. While a predilection for State or centralized control of industry and a desire to regularize if not increase the revenue accruing to the State can hardly have been absent from his mind, that he was also moved by an impulse to combat the social evil of alcoholism is proved not only by the purport of circulars issued to Treasury officials, but also by the coincident establishment of an elaborate system of State-aided "kuratoria" or temperance "guardianships," the function of which was to wean the people from habits of intemperance by the provision of counter-attractions. Some of these institutions, in particular the "People's Palace Tsar Nicholas II" established at Petrograd, were generously financed. The institution just named, housed in a building provided by a special grant of £100,000 made by the Finance Minister, offered varied attractions, among which dramatic entertainments at popular prices formed a large part, and in Petrograd an appreciable decline in the per capita consumption of vodka has been observed. Elsewhere the system has been hampered by lack of funds, and perhaps, as Mr. Sherwell thinks, by the too exclusively official complexion of the managing committees.

It is to be noted that, although the Government possessed a complete or virtually complete monopoly of the supply of vodka, it had no monopoly of its retail distribution. Indeed, in the last year for which statistics are available, less than half of the spirit shops were Government establishments. It is true that since 1894 there has been a very considerable reduction in the total number of spirit shops, but, since 1904, while the number of State shops has fallen by 2,000, that of private establishments selling on commission increased by more than 7,000.

With respect to the supposed consequences of the monopoly, the following results emerge: There has been a small increase in the per capita consumption

of vodka, chiefly within the last few years, but there is no reason to suppose that this change stands to the monopoly in the relation of effect to cause, in view of the exceptional social conditions which have prevailed since the war with Japan. In the second place, the increase of visible drunkenness is not evidence that the real prevalence of alcoholism has become wider, because, unlike their predecessors, the State shops sold vodka exclusively for consumption off the premises, and this must have tended to increase the amount of street drunkenness, men being no longer able to sleep off the effects of their drink in the shelter of the "kabak." Lastly, with respect to the revenue accruing to the State, it seems very doubtful whether, apart from some substantial increases of the selling price, the monopoly has yielded any actual net profit over and above that which would have been received under an ordinary excise system.

In any case, it is a patent fallacy to argue that an intemperate community will necessarily afford the State a higher income even with respect to the sale of alcoholic beverages. Students of English literature will be reminded of Berkeley's ingenious retort to the argument of Mandeville's "Fable of the Bees" contained in *Alciphron*, where the advocate of Mandeville's view, having incautiously admitted that "a sober, healthy man, therefore, in a long life, may circulate more money by eating and drinking, than a glutton or drunkard in a short one," finds a difficulty in meeting the retort, "Why, then, it should seem that he may be more beneficial to the public, even in this way of eating and drinking."

Turning to the effects of the recent prohibition, Mr. Sherwell points out that the drink problem has not been solved. In the first place, there has been a disquieting increase of illicit distillation and resort to the use of methylated spirit as a beverage. Dr. Novoselsky has given reasons for thinking that the mortality from drunkenness in Petrograd has developed in inverse proportion to the intensity of prohibitive measures. The table of deaths from delirium tremens in Petrograd, reproduced in the *Times* Russian Supplement for June 28th, seems to be the basis of Dr. Novoselsky's conclusion; but, even if deaths from delirium tremens were a fair criterion, which they are not, the table as published seems to us devoid of any statistical significance whatever. Nevertheless, the opinions of competent local observers must be had in mind.

A further obstacle is the unwillingness of local authorities to use their powers to prohibit the sale of other alcoholic beverages, including beer and wine, a circumstance which may have gone some way to neutralize the advantages of the imperial edict relating to the sale of vodka. Thus in Kursk, where, according to the *Novoye Vremya* of June 6th (1914), a new outbreak of disorder and intemperance has occurred; although the State vodka shops and the "third class" restaurants are closed, the authorities of the city, apparently for revenue purposes, have allowed "first class" restaurants, clubs, and wine cellars to remain open, and these have done an enormously increased trade; one "first class" establishment having become so democratic that its doors are open to all classes, including cabmen. It is concluded that simple prohibition cannot solve the problem, and that the provision of counter-attractions to alcohol on the lines followed in Petrograd is required.

It will be within the knowledge of most of our readers that such a system has been introduced on a modest scale in this country, as testified to by the small but growing number of licensed houses owned

¹ *The Russian Vodka Monopoly*. By Arthur Sherwell, M.P. London: P. S. King and Son. (Pp. 31, 3d.)

by trusts, and worked on the lines that the manager has no pecuniary interest in the sale of alcoholic drink. We have visited several of these houses, and invariably found them compare favourably with the average country inn. No obstacle is placed in the way of the traveller who desires to partake of fermented drinks, but he has not constantly before his eyes as the sole form of decoration the advertisements of So-and-so's whisky or somebody else's champagne. It would appear that the principal advantage of some form of public monopoly is the consequent extinction of private commercial interests, and that the establishment of such system is, at the most, a first step in the direction of reform which must ultimately be achieved by indirect persuasion under the form of carefully devised counter-attractions.

PRE-TRAUMATIC OBLIVION.

SIR PETER EADE'S experience, as quoted by Dr. Mercier the other day in the JOURNAL, in finding himself lying in a meadow immediately after, as far as his remembrance served, he was reading in the train, is an instance of what may be called pre-traumatic oblivion, an occurrence that is common enough. After a blow on the head severe enough to produce unconsciousness it is very frequent, it may almost be said to be the rule, for the injured person to find that he is oblivious not only of what happened during the time that he was unconscious, which is of course, but also that he has no memory whatever of anything that happened for a certain time previous to the blow on the head. In Sir Peter Eade's case it is very unlikely that he was first struck on the head and stunned and then shot out of the train. The probability is that his unconsciousness was produced by the fall on his head into the meadow; and yet he was oblivious not only of the fall, but of all that preceded it subsequent to a time when the train was travelling smoothly. This is, as has been said, the rule when unconsciousness is produced by a blow on the head. Not only is the blow forgotten, but all the experiences for a certain time before the blow was inflicted are wiped out of the mind and lost. The extent of this pre-traumatic oblivion varies much. It may be but a fraction of a second; ordinarily it is a few minutes; but it may extend to days, and even weeks. The late Professor Bain, after a fall which produced temporary unconsciousness, found that he had lost all recollection of everything he had experienced for a week or a fortnight before the fall. The memory of these pre-traumatic experiences sometimes returns, in more or less fragmentary manner, but more often it is permanently lost.

It is not difficult to frame a plausible hypothesis to account for these losses. It is generally admitted or assumed that every experience of which we are conscious produces a modification in the finer elements of structure in the cerebrum, though whether this structural change is to be thought of in terms of molecules, or in terms of dendrites, or of neurons, or other structural elements we do not know; but that the conscious memory of an experience answers to a structural modification of some kind all are agreed. Whatever the structural change may be, it is certain that it is produced by forces so immeasurably fine, so elusive, as only to have become appreciable by recent advances in science. The impact of light waves on the retina is altogether imperceptible, but we recognize by their effect upon a photographic plate that it is appreciable, and ponderous enough to stir material molecules and

shift them from their places. Some such stirring, some such shifting of the structure of the brain, takes place when sense impressions are conveyed to it by eye and ear. Since the structure of the brain is a physical structure, there is nothing inconsistent or extravagant in supposing it to possess the very common physical quality of elasticity—that is to say, in supposing that its structural elements not only oppose resistance to disturbance, but, when disturbed, tend in certain circumstances to resume their original positions. There is no doubt that when, under the action of sense impressions or otherwise, the structural elements of the brain are shifted into new positions, a considerable proportion of them—it may be the whole, or almost the whole of them—resume their original positions after a longer or shorter interval. To say this is only to say that we never remember all we see, or hear, or otherwise experience; that of much we experience we retain only a remnant, and that the process of forgetting begins as soon as the experience is over, and thereafter continues at a varying rate.

Many factors influence the fixing or obliteration of memories of experiences; many factors influence the rate at which the fixing or obliteration takes place. Vividness, repetition, vital importance of the experiences, the emotional state at the time, the degree of attention paid to it, and other factors, all have an important effect on the permanence or transience of a memory, and are well known to have this effect; but what is not usually recognized is the effect of sleep. Sleep has a twofold effect on memories. Some it fixes; some it wipes out. Every student knows that after a night's sleep he remembers better some things that he had a difficulty in committing to memory the day before. Every one of middle age will admit, when his attention is called to it, that though he can easily remember what he had for breakfast this morning, he cannot remember without a great effort what he had for breakfast yesterday, and cannot remember with any effort what he had for breakfast a week ago. We may conjecture that the effect of the superior anabolism during sleep is to fix in their new places those structural elements that have been widely moved, and to restore to their original places those that have been moved but slightly. However this may be, it is indisputable that sleep does have the effect of obliterating from our minds certain recently acquired memories; and it is difficult to think of this effect in terms of cerebral structure except by supposing that the shifted elements, not fixed in their new positions, but still retaining a tie with the old, still hankering conservatively to return whence they came, have their return facilitated by the conservative influence of sleep. In such a conjecture there is nothing extravagant, nothing inconsistent with the little we know of nervous and mental action. All that is assumed is that the effect on the brain of an experience is to shift certain structural elements to new positions, without, however, severing the ties that held them in the old; and that these ties, strong and elastic, tend day by day and month by month to drag the elements back into their old positions, and so obliterate the memories of experiences. And we know that in fact the memories of all experiences weaken and fade, and some disappear altogether; while those that have been longest formed and have survived longest are the least likely to be obliterated.

Now imagine a brain, in course of experiencing new impressions and of registering these impressions in its structure, to be violently shaken by a blow on the skull. The whole delicate structure will be

thrown out of gear, temporarily or permanently as the case may be, and the immediate result is the total abolition of consciousness. Soon, however, if the blow be not too severe, the shaken elements return to their places, and become capable of taking on their proper functions; and consciousness returns. But in the general shake-up some arrangements may be so badly shaken that they are altogether obliterated. Which are these most likely to be? Surely those that are the most recently formed, or that are only in process of formation; that are not fully organized; those whose new positions are, from novelty and recentness of formation, the most insecure. This is a plausible explanation of pre-traumatic oblivion. The shake-up catches the structural elements before they are securely fixed, even with temporary security, in their new positions, breaks up the incipient new organization, and destroys the physical basis of the memory of these recent experiences; but it leaves unaffected those of longer standing, which have had time to settle down and become inured to their new positions.

THE WAR EMERGENCY COMMITTEE.

THE War Emergency Committee, which meets at the house of the British Medical Association in London, transacted some important business at its meeting on September 15th, as will be seen from the report published in the SUPPLEMENT. The policy of the Committee is to urge all medical practitioners of military age and physically fit to enrol themselves with it, undertaking to come up for whole-time service when called upon to do so. The importance of the business done here largely in the means which have been taken to help medical men to take this course with the least inconvenience to the public and loss to themselves, and to the greatest benefit of the military medical services. For England, Wales, and Ireland it is estimated that out of every three men under 40, fit or unfit for military service, at least one is required to serve in the army as a whole-time commissioned medical officer; this estimate has been reached after very full consideration of the needs of the army as stated to the Committee by the War Office, and the needs of the civil population.

Among the points to which attention has been directed are the position of the resident staffs of civil hospitals and that of men of military age doing war work at home. A letter has been addressed to the governing bodies of hospitals pointing out the urgency of relieving from their hospital duties those junior members of their resident and visiting staffs eligible for commissions in the R.A.M.C. The British Hospitals Association, to which this letter has been communicated, has discussed the matter with the Director-General A.M.S., and as a result a scheme has been prepared, which is printed at page 453. Under it the members of the resident staffs of the hospitals connected with recognized teaching schools may be granted honorary commissions in the R.A.M.C. They will be called up to take general service with the R.A.M.C. after three months' residence, and may be so called up before the expiration of that period, if required, on forty-eight hours' notice. The War Office undertakes, on the other hand, that not more than one-third of the number of residents shall be called up on forty-eight hours' notice at any one time.

With regard to military work at home, the Committee has asked the Director-General not to retain or accept for work in military hospitals at home medical practitioners of military age physically fit

for military service, but to encourage such practitioners to accept commissions in the R.A.M.C. The Committee has been informed that the War Office is discouraging younger men who are physically fit for active service from engaging for home service only, and that the whole question of men of military age doing military work at home is under serious consideration. The question raised is, we understand, held to include not only medical officers, but also non-commissioned officers and men of the R.A.M.C., the hope being that much of the work done by male orderlies may in future be carried out by women.

Another matter which has been cleared up is that of the age of medical officers accepting temporary commissions. In future no medical man under 45 years of age will be employed unless he undertakes general service obligations for a year, and is found physically fit for duty at home and abroad, nor will any man under this age be re-engaged after the expiration of his first contract unless he offers for general service. The effect of this is that the age for general service has been advanced by five years; at the same time it has been decided not to accept for home service any man over 55 years of age, and this means a reduction of the age by five years.

The War Emergency Committee has made an appeal for the establishment throughout the country of local War Emergency Committees, and already 87 such committees, covering approximately 83 Divisions of the Association, have been established. This, however, leaves 87 Divisions in which, so far as is known, no such committee has been appointed.

It will be seen that the aim of the Committee is that the name of every medical man of military age and fit for service in every locality should be registered, and that each should be invited to enrol himself as ready to accept a commission for whole-time service at home and abroad when advised that it is his duty to do so. Each local Committee is advised of the number it should furnish on the basis of equal distribution through all districts. Opportunity is afforded to each individual to state whether he would prefer that when the need arises for men to be called up for service from his locality the selection should be made by the central or the local War Emergency Committee. In the advice that is given as to the arrangements which should be made for the carrying on by the local profession of the practices of practitioners who accept commissions, the precedent set by the Scottish War Emergency Committee, which meets at the Royal College of Physicians of Edinburgh, has been followed. Three classes of practices are distinguished—namely, town practices, combined town and country practices, and country practices—and the suggestion is that the remuneration should be divided in proportions varying with the nature of the practice. At the same time it is strongly advised that Insurance Committees in every district should be asked to discourage, as far as possible, the transfer of patients from a doctor absent on military duty, and that Panel Committees should arrange that no practitioner should take over as a panel patient any insured person on the list of a doctor absent on military service until twelve months after the latter's return.

The Secretaries of the Scottish and Irish War Emergency Committees are supplied with copies of all documents issued by the War Emergency Committee for England and Wales, but, at the request of the Irish Medical Secretary and Dr. Hayes, the circular issued to individual practitioners last month has been sent to all practitioners in Ireland.

SANITATION IN THE ANTILLES.

IN the tropical West Indian islands, as elsewhere, the proper disposal of human excreta is a problem of the highest importance to medical men engaged in local sanitary administration. In Grenada, one of the Windward Islands lying off the coast of Venezuela between the Caribbean Sea and the Atlantic, this question has recently been examined by Dr. Angus Macdonald, medical officer in charge of the International Health Commission of that island, who read a paper on the subject at a meeting of the local members of the British Medical Association, held at the invitation of the Colonial Surgeon, Dr. E. F. Hutton. According to Dr. Macdonald, ankylostomiasis, or hook-worm disease, is the great danger to be apprehended here. It is a disease of soil infection, and is spread by man. The spread is due to the rustic habit of defecation in any corner of the plantation, grass patch, cane field, or bush; this infects the soil for a longer or shorter period, and the barefoot individual of any age, race, or sex may easily be infected therefrom. In discussing the sanitary measures required for the prevention of this soil infection, Dr. Macdonald is careful to keep theoretical perfection apart from what is practically attainable. In urban districts the excreta should, he says, be disposed of by water carriage, at Grenada through drains into the sea. In rural districts this is not possible, and three other methods must be considered. The first of these, human carriage, requires the use of latrines with movable receptacles emptied by hand as required. Their contents are habitually employed to enrich the soil, and so infection of the soil is perpetuated. The second method, that of natural deposit *in loco* already alluded to, ensures the maximum pollution of surface soil and water, and must be discouraged firmly. The third method, that of original permanent disposal in the deep-pit privy, is Dr. Macdonald's method of choice. Destruction by burning or by chemical disinfection, theoretically admirable, is not a practical proposition outside public institutions for reasons of trouble and expense. The deep-pit closet, on the other hand, once it is constructed, needs no attention until in the course of years it becomes filled up, and then it may be either emptied, or covered up with soil and abandoned. Dug in gravel or sand, or at Grenada in tuff, cinder, or clay, the pit may be 10 ft. deep or more, and measure 6 ft. by 4, if rectangular. Its sides may be lined with brick or stone dry set; the bottom is left unlined, the top should have a storm-water wall a foot above ground, and this will support the suitable wooden hut above the pit. Instead of the dry earth or ashes usually recommended, Dr. Macdonald advises the use of equal parts of salt and sand to throw over the deposits in these closets. The salt keeps flies away, and tends to destroy the hook-worm ova. If for any reason it is necessary to instal bucket privies, or privies with shallow pits or trenches, employment of the salt and sand mixture is still recommended; the occurrence of soil infection through wash-outs by storm water, so common in the tropics, will be very hard to avoid. Dr. Macdonald has made out an excellent case for the deep-pit system for disposing of excreta, and writes with the authority of extensive practical experience.

SMALL-POX VACCINE FREE FROM BACTERIAL CONTAMINATION.

REMARKING that in spite of much effort no method has been perfected, up to the present time, for propagating the vaccine virus of small-pox or cow-pox in a pure state, Noguchi gives an account¹ of his own successful experiments in this direction. The method of propagating this virus universally practised to-day consists in transmitting the virus from the skin of one calf to that of another. In spite of all antiseptic and aseptic precautions, the fresh

product yielded by the vaccine vesicles contains a not inconsiderable number of different bacteria. The product is always ripened, or partially sterilized, by exposure to strong glycerine solution in a refrigerating chamber for from one to three months. But this process of ripening, though it tends to reduce the activity of the vaccine virus itself, does not destroy all the contaminating bacteria, although those that remain alive are not pathogenic organisms. Noguchi gives a full account of his experiments, and illustrates them with a large number of excellent photographs and microphotographs. He shows that a vaccine virus freed from all associated bacteria by means of suitable disinfecting agents can be propagated thenceforward in a pure state in the testicles of rabbits and bulls. The virus thus cultivated appears capable of indefinite transfer from one animal to another without loss of efficacy; sixty passages of a pure strain have been made in rabbits in thirteen months. Once the vaccine strain has grown accustomed to its environment in the testis, its activity equals that of a strain obtained in the usual way by growth on the skin. The multiplication of the vaccine virus within the testicle reaches its maximum on the fourth or fifth day after inoculation. Human beings, whether on vaccination or revaccination, react to the pure testicular strain of vaccine virus in an entirely typical manner, and just as they do to the ordinary skin strain of virus. Noguchi states that the ordinary virus used for vaccination against small-pox, although it may be contaminated with bacteria, is for all practical purposes to be regarded as pure; the contaminating micro-organisms are practically negligible. But he points out with justice that a really pure virus is preferable; and his experimental work seems to show that he has found a method of preparing it that is satisfactory from the commercial as well as from the scientific point of view.

THE MUNICIPAL MANAGEMENT OF TUBERCULOSIS.

WHILE London is still waiting for the materialization of the combined efforts of the Local Government Board, the County Council, the Insurance Commissioners, and the borough councils to set up tuberculosis dispensaries in the metropolis, the more coherent organization of the various bodies concerned in the city of Birmingham has been able to present a complete report of its work in the year 1914. The information embodied in this report will enable a fair estimate to be formed of the probable amount of work which will fall to future municipal undertakings and as to the relative amount of success which may be expected. In one respect the report is perhaps disappointing, in that it gives no indication as to the cost of the undertaking, nor is any mention made of the arrangements which are presumably in force with regard to the payment for insured cases. Upon both these points the London borough authorities have not as yet come to any uniform decision. It would seem that very few cases of tuberculosis escape notification in Birmingham. During the year 1914 there were 3,317 cases of pulmonary tuberculosis reported and 1,059 deaths, representing a case mortality of 32 per cent., but among the population as a whole the mortality did not exceed 1.20 per cent. Thus it may safely be affirmed that by far the larger number of notified cases recover. Both the pulmonary and non-pulmonary forms of the disease were found to be most prevalent in the poorer districts. Reports made on special forms by qualified nurse-visitors are submitted to the chief tuberculosis officer, working with his assistants at an antituberculosis centre, on receipt of notification from the medical officer of health. These reports have revealed the extent to which overcrowding has to be dealt with, and the relation between case incidence and defective ventilation. For the rectification of these evils it is necessary to have recourse to the assistance of charitable agencies. Isolation or segregation, the improvement of ventilation, the adjustment of labour conditions, and the provision of adequate food and

¹ H. Noguchi, *Journ. Laceration Med.*, New York, 1915, xxi, 539.

clothing can all be met to a limited extent, but the demand far exceeds the supply. It has been found that the introduction of hygienic methods into the home makes but little headway until some of the inmates have had personal experience of sanatorium life. Hence as many as possible are recommended for admission into one of the three available institutions if only for educational purposes. Of the 377 beds in these sanatoriums, 68 are reserved for early cases, while another hospital with 45 beds is used for acute cases only. To facilitate the examination of contacts, who show no great willingness to undergo the process, attendance is given in the evenings, and the whole-time staff of doctors is assisted by a part-time staff, and by them most of the evening work is done. Of 727 persons so examined, no fewer than 282 were found to be tuberculous. Cases are followed up, after undergoing the period of treatment that may be prescribed for them, by trained tuberculosis visitors, and it is through their agency that the household reforms which constitute the main feature of domiciliary treatment can be effected and maintained. The report is very full and comprehensive, and touches upon many points, such as the milk supply and other matters relating to the origin and spread of the disease. Some illustrations are appended showing the arrangements for open-air treatment as at present devised, from which it appears that its value is recognized for other conditions than those of tuberculosis, and that physicians and surgeons alike are treating cases on open verandahs and balconies in the different hospitals in the city.

OCCUPATION AND SYPHILITIC NERVOUS DISEASE.

Dr. G. E. RENNIE reports¹ two interesting cases of nervous lesions in patients with positive Wassermann reactions, in whom the distribution of the lesions appeared to be connected with the occupational overuse of certain groups of muscles. The first patient had been a tram driver for several years, and was left-handed. At work on three successive days he nearly ran over a child, upset a water-cart, and nearly killed a second child, each time suddenly pulling up sharp. In the next few days he felt nervous, and had numbness in the left hand, and intense headache with vomiting and clonic convulsions on the left side of the face and the left arm. The symptoms cleared up rapidly under the influence of mercury and iodide; Dr. Rennie suggests that they were due to a syphilitic cortical lesion, and that the localization of the lesion was determined by the man's left-handedness and sudden occupational overstrain. The second patient was a miner working with hammer and drill. The hammer was used in the right hand, the drill was steadied, and rotated between the hammer blows, by the left. He had lightning pains and a girdle pain, but came to hospital on account of weakness and wasting in the hands and wrists, particularly the left. There was wrist-drop on the left side, and wasting of the muscles of the hand and the extensors of the wrist on both sides. Both hands were numb; no reaction of degeneration was found. Dr. Rennie argues that it was the occupational overuse of the hands, and particularly of the left hand, that determined the incidence of the syphilitic nerve lesion for which the patient came under observation. Both these patients appear to be instances of Edinger's *Aufbrauch-krankheiten*, or exhaustion diseases, of the peripheral or central nervous system. Edinger was at work on this theory in 1894, and published a full account² of it ten years later. This exhaustion theory points out that nervous lesions are likely to declare themselves for choice in any part of the nervous system that is over-worked. Thus an alcoholic tapster, no doubt from often going up and down the cellar steps, was attacked by alcoholic neuritis in the legs; recovering from this, and

becoming an alcoholic waiter carrying heavy piles of plates, he got an alcoholic neuritis affecting the arms, and particularly the shoulder muscles. A publican, after amputation of one arm, suffered from alcoholic peripheral neuritis in the other; no doubt because, having but one elbow to lift, he worked it double tides. In the case of tabes dorsalis, Edinger argued that the incidence of the main symptoms was often determined by occupational overuse. If the tabetic patient is a postman, he will complain first of ataxia in the legs; if a tailor, of ataxia in the hands and arms. It was found that a tailor with tabes, complaining of ataxia in the legs, lived on the fourth floor and went up and down stairs several times a day. Tabetics with optic atrophy and blindness perform lead quiet sedentary lives, and so, it is argued, are spared many of the other common tabetic symptoms. The Argyle Robertson pupil is habitually an early sign of tabes, because the pupillary light reflex is so constantly active and at work in daily life: one may presume that the loss of this light reflex would be a sign of late onset in tabetic troglodytes. Be this as it may, there has been recorded the case of a tabetic patient whose occupation was to hold up frames containing eggs to the light, and to judge of their goodness or badness by their translucency, working through so many thousand eggs a day. In this patient the tabes declared itself in the form of optic atrophy and blindness.

COMMITTEE ON HEALTH OF MUNITION WORKERS.

THE Minister of Munitions of War, with the concurrence of the Home Secretary, has appointed a Committee "to consider and advise on questions of industrial fatigue, hours of labour, and other matters affecting the personal health and physical efficiency of workers in munition factories and workshops." The members of the Committee are: Sir George Newman, M.D. (chairman); Sir Thomas Barlow, Bt., K.C.V.O., F.R.S.; Mr. G. Bellhouse, Factory Department, Home Office; Professor A. E. Boycott, M.D., F.R.S.; Mr. J. R. Clynes, M.P.; Mr. E. L. Collis, M.B., Factory Department, Home Office; Dr. W. M. Fletcher, F.R.S., Secretary of Medical Research Committee; Professor Leonard E. Hill, M.B., F.R.S.; Mr. Samuel Osborn, J.P., Sheffield; Miss R. E. Squire, Factory Department, Home Office; and Mrs. H. J. Tennant, with Mr. E. H. Pelham as secretary. The Committee will hold its meetings at the offices of the Board of Education, and all communications should be addressed to Mr. Pelham there.

THE NATURAL ENEMY OF THE FLY.

To many there is a particular mental gratification in achieving an end by taking advantage of one of the processes of Nature rather than by reaching it through their arrest by some method which may be termed artificial. To such we commend an observation communicated to the last meeting of the Académie des Sciences by the Director of the Pasteur Institute in Paris. The search for the natural enemy of the domestic fly has not hitherto been very successful. The mould *Empusa* kills the flies it attacks, but no practical method of infecting the pestilent insects has been devised. The fly, as is well known, lays its eggs in manure, particularly horse manure, and M. Roux says it prefers the fresh droppings. The natural enemy of the fly, he says, is fermenting horse-dung. The eggs cannot withstand a temperature of 60° C., but fresh horse-dung, if kept well covered up from the cold, quickly ferments, and during fermentation the temperature rises to between 60° and 70° C. Therefore, M. Roux advises that horse-droppings should not be thrown on top of the manure heap, but that a hole should be made in it and the fresh dung shovelled in and covered over. It is a simple plan, and so little troublesome that the average stableman might probably be induced to follow it without much persuasion. The idea of the

² *Zentralbl. med. Wiss.*, 1904, pp. 1653, 1800, 1921.

manure "working" and killing the flies' eggs would probably appeal to him, and the farmer could not object that the fertilizing value of the manure was diminished.

THE WASTE OF ABILITY.

PROFESSOR RUTHERFORD paid a striking tribute in *Nature* last week to Henry Gwyn Jefferys Moseley, who was killed in the Dardanelles on August 10th. He was the son of the late H. N. Moseley, Professor of Zoology at Oxford, and during the last four years of his life had done work of fundamental importance in the study of radiation and of the structure of the atom; he made the discovery, of great and far-reaching importance, both on the technical and experimental side, that the properties of the element are defined by its atomic number. Sir Ernest Rutherford concludes his tribute with the following sentence, which will find an echo in many minds: "It is a national tragedy that our military organization at the start was so inelastic as to be unable, with few exceptions, to utilize the offers of services of our scientific men except as combatants in the firing line. Our regret for the untimely end of Moseley is all the more poignant that we cannot but recognize that his services would have been far more useful to his country in one of the numerous fields of scientific inquiry rendered necessary by the war than by exposure to the chances of a Turkish bullet."

MR. H. G. PLIMMER, M.R.C.S., F.R.S., Pathologist to the Zoological Society, has been appointed Professor of Comparative Pathology in the Royal College of Science.

THE arrangements for the exhibition of various forms of apparatus which have been found most useful in the treatment of fractures met with in the war, which is to be held at the house of the Royal Society of Medicine, 1, Wimpole Street, W., from October 8th to 11th, are proceeding satisfactorily. They are under the management of a committee consisting of Mr. Charles H. Fagge, M.S., Lieutenant-Colonel F. F. Burghard, M.S., Major Robert Jones, F.R.C.S., and Mr. J. Y. W. MacAlister, who is also acting as Honorary Secretary for the committee. Exhibits are only accepted through the consulting surgeons of district commands, and those desiring to send in any apparatus should first submit it to the consulting surgeons of the command, who, if they consider them of sufficient importance, will recommend them to the committee.

Medical Notes in Parliament.

Compulsory National Service.—On the reassembling of Parliament, on September 14th, the greater part of the time of a session which only occupied about an hour and a half was taken up by an inconclusive discussion on compulsory national service, raised on the motion for the adjournment. In reply to a suggestion that the House should meet in secret session, in order that facts with regard to the conduct of the war which it was not expedient to make public to the country at large should be known to members of the House, the Prime Minister said that he had received no indication of any general desire for such a session, and expressed the opinion that, under the conditions in which parliamentary life in these days is conducted, it was certain that imperfect, incomplete, inaccurate, and distorted accounts of what had taken place would be given, and that no commensurate object in compensation for that great evil would be gained. With regard to the principle of compulsory service, he said that when the Government, without undue delay, but with as much deliberation as the gravity of the subject demanded, had arrived at its conclusions, they would be presented to the House and would become the subject of parliamentary discussion. On the second day of the session, after the Prime Minister had made his statement on war expenditure, which, he said, now amounted to rather over three and a half millions

sterling a day net, discussion turned mainly on compulsory service, except when Mr. Balfour was giving an account of aerial defence. Mr. Asquith said that, adding to those serving in the navy and army or called up to serve at the outbreak of war, the numbers who had since enlisted, "an aggregate of not far short of three millions of men, first and last," had offered themselves to the country. Recruiting during the thirteen months had kept at a fairly steady figure, but there had been signs of falling off during the last few weeks. Though the total casualties already amounted to over 300,000, the rate of recovery from wounds was happily such that the net wastage was very considerably less. The response of the country in respect both to recruits and munition workers had vastly exceeded any standard dreamed of before the war, but the war, as it proceeded, constantly raised the standard, making new requirements, and demanding new sacrifices in men, in munitions, and in finance. Mr. Amery alleged that drafts recently sent to the front included a large proportion of ineffective unable to march, or to see well enough to shoot; and Sir R. Cooper said that within the last six weeks one battalion alone had recruited ten men previously discharged as permanently unfit for service. Mr. Amery, in view of the failure to break through in the West and the creak in the Dardanelles, urged that the time had come to devise means for finding more fit men, and that it was the duty of the Government to make up its mind about national service. Sir L. Chiozza Money maintained that Germany was stronger now than when the war began nearly fourteen months ago, and urged that the opposition to compulsory service was due largely to prejudice. Mr. S. Walsh, a Labour member, while maintaining that if the voluntary system was abandoned the House must be completely satisfied that the existing situation rendered that course necessary, added that if it were shown that compulsion was necessary for the preservation of the State, conscription must be accepted. Under the voluntary system nearly a quarter of a million men a month had been enlisted, and the evidence that compulsion was necessary must be unassailable. In the House of Lords, on the same day, Lord Kitchener said that as the new armies became trained and ready to take the field, considerable reinforcements had been sent out, and Sir John French had reported that the units were well officered and commanded, and had efficient equipment in good order. Other armies would quickly follow for service abroad. There had recently been a falling off in the numbers coming forward to enlist, and this had accentuated the anxiety felt with regard to the provision of men to keep the armies up to their strength during 1916. The returns under the Registration Act would afford a basis for calculating the numbers that would be available for the army after providing for the necessary services of the country as well as for munition works. The decision, which would, he hoped, soon be reached, as to how an adequate supply of men was to be maintained, would be founded on the military requirements for the prosecution of the war and the protection of our shores.

Total Army Casualties.—In reply to Mr. Hogge, who asked for the total number of casualties for the first complete year of the war, and whether means had been taken to announce further casualties at regular intervals, Mr. Tennant said: The practice which has been indicated as desirable in regard to statements of total casualties has been to give them from time to time when the exigencies of the military situation permit, and not at regular intervals. There are still objections to making periodical announcements of the aggregate casualties; and my noble friend considers it desirable that discretion should be reserved to the Government as to when such statements may be made. Subject to the above remark, I may inform the House that the total casualties for the first year of the war—that is, up to August 21st—arc as follows:

	Officers.	Other Ranks.
Killed; died of wounds, etc. ...	4,965	70,992
Wounded	9,973	241,086
Missing	1,501	53,466
	16,439	365,544
Total		381,983

THE WAR.

NOTE ON THE CAUSE OF DEATH DUE TO HIGH-EXPLOSIVE SHELLS IN UNWOUNDED MEN.

SURGEON-GENERAL W. F. STEVENSON, C.B., writes: M. ARNOUX, a French civil engineer, has suggested recently (*Le Journal*, July 6th, 1915) an interesting theory as to the immediate cause of death in certain cases reported from the front in this war of men who were killed by the bursting of high-explosive shells in their immediate neighbourhood, without having been actually struck by any fragments of the missiles. These men were found fixed in the positions occupied by them at the moment of death—"in the lifelike attitudes they were in at the last instant of life."

M. Arnoux bases his theory on what was seen to have happened to a pocket aneroid barometer carried by an officer who had been exposed to an explosion of the kind referred to, and was put out of working order by the force of the concussion. M. Arnoux had the aneroid repaired and placed it under the reservoir of an air pump in order to ascertain by experiment what atmospheric pressure would be required to cause the index to register the same as that produced by the explosion. It is unnecessary to enter into the details of his calculations on this matter, but, presuming them to be correct, he found that the dynamic pressure exerted by the surrounding air on bodies within a few yards of the exploding shell had amounted to over "10,000 kilos to the square metre. . . . Men standing close to the exploding shell would be blown into the air or dashed against the ground with great violence, but in the case of men supported by leaning against a tree, the side of a trench, a wall, etc., only the static decompression (*depression statique*) of the surrounding air could affect them. "What," asks M. Arnoux, "would be the effect on the human organism of so powerful and so sudden a decompression? It would," he answers, "be similar to that which causes the deaths of aeronauts who make too rapid an ascent or of workers in compressed air caissons who leave their caissons too quickly and without taking proper precautions for their slow decompression," namely, the sudden escape from the blood in the form of bubbles of the air and carbonic acid gas which it had absorbed while subject to the high atmospheric pressure in the caissons. *Post-mortem* examinations and experience have proved this to be the cause of sudden deaths in caisson workers. If, after some hours' work in a caisson, a man is suddenly exposed to the ordinary atmospheric pressure by his removal without sufficient care to ensure gradual "decompression" by passing him through a series of compartments of less and less air pressure, the air and carbonic acid which have been absorbed by the blood during the time of his work under the high pressure of the caisson are suddenly discharged into the blood stream as bubbles—the blood, in fact, developing a condition of effervescence—which block all capillary circulation throughout the body and produce immediate death.

M. Arnoux's theory—and a theory only, for he has brought forward no evidence whatever to prove it—is, then, that the same thing happens to victims of the high-explosive shell as happens to the caisson worker; that the sudden and enormous increase of atmospheric pressure produced on a man's body by the explosion is capable of producing such an absorption of air and carbonic acid by the blood as would produce death by their rapid discharge into the blood stream—in fact, air embolism. But the conditions of the two cases are quite different; the high pressure produced by the explosion is only of a moment's duration, that of the caisson has lasted for some hours. The absorption of the gases by the blood in the latter case is not sudden; it does not occur immediately the pressure is applied, but increases directly as the time of exposure to it is prolonged. Is it possible that a sudden increase of atmospheric pressure lasting only for a fraction of a second, no matter how great it might be, could so charge the blood with gases that their discharge into the blood stream when the pressure ceases would cause death in the same manner as a too rapid return to ordinary atmospheric pressure does in caisson workers?

Indeed, one may go further and ask, Is it likely that any absorption at all of gas by the blood occurs in the case of the shell explosion?

Perhaps some expert scientist will answer these questions. To me, judging by the little evidence we have, it would seem that the effects of high explosive shells on men who are not wounded by them or their fragments are to be seen, not in causing sudden death as met with in caisson workers, but by producing concussion of the brain and interference with the functions of nerve centres which are essential to life, and the interruption of which means instant death. I have seen many men come from the front who have been exposed to these explosions; all their symptoms and all their accounts of their experiences tend to confirm this belief, for it is to the less severe injuries to these centres that the symptoms of men who recover and come home all point. M. Arnoux sets out to explain some cases of the lifelike attitudes of dead men which have been reported from this war, and considers that it is to the suddenness of the occurrence of death that their fixed positions are due. But most people will have read accounts of cases of this kind, and possibly may have seen pictures of them in illustrated papers before "high explosives" were used in war.

ARMY MEDICAL PROCEDURE.

The temporary enrolment of civilian practitioners in the ranks of the Royal Army Medical Corps is not, as some suppose, an emergency procedure consequent on the sudden outbreak of the existing war, but a fully pre-arranged plan which included the granting, as on the present occasion, of military titles to these "special enlistments." For a good many years past an Expeditionary Force has had a paper existence, and the authorized establishment of all medical units which would form part of such force the instant it was mobilized has always included a certain proportion of civilian medical men.

The idea of course was to provide for the needs of this force without disturbing too much the medical arrangement made for the benefit of troops not directly concerned with its movements, and it is made feasible by the fact that a great deal of the knowledge required for work in the army is common both to civilian and military practitioners.

The plan has the advantage of allowing the strength of the Royal Army Medical Corps to be kept down to a minimum during peace, and such disadvantages as it presents are likely to become obvious only when it is extended beyond its originally intended limits.

So long as the proportion of civilian medical men to the total strength of the corps in officers is small, and so long as it is possible to retain a civilian medical practitioner at the unit to which he was originally appointed, any disadvantages naturally inherent in the plan are readily overcome. The medical and surgical knowledge of the civilian practitioner fits him from the beginning to undertake with ease all the strictly professional work of the unit to which he is attached, and with a little tactful assistance from its regular officers—including the quartermaster, sergeant-major, and senior sister, if any—he is likely soon to acquire sufficient knowledge of its special routine to make him, in respect of all bedside and allied duties, an efficient executive officer.

The case alters, however, if the number of units that have to be staffed is very large, and where, as in present circumstances, the field operations endure so long that it may become necessary to shift men not infrequently from one unit to another. Then not only must the men who are thoroughly trained and experienced in all branches of military administrative medical work be scattered over a very wide area, but the body of civilian practitioners, however high a degree of professional talent it may collectively represent, loses a certain measure of its utility in respect of the special duties that it has undertaken. For an individual medical man who has been sufficiently long with a given unit to become a thoroughly efficient member of its staff by acquiring sound practical knowledge of its routine, temporarily loses a part of his efficiency on transference to a unit of a different kind.

Though the medical authorities of the army endeavour to employ all civilian practitioners on the kind of work for which they are best fitted by their previous experience, and though the latter are permitted to express a preference

for one kind of work rather than another, they are liable to be employed either at home or abroad in any position that can properly be filled by a medical man. Consequently, a civilian medical practitioner who desires to become a thoroughly efficient member of the corps that he has joined must extend his knowledge beyond that with which he was fully equipped when he entered the army.

Military medical formations are numerous—general hospitals, stationary hospitals, casualty clearing stations, field ambulances, hospital ships, ambulance trains, motor ambulance convoys, and sanitary and regimental appointments; but even without entering them a medical man can learn a good deal of the routine and organization of all of them. It is well worth his while to do so, not only because of the liability which has been mentioned, but also because some knowledge of the general organization of the medical department of the army, and of its inter-relationships with other departments and divisions of an expeditionary force, greatly increases the interest of the time passed by him in the capacity of a soldier. For that matter, too, knowledge of this kind may often enable a man better to understand the bearing of the regulations to which he is subjected, and prevent him feeling ill-used by any orders he may receive.

To acquire this knowledge or a fair amount of it has never been difficult since the various textbooks relating to the work of the Royal Army Medical Corps, as also regarding field operations as a whole, are very clearly written and easily read. But it has been particularly easy during the past few months, since, in view of some of the considerations which have been set forth above, and in anticipation of existing circumstances, the Director-General of the British Army in the Field issued in the spring an order to the effect that all Commanding Officers of medical units should take every possible opportunity of instructing the officers under their command not only in the general organization and functions of the unit in which they were serving, but also in regard to the formations to which they were liable to be transferred.

The memorandum in which this order was conveyed recognized that the conditions of active service imposed heavy restrictions on theoretical teaching, but pointed out that in every unit ample opportunities for the imparting of general instruction were likely to occur from time to time. This has in fact proved to be the case, and in many units short courses of lectures and demonstrations have been provided. Moreover, as far as can be gathered, the suggestion made in the memorandum in regard to the instructional work has usually been adopted, this being to the effect that the list of subjects which follows should be taken as a guide to the kind of knowledge to be imparted.

- (a) The general organization of the army in the field and the working of its administrative services.
- (b) The general organization of the medical service of field formations and its modifications under various tactical conditions.
- (c) The system of evacuation and the general organization of the medical service on the lines of communication.
- (d) The sanitary problems of field formations and of the lines of communication.
- (e) Map-reading and field sketching.
- (f) The organization, interior economy, and equipment of medical units. The various sources (medical, ordnance, and A.S.C.) from which equipment is supplied, and the methods of replenishment.
- (g) Discipline, pay, personal documents, records and returns.

THE PERSIAN GULF EXPEDITION.

DISPATCHES.

DISPATCHES have been published in India on the operations in Turkish Arabia, in April last, by Major-General C. I. Fry on the action of Shaiba on April 12th; a second by Major-General Melliss, who took over command on the night of April 12th from General Fry, and a covering dispatch from General Sir John Nixon, in command of the whole force. Among the officers specially mentioned in these dispatches are the following medical officers:

Major-General Fry's Dispatch.

Medical.—I cannot speak too highly of the behaviour of the Medical Department in all its ranks. There was

no flinching during the bombardment, and perfect steadiness, and their work was done in a most efficient manner under the able direction of Lieutenant-Colonel J. Hennessy, R.A.M.C. As I have already noted during this campaign, the Army Bearer Corps and Hospital Corps behaved excellently. I would particularly bring to notice the good work done by Major J. G. Foster, R.A.M.C., and Captain R. E. Wright, I.M.S., No. 3 Field Ambulance, who were working in the fort section of the defence, and were most exposed to fire.

Major-General Melliss's Dispatch.

Lieutenant-Colonel H. O. B. Browne-Mason, R.A.M.C., acted as my Assistant Director of Medical Services during the operations of 13th and at the battle of 14th. His arrangements for evacuating the large number of our wounded during the battle of Barjisiyah showed marked ability and organizing power. I feel greatly indebted to him.

2nd Norfolk Regiment.—Lieutenant M. Burnett, R.A.M.C., for conspicuous courage, attending to the wounded in the open in the firing line under very heavy fire, where his work necessitated his being very exposed. He lost his life in the firing line doing so, and his work was beyond praise. Third Class Assistant Surgeon J. V. Fernandez, I.S.M.D.

110th Mahratta Light Infantry.—Captain R. Knowles, I.M.S.

117th Mahrattas.—Lieutenant N. K. Bal, I.M.S., for conspicuous bravery in attending wounded men under a heavy fire in the open. He attended the wounded of the 22nd Company 3rd Sappers and Miners, as well as those of his own regiment.

119th Infantry.—Captain J. J. Harper Nelson, I.M.S.

Medical Services.—Captain R. E. Wright, I.M.S., displayed exceptional ability in handling his subdivision of No. 3 Field Ambulance throughout the day. He displayed particular initiative in proceeding to the firing line of the 18th Brigade under a heavy fire, and by ascertaining personally the position of the groups of wounded, was able to conduct a detachment of Jaipur transport carts direct to the place where they were most required when speedy evacuation was most essential. He afterwards superintended the main advanced dressing station at South Mound in a most efficient manner.

Captain F. C. Fraser, I.M.S., displayed great coolness in bringing his subdivision forward under heavy shell and rifle fire, and was in close touch with the 16th Brigade throughout the day. I was particularly struck with the steadfast behaviour of the Army Bearer Corps men of this subdivision, and attribute it in great part to his excellent example and leading.

R.A.M.C.—Lieutenant-Colonel J. Hennessy, Major J. G. Foster, Major F. C. Lambert.

I.M.S.—Major L. Cook, Captain H. E. Stanger-Leathes, Lieutenant L. A. P. Anderson.

I.S.M.D.—Assistant Surgeon A. E. Phauve, Sub Assistant Surgeon Sunder Singh, Sub-Assistant Surgeon Sheikh Mahomed Dada Sahib.

Army Bearer Corps.—Bearers Samedin, Subhan Singh, Gariba, Dhonde, Ram Charan, and Rafawa.

Army Hospital Corps.—Ward servants Abba Pira, Gangaram Gainu; sweepers Mohan, Nathu Singh; water-carriers Bharda, Gainu Balu, Raja Piussal, Sheikh Amur.

General Sir John Nixon's Dispatch.

Colonel P. Hehir, I.M.S., Acting Deputy Director of Medical Services, materially assisted the operations by the ability and untiring energy which he displayed in the working of the important department over which he at the time was presiding.

Major H. A. Bransbury, R.A.M.C., commanded the sections of No. 19 Combined Clearing Hospital that carried out the evacuation of the wounded after Shaiba, attending himself to all cases (over 1,100 wounded, including those of the enemy) as they arrived, displaying much initiative and resource.

Fourth Class Assistant Surgeon H. N. Murphy, I.S.M.D., was attached to No. 19 Combined Clearing Hospital, during the evacuation of wounded from Shaiba, worked with untiring energy and marked intelligence, proving himself to be very capable and reliable.

Others of the medical services I consider worthy of

* Lieutenant Burnett was gazetted Captain from March 30th.

commendation are Lieutenant-Colonel H. M. Anderson, R.A.M.C., commanding No. 3a British General Hospital up to April 21st; Lieutenant-Colonel G. B. Irvine, I.M.S., commanding No. 9 Indian General Hospital; Lieutenant-Colonel D. G. Collins, R.A.M.C., commanding No. 3a British General Hospital after April 21st; Lieutenant-Colonel F. J. Palmer, R.A.M.C., surgical specialist, No. 3a British General Hospital; Major H. K. Brown, I.M.S., commanding No. 19 Combined Clearing Hospital; Captain C. C. Shaw, I.M.S., No. 19 Combined Clearing Hospital; First Class Assistant Surgeon W. H. Brown, I.S.M.D., Medical Store Dépôt.

HONOURS.

ROYAL NAVY.

On September 13th the Admiralty published a list of honours conferred upon officers and men of the Royal Navy, including ten appointments to the Distinguished Service Order and eighteen grants of the Distinguished Service Cross, also a large number of the Conspicuous Gallantry Medal and Distinguished Service Medal. Among those decorated with the Military Cross are two French naval officers. One medical officer's name appears in the list, that of Surgeon B. A. Playne, R.N., who receives the D.S.O. for the following services:

Surgeon Basil Alfred Playne, R.N., R.N.D. For gallantry and good service during operations near Gaba Tepe from April 28th to May 1st, 1915. On several occasions he rushed across the open (the communication trench being incomplete) into the fire trenches and attended the seriously wounded, regardless of the severity of the enemy's fire; on one occasion he carried a wounded officer on his back from the fire trench to the communication trench under heavy fire. His conspicuous bravery not only inspired the stretcher-bearers to perform fine work, but gave confidence and spirit to all ranks. He was again several times brought to notice for gallant deeds when attending wounded on May 3rd and 4th.

ARMY.

On September 15th the War Office issued a further list of awards to officers and men, which included the following members of the medical service:

Captain Hugh G. Monteith, R.A.M.C., attached to the 2nd Duke of Cornwall's Light Infantry, receives the D.S.O. for conspicuous gallantry and devotion to duty in picking up and attending to the wounded under heavy fire in the actions near St. Jean and Wieltje, east of Ypres, between April 23rd and 27th, 1915, when the casualties in the battalion to which he was attached were very heavy.

Lieutenant William B. Keith, M.B., R.A.M.C.(T.F.), 1st Home Counties Field Ambulance, is awarded the Military Cross, for conspicuous gallantry at Hooge on the night of April 23rd-24th, 1915. When a shell killed two stretcher-bearers who were bringing in a wounded officer he went out to assist, and under a heavy fire brought the wounded officer into the dressing station. He has performed many acts of a like nature, and has consistently shown coolness and resource under fire.

TERRITORIAL FORCES.

The *London Gazette* of September 10th notifies that the Territorial Decoration has been conferred upon twenty-two officers, including the three following medical officers:

Surgeon-Major John F. Gordon-Dill, M.D., Norfolk Yeomanry.

Surgeon-Major George Mackie, M.B., Shropshire Royal Horse Artillery.

Lieutenant-Colonel Arthur Cary, R.A.M.C., 2nd South-Western Mounted Brigade Field Ambulance.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Died.

Surgeon David Revell Bebell Siveight, R.N., is reported to have died in the Dardanelles on September 5th. He was educated at Fettes College, Trinity College, Cambridge, and Edinburgh University, and took the B.A. Cambridge in 1902 and the M.B. and Ch.B. at Edinburgh in 1910. After qualifying he served as house-surgeon successively in the eye wards and in the out-patient department of Edinburgh Royal Infirmary, and then went into practice at Murrayfield, Edinburgh. He joined the navy as a temporary Surgeon on January 25th, 1915, and was attached to the Royal Naval Division Field Ambulance. His death adds one more to the list of famous Rugby international football players who have fallen in the service of the country. He played for four years,

1899 to 1902, in the Cambridge football fifteen, being captain in the last two years, and in that of Edinburgh University for four years more, 1905 to 1909, captaining that team also for two years. He represented Scotland in twenty international matches, including those against the "All Black" New Zealand fifteen and the South African fifteen, and captained the English Rugby team which went to Australia in 1904. In 1909 he was also amateur heavy-weight boxing champion of Scotland.

ARMY.

Died of Wounds.

Lieutenant C. M. Harris, R.A.M.C., is reported to have died of wounds in Flanders, in the casualty list published on September 10th. He was attached to the 7th Battalion Royal Scots Fusiliers, and was reported as wounded in the casualty list published on August 15th. (We cannot trace this officer in the *Army List or Medical Register*; possibly the initials are incorrect.)

Wounded.

Major R. Kelsall, I.M.S., Flanders.
Captain J. H. Magoveny, R.A.M.C. (Special Reserve), Dardanelles.

Captain O. Teichmann, R.A.M.C.(T.F.), Dardanelles.
Lieutenant J. Brown, R.A.M.C. (temporary), Dardanelles.
Lieutenant G. B. Pearson, R.A.M.C.(T.F.), Dardanelles.
Lieutenant L. H. Skene, R.A.M.C. (temporary), Dardanelles.

DEATHS AMONG SONS OF MEDICAL MEN.

Jephson, John Noble, Major 6th Battalion Royal Munster Fusiliers, second son of the late Deputy Inspector-General William Holmes Jephson, Army Medical Department, formerly of the King's Dragoon Guards, died at Mirdos on August 29th, of wounds received at the Dardanelles on August 16th. He was born at Bangalore on October 8th, 1864, educated at Kelly College, Tavistock, and entered the Manchester Regiment as Second Lieutenant on February 7th, 1885. He joined the Indian Army in 1889, being posted to the 5th Bengal Light Infantry, became Major on February 7th, 1903, and retired on December 2nd, 1905. He then joined the Devon Territorials, as Commandant of the 4th Wessex Brigade, R.F.A., resigning this command shortly before the war. Returning to duty when the war broke out, he was appointed Major and second in command of the 6th Royal Munsters, landed with his regiment at Suvla Bay, and took part in the fighting there from August 6th to the 16th, when he was shot in the head while leading a charge. He leaves a wife and two sons.

Kearney, James John, Royal Gloucester Hussars, son of the late J. F. Kearney, M.R.C.S., killed in the Dardanelles, August 21st.

King, S. W. Thacker, Second Lieutenant 4th Battalion Cheshire Regiment, son of Dr. R. Thacker King, of Wyst Kirby, Cheshire, killed in the Dardanelles in August. He got his commission on February 22nd.

A CORRECTION.—We are glad to learn that the announcement of the death of a young medical officer in Flanders, of Lieutenant E. Roberts, 7th East Yorkshire Regiment, the son of Dr. E. Roberts of Leeds, is incorrect. Lieutenant Roberts was wounded, but he is now rapidly convalescing.

MEDICAL STUDENTS.

Dobbin, George F. Second Lieutenant 6th Battalion Royal Irish Fusiliers, killed at the Dardanelles on August 10th, aged 20. He was the second son of Mr. J. L. T. Dobbin, of 115, Morehampton Road, Dublin, was educated at Strangeways School, Dublin, and entered Trinity College, Dublin, as a medical student in 1912. He was in the O.T.C. at college, and got his commission on September 29th, 1914.

Duggan, John Lewis, Lieutenant 5th Battalion Royal Irish Regiment, fifth and youngest son of George Duggan, of 5, College Street, Dublin, killed in action in the Dardanelles on August 16th, aged 20. He was educated at Dublin High School, and entered Trinity College, Dublin, as a medical student in 1912. He got his commission on January 28th, 1915. His elder brother—Captain G. G. Duggan, of the Royal Irish Fusiliers—fell at the same time, dying of wounds on August 17th.

NOTES.

REST HOSPITALS.

THE National Advisory Committee on War Output announces that by arrangement with the War Office and the Ministry of Munitions a series of parties representing workmen employed in the various munition areas will pay visits to the front; eight such parties, consisting of seven representative workmen, have been arranged, and one Labour member of the Parliamentary Munitions Committee will be attached to each party. The first party, consisting of members of the National Advisory Committee and three members appointed by the Parliamentary Committee, reached general head quarters in France on

August 27th, and issued a report of their observations on September 13th. The main part of the report is concerned with the requirements of the army in the field, which, it is stated, are "enormously in excess of all previous calculations," and an appeal is made to munition workers on behalf of their fellow-workmen in the trenches, who, to preserve our homes and our liberties, have to endure hardships and privations. The report contains a striking tribute to what has been done for the safety and comfort of the troops. After mentioning the good feeling which existed between officers of all degrees and their men, the report states:

Members of the party were much impressed with the care and attention which is evidently devoted to the safety and comfort of the troops both in the trenches and behind the front. In the trenches every ingenious device, in the way of dug-outs and shelters, has been contrived to protect our men against the enemy's fire and make their days and nights as comfortable as possible. Behind the firing line we visited an open-air rest hospital, where men were given a fortnight's treatment. There are about 1,200 patients in the hospital, and a very high percentage are able to return to the colours after their course of treatment. The hospital is splendidly organized and has formed a model on which similar institutions have been founded from time to time; the cooking arrangements would do credit to a first-class hotel, and dental and ophthalmic departments are attached and are kept exceedingly busy. Football and cricket are provided for the patients, elaborate arrangements for cleaning and repairing clothing and accoutrements exist, and after treatment the men are generally returned to their regiments sound in mind and body. This humanitarian side of the war is doing noble work in relieving the strain of campaigning.

HOSPITAL RESIDENTS.

As the result of an interview with Sir Alfred Keogh, Director-General A.M.S., the British Hospitals Association has received the following details of the scheme under which the resident staffs of hospitals are granted honorary commissions in the Royal Army Medical Corps:

1. This scheme is only applicable to hospitals connected with recognized teaching schools (not post-graduate schools).
2. All candidates for commissions must be registered medical practitioners.
3. They must be physically fit for general service.
4. They shall be called upon to take general service with the Royal Army Medical Corps after three months' residence, and shall be liable to be called up for service before the expiration of that period, if required, on forty-eight hours' notice.
5. As far as practicable, not more than one-third of the number of residents will be called up on forty-eight hours' notice at one time.
6. Each candidate shall, on being approved for a temporary honorary commission, receive a grant of £20 as an allowance for the purchase of uniform. This is part of the grant of £30 issuable on taking general service.
7. No resident can be entered into that any residents called up for service will be replaced by the War Office.
8. Applications for temporary commissions should be made to the War Office by the hospital authorities concerned, who will vouch for the candidates whose names they submit.
9. The authorities of any hospital who wish to avail themselves of this scheme should inform the War Office of the number of beds maintained in the institution, and the number of residents employed.

SCOTLAND.

Extended Hospital Accommodation for the Wounded.

Fonab Castle, Pitlochry, has been given by the proprietor (Mr. Alister C. Sandeman) as a convalescent home for wounded soldiers for the duration of the war, and work will be begun in it on the expiry of the six months' tenure of Bonskeid House in the same district. Fonab Castle will be managed by the Pitlochry Women's Red Cross and Voluntary Aid Detachment, under Miss Ferguson, commandant.

Kicr House, Dunblane, which during last winter was occupied as a hospital for wounded Belgian officers and men, has now been reopened as a Voluntary Aid Detachment auxiliary hospital in connexion with the Red Cross organization. The hospital is under the charge of Dr. Hosack Fraser of the Bridge of Allan, and there are some twenty-four patients in it, most of whom are convalescents from the Dardanelles. Colonel and the Hon. Mrs. Stirling have placed the house at the disposal of the authorities.

One-half (100 beds) of the accommodation of the new Children's Hospital at Yorkhill, Glasgow, has been allocated by the War Office for the reception and treatment of wounded officers, and constitutes the first hospital in Scotland set apart for this special purpose. It is to be called the Yorkhill War Hospital for Officers, and the buildings, no less than the grounds, are admirably suited

for the object in view. The other half (with 100 beds) of the hospital is occupied by children under 12 years of age.

An ambulance train with 100 wounded soldiers arrived in Aberdeen on September 4th. The patients, who were all from the Dardanelles, were placed in the base hospitals at Oldmill and in the Central Higher Grade School. Another contingent of 100 wounded soldiers arrived at Springburn Hospital, Glasgow, from France. Most of the men, both at Aberdeen and Glasgow, belonged to English regiments.

The Provost and magistrates of Moffat have granted the use of the Proudfoot Institute as an auxiliary Red Cross hospital, and the opening ceremony was performed on September 7th by Lady Cross, Marchbankwood, Provost Huskie presiding. There are two wards, one for twenty-five and the other for fifteen patients; there is a large library and a billiard-room, and (as Lady Cross added), there are the famous Moffat mineral waters available for those to whom they may be useful. There are also fifteen wounded soldiers at the Ivybank Voluntary Aid Detachment Hospital at Nairn.

Scotland, therefore, is doing her share in the provision of hospital accommodation for the wounded in this crisis in the United Kingdom's history.

The ambulance train, to which reference was made in the JOURNAL of September 11th, p. 418, was visited by over 40,000 persons in Glasgow and by 25,000 in Edinburgh. The funds of the Red Cross Society (Scottish Branch) will therefore benefit to a considerable amount, for the charge for viewing the train was 1s.

NEW RED CROSS HOSPITAL AT ENGLEFIELD GREEN.

A pavilion hospital for wounded sailors and soldiers has been erected on Crown property at Englefield Green, a mile or so from Egham, and almost on the south-eastern border of Windsor Great Park. On September 11th, in the presence of the Princess Christian, who has greatly interested herself in the project, the hospital was informally opened and handed over to the War Office. Sir Alfred Keogh represented that department on the occasion, and the British Red Cross Society, which has contributed £10,000 towards the undertaking, was represented by the Hon. Arthur Stanley. The 120 beds which the hospital comprises are arranged in six pavilions, which have been built in a semicircle facing southwards; each pavilion has a canvas-covered verandah projecting some 8 ft. from the floor of the ward, so that the patients can be wheeled into the open to enjoy a view which embraces some of the finest prospects in Surrey. In addition to these pavilions, there are twenty-seven other buildings in the camp. These comprise mess-rooms, kitchen, stores, dispensary, and private apartments for the resident medical officers, matron, and nurses. One covered octagonal building, like a bandstand in appearance, is for use as a recreation and dining room during summer. The buildings are all constructed of well-seasoned pitch pine, and their yellowish brown hue with decorative green gives a feeling of warmth and cheerfulness to the camp. In one building is an operating theatre, and attached to it an exceptionally well equipped x-ray room, with every required unit of installation, including the most precise localizing apparatus. The interiors of all the buildings are lined with asbestos; they are heated by gas radiators and slow combustion stoves, lighted by electricity, and connected up by telephone. A plentiful supply of baths has also been provided, and the drainage has received special attention. The commandant of the hospital is Sir William Taylor, K.C.B., formerly Director-General of the Army Medical Service, and the assistant commander is Major Buckley, R.A.M.C. These two officers, who will reside in the camp, will be assisted by five local practitioners. Save for the male orderlies, who are members of the St. John Ambulance Brigade, the remainder of the staff, including the quartermaster and the superintendent of the x-ray department, are ladies. It says much for the energy of all concerned that the building, which is to be known as the Princess Christian British Red Cross Hospital, has only been twelve weeks in erection.

CASUALTIES AMONG GERMAN ARMY DOCTORS.

From an investigation by a medical journal in Berlin of the first 200 casualty lists it appeared that of 603 medical men then lost, temporarily at any rate, to the German army the causes were as follows: Slightly wounded 220,

severely wounded 66, dead 167. Of the deaths, 1 was due to gas poisoning, 46 were due to disease, and 120 were due to casualties in the field. Further, 1 medical man was ill, 55 were prisoners, and 119 were missing. Two of the prisoners and 23 of the missing had returned; and, by the subtraction of these 25 from the grand total of 628, the total loss, as above stated, was estimated at 603. The loss of the well-known authority on tuberculosis, Cornet, whose death was due to typhus contracted from Russian prisoners, has been followed by that of Professor Lüthje, whose name is associated with the disorders of metabolism. He was only 44 years old when he died on June 9th. In his case also death was due to typhus contracted while he was attending Russian prisoners.

Ugeskrift for Lægegy for August 5th gives the following particulars, published in the *Berliner Aerztekorrespondenz*, showing the casualties in the German medical profession. Killed 227 (including 72 deaths from disease), severely wounded 82, slightly wounded 261, prisoners 70, and missing 93; total, 733.

MEDICAL OFFICERS WANTED.

59th Divisional Casualty Clearing Station.

The 59th Divisional Casualty Clearing Station, now stationed at Derby, requires three medical officers. Those desiring to serve with a unit of this nature should apply to the Officer Commanding, 59th Divisional Casualty Clearing Station, 91, Siddals Road, Derby.

Wessex Field Ambulances.

Officers are called for to fill establishments of the six Wessex field ambulances—namely, 21st and 31st, head quarters Exeter; 22nd and 32nd, head quarters Plymouth; 23rd and 33rd, head quarters Southampton. Applicants, who should be registered practitioners, physically fit, and under 45, will receive commission as lieutenants, and promotion after six months' service to captain. These units are at present camped on Dartmoor and in the New Forest. Apply to A.D.M.S., Wessex Division, Exeter.

Ireland.

DISPENSARY DOCTORS AND THE WAR.

At the New Ross guardians' meeting last week one of their medical officers, Dr. Shorton (Duncannon) applied for twelve months' leave of absence, as he had received a commission in the R.A.M.C., and also asked the guardians to allow him half his fixed salary whilst away. The guardians granted the leave, refused the salary, and appointed Dr. Sheridan (insurance doctor, New Ross) as substitute, subject to the sanction of the Local Government Board, at the salary Dr. Shorton had been receiving.

Dr. F. Creighton Fitzgerald, medical officer of Newtownbutler (co. Fermanagh) Dispensary District, in Clones Union, aged 70, late High Sheriff of co. Fermanagh, has asked the guardians for a year's leave and half-pay, provided he could get another doctor to act for him at his present salary, in order that he might volunteer for military service. The members present expressed high approval of the doctor's decision, and it was decided to summon a special meeting to deal with his application.

MEDICAL CERTIFIERS AS SUBSTITUTES FOR POOR LAW MEDICAL OFFICERS.

The Local Government Board (Ireland) has written to the Kilmacthomas (co. Waterford) Board of Guardians acknowledging the receipt of replies to questions respecting the proposed appointment of Dr. Bryan Foley as substitute for Dr. O'Byrne, Medical Officer of the workhouse, and of the Kilmacthomas Dispensary District, during his absence on vacation. The Board points out that Dr. Foley is Medical Officer of the Bonmahon Dispensary District, and, in addition, acts as certifier under the National Insurance Acts for the Bonmahon, Kilmacthomas, Kilmacdon, Tramore, Waterford Rural, and Woodstown Dispensary Districts, with a total area of 132,532 acres, and a population of 17,982. In view of all the duties that devolve upon him, the Board is not prepared to approve of the employment of Dr. Foley as temporary medical officer of the workhouse and Kilmacthomas Dispensary District, and desires that the medical officer should be requested to nominate a practitioner who would be prepared to reside in Kilmacthomas while acting as temporary medical officer. His attention should at the same time be drawn to Article 28 of the Dispensary Rules, and he should be cautioned not to relinquish the dis-

charge of his duties until the Local Government Board has approved of the arrangements made in regard to his substitute.

The Local Government Board, in a letter to the Thomastown Guardians (co. Kilkenny), also refused to sanction the appointment of Dr. R. E. Griffin, Kilkenny, as substitute at Knocktopher district in the absence of Dr. T. G. O'Brien, on the grounds that he held the office of medical certifier under the Insurance Acts for nine dispensary districts, with a population of 36,640. The guardians decided to advertise for a doctor, preference to be given to a lady doctor.

England and Wales.

VISIT OF THE KING AND QUEEN TO WEST OF ENGLAND HOSPITALS.

THE King and Queen, last week, made a short tour in the West of England to visit the principal military hospitals.

A visit was first paid, on September 7th, to Bristol, where the Royal party went to the hospital at Southmead, where part of the 2nd Southern General Hospital (I.F.) is established. Between four and five years ago the building of a detached surgical wing to the Bristol Royal Infirmary was begun as a memorial to King Edward; it was opened by their Majesties in June, 1912, and when the present war broke out it was at once set aside for military purposes. The Bristol Board of Guardians offered the use of their new workhouse infirmary at Southmead, then approaching completion, and it was taken over; since then temporary wards have been erected to make up a double strength military general hospital. At Bishop's Knoll, in the private house of Mr. R. E. Bush, who has defrayed all expenses, there is an annexe containing 100 beds, and 100 more beds have been maintained by Miss Mawe and her friends at the Royal West of England Sanatorium, Weston-super-Mare. At Charlton Park the Countess of Suffolk has provided 30 beds, and at Merthyr Guest Hospital, Templecombe, Lady Theodora Guest, 15. The 2nd Southern General Hospital is connected with many other hospitals, mainly voluntary aid institutions, in the counties of Gloucester, Somerset, and Wilts, providing altogether 2,150 beds. The total number of patients treated in the hospital itself since the beginning of the war is 13,725. The rate of mortality has been 0.54 per cent. Their Majesties were received at Southmead by Lieutenant-Colonel Paul Bush, F.R.C.S., C.M.G., Officer Commanding the 2nd Southern General Hospital; Lieutenant-Colonel J. Michell Clarke; and the matron, Miss Harvey. Members of the Territorial Nursing Service and of the Women's Voluntary Aid Detachments were present. The King and Queen visited ten wards, and then proceeded to the Infirmary, where Lieutenant-Colonel Prowse, F.R.C.S., and Miss Baillie, the principal matron, were in attendance. After going over the hospital, their Majesties visited the open-air ward, and then, accompanied by the Lord Mayor, went to Beaufort Military Hospital at Fishponds, where they were received by Lieutenant-Colonel Blackford. The hospital, which contains 400 beds, was inspected and its situation much admired. The Royal party afterwards went to Temple Mead Station, where the King awarded certain decorations to wounded soldiers.

Their Majesties reached Exeter on September 8th, and first visited No. 1 Hospital, established, as is described in the JOURNAL of August 28th, in the West of England Eye Infirmary, where they were received by Miss Buller, Deputy County Director, V.A.D., and the medical officer in charge, Mr. A. L. Candler, F.R.C.S. Their Majesties next went to No. 5 Hospital, in the College Hostel for Women and Congregational Church Schools, near the Castle, where they were received by the medical officer in charge, Mr. Brennan Dyball, F.R.C.S., and the other medical members of the staff.

On the same day the King and Queen went to Plymouth, and after the inspection of troops by the King their Majesties visited Keppel Place Hospital, where they were received by Lieutenant-Colonel A. G. Kay, R.A.M.C. (A.D.M.S. Plymouth), commandant, Major Steele, R.A.M.C., and the Military Hospital commandant, Lieutenant-Colonel Weston, R.A.M.C. On the following day their Majesties inspected the Royal Naval Hospital, where they were received by Surgeon-General W. H. Norman and Surgeon-General Johnson; from there they

went to the Salisbury Road Hospital, where they were received by Lieutenant-Colonel Webber, R.A.M.C., (officer in charge of the 4th Southern General Hospital), and the commandant, Major Wilson, R.A.M.C. From there they went to the Hyde Park Hospital, of which Major Whitmore, R.A.M.C., is commandant, and the Ford Hospital, of which Major G. C. Sandford, R.A.M.C., is commandant.

On September 10th their Majesties ended their tour by a visit to the Red Cross Hospitals at Torquay. They first went to the Town Hall, where, in part of the new Municipal Buildings, including the large Assembly Hall, 125 beds have been provided. They were received by the county

director (Mr. J. S. C. Davis), the assistant county director (Dr. Quick), Dr. Sylvia Payne, the officer in charge, and Drs. Whitewick, Winter, Crowley, Cumming, and the matron. Men from the convalescent hospital at Rockwood, as well as from the Torbay and the Western Hospitals, parts of both of which have been set aside for wounded men, were present. The Royal party then went on to Stoodley Knowle, which is used for wounded officers; it is the house of Colonel C. R. Burn, M.P., and the Hon. Mrs. Burn, and has accommodation for twenty patients. Mr. A. H. Ward, the officer in charge, Mr. J. L. Payne, visiting surgeon, Mr. L. Bennett, radiographer, Mr. T. G. Fenton, otologist, Mr. P. Rhodes, dental surgeon, and others were presented to their Majesties, who afterwards visited the wards. Before leaving Torquay the King, in thanking the Mayor, said that he had visited something like one hundred hospitals, and therefore regarded himself somewhat as an expert, and he could say that he had never seen a hospital better managed or one quite like that in the Town Hall.

PRESENTATION TO PROFESSOR RUTHERFORD MORISON.

An interesting ceremony took place in No. 1 Theatre of the Newcastle-upon-Tyne Royal Infirmary, on August 18th. On that occasion as many as possible of Professor Morison's house-surgeons met together for the purpose of asking the professor to accept a life-size medallion in bronze which had been erected in the theatre where he worked.

Dr. G. W. Harbottle, who was Professor Morison's first house-surgeon, presided, and explained that it was the unanimous wish of every one of his house-surgeons that some permanent memorial should adorn the hospital for which their teacher had done so much, and be an incentive for those who followed him to carry on the traditions of the School of Surgery which he had founded.

Mr. G. Grey Turner in making the presentation said:

We apologize, Sir, for the delay in the holding of this ceremony, due not only to the war emergency, but to

other circumstances over which we also have had no control. That there are so few present is due to the exigencies of the times, and to the fact that since the memorial was mooted death has robbed us of two of our number, Dr. James Smith and Mr. Howard Hunter,* while many are serving in the forces in various parts of the world or on the sea. All are present in spirit to do homage to their teacher and friend. We are all proud of your world-wide influence on surgery, and yield to no one in our admiration of your work for our school, but to-day we are concerned with that closer relationship which as house-surgeons we have been privileged to enjoy.

The lessons we have learnt from you are proving invaluable. Many of us first learnt the salutary value of hard work and how it might be lightened by enthusiasm and its usefulness increased by a cheery optimism. Your example of system and thoroughness we can never over-estimate, while your insistence on the importance of principles has been the foundation of much of any success that we have enjoyed. Your devotion to hospital work has set a standard which, though sometimes a little hard to follow, we all recognize as ideal. As part of the profession we feel the value of the work you have done for our calling, and we are constantly reminded of that happy relationship of the surgeon with the practitioner which you inculcated, and which has been a useful example for us all. As beginners we have one and all felt the untold value of your help, and we all know that your generosity was never appealed to in vain. There are few

of us that have not had recourse to your professional skill, if not for our persons, at least for our families and relatives, and our indebtedness will always remain. You, Sir, might be disappointed if I did not say that we have all felt the value of your chastening, but your honesty of purpose and absolute fairness always supplied the balm with the sting, and we gratefully acknowledge the lessons impressed in this way. All these considerations make us look back to the time of our association with you as the most valuable and happiest periods of our lives. It is, therefore, with the very greatest pleasure that we ask you to accept this medallion as a token of our admiration and gratitude for your valuable teaching, esteem for your worth, and affection for those qualities which have endeared you to us all.

In replying, Professor Morison said it was impossible for him to express all that he felt. There was not one of his house-surgeons of whom he could not say that he had been on terms of intimate friendship. He felt that if his house-surgeons had learnt as much from him

* Killed in Flanders.

as he had learnt from them, it might, after all, be worth while commemorating their association. He thanked them most deeply for their handsome gift, of which he should always feel proud.

On the same occasion Dr. Aliver Parkin asked the Professor to accept a group photograph of all his house-surgeons as a personal memento which he could always have before him. He emphasized the great value of a house-surgery under such a teacher, and endorsed the feelings of regard and affection which had been expressed by the previous speakers.

Professor Morison replied, after which the company took tea together in the staff-room.

The medallion is the work of Mr. Ernest G. Gillick, of Chelsea, and is a most successful piece of portraiture.

MATERNITY WARDS AT CARDIFF HOSPITAL.

AN ANONYMOUS donor has presented £5,000 to the King Edward VII Hospital, Cardiff, for the establishment of a maternity flat to be built over the Butc wards. The donor, in a letter transmitting the money, said that he was pleased to do something for Sir William James Thomas's great scheme for a complete national school of medicine for Wales. Apart from what the wards might do to save many valuable lives, such an establishment was necessary to meet the requirements of a teaching hospital, which, the writer ends, "I fervently hope yours will be, in a real and complete sense, in the very near future." The chairman, Colonel Bruce Vaughan, in announcing the gift, said that it would enable the hospital to fulfil a promise made to the Marchioness of Bute so far back as 1911, and to carry out the resolution of the board of management on July 14th last—a resolution based on the report of a subcommittee which had met the chairman (Dr. Robinson) and representatives of the Health Committee of the Cardiff City Corporation to discuss the report of Dr. Walford, the medical officer of health, on the establishment of a maternity centre or centres for Cardiff. By the resolution of July 14th the hospital was committed to provide twelve beds. It would now be able to inform the Health Committee that through the generosity of an anonymous donor it could promise to devote, when the wards were built, eighteen beds to this purpose.

In moving a vote of thanks to the donor, Dr. Ewan Maclean (Major R.A.M.C.T.) said that the need for beds to be devoted to this purpose had been felt to be urgent for years.

Correspondence.

MEDICAL SERVICE IN THE HIGHLANDS AND ISLANDS.

SIR,—I do not complain of the general tone of your Edinburgh correspondent in taking notice of my letter of August 25th written in reply to Dr. Mackenzie's criticism of the procedure and proposals of the Medical Service Board as published in the *Scotsman* of August 23rd. On the whole, it seems to be admitted that the purposes entrusted to the new Board are of a benevolent nature, that at the least they offer the prospect of improving the conditions and status of general practice in the area defined, and your correspondent even contemplates the possibility of "measures and arrangements" being "evolved which will prove a charter of emancipation for practitioners resident in the Highlands and Islands." All this is much. The only difference between us is that I consider the charter is already secured.

For nearly seventy years the profession has been agitating without ceasing for the attainment of security of tenure for parochial medical officers. Governments have come in and gone out, private members have endeavoured to pass the required bill into an Act, but never was the measure accomplished until this modest little medical service statute of 1913 conferred the boon on medical officers to parish councils in the Highlands and Islands of Scotland. Let the chronicles of oppression, of duress, of strain and trial endured by many Highland practitioners for generation after generation be examined, and who can deny that security of tenure signifies professional emancipation?

It is notorious that, coupled with the uncertainty of

appointments, insecurity of livelihood—of the "living wage"—was a pressing anxiety in many a struggling doctor's home. To quote a well known Gaelic phrase: "The very stones of the forest tell the tale." The second volume of the Minutes of Evidence of the Dewar Committee record pathetic instances enough.
