 Alcohol for commercial purposes, prizes offered by Russian Government for invention of methods of using, 255
 Alcohol consumption in different armies: Figures published in the BRITISH MEDICAL JOURNAL, stated by Walther Sirach to be incorrect, 659
 Alcohol and drug addiction (Sir William Collins), 613
 Alcohol in France, sale of, 299, 412, 696, 767
 Alcohol in hospitals, duty-free, 23, 66, 67, 107, 114
 Alcohol problem in the United States (John S. Billings, jun.), 670
 Alcoholic poisoning in a child, 908
 Alder Hey, war orthopaedics at, 655
 Alderley, Smith, charge against, 693
 ALDRIDGE, C. R. Mooring: Pneumothorax following pneumonia, 926
 ALEXANDER, Lieut. David Carnegie, Military Cross conferred upon, 733
 ALEXANDER, Frederick W. : Electrolytic disinfectant, 38
 ALEXANDER, J. : *The Cure of Self-Consciousness*, rev., 437
 ALEXANDER, Lieut. Jack A. E., killed in action, 341
 ALEXANDER, M. : Treatment of fractures of the tibia, 329
 ALEXANDER, S. R., elected Mayor of Faversham, 736
 Alimentary canal, standard opaque meal for radiographic examination of, 219—Correspondence on, 349
 Alimentary stasis (Arthur Keith), 14—Leading article on, 62
 ALLAN, Lieut. James Grant, killed in action, 550
 ALLAN, James W. : Typhus fever and lice, 841

ALLAN, John, obituary notice of, 947
 ALLAN, Lieut. Marshall T., killed in action, 585
 ALLARDYCE, W. G. : Bullet wound of the humerus, 56—Bullet wound of left chest, 56
 Allantoin in human beri-beri (Williams and Saleeby), 399
 ALLEST, Sir Thomas Clifford: Appreciation of Howard Marsh, 37—*Diseases of the Arteries, including Angina Pectoris*, rev., 293
 ALLEN, F. J. : A neci-association, 422
 ALLEN, F. M. : *Studies concerning Glycosuria and Diabetes*, rev., 15—Fasting treatment of diabetes, 611
 ALLEN, Capt. Herbert Thomas, killed in action, 585
 ALLENUTT, Capt. E. B., Military Cross conferred upon, 689
 ALNWICK, William Williams, case of, 161
 ALVAREZ, prize, 777
 Alveolar carbon dioxide. *See* Carbon dioxide amblyopia, hysterical (Kenneth Campbell), 455. (O)
 Ambulance, American, in Paris, number of wounded transported by, 711
 Ambulance Association, St. John, 30, 196, 237, 238, 325, 421
 Ambulance cars presented to France by Eton boys, 39
 Ambulance Corps, the Bengal, 196
 Ambulance, field, work of at Anzac (C. Mackie Begg), 805. (O)
 Ambulance hospital, movable, 30
 Ambulance, Italian river, 519
 Ambulance service, motor, for London, 73, 763
 Ambulance train, 155
 Ambulances, coal owners' and miners', 622
 Ambulances, field, work of in France, 655
 Amenities, international medical. *See* Medical profession
 America. *See* United States
 American College of Surgeons and distinct medical and surgical degrees, 331
 American medical men (parliamentary question), 904
 Amoebae in pyorrhoea alveolaris, 870
 Amoebic carriers, 729. *See also* Dysentery
 Anemia, pernicious, and spinal degeneration (Bramwell), 21
 Anaerobic organisms, simple method for cultivation of (Lyn Dinwood), 778. (O)
 Anesthesia, review of books on, 857
 Anesthetists and infection, 613
 Analgesia in intranasal surgery (Adair Dighton), 113
 Anatomy, review of books on, 140, 506
 ANDERSON, Private David, killed in action, 873
 ANDERSON, Lieut. Laurence, killed in action, 689
 ANDREWS, Lieut. Alan Charles Findlay, killed in action, 271
 Aneurysm of the arch of the aorta (J. W. Davies), 57
 Aneurysm, arterio-venous, anastomosis of vein and suture of artery (H. J. Godwin), 925. (O)

Aneurysm of popliteal vessels, arterio-venous (Ernest Connel), 326
Aneurysm, traumatic, and arterio-venous (Captain F. A. Graves), 924. (O) (Sir George Makins), 938
Aphasia pectoralis, review of books on, 293
Angioma perignathicum (Graham Little), 219
Aniline dyes used medicinally, brown, 280
Animals, diseases of, report of inspector, 578
Animals, living, experiments on, report, 571, 574
Ankylostomiasis, beta-naphthol poisoning in (William Bryce Orme), 176
Annual Charities Register and Digest, rev., 423
A-noci-association, 346, 422, 457
Anti-association applied to medical practice (F. M. Rowland), 207. (O)
Anti-cholera vaccination made compulsory in the Italian army, 523
Antiles, sanitation in the, 447
Anti-pneumococcal serum and optoquin, 542, 543
Antirabic treatment, paralysis during (Hasseltine), 532
Antisepsis v. asepsis (Schaechter), 619
Antiseptic acid of hypochlorous acid. See Hypochlorous acid and Ensol
Antiseptics, research in report of the Medical Research Committee, 251, 331—Correspondence on, 332, 332, 460—Leading article on the work of Drs. Dakin and Carrel, 331. See also Medical Research Committee
Antiseptic substances in the treatment of infected wounds (H. D. Dakin), 318. (O)—(Charles A. Morton), 778. (O)
Antityphoid inoculation, 68, 148, 230, 401, 484, 510, 584, 686, 337—In France and elsewhere, 230, 510, 584, 686—Leading article, 610—In the German army, 484—In Hungary, 684—Parliamentary questions on, 68, 148, 188, 686, 937—Review of books on, 401—Sick leave and 188—See also inoculation
Antityphoid vaccination in North Africa, 870
Anzac, field ambulance work at (C. Mackie Regd), 806. (O)—Water supply at, 873
Argument by used in cases of loss of consciousness, 244
Apothecaries' Hall of Ireland, 161, 242, 367, 766, 789
Apothecaries' Society of London, 34, 203, 266, 551, 563, 663, 798
Appendicitis and medical treatment (T. A. R. Aylar), 926
Appendicitis, mortality of, 118
ARCHIBALD, Captain R. G.: Amoebic carriers, 729
Archevizi Italiano di Ginecologia, temporary suspension, 108, 244

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, JULY 3RD, 1915.

THE IDENTIFICATION OF THE PATHOGENIC MEMBERS OF THE TYPHOID-COLON GROUP OF BACILLI.

By J. HENDERSON SMITH, M.B., CH. B. EDIN.,
LISTER INSTITUTE OF PREVENTIVE MEDICINE, LONDON.

EVERY year an immense amount of work is done in this country on the isolation and examination of organisms belonging to the typhoid-colon group of bacilli. Much of it is concerned with the routine examination of water, but a considerable proportion is directly concerned with the examination of excreta, and in many laboratories an extensive experience has been gained of satisfactory methods of isolating and identifying the important pathogenic members of the group. This year, however, war conditions have brought about an enormous expansion in the amount of such work, and at the same time exceptional urgency for its rapid execution. Partly as a result of this, there are already engaged in the examination of excreta many workers whose previous bacteriological experience has been mainly concerned with other departments, and who have not hitherto had to deal with the routine examination of large quantities of such material; and their number is likely to increase still further, as we must anticipate a large and progressive increase in the volume of work with the arrival and continuance of the hot weather. Such men have not the time to look up the recorded experience of others, and perhaps not always the opportunity to consult those whose previous work has made them more familiar with the best methods to adopt. It is hoped that the present paper may be of service to them, based as it is not only on the literature but also on the very large experience of this Institute for many years past, both in the identification of the pathogenic organisms and in the rapid examination of large quantities of material.

The typhoid-colon bacilli are all Gram-negative rods which grow freely on ordinary media at 20°-37° C. and do not form spores, and they are subdivided into two main groups, according to their action on lactose. Those which ferment lactose, producing from it acid with or without formation of gas, are labelled with the general name of *B. coli*, and do not concern us further here. They are practically ubiquitous, and many of them are pathogenic in certain regions or under certain conditions, but they do not produce epidemic disease with predominantly intestinal symptoms. The lactose non-fermenters are again divisible into two main groups by their action on gelatin. The gelatin liquefiers pass into the great group of *B. proteus* (some of them, like *B. coli*, occasionally pathogenic), and with these also we are not further concerned. All the organisms of the group recognized as regularly producing epidemic intestinal disease are included amongst the lactose non-fermenters and gelatin non-liquefiers.

The application of these two tests excludes the great majority of the organisms which belong to the colony-typhoid group, and the first elimination is largely effected by the addition of lactose and a suitable indicator to the medium on which the material is plated in the first instance. Thus in MacConkey's medium any organism which has produced acid from the lactose affects the

neutral red in the medium, and the colonies are red lactose non-fermenters remaining colourless. But there is a source of fallacy in the primary subdivision which must be continually kept in mind. There is a fairly extensive group of organisms which are really akin to the lactose fermenters but do not ferment lactose in the first few days of growth. After an interval of perhaps as long as six to seven days' growth on the sugar they produce descendants which do ferment it, but in the first period they are lactose non-fermenters. In practice one must include in the first selection these late lactose fermenters along with the non-fermenters. Before the final diagnosis is made they will have declared themselves, and if it is realized that the first selection has not been absolutely exclusive of all *B. coli*, they rarely cause serious trouble in the subsequent procedure.

This difficulty of variable characteristics is one which runs through the whole of bacteriological classification. The classification is based on certain characters, which in the group consist of behaviour towards certain substances (carbohydrates, gelatin, milk, etc.) and of serological reactions. Probably none of the characters of any particular organism is so absolutely fixed that it cannot possibly be altered. The difficulty, however, is, so far at least as is known at present, only occasionally a practical one. It may be and is possible under certain conditions to induce a typhoid bacillus to ferment lactose, or to breed a Gaertner bacillus which does not produce gas from glucose; but in clinical typhoid or Gaertner infections the one is not in fact a lactose fermenter, and the other produces gas, and in the practical conditions of the present time any organism which does not conform to the characters described may be rejected as not one of the known pathogenic members of the group. (The only exception which is perhaps worth mention here is in the case of *B. paratyphosus A*. This organism normally produces gas from the carbohydrates it ferments, but occasionally the production of gas is very slight or absent on some or all of them. Suspicion will be aroused by the fact that acid is produced only in the sugars attacked by the typical bacillus, especially if gas is present in one or more of them, and an agglutination test will settle the point.)

The genuine lactose non-fermenters and gelatin non-liquefiers, then, are the important group, and of these a table is given. This explains itself. No attempt has been made to make it exhaustive or strictly systematic. It is intended only as a guide in practical work, and is in fact constructed in accordance with the steps recommended for actual procedure later on; but it contains all the diagnostic characters required for the recognition of the pathogenic bacteria, whatever the system of classification adopted. In two instances, namely, the mannite fermenting group of dysentery bacilli and *B. paratyphosus B*, further subdivisions are frequently recommended. These have not been included in the table, because no result of immediate practical importance is gained thereby, but they require some notice.

Mannite Fermenting Dysentery Bacilli.—This is a group where classification presents exceptional difficulties. In the case of infection with typhoid, Gaertner, or the other pathogenic bacilli of the typhoid-colon type, we have to deal with organisms which present a fairly definite and uniform combination of characters. But in the dysentery due to mannite-fermenters such uniformity does not exist.

They are all non-motile and all produce acid on mannite, and of course they do not ferment lactose or liquefy gelatin, but, beyond this, uniformity either of cultural or serological characters ceases. In different epidemics the causal organisms may conform completely to a recognized type, such as Flexner's original bacillus, or they may differ in one or more particulars from any of the types previously established. Under such circumstances detailed subclassification is of no value for our purpose here. If a table were constructed subdividing into groups by the successive application of different tests, it would have a certain value in systematic differentiation, and the separation of a subgroup, that of *B. dysenteriae* Y, by the use of maltose has become in some sort classical. But even the academic value of such differentiation is doubtful because of the uncertainty whether these organisms are stable in the characters they are found at one time to possess or may not change in one character or another from time to time. The system adopted in the table is to regard all organisms which are agglutinated by Y serum as possible causes of dysentery. *B. dysenteriae* Y is an organism very closely related to Flexner's bacillus, from which it differs in the fact that it does not ferment maltose at the time of isolation, and in its variable production of indol. Serum prepared with it is found to agglutinate all the tested strains of clinically pathogenic bacilli except the bacillus of Stroug. It also agglutinates a number of organisms agreeing with the pathogenic bacilli in the mannite and non-motility characters, but differing from them all in one or more respects when other tests are applied, and not yet found in association with clinical dysentery. These minor differences are not sufficient, in view of the want of uniformity in the known pathogenic bacilli, to justify their exclusion from the dysentery organisms, and any organism agglutinating with Y serum should be regarded as a potential cause of the disease.

Stroug's bacillus is of rare occurrence. It has apparently been isolated in only one epidemic hitherto (in the Philippine Islands), and can only be finally identified by use of a serum prepared from another strain of the same organism; but it should be looked for, and its characters are given in the table.

B. paratyphosus B.—It is claimed by several English and some foreign workers that a distinction is possible between this bacillus and an organism isolated from attacks of food poisoning. This bacillus, which is known under various names, as *B. suispestifer*, *B. aertryck*, etc., agrees in cultural and ordinary agglutination characters with paratyphoid B, and is considered by many authorities to be identical with it; but a distinction is said to be possible by means of the absorption technique. This procedure, however, can scarcely be carried out in the routine examination of excreta on a large scale, and certainly not by those who are inexperienced in such work.

Agglutination tests may be performed microscopically or macroscopically. The latter method is to be preferred. It takes little or no more time to make the preparations, makes subsequent examination easier and more definite, and allows a final examination to be made even after twenty-four hours without the risk of drying. The test serums should be used in high dilution in salt solution, at least 1 in 500, and preferably 1 in 1,000. Proper controls are essential. Spontaneous agglutination is not uncommon in this group—for example, especially with *B. paratyphosus* B. It should be remembered that with dysentery bacilli the processes of agglutination usually proceed much more slowly than is the case with typhoid, and even with strong immune serum it is advisable to wait several hours before deciding that a test is negative.

METHOD OF PROCEDURE.

This must vary according to the circumstances of the worker, the pressure on his time, the extent of equipment, the quantity of material to be examined, the hour of its arrival and so on, and must be modified to suit the individual. The method first given below is that recommended as desirable wherever possible. It gives a reasonably complete examination of the material, and will lead to the discovery of pathogenic organisms if present in as great a percentage of cases as is practically attainable. It involves a considerable but, except in periods of great stress, quite practicable expenditure of time and material on the first day of isolation of the colonies. By concen-

trating the greater proportion of the work on each sample or batch of samples on the day succeeding their receipt, it greatly lightens the subsequent labour and clears the way for the investigation of subsequent samples. In circumstances of great urgency or pressure full examination may not be possible. An abbreviated technique must then be adopted, but this involves missing a number of cases discoverable by the fuller method. Such abbreviated methods are given below.

1. Plate the suspected material on MacConkey's medium (bile-salt neutral-red lactose agar), and incubate at 37° for at least eighteen hours. If no colourless colonies are present by that time, replace in incubator for twenty-four further hours and examine again.

2. Colonies must be selected from uncrowded parts of the plates. It is best, until experience has been gained, to select colonies differing in appearance. Pick off five colourless colonies and emulsify each in a few drops of sterile broth. If time allows subsequent inoculation of the sugars, etc., the same day, incubate the broth emulsions for two to three hours before proceeding; if not, proceed at once to inoculate from each emulsion a set of eight tubes, containing mannite, glucose, saccharose, dulcitol, broth, litmus milk, gelatin, lactose. Grow the gelatin at room temperature, the others at 37°.

3. After twenty-four hours proceed to provisional diagnosis. If all colonies have given identical results, it is unnecessary to examine further more than two; if the results differ, specimens of each kind must be considered.

PROVISIONAL DIAGNOSIS.

Reject all organisms fermenting lactose or liquefying gelatin. The remainder fall into three groups according to their action on mannite.

A. No Change on Mannite.

The only important organism here is *B. dysenteriae* Shiga, and its identification may be completed almost at once. Morgan's No. 1, an organism frequently associated with epidemic summer diarrhoea, should also be looked for.

No Change on Glucose excludes Shiga; such an organism is probably *B. alcaligenes* (and may be definitely diagnosed if the milk is already alkaline, and no change has occurred in the saccharose and dulcitol tubes).

Acid on Glucose without Gas: makes Shiga probable, practically the only other possibilities being some members of the *alcaligenes* group and some water bacilli. Reject any organism which have fermented saccharose or dulcitol, and test the others with Shiga serum. Negative result excludes, positive result identifies, Shiga; confirm by absence of motility on the broth tube.

Acid and Gas on Glucose: without change on saccharose or dulcitol makes Morgan's No. 1 probable; confirm by presence of motility.

There remains for subsequent examination in this section only the confirmation of organisms identified provisionally as Shiga.

B. Acid only on Mannite.

The important organisms here are *B. typhosus*, the group of dysentery bacilli of Flexner type, and *B. dysenteriae* Stroug. Inoculate liberally from the broth tube a second broth tube, and incubate for four to five hours, and test for motility. Meanwhile test with typhoid serum all strains except those fermenting saccharose. Positive result identifies; confirm the same day by presence of motility. Test with Y serum those which ferment cane sugar as well as those negative to typhoid serum. Positive result identifies as a member of the Flexner group; confirm the same day by absence of motility.

Amongst the remaining organisms—that is, those negative to both Y and typhoid serum—there may be: (1) Inagglutinable typhoid and dysentery strains; (2) *B. dysenteriae* Stroug. These cannot be recognized without further time, and each organism is to be subcultured daily on broth meanwhile.

For subsequent examination in this section there are thus: (1) Confirmation of identified strains; (2) the unagglutinated strains.

C. Acid and Gas on Mannite.

The important organisms are those of the paratyphoid-Gaertner group. Reject at once all which have fermented saccharose or clotted milk. Omit for

A = Acid only; AG = acid and gas; Sl. A = slight acid; C = chat; Alk = Alkali.
 *There is some uncertainty as to the characters of *B. dysenteriae* Strong. Those tabulated areas given by Morgan, *Journ. of Hyg.*, 1911, vol. xi, p. 1.

the present (but do not yet discard) all which have failed to produce acid and gas on dulcité. With the remainder proceed as follows: Inoculate a salicin tube and add it to the set of eight tubes. Then test each organism with three serums in this order: Paratyphoid B, paratyphoid A, and Gaertner. Positive result identifies. Subculture the negative strains daily.

For subsequent examination in this section there remains: (1) Confirmation of identified strains; (2) consideration of unagglutinable strains and those which had not fermented dulcité.

By this preliminary examination we have recognized within thirty hours of isolation the great majority of the pathogenic bacilli of the group and got rid of a very large number of organisms certainly not pathogenic. The remaining unidentified bacilli may include *B. dysenteriae* Strong, or inagglutinable strains of the other pathogenic organisms. Temporary inagglutinability is a phenomenon which while it occurs in only a small proportion of the cases is yet so frequent in the examination of large numbers that we must be prepared to meet it. It usually disappears on repeated subculture on artificial media.

The subsequent examination must be delayed till the result of the indol and milk tests can be obtained. The interval should be six further days—that is, a week from first inoculation of the sugars, etc. It must begin always with verification of the lactose and gelatin tests.

SUBSEQUENT EXAMINATION.

A. No Change on Mannite.

We have here only to confirm the diagnosis of the organisms identified as Shiga and Morgan. *B. dysenteriae* Shiga does not produce indol, produces no change in mannite, saccharose, or dulcité, and initial acidity in milk is replaced by alkali: it is non-motile. Morgan's No. 1 produces indol, acid followed by alkali in milk, acid and gas on glucose, no change in other carbohydrates (except levulose and galactose), and is motile.

B. Acid only on Mannite.

Confirmation of Previous Diagnosis.

1. *TypHOID Bacillus*.—Acid only and permanently in milk, no indol, no action on saccharose, acid only on mannite and glucose, no change on dulcité or late acidity, motile. (Non-motile strains occur, but are extremely rare.)

2. *Dysentery of Flexner Type*.—Test for agglutination with Flexner serum. Positive result places the organism among the close allies of Flexner. Typical Flexner produces indol, acid followed by alkali on milk, acid only on glucose and mannite, no change in saccharose or dulcité, and is non-motile. For further subdivision, *vide supra*.

Examination of Unclassified Strains.

1. *Motile Strains*.—These cannot be dysentery; the only possibility is inagglutinable typhoid. Reject any organism whose characters do not agree completely with those just given for typhoid. Test the remainder with the last subculture on broth and typhoid serum. Positive result identifies definitely; but a negative result with an organism of correct cultural characters must be returned as inagglutinable typhoid. (Preserve such strains for later examination.)

2. *Non-motile Strains*.—Examine the last subculture with Y serum. Negative result leaves the possibility of Strong's bacillus (and non-motile typhoid; note characters). Reject those which have not produced acid only on saccharose. *B. dysenteriae* Strong produces indol, acid on glucose, saccharose and mannite, and should give late clot on milk (*vide supra*).

C. Acid and Gas on Mannite.

Confirmation of Identified Strains.—All these produce acid and gas on glucose, mannite and dulcité, no change on salicin and saccharose, fail to produce indol, and are motile. Paratyphoid A produces acid only and permanently in milk; Paratyphoid B and Gaertner produce acid followed by alkali in milk.

Unidentified Strains.—Reject all which have failed to produce acid and gas on dulcité, and all which do not conform exactly to the above cultural characters of Paratyphoid A or Paratyphoid B. Test with Paratyphoid A serum the last subcultures of those agreeing with Paratyphoid A; and with Paratyphoid B and Gaertner serum those agreeing with Paratyphoid B.

If still negative they are not to be identified as pathogenic, but the strains should be preserved. (*Vide supra* for subdivision of the Paratyphoid B organisms.)

ABBREVIATED METHODS.

These all fail to detect pathogenic organisms in some cases in which the fuller method would have been successful, and the proportion of such failures is greater the more rapid the method. All will detect the greater number, and in periods of stress it is better to examine by a short method in order to cover a larger number of samples. In all of them the first step is to plate on MacConkey's medium and incubate as before for at least eighteen hours.

I.

Pick off five (or more) colourless colonies direct into a mannite tube and incubate till next day. If the result is no change, or acid only, in all tubes, select one only and proceed as follows, according to the action on mannite; if the results differ, take one of each kind:

- No change*. Inoculate a broth tube, and in four to five hours test for motility. If non-motile, test with Shiga serum; positive result identifies.
- Acid only*. Inoculate a broth tube, and in four to five hours test for motility. If motile, test with typhoid serum; if non-motile, with Y serum. Positive result identifies as typhoid or mannite fermenting dysentery.
- Acid and gas*. So many non-pathogenic organisms have this action that it is advisable to inoculate all five organisms into saccharose, dulcité, litmus milk, broth, and gelatin. Next day reject the organisms which ferment saccharose and do not ferment dulcité; and test the others with paratyphoid B, paratyphoid A, and Gaertner serum.

Confirmation of identified strains may be carried out. This method will detect a high proportion of the pathogenic organisms. It misses all inagglutinable strains, and by assuming under (a) and (b) identity of all the five organisms from their action on one carbohydrate, misses a further proportion, and it delays the identification of the acid and gas producers for a further twenty-four hours. It saves the considerable expense of the carbohydrate examination of the (a) and (b) groups, and the labour thereby involved, though more agglutination tests are necessary.

II.

Inoculate five or more colourless colonies into broth, and examine for motility in four to five hours. If motile, test with typhoid, Paratyphoid B, Paratyphoid A, and Gaertner serums. Clinical information may help to determine the order of testing. If non-motile, test with Shiga and Y serums. This is probably the best method when the full examination is impossible. It omits more inagglutinable strains than the last, but is rapid, economical, and will detect most of the pathogenic organisms present.

III.

Test by agglutination with the six serums colourless colonies taken straight from the plate, guiding the order by clinical information. Examination of the preparation directly it is made will frequently show the presence of motility, and save the labour of examining with the dysentery serums, but the absence of motility under these conditions does not necessarily mean that the organism is non-motile. This method of examination is the most rapid of all, but the proportion of inagglutinable strains missed is still higher under these conditions.

Various modifications of these methods are, of course, possible, but the full method is recommended wherever practicable, and the second abbreviated method as an alternative. There are several ways in which the experience can save time and increase the probability of finding any pathogenic organisms present. Most important of these is the initial selection of likely colonies, and the appearance of the plate is also of great assistance. The use of large plates or substitutes, on each of which two or more samples can be plated at the same time without mixing, saves a great amount of sterilizing, washing, pouring, etc. The use of plates already warmed on inoculation increases markedly the size of the colonies at the time of examination, and enrichment media for preliminary incubation may increase the chance of detecting the organisms.

sought. But modifications of this kind cannot be discussed in this paper, and must be left to the individual himself to work out.

Copies of this paper with, if desired, the table mounted on card, may be obtained from Dr. Henderson Smith, Lister Institute, Chelsea Gardens, London, S.W.]

The Croonian Lectures

ON

TRYPANOSOMES CAUSING DISEASE IN MAN AND DOMESTIC ANIMALS IN CENTRAL AFRICA.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON,

BY SIR DAVID BRUCE, C.B., F.R.C.P., F.R.S.,

SURGEON-GENERAL, A.M.S.; LATE DIRECTOR OF THE ROYAL SOCIETY'S COMMISSION ON SLEEPING SICKNESS.

LECTURE II.—GLOSSINA MORITANS: TRYPANOSOMA BRUCEI: WILD GAME.

In my first lecture an attempt was made to introduce the subject—the trypanosome diseases of man and domestic animals in Central Africa—by a few introductory remarks on trypanosomes generally, and their classification; and also by a short description of their carriers, the tsetse flies. In this lecture I propose to deal with one of the species of trypanosomes more in detail, describing its morphology, its pathogenic action on various animals, its carrier—the tsetse fly, *Glossina morsitans*—and the reservoir of the virus—the wild game.

TRYPANOSOMA BRUCEI.

The first species of Group A is *Trypanosoma brucei*, and it will be convenient to begin with it, as it is also first chronologically.

That is to say, it was the first pathogenic trypanosome discovered in Central or South Africa, and if you will allow a short autobiographical digression, I shall relate the circumstances leading up to the discovery.

Investigations in 1894-96.

Shortly after I arrived in South Africa in 1894, the late Sir Walter Hely-Hutchinson, the then Governor of Natal and High Commissioner of Zululand, asked me to go to the north of Zululand in order

to report on an outbreak of disease, called nagana, which had broken out among the native cattle.

Travelling at that time was no easy matter, as the railway into Zululand had not been constructed. My wife and I left Pietermaritzburg on October 27th, 1894, going by mule wagon; we arrived seven days later in Eshowe, the capital of Zululand. There an ox wagon was provided, and in it we trekked to Ubombo, a magistracy in the north of Zululand, and in the centre of the affected district. This was reached, after a month's journey, on November 24th, 1894.

Fig. 1 represents the small wattle and daub hut which was provided for living in. The verandah was used at first as the laboratory, but afterwards, with the aid of the natives, a special hut was built. Shortly after we arrived

some of the affected cattle were brought in by the natives. As I had just come from the Army Medical College, Netley, where I had been teaching bacteriology for five years, it was natural that a bacteriological examination of the blood and organs of the infected cattle should first be made. This proved negative.

About this time (1894) the study of the blood had become popular, thanks probably in great measure to Ehrlich, and it was the fashion to make elaborate examinations of the red and white blood corpuscles. To this the discovery of the nagana parasite was probably due. It must be remembered that these parasites are, as a rule, very few and far between in the blood of oxen, and also that our staining methods in those days were rather primitive. After some days of this blood examination it began to be remarked that a curiously-shaped object, different from anything previously found in blood, was sometimes seen lying among the blood corpuscles. At first it was thought to be accidental, due to the carbol-fuchsin stain which was being used, but soon it became evident that it might be a blood parasite. It was then thought that if it was it might be motile in the living state. Fresh preparations of blood were made, and after a long search a rapidly moving object was seen lashing about among the red blood corpuscles. At that time I knew nothing about trypanosomes, and at first thought that the wriggling object might possibly be a small filaria. There were few or no allusions to these haematozoa in medical literature at that time, but when I returned to Natal and had an opportunity of consulting books it soon became evident that the rapidly vibrating body was probably a trypanosome.

But there was as yet no proof that the organisms seen had any causal connexion with the disease. They might well be harmless blood parasites, and they were so scanty in numbers in the blood of the oxen that this might well be so. This led to trying the effect of injecting the blood of nagana cattle into horses and dogs. In these animals the disease is much more acute than in cattle, and the blood swarms with the parasites. In this way it began to be evident that these haematozoa had a causal connexion with the disease.

But at that time there was no suspicion that nagana and tsetse-fly disease were one and the same. It was believed by everybody that the tsetse fly killed horses and cattle by injecting a poison into them. Moreover, these cases of nagana were occurring among native cattle many miles away from the "fly belt." The work was being done on the top of the Lebombo, a range of hills some 2,000 ft. in height, running north and south, about 50 or 60 miles from the coast. Between the

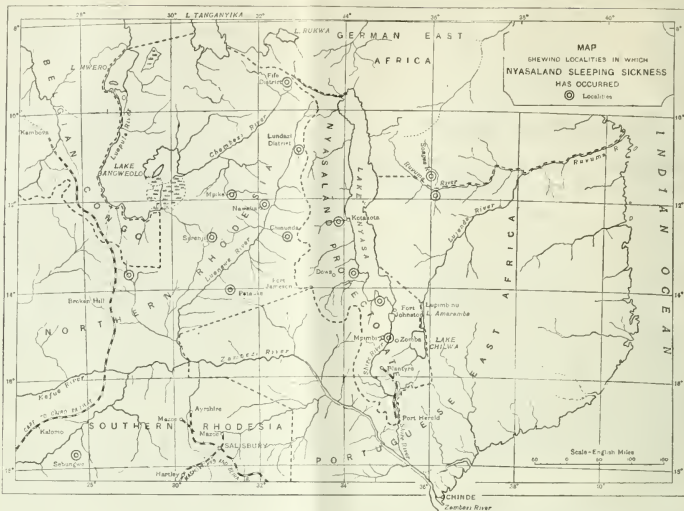

Fig. 1.—Laboratory Hut, Ubombo, Zululand.

hills and the sea there was a low-lying coast plain, some parts of which were infested with tsetse flies. Now, I had read in Livingstone and other African travellers and hunters about the tsetse-fly disease, and was curious to know what it was like. Two young oxen and several dogs were therefore sent down into this "fly belt" and herded among the fly for a fortnight. At the end of this time they were brought back to the hill, and it was a great surprise to find the same parasites in their blood as that found in the nagana oxen. In this way the fact gradually unfolded itself that nagana and the "fly disease" of the travellers and hunters were identical. This, then, was the manner in which the discovery of the part played by trypanosomes in tsetse-fly disease was made.

I arrived at Ubombo on November 24th, 1894, and was

recalled to duty in Natal two months afterwards, on January 26th, 1895. This was done by the military authorities in South Africa, who evidently thought they had not been sufficiently consulted in the matter of this investigation in Zululand. It was a year before the Governor could obtain from England the authority of the Secretary of State to enable me to return along the long road, and take up the broken investigation. I mention this to show that if it had not been for the energy and determination of the Governor of Natal, the Hon. Sir Walter Hely-Hutchinson, this discovery might have been delayed for years. The initiation of the inquiry into the nature of nagana was wholly due to him. In spite of much difficulty and obstruction he persevered in the furtherance of the investigation, and certainly without his active aid nothing at that time would have been accomplished.

The nagana parasite was, in 1896, sent in the living condition to the Royal Society in London, when it was placed in the hands of Messrs. Kortholt, Durham, and Blandford. Their investigation lasted two years, and was published in the *Proceedings of the Royal Society* in 1898. In that year the trypanosome was handed over to Bradford and Plimmer at the Brown Institution, and described and named by them in a paper written in 1899. At this time the nagana parasite found its way into many laboratories and much of the earlier work on trypanosomes was founded upon it.

Nyasaland Sleeping Sickness.

A new and very important page in the history of this haematooxon was turned in February, 1910, when Professor Stephens, of the Liverpool School of Tropical Medicine, while examining in class work a stained specimen of rat's blood, containing what was supposed to be *Trypanosoma gambiense*—that is, the trypanosome of ordinary sleeping sickness—noticed a marked peculiarity in the morphology. This made him doubt whether the micro-organism was really *Trypanosoma gambiense* or not. These parasites were obtained from a man, under treatment in Liverpool, who had been infected in North-East Rhodesia in September, 1909.

Stephens, in collaboration with Fantham, then studied this organism more closely, and came to the conclusion that it

was a different species from *Trypanosoma gambiense*, and called it *Trypanosoma rhodesiense*.

In this way, then, came about the separation of the Nyasaland form of sleeping sickness from the old Congo form, and you will agree with me that the greatest credit is due to these gentlemen for being the first to bring this far-reaching and important discovery to light.

The Commission of 1911.

In 1911 a Commission was sent to Nyasaland by the Colonial Office, under the direction of the Royal Society, to inquire into this and other questions of a like nature.

The Commission came to the same conclusion as Stephens and Fantham—that Nyasaland sleeping sickness and Congo sleeping sickness are separate and distinct diseases. We were, however, soon struck by the fact that although the fly country of Nyasaland extends almost uninterruptedly into the Zululand fly country, no nagana trypanosomes—the common trypanosome of wild game in this part of Africa—could be found. Everywhere, in the wild tsetse flies and in the wild game, it was always *Trypanosoma rhodesiense*, and this in spite of the fact that nagana was reported from Portuguese East Africa, German East Africa, and in fact all round about except Nyasaland. It then began to dawn on the mind of the Commission that perhaps *Trypanosoma rhodesiense* was in reality the old nagana parasite masquerading under a new name. As soon as possible a strain of the latter was procured from Zululand for purposes of comparison, and the Commission, after a good deal of work, came to the conclusion that the nagana parasite and *Trypanosoma rhodesiense* are in reality one and the same. They are identical in morphology, in their action on animals, and in their manner of development in the tsetse fly, and until further proof is brought forward that they are separate species the Commission decided to consider them as identical.

This is a very important matter, because if *Trypanosoma brucei* and *Trypanosoma rhodesiense* are identical, then we may expect to find cases of "Nyasaland sleeping sickness" cropping up in all parts of Africa where nagana occurs—in the Sudan, Uganda, British East Africa, North-Eastern Transvaal, and Zululand.

If, on the other hand, they are separate species, then cases of this disease would only be expected to occur

where *Trypanosoma rhodesiense* is found in addition to nagana. In the past nagana has always been regarded as harmless to man, and certainly no harm seemed to

Fig. 2.—*Trypanosoma brucei*; Zululand, 1913.

come to those who lived or travelled in "fly country." To this it may be answered that it is only within recent years that microscopic examination of the blood of such cases has been made. Many cases of death occurred among hunters and explorers which were usually put down to malaria, but it is possible some of these may have been due to infection by nagana. This is a question

which I will not pursue further; time and further knowledge are wanted before a completely satisfactory answer can be given. But it must be understood that in the following description of *Trypanosoma brucei*, *Trypanosoma rhodesiense* is included.

So much for the history of the nagana parasite. Let us now consider the distribution of this trypanosome in Africa.

Geographical Distribution of Trypanosoma brucei.

The distribution of the nagana parasite, *Trypanosoma brucei*, in Africa, is shown in the map published to illustrate my first lecture (p. 1074). It will be seen that *Trypanosoma brucei* and the disease caused by it—nagana—are widely distributed in Africa, extending from the Sudan to Zululand, and from the Gambia to Zanzibar; in fact, it is the most widely distributed pathogenic trypanosome in Africa.

Fig. 3.—*Trypanosoma brucei*; human strain; Nyasaland.

It may be that in the future strains of nagana in widely separated parts of Africa may be found to differ from each other sufficiently to enable them to be ranked as separate species. As a matter of fact, the nagana of Togoland has lately been named *Trypanosoma togolense*, and that of Uganda *Trypanosoma ugandae*. But until more is known of these varieties I think it better for the sake of simplicity to include them all under one specific term.

In the map here given (p. 6) the districts of Central Africa are shown in which up to the present cases of this disease in man have been discovered.

Morphology of Trypanosoma brucei.

The Zululand strain of *Trypanosoma brucei* we had sent to us in Nyasaland in 1913 from Pretoria, in order to compare it with the Nyasaland human strain—the *Trypanosoma rhodesiense* of Stephens and Fantlam—is shown in Fig. 2. This trypanosome is dimorphic or polymorphic. This merely means that between the shorter and longer forms a greater diversity of shape is found than in the

species belonging to the other groups. The short forms are broad and stumpy in appearance, and have no free flagellum, whereas the long are much more slender in appearance, and have a well-marked free flagellum.

In the living and unstained preparations this dimorphic character can be readily made out, and the parasites are seen to be actively motile, although they do not move far from one place, they have little or no power of translation. The long and slender are very similar in shape and appearance to *Trypanosoma gambiense*, but the short forms have often broader and blunter ends.

In well stained specimens the protoplasm of many of the trypanosomes shows granules, especially in the anterior portion of the cell. The nucleus is oval in the long and slender, and round or oval in the short and stumpy. One peculiarity about the nucleus of this species is that it is frequently placed far back in the body of the organism. This peculiarity is only found in the short forms, never in the long. The percentage of these so-called posterior nuclear forms is often large—even as high as 50 per cent. The micronucleus is small and round, and situated on an average 2 microns from the posterior extremity in the long and slender forms and 1.4 microns in the short and stumpy. The undulating membrane is well developed and thrown into bold folds and undulations.

The flagellum in the long and slender averages 5.8 microns (maximum 11, minimum 2). There is no free flagellum in the short and stumpy forms.

From the drawings (Figs. 2, 3, 4, and 5) it is abundantly evident that the *Trypanosoma brucei* of Zululand 1894 and 1913, of Nyasaland, and of Uganda are all identical in morphology. I would especially call attention to the Zululand 1894 drawings. These are taken from the original preparations made in Zululand in that year. An attempt has lately been made to make out that the original nagana parasite was a monomorphic species. These drawings, made from the old preparations, absolutely disprove this.

One useful point in the morphology of these strains has not yet been mentioned—I mean the length. From Table I (p. 8), which gives the length of various strains of this species, it will be seen that the measurements of trypanosomes, taken from widely separated parts of Africa, come out fairly regularly. The human strain is the longest, having an average length of 24.2 microns, whereas the Zululand 1913 strain is the shortest—21.0 microns. It is rather remarkable that the wild game and the wild *Glossina morsitans* strains should have resulted in exactly the same measurements.

The breadth of the long and slender averages 2.76 microns, the intermediate 3.25, and the short and stumpy 3.53.

SUSCEPTIBILITY OF ANIMALS TO TRYPANOSOMA BRUCEI.

Having described the morphology of this species and having shown that the various strains found in Uganda, Nyasaland, and Zululand are absolutely identical in appearance, I will pass on to the second part the pathogenic action of this trypanosome on various animals.

Many mammals, including man, horses, mules, donkeys, oxen, goats, sheep, monkeys, dogs, and many others, are attacked by this parasite. Birds and the cold-blooded vertebrates, such as crocodiles, lizards, and frogs, are quite unaffected by it.

A single trypanosome seems to be just as efficacious in setting up infection as a million, and it does not seem to matter whether the kind of trypanosome injected is one of the long and slender forms or one of the short and stumpy.

As I have mentioned already, passage through one species of animal usually heightens its virulence towards that animal. At the Army Medical College, when the nagana trypanosome begins to kill rats in two or three days, it is usual to pass it a few times through the rabbit, which has the effect of materially lowering its virulence towards the rat, and making its passing through the rat less irksome.

In regard to modes of infection, it is extremely easy to infect an animal through the skin; it is usually sufficient to dip a needle in infected blood, and merely to scratch the skin of the experimental animals. There is evidence also that infection may take place through the mucous membrane; dogs are sometimes infected in this way through eating infected meat, but it is possible that in these cases there is some scratch or wound of the mouth.

Experiments have been published to show that infection can even take place through unbroken skin, but this must be a rare accident, else why have we escaped infection who have made hundreds of *post-mortem* examinations on cases of sleeping sickness in man and other animals.

In nagana I think we are safe if we lay down as a rule, that the infection is conveyed in nature, in the vast majority of instances, by the bite of the tsetse fly.

Table II gives the average duration in days of the

disease caused by various strains of this trypanosome, also the number of animals employed. It will be seen that this disease runs a fairly rapid course in man, killing him,

as a rule, in three or four months. This, as we shall see, is in marked contrast to the much more chronic course of the Congo sleeping sickness caused by *Trypanosoma gambiense*. In horses, donkeys, and mules, nagana runs its course on an average in thirty-eight days. No opportunity of studying the disease in horses occurred in Uganda or Nyasaland, as horses are very seldom seen in these countries. In the ox the disease is chronic and a certain proportion recover. In the other animals it may be said broadly that the disease runs a fairly similar course, and that little or no difference in the virulence is seen between the different strains.

Nagana is, as a rule, a fatal disease, and this is shown in Table III, from which it will be seen that no recoveries

TABLE III.—Percentage of Recoveries in various Animals infected with *Trypanosoma brucei*.

have been reported up to the present in man. In oxen 80 and 83 per cent. of recoveries are noted. The number of animals employed, however, is so small that these figures are not reliable. With the exception of the oxen almost all the other animals die. Out of 318 employed in these experiments only 3 recovered.

From its action on animals, then, just as from its morphology, it is apparent that *Trypanosoma brucei* as it occurs in Zululand differs in no way from the Nyasaland strain, called by Stephens and Fantham *Trypanosoma rhodesiense*. It is true that cases in man have not been reported from Zululand, nor from the Sudan, Uganda, or British East Africa, but I expect this hiatus will be filled up within the next few years.

It is true that Dr. Taute tried to infect himself with *Trypanosoma brucei* got from the wild game in Portuguese East Africa, and is of opinion that his failure proves that the trypanosome of man and of wild game are different species, but even this does not disturb my belief that the nagana parasite and that causing disease in man in Nyasaland are one and the same. It is of course possible that there may exist in Nyasaland a separate species of trypanosome confined to man and exactly identical in morphology and action on animals with the trypanosome found in the surrounding wild game and the wild fly; it may be possible, I say, but it is highly improbable.

THE CARRIER OF TRYPANOSOMA BRUCEI.

Having described the morphology of the *Trypanosoma brucei*, and its action on animals, I now come to the question how this protozoon is conveyed from the sick to the healthy. In Zululand, when it became apparent that nagana and tsetse fly disease were identical, experiments were made to find out if the fly was the carrier of the disease, or merely a concomitant of the low-lying unhealthy country. It was commonly believed by the Zulus that their cattle contracted the disease by drinking out of the same waterholes as the wild game. Healthy horses, therefore, were sent for a few hours into the "fly country," muzzled in such a way that they could neither eat nor drink while there, but they contracted the disease. On the other hand, bundles of grass and supplies of water brought from the heart of the "fly country," and fed to healthy horses on the top of the hill, failed to infect; but tsetse flies brought up in cages from the low country and placed straightway on healthy animals were found to give

rise to the disease. By these and other experiments it was proved beyond question that the tsetse flies, *Glossina morsitans* and *pallidipes*, were carriers of nagana, and one of the first questions which presents itself is, What proportion of the wild tsetse flies found under natural conditions are infected?

THE INFECTIVITY OF WILD TSETSE FLIES (*GLOSSINA MORSITANS*).

When in the "fly country," and being bitten by tsetse flies, it is interesting to know how many times one may be bitten without encountering an infected fly.

Methods Employed.

The method employed in Nyasaland in studying the infectivity of the wild flies was as follows: Native boys were employed in catching the flies in the low country, and these were brought up the same day to the camp in small cages by a native cyclist. Each cage was fed on three healthy animals; the first day on a monkey, the second on a dog, and the third day on a goat. To ensure to some extent that each animal was fed on by every fly, the flies were fed daily for nine days, three times on each animal. It is doubtful, however, whether, even with these precautions, every fly did feed on all three animals.

The number of flies in each cage averaged about sixty, and as each animal was fed on by three different sets of flies, each monkey, dog, and goat ran the gauntlet of some 180 flies. If any animal became infected with *Trypanosoma brucei*, it was reckoned that there was only one infective fly in the batch. There may, of course, have been two or more. The method was not very accurate, but probably near enough for practical purposes.

The result is shown in Table IV, and, as will be seen,

TABLE IV.—Proportion of Tsetse Flies (*Glossina morsitans*) naturally infective with *Trypanosoma brucei*, in Nyasaland.

there were 56 experiments, in which 10,081 tsetse flies (*Glossina morsitans*) were employed. In the 56 experiments *Trypanosoma brucei* was found 20 times (35.7 per cent.); 9 monkeys, 14 dogs, and 11 goats were infected. This gives a proportion of 1 in 500 or 2 flies per 1,000 caught in the sleeping-sickness area, Nyasaland, infective with nagana. This is only allowing one infective fly to each series of flies fed on the experimental animals, and is therefore the irreducible minimum.

Months and Seasons.

From these experiments it is also seen that these infective flies occur all the year round, and are just as numerous during one season as another.

To conclude, then, in regard to the natural infectivity of *Glossina morsitans* with this species of trypanosoma, it may be said that if a man is bitten by a tsetse fly in the sleeping sickness area of Nyasaland, it is 500 to 1 against his taking the disease, since only 1 in every 500 flies is infective with the specific parasite.

Cycle of Development.

I ought now to describe the cycle of development of the nagana parasite in the tsetse fly, but as this development is identically the same as that of *Trypanosoma gambiense* in *Glossina palpalis*, and as the cycle was first worked out by us with the latter, it will be better to defer the description of this cyclical development until we come to discuss *Trypanosoma gambiense*. I shall therefore now pass on to consider the reservoir in order to answer the question, Whence does the tsetse fly obtain the nagana virus?

The Reservoir.

In Zululand in 1896, when it became certain that nagana or tsetse fly disease was conveyed to the animals by the fly, the question arose as to where the fly obtained the virus. In the Zululand fly country there were no natives, since cattle could not live there, and with the Zulus cattle stand for everything. There were therefore no horses, oxen, goats, or dogs suffering from nagana from which the fly could obtain the parasite.

But the place being a Government Reserve, was swarming with wild animals on which it was evident the fly fed, if one of these animals was shot in the "fly country," many tsetses would often be found still feeding on the dead body. This led to the examination of the buffalo, koodoo, wildebeeste, and other wild game found in the district. As soon as an animal was killed a quantity of its blood was sent off, by a native runner, to the top of the hill, where it was injected into a healthy dog. Smears were also made and examined microscopically. In this way it was proved both by animal experimentation and direct microscopical examination that the blood of many of these wild animals contained the same trypanosoma as that which gave rise to nagana. The mystery of the reservoir was cleared up.

Since 1896 further observations have been made regarding the presence of these parasites in the blood of wild game in different parts of Africa—on the West Coast, in Uganda, and notably in North-Eastern Rhodesia by Kinghorn and Yorke. In Nyasaland we also examined the wild game with some care, and I shall now proceed to describe the results.

Trypanosomes found in the Blood of Wild Animals Living in the Sleeping Sickness Area, Nyasaland.

The method of examining the blood of wild game was much the same as that used in Zululand. When an animal was shot a small quantity of its blood was taken in a sterilized bottle containing potassium citrate to prevent coagulation. Smear preparations were made at the same time. As the animals were often shot thirty or forty miles away from the camp, a motor cycle was used to get the blood up the hill as quickly as possible. When the blood arrived at the laboratory it was at once injected into a goat, a monkey, and a dog. In this way 180 specimens of blood of wild game living in the fly area were examined, and 57 were found to harbour pathogenic trypanosomes (32 per cent.).

This is, however, probably much below the actual percentage. A wild animal is only examined once, and that often under unfavourable conditions. If it were possible to examine the same animal several times it is probable that many more would be found infected. The parasites come and go in the blood, one day they may be present the next day absent. The big game live in the "fly country" among swarms of infected flies and are constantly liable to infection and reinfection.

Table V (p. 10) records the number of times *Trypanosoma brucei* was found among the 180 wild animals examined, and the species of game which harboured it. It will be seen that fourteen animals among the 180 harboured the nagana parasite (7.8 per cent.), and that the waterbuck, hartebeeste, reedbuck, and duiker seem to be the most dangerous neighbours to man, for 23 per cent. of the waterbuck, 14 per cent. of the hartebeestes, 16 per cent. of the reedbuck, and 14 per cent. of the duiker had *Trypanosoma brucei* in their blood. If, then, my contention that this parasite found in the wild game is the cause of Nyasaland sleeping sickness be proved to be true, then it is abundantly obvious how dangerous these wild animals are to man; and it must be borne in mind that in this Nyasaland fly area *Trypanosoma brucei* is only one of the pathogenic species of trypanosome found in the wild game.

TABLE V.—Showing the Number of Times *Trypanosoma brucei* was found among the 180 Wild Animals Examined and the Species of Game which Harboured it.

Species of Animal.	Number Examined.	Number Infected with <i>T. brucei</i> .	Species of Animal.	Number Examined.	Number Infected with <i>T. brucei</i> .
Eland ...	10	0	Deer ...	7	1
Seble ...	5	0	Buffalo ...	9	0
Waterbuck	13	3	Lion ...	1	0
Koodoo ...	3	0	Hyena ...	3	0
Bushbuck	10	0	Elephant	2	0
Hartebeeste	35	5	Warthog	33	1
Roadbuck	19	3	Wild cat	3	0
Oribi ...	26	1	Porcupine	1	0

Three other species pathogenic to the domestic animals are also found—*Trypanosoma pecorum*, *Trypanosoma siniae*, and *Trypanosoma caprac*—*Trypanosoma pecorum* in 14.4 per cent.; *Trypanosoma siniae* in 1.7 per cent.; and *Trypanosoma caprac* in 11.1 per cent. of the wild game examined; therefore I do not think I was using too strong language when I wrote in a report to the Royal Society:

It is self-evident that these wild animals should not be allowed to live in "fly country," where they constitute a standing danger to the native inhabitants and the domestic animals. It would be as reasonable to allow mad dogs to live and be protected by law in our English towns and villages. Not only should all game laws restricting their destruction in "fly country" be removed, but active measures should be taken for their early and complete blotting out.

It must be strictly borne in mind that this only refers to wild animals living in "fly" areas. No pathogenic trypanosomes have up to the present been found by the Commission in the blood of animals living in fly-free areas.

H. MEADE, F.R.C.S.I.,

ASSISTANT SURGEON TO ST. VINCENT'S HOSPITAL, DUBLIN.

WHILE acting as consulting and operating surgeons to the French army during the last six months, we had many opportunities of seeing cases of nerve injury caused by modern weapons, and we performed several operations for their relief. In only two cases, however, were the patients under our observation for a sufficient length of time to allow us to judge the results of these operations. The following is a short account of these two cases:

CASE I.—Bullet Wound of Ulnar Nerve.

A. P., a soldier wounded at the Marne by a rifle bullet, September 7th, 1914, was seen by us in December. He then had two unhealed wounds on the front and back of the inner side of the left forearm, about 2 in. below the elbow; the X rays showed a united fracture of the ulna with several sequestra and small pieces of metal, probably pieces of the mantle of the bullet. There was complete loss of function of the ulnar nerve, paralysis of the muscles with claw-contraction of the three inner fingers, and loss of sensation of the ulnar side of the hand and inner two fingers back and front.

An operation was performed on December 18th for the removal of the sequestra and pieces of metal, after which the wounds healed rapidly.

On January 19th, 1915, a vertical incision was made over the course of the ulnar nerve for about 4 in., the nerve was exposed above and below the seat of injury, and then traced through a dense mass of fibrous tissue. There was continuity between the two segments of the nerve, but in the region of the wound there was a large, somewhat oval mass of tissue, almost as hard as cartilage, and the upper part of the distal segment was greatly wasted. It was necessary to remove nearly 1 in. of tissue before nerve fibres could be found on the cut surface of either end. In spite of freeing the proximal end of the nerve up to the internal condyle and the distal end for several inches, and flexing the wrist and fingers, it was found impossible to bring the cut ends into contact, and they were finally sutured together, leaving a gap of about 1 centimetre between them.

Two relaxation sutures of No. 1 silk were passed at some distance from the cut ends, which were then sutured with No. 1 and No. 0 silk; although there were over a dozen strands of silk bridging the gap between the two ends of the nerve.

The operation wound healed normally, and the flexion of the wrist and fingers was gradually reduced after the first fortnight; massage, movements, and electrical stimulation (both faradic and galvanic) were then started and continued until the patient's discharge from the hospital early in May.

Within two months of the operation there was good voluntary power of contraction of the flexor carpi ulnaris, and on rolling the ulnar nerve under the finger between the internal condyle and olecranon a tingling sensation was felt down to the base of the little finger; before operation this sensation had only been felt down to the level of the wound. From this time on improvement was continuous, and on his discharge from hospital, about 3½ months after the operation, motor power had returned in the flexor carpi ulnaris, probably in the flexor profundus digitorum (shown by his better power of flexion of the phalanges), there was commencing response of the intrinsic muscles of the hand to faradic stimulation over the course of the ulnar nerve, and sensation had returned completely with the exception of the little finger, though tingling could be felt to the tip of this finger on stimulation of the nerve above the point of suture. The characteristic deformity of the hand had almost entirely disappeared.

Between the time of injury and the operation the patient stated that there had been no change in the condition of his forearm and hand, and during the month he was under our observation between the two operations there was no change, except a slight increase in the deformity, although he was daily receiving massage and electrical treatment.

CASE II.—Bullet Wound of Musculo-spiral Nerve.

B. D., a soldier, was first seen by us on December 28th, 1914. He had been wounded by a rifle bullet on the outside of the right arm above the elbow, about 4 in. from the elbow. He was treated at a hospital close to the front. While there he had, about five days after he was wounded, a severe hæmorrhage, for which an operation was performed to stop the bleeding, and at the same time the musculo-spiral nerve was sutured. Whether the nerve had been divided by the bullet or was cut during the operation we were never able to discover.

When the patient came under our care he had a large oblique incision, nearly healed, running upwards, outwards, and backwards for about 4 in. from the outer part of the front of the elbow. There was complete loss of power of the extensor muscles of the wrist and fingers, and loss of sensation over the area of distribution of the radial nerve. He was treated by massage, movements, and electricity (both faradic and galvanic). At the end of two months sensation was commencing to return, and at the end of April he was transferred to a special hospital for mechanotherapy. Sensation was then normal, and he was able to raise the hand when prone from the fully flexed position to the straight position. Power of extension of the fingers was almost, if not quite, non-existent.

The improvement in this case was not so marked as in the other, but this may be explained probably by the fact that the patient did not seem to take so great an interest in his own treatment and cure, and therefore made less voluntary effort to recover the lost movements.

In only one case did we have an opportunity of suturing a nerve at an early stage after injury.

CASE III.—Bullet Wound of Ulnar Nerve.

Soldier, wounded March 25th, 1915, by a rifle bullet which passed through the inner side of the right forearm just below the middle, fracturing the ulna. On admission to hospital, three days later, there was loss of sensation of the little finger, back and front, with paralysis of the intrinsic muscles of the hand supplied by the ulnar nerve. As the loss of sensation was only partial we hoped that the nerve was only slightly injured and that recovery would be rapid, and massage and electrical treatment were commenced after a few days.

At the end of three weeks the condition was in no way improved and well-marked contraction had commenced in the three inner fingers. On April 14th, therefore, an incision was made and the nerve exposed in the region of the wound, which had healed. It was found that about three-quarters of the nerve trunk had been divided and that the cut ends were considerably separated and turned backwards into the muscles. There was a great deal of soft granulation tissue surrounding the injured portion of the nerve, which would in time have formed the very dense, hard, fibrous tissue we found in all the cases operated on at a late period after injury. The cut ends were freed and sutured together with silk without interfering with the undivided portion of the nerve. When this patient was last seen, about six weeks after operation, there was no appreciable change in his condition.

In another case only a portion of the nerve was divided, but it did not come under our care till several months after the injury.

CASE IV.—Bullet Wound of External Popliteal Nerve.

A soldier in the front line was wounded in August, 1914, by a bullet which entered just behind the border of the biceps tendon and fractured the femur. There was some loss of power in the

muscles of the anterior tibio-fibular compartment with marked foot-drop, the paralysis was not absolutely complete, and sensation, though dulled, was not wholly lost over the region supplied by the musculo-cutaneous and anterior tibial nerves.

The condition of this patient's leg had remained stationary for several months in spite of massage and electrical treatment. On February 25th, 1915, an incision was made exposing the external popliteal nerve behind the knee. There was a large thickening of the nerve at the level of the joint, and just above this a branch nearly half the size of the nerve apparently passed into the biceps tendon. This proved to be a divided portion of the nerve firmly adherent to the tendon. It was separated and the trunk of the nerve freed for about 2 in. from the abundant fibrous tissue which was present; the nerve was then split vertically in the thickened portion, and as what appeared to be nerve fibres were found, the branch was implanted in the split and the nerve sutured together over it. This case was transferred to another hospital for special treatment a few weeks after operation, before there was time for the appearance of any change in the condition.

In two cases of division of the musculo-spiral nerve one was divided just above the bend of the elbow by a rifle bullet, and in the other the nerve was divided in the middle of the arm and the case was complicated by a comminuted fracture of the humerus. In another case the ulnar nerve was divided by a bullet close to the junction of the upper and middle thirds of the forearm. These three cases were not seen by us until several months after the receipt of the injury and were transferred to other hospitals too soon after operation to allow of any improvement taking place before we lost sight of them.

We saw a few cases with wounds in the neighbourhood of large nerves, which showed only temporary signs of loss of function; in these the loss of sensation was only partial and the paralysis was not absolute, and the symptoms cleared up within a fortnight. These cases may be spoken of as nerve concussion, the nerve not being materially injured, its function being interfered with or lost for a short period.

CONCLUSIONS.

From our experience of these cases we have drawn the following conclusions concerning nerve injuries caused by modern missiles:

1. The function of a nerve may be interrupted without material injury, in which case the loss of function is only partial and returns early, probably always within a fortnight or three weeks.
2. When a nerve is partially or wholly divided loss of function is marked and permanent, and may even tend to increase. In these cases it is useless to expect spontaneous regeneration owing to the distortion and separation of the cut ends and the great development of dense fibrous tissue which appears to follow in all cases.
3. When a nerve is divided, the sooner an operation for its suture is performed the easier it is and the greater the likelihood of an early cure. In cases, however, where the wound is septic, it may be advisable to allow time for the wound to heal.
4. Even when nothing has been done for several months, there is still a chance of a successful result if late suturing is undertaken, so that no case need be looked upon as necessarily hopeless.

LOCALIZATION OF FOREIGN BODIES BY X RAYS.

By J. II. SHANBY, CAPTAIN R.A.M.C.(T.),

3RD WESTERN GENERAL HOSPITAL, CARDIFF; LECTURER IN PHYSICS, UNIVERSITY COLLEGE, CARDIFF.

THE method of localization which I use in this hospital (described in a paper to be published by the Röntgen Society) may be of interest to your readers. It is simple and accurate, and abolishes measurement and calculation.

If, during the two exposures of an ordinary localization, an opaque body lies at the same depth from the plate as the foreign body whose position is required, then the shadow displacement of this control body is of course equal to that of the foreign body. As the depth of the foreign body is initially unknown it is necessary for the control body to exist at all possible depths, and for its various points to be recognizable from their shadows. I fulfil these conditions by using as the control a sort of miniature ladder with lead wire rungs, parallel and equi-

distant, but oblique, as shown in Fig. 1. The step distance is 1 cm., and the length of each rung 3 or 4 cm. The ladder is set up with its plane perpendicular to the photographic plate and its end AB as close as may be to the plate. Its position is chosen so that the two shadows of the rungs thrown on the plate in the two exposures of the localization lie one on each side of the base of the ladder, as in Fig. 2, a tracing from a negative. Thus any two corresponding points in the pattern are immediately referable to the point on the ladder whose shadows they are—for example, the points marked by dots and referred to as A_1 and A_2 are the shadows of a point half-way along the third rung, that is, of a point 2.5 cm. from the plate. Now the distance $A_1 A_2$ is equal to the distance $X_1 X_2$, between corresponding points of the shadows of the foreign body, which is therefore also 2.5 cm. from the plate.

Fig. 1.

The procedure, then, to determine the depth of the foreign body, is to set off the distance $X_1 X_2$ with dividers, transfer the latter to the ladder pattern, and find there the points $A_1 A_2$ showing the same displacement. Of course, care must be taken that $A_1 A_2$ is parallel to $X_1 X_2$, and that A_1 and A_2 are on the two shadows of the same rung—that is, are shadows of the same point on the ladder. The distance (if any) from the plate to a fuse-wire cross on the skin can be similarly found and deducted from the previous measure to give the net depth of foreign body below the skin. Usually, as in Fig. 2, the plate is close to the skin, and there is no deduction to be made.

Fig. 2.

If the fuse-wire cross has not been set exactly over the position of the foreign body by one of the usual screen methods, the point on the plate which is exactly over the foreign body can be found by Barrell's method, using the vertical lines through the two ends of the lead rungs instead of two vertical cylinders. That is to say, the lines CB and ED are produced; they meet at a point on the plate vertically over the focal spot of the target in the first position of the bulb. The lines FB and HG similarly intersect in the corresponding point for the second position

of the bulb. The two points thus found are joined respectively to X_1 and X_2 , and the intersection of these last lines is vertically over the point of the foreign body which casts the shadows X_1 and X_2 .

The ladder can be affixed immediately to a plate facing in any direction, and can be used with any type of apparatus. The procedure is quick and simple, and could be used at the bedside in case of need. The distance from plate to anticathode and the distance the bulb is moved are not required; the shadow displacement has not to be measured, but merely set off with compasses and matched, a simpler and more accurate proceeding. The estimation of depth can be easily made to a millimetre without any measurement whatever, and the one plate carries the complete data of localization of all foreign bodies whose shadows fall upon it. The instrument is made by Messrs. Newton and Wright, 72, Wigmore Street, W.

NOTE ON THE TREATMENT OF THE SYMPTOMS ARISING FROM INHALATION OF IRRITANT GASES AND VAPOURS.

By W. L. SYMES, M.R.C.S.,

ASSISTANT DIRECTOR OF THE PHYSIOLOGICAL LABORATORY OF THE UNIVERSITY OF LONDON.

(From the Physiological Laboratory of the University of London, South Kensington.)

INTRODUCTION AND MODE OF EXPERIMENT.

THE following observations deal with the early stages of the bronchial and bronchiolar obstruction set up by inhalation of irritant gases.

They represent a preliminary account of unfinished work, and are given so early partly on account of immediate call for treatment of the condition in question and partly on account of the striking failure of treatment *via* the blood stream.

The animals employed were cats, initially anaesthetized by ether, then pithed through the foramen magnum, and supplied with air by a method of artificial respiration, previously devised by Golla and Symes, which has already been described in full detail.

The principle of the method is as follows: The lungs are made to dilate rhythmically by rhythmically diminishing the pressure on their outer surface by means of a pump, the piston of which produces the same pressure changes in the pleural cavity as are produced normally by the diaphragm. As in spontaneous breathing also, the lungs are emptied by their elastic recoil.

The condition of the airway (bronchioles) was recorded by a sensitive membrane manometer connected with the trachea. This shows, as in spontaneous breathing, negative pressure (downstroke) during inspiration and positive pressure (upstroke) during expiration.

Obstruction of the airway is indicated by diminished amplitude of the respiratory tracing, whilst conversely augmented amplitude of the tracing shows relief of the obstruction.

The "gas" (bromine vapour) was administered through a tracheal cannula. Its usual effect was rapid obstruction of the airway. Less commonly the obstruction came on gradually, several minutes elapsing before the tracing was reduced to one-half of its initial amplitude. In some cases profuse bronchorrhoea appeared in the course of an hour.

In all cases the relief afforded by intravenous injection of broncho-dilator drugs has been little or nothing, whilst the same (or similar) drugs administered by inhalation have consistently given relief, which, though not always great, has at times been considerable. The relief shown in the figure is moderate in degree and of short duration.

The drugs so far tested are the following:

Amyl Nitrite.

Injected intravenously, in suspension in normal saline, or subcutaneously without dilution, this body has given no relief. Inhaled, it has at times produced slight and temporary dilatation of the airway, but has more than once appeared to increase bronchorrhoea.

Atropine.

Atropine sulphate, in intravenous doses ranging from 0.5 mg. to 10.0 mg., has been without effect on the airway.

Adrenalin.

Intravenous administration of 0.1 mg. of adrenalin chloride has, on one occasion, afforded slight and temporary relief, but in the majority of cases has been without benefit.

Stramonium.

Intravenous injection of an infusion of stramonium leaf was without effect. Inhalation of the fumes from the smouldering powdered leaf, on the other hand, has consistently relieved the obstruction. The degree of relief depends, obviously, on the amount of fume inhaled. With respiration diminished by pronounced obstruction the relief is consequently small; but when the force of (artificial) respiration is augmented, and pulmonary ventilation thereby increased, stramonium fumes produce considerable and lasting dilatation of the airway.

The upper tracing shows bronchial spasm produced by bromine vapour, the middle tracing its relief by stramonium fumes, and the last gives the time 15 minutes.

Lobelia, Tobacco, Opium.

Pulv. lobeliae eo. (Martindale), a powder containing a little lobelia in addition to stramonium, has also worked well, though, up to the present, it has not seemed more efficacious than the stramonium alone.

Fumes from smouldering tobacco (or snuff) have also dilated the airway.

Opium fumes have been found to give relief. The dilatation has not been great but has, once, proved relatively lasting.

Chloroform.

Chloroform vapour has on one occasion distinctly increased the obstruction. On no occasion has it appeared to give relief.

DISCUSSION OF RESULTS.

The failure of atropine injections to relieve the respiratory obstruction was surprisingly complete. In view of this failure and of the equal non-success of stramonium infusion and of adrenalin, contrasted with the efficacy of stramonium and other fumes, it appears that the bronchial circulation was largely, if not completely, arrested by the bromine vapour, and that relief was only afforded by direct contact of the remedies with the bronchial (and bronchiolar) mucosa. The efficacy of the stramonium fumes indicates further that muscular spasm is a factor in the obstruction.

Of the drugs that have been tried stramonium has, so far, been the most successful. Mixed with a little nitre it is readily ignited and smoulders freely. The fumes should, for obvious reasons, be inhaled through the nose rather than through the mouth. Overdosage from absorption of the active principles—atropine, hyoscyamine, hyosine—through the pulmonary alveoli will be shown so clearly by thirst, by dilatation of the pupil, and by acceleration of the pulse, that dangerous dosage should be readily avoidable. Moreover, it may be anticipated that early and

repeated administration will diminish the distressing bronchorrhoea of the later stages of gas poisoning.

Lobelia, tobacco, and perhaps opium, may fairly be tried, either alone or with stramonium. The objections to the use of opium fumes are obvious and serious. But in the absence of relief from other sources, and given adequate ventilation of the ward, these objections do not suffice to debar a careful trial.

For the reasons given above both chloroform and amyl nitrite appear to be objectionable, and their use, if adopted, should be carefully watched.

Conclusions.

The respiratory obstruction set up by inhalation of irritant gas is relieved by inhalation of stramonium and other fumes.

Treatment through the blood stream, either *via* the mouth or by injection, appears to be inefficacious.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TECHNIQUE OF ANALGESIA IN INTRANASAL SURGERY.

AN article under the above heading appears in the *JOURNAL* for June 26th, and in it the use of cocaine and adrenalin for intranasal anaesthesia is deprecated, and a complicated and lengthy technique advised. Now, for the past five years I have operated, both in private and in hospital, upon the turbinal bones and nasal septum, under cocaine-adrenalin anaesthesia, without a single bad result that could in any way be ascribed to the anaesthetic, and, what is more, without any of the symptoms, such as marked excitability, difficulty of breathing, etc., that Dr. Wilson describes.

My technique is simple: The nose is packed with ribbon gauze soaked in a mixture of 20 per cent. cocaine and adrenalin—equal parts of each—half an hour before the time fixed for the operation. The patient walks to the operating theatre, the packing is removed, the operation is performed, and, after the nose has been plugged with Simpson's sponge splints and half an ounce of brandy and 10 grains of aspirin have been administered, the patient returns to bed. In this way I have operated on some 75 private patients, including some members of our own profession, and some 150 hospital cases, and in no single case have I ever seen any after-sickness or has any case had to have stimulants administered. In hospital practice the patients remain in until the plugs are removed on the following day, and in private I arrange for the operation on a Friday, and they return to their work on the following Monday or Tuesday.

Some twelve months ago I was persuaded to try quinine-urea anaesthesia in these cases, and my results were most unsatisfactory, as not only is the sloughing more, but it leads in some cases to post-operative haemorrhage. In conversation with an American nasal surgeon recently he told me that for these reasons urea-quinin anaesthesia was dying out in the States.

My apology for taking up so much of your space is that it seemed that my results were so much at variance with Dr. Wilson's that they would be of interest. With my technique the whole operation, from time of packing to the return to bed, does not occupy more than an hour, whereas with Dr. Wilson's an hour and twenty-five minutes elapses before the operation commences.

I may add that my technique is not in any way original, but is the one in ordinary use at the Eye and Ear Infirmary here.

Liverpool.

ADAIR DIGHTON, F.R.C.S.

Paris Médical states that a medical officer who has recently returned from the front tells the following story. A wounded German was taken to an ambulance which was soon afterwards shelled. The French staff was naturally indignant at this violation of the laws of civilized warfare, but the comment of the "cultured" Teuton was: "It is quite natural. Why didn't you remove your Red Cross flag?"

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

BOMBAY BRANCH.

A CLINICAL meeting of the Branch was held on March 26th, Lieutenant-Colonel ASHTON STREET, I.M.S., in the chair. The CHAIRMAN showed: (1) A specimen of *Ruptured spleen* successfully removed by him; (2) a case of *Molluscum fibrosum* where he had removed a small and a large tumour; (3) a specimen of *Sarcoma of the testicles*; (4) a case of *Sarcoma of the eye*. Miss A. M. BENSON, M.D. showed a boy, aged about 9, who had *Superficial nodules on the shins, elbows, and on the back of the forearms*, of two years' duration. Dr. SORAE K. ENGINEER showed: (1) A *Cluster of bronchi and their branches with the trachea of a fowl*. They had been palmed off by a quack as the mass of haemorrhoids removed by application of specific medicines. (2) A case in which the *Intramuscular injection of salvarsan* (Italian preparation) worked satisfactorily. (3) Various photographs of *Tuberculous lesions*. Dr. S. B. NAYAK showed skiagrams, one of which indicated *Very early phthisis pulmonalis* by the peculiar malposition of the cardiac shadow, and in this case no physical signs were then made out. Dr. F. D. BANA showed a simple *Electroscope for nasal and oral work* improvised by him. Dr. A. POWELL showed specimens of *Aortic aneurysm and brain tumour*. Professor Y. G. NADGIR took the members round his anatomical department and exhibited some excellent specimens dissected by him.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

At a meeting on June 17th, Dr. J. J. PRINGLE, President, in the chair, Dr. E. GRAHAM LITTLE showed (1) a middle-aged lady suffering from *Mycosis fungoides*, the initial phase of which had been diagnosed as psoriasis, and for which x-rays had been applied over almost the entire body surface. The tumour formation followed the x-ray treatment, and Dr. Little thought there was causal connexion between the two conditions. The PRESIDENT, Dr. SIBLEY, Dr. PERNET, Dr. DOLE, Dr. SEQUEIRA, and Dr. ADAMSON considered the development of tumours to be fortuitous, and urged continuance of the x-ray treatment as being the only method of controlling the tumour growth. (2) A boy, aged 12, who was in a condition of profound cachexia accompanied by excessive diarrhoea and a very extensive *Pigmentary follicular eruption over the trunk and limbs*. Dr. LITTLE suggested the diagnosis of pellagra. Dr. PARKES WEBER thought Addison's disease more likely. Mr. STEEBING showed, for Mr. LAMING EVANS, a case of *Acute linear atrophy of the skin in the lumbar region*. The patient exhibited no toxicæmic manifestations, but had been inoculated against typhoid last October. The case was discussed by the PRESIDENT, and Drs. ADAMSON, PARKES WEBER, ABRAHAM, GRAHAM LITTLE, and WALSH. Dr. STEEBING also showed a case of *Hydroa aestivale* of mild type in a girl, aged 14, the typical seasonal variations of which were unusually marked. The case was discussed by Dr. PARKES WEBER, Dr. ADAMSON, Dr. PERNET, and the PRESIDENT. Dr. PHINEAS ABRAHAM brought forward a case of *Oriental sores* in a young man dating since February, 1915, and contracted in the Persian Gulf, where he had suffered much from mosquito bites. The sores had been successfully treated by scraping and pure carbolic acid. Sections from the case exhibited characteristic Leishman-Donovan bodies. The case was discussed by Mr. T. P. BEDDOES and Dr. PERNET. Dr. J. A. NIXON (Bristol) exhibited a man, aged 23, with deep *Universal pigmentation of the skin and mucous membrane of the mouth*, of six years' duration, accompanied at its onset by severe dyspepsia and neurasthenia. The pigment was always increased by exposure to the sunlight. Dr. NIXON thought there probably had been some lesion involving the supra-

renals or solar plexus. Dr. SEQUEIRA referred to a case presenting similar pigmentation who had all the signs and symptoms of pernicious anaemia; great improvement, however, took place, even as regards the pigmentation, under arsenical treatment. Dr. PARKES WEBER supported Dr. Nixon's view that the patient had had Addison's disease, and the PRESIDENT shared this opinion, having had a similar case under his observation. Drs. ABRAHAM, WALSH and SIBLEY also spoke. Dr. FERNET showed (1) a typical case of *Morphoeic sclerodermia* on the thigh of a girl, aged 14. (2) An *Extra-genital primary syphilitic sore on the wrist* of a boy, aged 15, with a characteristic, generalized, syphilitic eruption. Dr. PARKES WEBER showed a woman, aged 67, who presented *Blue staining similar to tattoo marks* over the seats of the injections into the arms and front of the chest. She had been an habitual morphinomaniac for forty years, and he attributed the colour of these spots to some iron substance derived from the needle of the hypodermic syringe. There were also a few small cheloids, upon the rarity of which in Europe Dr. Weber commented as compared with their frequency among the Chinese and black races. Dr. E. A. COCKAYNE (introduced by Dr. PARKES WEBER) exhibited a child with *Congenital sclerodermia and sclerodactylia*. The child was hydrocephalic, but the Wassermann reaction was negative. Dr. WEBER and Dr. ADAMSON confirmed the exhibitor's diagnosis of true congenital sclerodermia rather than that of sclerema neonatorum. Dr. DAVID WALSH showed a *Case for diagnosis*, with microscopic sections, in a man aged 25, who had a nodular eruption on the right side of the forehead, with some atrophic pits and scars. Dr. J. M. H. MACLEOD regarded the case as allied to acne agminata, a view which was shared by Dr. ADAMSON, Dr. A. M. H. GRAY, and the PRESIDENT. Dr. J. H. STOWERS brought forward: (1) A very well-marked case of severe *Lichen planus atrophicus* affecting the back of the neck of a young woman; (2) a well-marked case of *Adonoma sebaceum*. Dr. S. E. DORE showed a woman, aged 43, with *Folliculitis decalvans* and associated lichen spinulosus of the body which closely resembled a case shown at a recent meeting by Dr. Graham Little, in which the diagnosis of Darier's disease had been discussed, but negated after microscopic examination. Dr. LITTLE, Dr. ADAMSON, and Dr. MACLEOD discussed the case. Dr. A. EDWARDS exhibited a case of circinate and atrophic *Lichen planus*, in a woman aged 30, of one year's duration, accompanied by intense itching. The PRESIDENT suggested x rays to allay the irritation.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At a meeting on June 25th, the President, Mr. ASLETT BALDWIN, in the chair, Professor ARTHUR KEITH delivered the Cavendish Lecture, taking as his subject *Alimentary stasis*. An examination of Auerbach's (mesenteric) plexus showed that at all parts of the alimentary canal it was a composite tissue, containing nerve cells, numerous fine nerve fibres, and an abundant third element—a form of branched cell which in its structure and staining reaction seemed to be intermediate between nerve cell and muscle cell. Apparently the plexus effected direct unions with the muscle cells through the third or intermediate element. The nodal tissue in which the heart beat arose and the bundle by which the impulse was distributed in the heart he regarded as of the same nature as Auerbach's tissue. At points where movements commenced in the alimentary canal Auerbach's tissue was particularly abundant, in some cases forming nodes. Physiologists had shown that every part of the alimentary canal had its own rhythm and was always in a state of rhythmical contraction. Further, it had been shown that in the duodenum, jejunum, ileum, and proximal part of the colon the intrinsic rhythm decreased from the commencement to the end of each segment. The lecturer regarded the alimentary canal as divisible into seven rhythmical segments or zones, just as the heart was divisible into two zones—auricle and ventricle. It was at the junction of the two zones of the heart that interruption of rhythm was most liable to occur, giving stasis or "back-pressure" in the veins. Interruptions of the rhythm of the alimentary canal might be expected at similar junctional points. A review of the

observations of radiologists showed that the usual sites of stasis were at such junctional regions—the junction of the oesophagus and stomach, of the stomach and duodenum, of the duodenum and jejunum, of the ileum and caecum, of the proximal and distal colon, and the junction of the colon and rectum. Professor Keith thought that all forms of alimentary stasis would find a satisfactory explanation when more was known of the motor mechanism of the canal musculature.

After the lecture, which was most enthusiastically received, the members and guests adjourned to the rooms of the Post-Graduate College, where a conversation was held, including medical and surgical exhibits.

Rebivus.

THE BRITISH DOCTORS ABOUT NAPOLEON'S DEATH.

DR. ARNOLD CHAPLIN's painstaking researches into everything concerning the last illness and death of Napoleon entitle him to be regarded as the chief historical authority on the subject. His first book was reviewed in the *BRITISH MEDICAL JOURNAL* of December 12th, 1912 (p. 1761). He has now supplemented his account of the final scenes of the tragedy of St. Helena by short biographical accounts of Dr. Thomas Shortt and some of the other medical men who were in attendance, mostly from original sources.¹ Shortt was a descendant of the Thomas Shortt to whom Sydenham dedicated his treatise on gout. He also played a part in the last scene of the life of a monarch. Bishop Burnet in his *History* says: "Shortt, another physician who was a papist, but after a form of his own, did very much suspect foul dealing in the death of Charles II, and talked more freely of it than any of the Protestants durst do at that time. But he was not long after taken suddenly ill upon a large draught of wormwood wine which he had drunk in the house of a popish patient that lived near the Tower who had sent for him, of which he died." Another Thomas Shortt was physician to George II, and published *An Essay proving beyond doubt that the Chevalier Charles Stuart was not and could not be the son of James II of England and Seventh of Scotland*. The Thomas Shortt who was at St. Helena was born near Dumfries in 1788, educated at Edinburgh, and, entering the army as a surgeon, saw much foreign service. In 1815, at the end of the great war, he was appointed physician to the forces in recognition of his services, but placed on half-pay although only 30 years of age. In those days, as at present, men often gained the experience of a lifetime before they reached middle age. Shortt settled in practice at Edinburgh, and in 1819 was appointed Physician Extraordinary to the king in Scotland. In 1820 he was ordered to St. Helena as principal medical officer to the king's forces, with care of the establishment of the Honourable East India Company and the civil population. Shortt came on the scene at St. Helena when the disputes about the illustrious captive had reached their height. The British Government had insisted that the climate was healthy, and that Napoleon's illness was being exaggerated by those about him. The expression of a different opinion by any British doctor was punished by dismissal, or such marks of official displeasure as made the position very unpleasant for the offender. The painful story of the intrigues and petty annoyances which vexed the last hours of the great Emperor need not be repeated. Although Shortt never saw Napoleon, Dr. Chaplin thinks it not unlikely that Scott owed to him many of his facts concerning the conduct of the British authorities during the last three months of the captivity. After the death of Napoleon, Shortt left St. Helena and returned to Edinburgh. In 1828 he was appointed physician to the Royal Infirmary and lecturer on medicine. He was also managing director of the Royal Lunatic Asylum and inspector of madhouses in Scotland, and physician to the fever hospital in Edinburgh. He died in the Isle of Wight in 1843.

Dr. Chaplin gives sketches of the lives of George Henry

¹ *Thomas Shortt (Principal Medical Officer of St. Helena). With Biographies of some other Medical Men associated with the Case of Napoleon from 1815-1821.* By Arnold Chaplin, M.D. London: Stanley Paul and Co. 1914. (Cr. 8vo, pp. 70; two portraits. 2s. net.)

Rutledge, Walter Henry, James Roche Verling, Archibald Arnott, Barry O'Meara, Francis Burton, and Alexander Baxter, all of whom had some connexion, direct or indirect, with the case. Rutledge was the junior surgeon present at the autopsy and was selected to keep guard over the body to prevent any tampering with it. The one whose name is best known now is Barry O'Meara, whose *Life from St. Helena* made a great noise when it was published. Dr. Chaplin says that "of all the memoirs dealing with St. Helena (it) easily holds the first place for interest and literary merit." Our own opinion, however, inclines rather to that of Lord Rosebery, who describes it as the most worthless of all the books written on the subject. A more dignified figure is that of Archibald Arnott, who was called in at Antommarchi's request when it became clear that the case was serious. The Emperor conceived a warm regard for him, and before his death presented him with a gold snuffbox; he also ordered his executors to give him 600 napoleons in recompense for his services. When Napoleon noticed that the gold snuffbox bore no mark of identification, he scratched an N. on the lid with a penknife. Napoleon also gave Arnott a copy of Cox's *Life of Marlborough* for presentation to his regiment, the 20th Foot. It was directed, however, that the books should be returned because they bore the Imperial title. Apparently the regiment was unwilling to give them up, for they were sent home with an appeal to the Duke of York, then Commander-in-Chief. He replied that "Such a gift from Napoleon was most gratifying to him, and that the safe detention of Napoleon was sufficient testimony that the regiment had done its duty, and the presentation of the books was a satisfactory and flattering acknowledgement that a delicate and difficult duty had been performed in a generous and gentlemanly spirit." Dr. Chaplin says the books are now in the archives of the officers' mess of the first battalion of the Lancashire Fusiliers. Francis Burton was a cousin of the famous physician Graves. Having some skill in making casts he moulded the head of Napoleon. The cast, however, disappeared, and nothing more was heard of it till 1833, when Antommarchi claimed it as his own. This moulded Graves to deliver a lecture (published in the *London Medical Magazine* of July 18th, 1835), in which he brought forward proofs of the fact that Burton had taken a mould of Napoleon's face after Antommarchi had failed.

Dr. Chaplin's book should be read by all who wish to know the details of a historical episode which has many points of medical as well as general interest. It is a necessary addition to the *apparatus criticus* for the investigation of a subject which will doubtless continue to fascinate students of the byways of history.

POISONOUS GASES IN WARFARE.

The Poison War,² by M. A. A. ROBERTS, is a collection from various sources of a good deal of interesting information with regard to the uses of poisonous gases and missiles by the Germans, some notes on explosives and sprays of burning liquid, with a good deal of padding. The chapters into which the book is divided are called Articles I to VI, and, although it is not so stated, they read as though they had been written somewhat hurriedly for the lay press. According to Mr. Roberts, at least three poisonous gases have been used—chlorine, nitrogen peroxide, and carbon monoxide; but he speaks of sulphur dioxide and bromine as also being employed. Some of the principal details of the properties of these gases are given, and apparatus suitable for the liberation of certain of them is described. The author further remarks that "the fact that they" (the Germans) "intend to utilize poisonous asphyxiating gases in naval engagements will be unknown to the general public," and he gives a rather unintelligible description of plant for the liberation of such gases at or near the surface of water; this is illustrated with a drawing, and it is stated that in order to retain the pipe by which the gas is to be delivered under the water, it is attached to floats, and the floats are kept below the surface by means of buoys attached thereto. In the drawing the buoys are represented as floating just below the surface of the water, while the "floats" are below them and attached to them

by chains; this seems to show that the description of the apparatus has been given without sufficient consideration. In considering the gas to be used in this way, Mr. Roberts states that, unless the nozzle giving off the gas is allowed to protrude a few inches above the water surface, chlorine could not be utilized, owing to its solubility, and that bromine forced through a little water would lose a considerable percentage of its toxic qualities, but that sulphur dioxide would be easy to generate and might be more readily employed with the nozzle at or in close proximity to the surface. This does not appear to indicate a very profound knowledge of the properties of the substances mentioned, since sulphur dioxide is many times more soluble in water than chlorine, and bromine, being an element, cannot lose a considerable percentage of its toxic qualities by being forced through a little water. Other loose statements of this kind occur throughout the book, which, nevertheless, is of interest and value as a collection of some of the chief statements from reports from the seat of warfare as to the means being used by the enemy.

Mr. Roberts insists that the Germans have been deliberately employing poison since the beginning of the campaign, and long before they began to dislodge clouds of chlorine or other gas. In making this statement he refers particularly to the production of carbon monoxide from shells, and also to the fact, which appears to be well established, that their shrapnel bullets have rough surfaces, and are packed in the shell with a powder consisting chiefly of phosphorus; we commented on the latter fact some time ago, and expressed the opinion that the phosphorus could not well be employed for any other purpose than that of inflicting far more dangerous wounds than would be caused by shrapnel bullets alone, and this is the view taken by Mr. Roberts. A good deal of historical material referring to the practice of poisoning in past times, extends from *Pepys's Diary* as to the interest taken by Charles II and his courtiers in the chemistry of that era, and a good deal of similar matter in the book are really of no interest, and merely serve to dilute the actual information given. The various explosives chiefly in use now are described somewhat briefly; in connexion with trinitrotoluene, it is stated that "Toluene is a colorless liquid obtained from resins such as tolu, the latter being the product of a South American tree; some of the medicinal preparations of this resin are well known to the public, as 'balsam of tolu' and 'Friars balsam,'" but there is no indication that toluene is derived from coal tar, which is of course its sole commercial source. Mr. Roberts thinks it necessary to point out that picric acid has nothing to do with picric acid, the latter of course being mentioned under lyddite, but this is hardly sufficient reason for describing the way in which picric acid is used as a fish poison. The opinion is expressed that the blowing up of the battleship *Bulwark* last November was due to spontaneous decomposition of cordite.

In another chapter the projection of jets of petrol, either set on fire at the moment of discharge or ignited after it has reached the trenches by means of incendiary shells, is described, and special correspondents are quoted to show that this horrible method has been employed and with considerable effect. A short reference to the precautions to be adopted against poisonous gases includes the recommendation of a solution of 5 oz. of sodium hypsulphite, and 1 oz. sodium carbonate or bicarbonate dissolved in water, with the addition of 1 oz. of glycerine, in which respirators are to be soaked. Some interesting statistics are given showing the percentages of total casualties and the proportion of killed to wounded in a number of battles and campaigns of the past, while a series of short appendices contain extracts from the several Hague Conventions dealing with the use of asphyxiating gases and contact mines.

GLYCOSURIA AND DIABETES.

The large volume of nearly two hundred pages which has been published by Dr. FREDERICK M. ALLEN, a Research Fellow of Harvard Medical School, under the title *Studies Concerning Glycosuria and Diabetes*,³ is difficult to criticize or even to analyse adequately. It represents the results of three years of research and study, and

²*The Poison War*. By Alfred A. Roberts. London: William Heinemann. (Demy 8vo, pp. 144; 10 illustrations. Price 5s. net.)

³*Studies Concerning Glycosuria and Diabetes*. By F. M. Allen, A.B., M.D. London: H. Milford, Oxford University Press, 1921. (Roy. 8vo, pp. 197; 16 figures. 38s. net.)

incorporates numerous original experiments on animals. The author has endeavoured to obtain information concerning the physiology of sugar, the origin and nature of diabetes, to produce a satisfactory reproduction of human diabetes in animals and to try various methods for modifying the disease thus produced. We admire the results permitted by the large financial resources possessed by some of the American medical schools and sincerely respect the industry and single-minded purpose with which American students are devoting themselves and their private means to researches which offer no prospect of pecuniary advantage. We commend this volume to all who are interested in the sugar problem; they will find that Dr. Allen propounds many questions and has earnestly tried to find answers to them. These may in many cases appear to be altogether at variance with clinical experience, but we will not rashly undervalue them on this account. His work deserves, and we are sure will receive, careful consideration, but it is startling to be assured that there is no limit to the tolerance for glucose, that sugar is not a diuretic, that hyperglycaemia does not cause glycosuria, that excess of sugar in the blood has no harmful effect, that human diabetes is in most cases a functional disease of the nervous system manifesting itself by its effect on the pancreas, that the liver is without specific importance in relation to diabetes, and that fat storage is not increased by hyperglycaemia. The author believes that sugar normally exists in the blood in combination and applies the ambocceptor theory, the side chains being supplied in health by the pancreas. In diabetes insipidus he suggests there is a deficiency of ambocceptors for sodium chloride, and that these may be normally supplied by the hypophysis. The book is not provided with an index, but has a full table of contents.

The year before last we spoke favourably of a little book on diabetes by Dr. A. SOPP.⁴ As was then pointed out, it is primarily intended for the use of patients, and there is no disease in which it is more desirable that the physician should be assisted by the intelligent co-operation of the patient, who will follow the instructions given much more carefully if their intention is understood. But there is much in the book that any medical practitioner may read with advantage, and the tabulated information at the end is so useful that we may again express our regret that no such useful little work exists in the English language. Dr. Sopp mentions hedisit (lactose of glucoheptonic acid), a comparatively newly introduced sweetening agent, but, as he admits, its sweetness is so slight that it is not of much practical value for this purpose. As a carbohydrate it may be employed, but it would be an expensive food. It is soluble in water, and the dose recommended is 10 grams daily, or 30 grams every third or fourth day. We are glad to see that in this edition the author recognizes the value of potato as a useful form in which a certain proportion of the carbohydrate should be given, and he especially draws attention to the possibility of combining a good deal of fatty matter with these vegetables.

NOTES ON BOOKS.

The first fasciculus of *Injuries and Diseases of Human Bones*,⁵ as demonstrated by series of specimens in a Russian museum, treats of fracture of the surgical neck of the humerus. Professor H. TURNER describes the four plates, which are highly instructive to the surgeon as well as to the student. The first shows the upper end of a normal humerus and the disposition of the epiphysal lines. There are two photogravures and a good diagrammatic outline drawing, lettered, and with explanatory letterpress. The second plate represents a fracture of the surgical neck in the adult, seen from before and behind. The line of fracture corresponds to the former epiphysal line. The displacement of the head of the humerus is

indicated by means of a skiagram, and, as in Plate I and in the succeeding plates, there is an explanatory outline drawing. In Plate III another specimen of fracture of the surgical neck is shown. The dislocation is much more marked and there is abundance of callus, which has assumed a definite form for physiological or static purposes. The skiagram in this plate is most instructive. Bony buttresses run from the callus down to the middle third of the humerus. The fourth plate shows a fracture running along the same line. Professor Turner explains how it demonstrates the transformation of the callus for future physiological service, the injury being apparently as severe as in the previous specimen, but more recent.

The heroine of Mrs. FLORENCE L. BARCLAY'S story, *In Hoc Vinco*⁶ shows a belief in German respect for the Geneva Convention which seems to prove that it was written very early in the present war, before the enemy's flagrant violation of the articles of that agreement had destroyed such belief for ever. But the sanctity of the Red Cross flag forms a peg on which to hang a very touching little story which originally appeared in *King Albert's Book*. The author of *The Rosary*, it is said, has perhaps more readers than any novelist in the kingdom; and this story, which is partly founded on fact, gives plenty of scope for those qualities which have made her name a household word in thousands of British homes.

MEDICAL AND SURGICAL APPLIANCES.

Electrophone Bullet Probes.

AN electrophone bullet probe has been designed by Dr. Charles Finch, F.R.C.S., Consulting Surgeon to Gravesend Hospital, who has sent us the following description: It consists of a silver tube, 8 in. or 9 in. long, of the size of a No. 3 catheter, lined with india-rubber, and a central wire or core. The tube is connected with one terminal of an electric bell and battery combined, and the core with the other terminal. When the tube and core both touch the bullet, or any metal body, the bell rings. The core is freely movable within the rubber-lined tube, so that it can be made to project about 1 in. at the lower end.

This enables a bullet to be discovered when the tube is not end-on to it, but passing it on one side of a sinus; then, by projecting the core and slowly withdrawing the probe, one can get a ring at the moment they both touch the bullet. In this way it is possible to map out the position and size of the bullet or foreign body. The probe is readily dismantled for sterilizing purposes. I have found this little instrument of great service in locating bullets and shrapnel, and even wire, especially when imbedded in bone; and it has given valuable negative as well as positive evidence in some doubtful cases. It can be obtained at a very reasonable price from Messrs. Maw, Son, and Sons, Aldersgate Street, London, E.C.3.

Dr. David Findlay, Medical Officer in Charge Electrical Department, West End Hospital for Nervous Diseases, has also sent a description of a telephone probe. It consists of a rod of silver insulated from a sheath of the same metal; these form the two electrodes of an electric circuit, and are attached to a plug by insulated wires encased in rubber tubing. In the lid of the box are fixed the plug holder, a specially wound telephone and a dry cell of the flash light pattern. The latter when exhausted can be replaced at the cost of a few pence. When the plug is in its holder an electric current will be established on the probe being inserted into a wound, contact taking place between rod and sheath through the moist surfaces. Any disturbance of the flow, or interference with the lines of force of the current, as when a piece of metal is touched

⁴Die Zuckerkrankheit (Diabetes Mellitus), ihre Ursachen, Wesen und Bekämpfung. Von Dr. Med. A. Sopp. 2. verbesserte u. erweiterte Auflage. Würzburg: Curt Kabitzsch. 1914. (Post 8vo. pp. 80. M. 1.50; Cart. 1.80.)

⁵Поврешденија и Болести Кости Теловоука по Данноен Хирургическог Музеја Императорског Воено-Медицинског Академије. Part I. (Injuries and Diseases of Human Bones as Represented by Specimens in the Surgical Museum of the Imperial Military-Medical Academy.) By Professor H. Turner. Petrograd, 1915. (Pp. 14; 4 photographs.)

by the probe, will be indicated by a noise in the telephone. The chief points claimed for this probe are its simplicity and efficiency, and that it is not liable to get out of order. There is nothing to fix on the head of the operator, nor on the body of the patient. The noise in the telephone is quite audible to everyone in the neighbourhood. The probe can be bent as freely as the ordinary surgical probe, and with its connecting wires and plug forms a unit that can be sterilized by boiling. Messrs. Down Brothers have the instrument in hand.

THE DIFFERENTIATION OF MENTAL DEFECTIVES.

A NUMEROUSLY attended conference, organized by the National Association for the Feeble-minded, was held at the Guildhall on June 25th. The proceedings were opened by the LORD MAYOR, who expressed his interest in the subjects for discussion from their social, administrative, and educational aspects.

On his departure the chair was taken by Sir H. BRYAN DONKIN, M.D., F.R.C.P., who, in his opening remarks, spoke of the practical character of the conference, its promoters hoping that its deliberations would help to clear some of the misapprehensions met with as to the application of terms which usage had rendered ambiguous, such as that of "feeble minded," which had been applied—(1) to the whole class of mental defectives (an acceptance which until lately had prevailed in America), and (2) to the highest subdivision only as set forth in the definitions of the Mental Deficiency Act. Certain tests for measuring intelligence, of which those of Binet and Simon had been most in evidence, had been propounded; and it would be for the meeting to discuss their practical value in classification, excluding on the present occasion the consideration at any length of the etiological aspects of the subject.

The first paper read was by Dr. ROBERT HUGHES, School Medical Officer, Stoke on-Trent, setting forth the means he had proved serviceable in diagnosis, amongst which he laid stress on the systematic examination of the sense organs, describing simple appliances for this purpose found useful in his psychiatric department to supplement the Binet-Simon and Montessori tests. He also gave some particulars of the results of treatment in his school clinic.

Mr. W. H. WINCH, M.A., District Inspector of Schools, L.C.C., testified to the value of the Binet-Simon tests in classification in schools, contending that under guidance and supervision teachers were competent to apply them. He admitted that the system was by no means perfect, and had suggested certain modifications to render them more suitable for English children.

Dr. BOUTLENGER (late of Brussels), Director of the Farm Colony for Defectives at Waterloo, compared the differences he had noticed in English and in Belgian children respectively, and testified generally to the value of the Binet-Simon tests in the differentiation of defectives.

Dr. W. A. PORRS (Birmingham) discussed the subject of tests in childhood best calculated to throw light upon capacity for useful work such as in the future would lead to self-support. He emphasized the importance of the following as criteria: (1) Ability; (2) strength of will and character; (3) good health; and (4) pluck; the absence of one or more of these attributes proving a serious handicap. Luck as to employers was also a factor not to be overlooked in the attainment of success. From his experience as chairman of the Birmingham After-Care Committee, and later as medical officer to the Mental Deficiency Committee, he cited cases both of success and failure, incidentally mentioning that some who had passed through special schools were serving with the colours—efficiently so far as he knew.

Dr. ALLAN WARNER (School Medical Officer, Leicester) spoke of the value of a uniform examination of the feeble-minded for educational purposes, and described in detail the system he had found serviceable in determining educability.

Dr. R. LANGDON-DOWN (London) discussed the practical application of the Binet tests. He regarded the system as on the whole the best yet devised for standardization of intelligence, though he thought it in some respects susceptible of improvement. He read, on behalf of Dr. W. B. Drummond of Edinburgh, a paper entitled "Binet-Simon tests as a means of grading mental defectives under the Mental Deficiency Act," in which the opinion was

expressed that these tests would be found of great assistance to the medical expert in all cases of suspected imbecility and feeble-mindedness. Though some modifications might be necessary, the system was fundamentally sound. According to Binet, a child of 9 years or upwards must be adjudged defective if his intelligence, as ascertained by the tests, is retarded by 3 years.

In opening the discussion on the foregoing papers, Dr. SUTTLEWORTH referred to the fact that some confusion existed with regard to the certification of children for special schools, which he thought still rested upon the definitions in the Elementary Education (Defective and Epileptic Children) Act of 1899 rather than upon those of the Mental Deficiency Act, which did not become operative till the age of 16. The test of fitness for admission to a special school was incapacity to receive benefit from instruction in an ordinary school, with presumptive capacity for benefiting by special instruction. This differed from the condition underlying the definitions of the Mental Deficiency Act, which presupposed original and permanent defect. The special school, indeed, formed the testing ground as to this, and the yearly application of the Binet-Simon tests was of great value in this connexion. The particular tests were admittedly empirical and the system had not reached finality. Still they were helpful in assessing a child's intelligence, and combined with expert clinical observation furnished valuable results. They must, however, be applied without bias from extraneous knowledge of the child's educational performances, and for this reason he did not think their application should be left with the child's teacher, though of course educational progress had also to be considered. As Goddard put it, the examinee must be regarded simply as *x*, the value of which had to be ascertained. Children should certainly not be sent to special schools simply because they did not keep pace with ordinary scholastic standards; physical ailments and other retarding causes must be taken into account and if possible corrected. Some retarded infants benefited by an extra year or so in infant departments; for others education in intermediate classes for backward (as distinguished from defective) children was desirable; and open-air schools seemed specially adapted for such cases. Parents as well as teachers should always be invited to special school examinations, though it was generally advisable that the Binet-Simon tests should be applied independently of them.

Mr. H. HOLMAN (late H.M. Inspector of Schools) called attention to the need of applying sensorial tests (as long ago advocated by Seguin) and of testing the neuro-muscular condition of the fingers, so important in manual training.

Canon ROWNTREE (York) emphasized the motto "*festina lente*" both as regards the testing and training of defective children, and deprecated stringent forms.

Dr. J. LETHIA FAIRFIELD (L.C.C.) criticized some of the Binet-Simon interrogatories, thinking them puzzling to adults and incomprehensible to children. Mrs. KNOTT-BOWER emphasized the importance of women taking part in the examinations.

Subsequently papers were read by Drs. SHERLOCK (Darent), H. W. SINCLAIR (ESSEX), and GORING (Brixton Prison), and the proceedings closed with a vote of thanks to the Chairman (proposed by Sir WILLIAM CHANCE, Chairman of the National Association), and to Miss Kirby, the Secretary.

An extensive and interesting exhibition of the products of industrial training at various institutions was on view in the Council Chamber corridor.

THE Egyptian Government has issued a return of births and deaths occurring in the principal towns, governorates, and chief towns of provinces of Egypt during 1914. It records 76,322 births (not including 2,774 stillbirths) and 58,641 deaths. The birth-rate is slightly below that of 1913—44.6 as against 45.1—but the natural increase is somewhat greater, for the death-rate has fallen from 35.2 to 34.3. Typhus is responsible for the largest number of deaths attributed to infectious diseases, the total number of cases being 9,350, the provinces of Daqahalia and Beheira each returning more than two thousand, with 2,531 deaths. Small-pox is represented by 6,788 cases and 1,568 deaths, and measles produced 5,045 cases with 2,272 deaths. Only 219 cases of plague were reported, 59 of these from Port Said. Typhoid was responsible for 1,965 cases and 612 deaths. The estimated population (July 1st, 1914) was 1,710,857.

British Medical Journal.

SATURDAY, JULY 3RD, 1915.

OVERTIME AND EFFICIENCY.

In the published returns given in the White Paper "Particulars of Time Worked in Week ending April 13th, 1915, among shell workers," it is stated that no less than three-quarters of the workers are doing overtime, that is, more than the forty-eight hours a week which is considered to be the ideal amount for the maintenance of national health and efficiency. Nearly 10 per cent. are working eleven hours a day for a seven-day week, or over thirteen hours a day for a six-day week. Thirty-six per cent. are working ten or over ten hours a day for seven days a week, or twelve or over twelve hours a day for six days a week. A quarter of the men are to be regarded as slackers doing less than fifty-three hours a week; it must be borne in mind that probably nearly all these are less efficient, being elderly or debilitated, or men of weak characters, intemperate, taken on to replace the efficient, the young, strong, and great-hearted men who have enlisted.

The danger of impelling the best of the workmen who remain to average ten hours a day for seven days a week is obvious, and among the appointments made by the Minister of Munitions we look for that of a Medical Board for controlling the hygiene of the munitions factories. A Central Liquor Board has, it is true, been established, but this Board has powers only to deal with the sale of alcoholic liquor, and the provision of canteens where food and non-alcoholic drinks can be obtained. What is urgently needed is a committee of experts to advise on the length of shift, the periodicity of the night and day shifts, the number and duration of short periods of relaxation during the shifts (the elevens and fours of the agricultural labourer), the maintenance of the Sunday and other holidays, and the ventilation of the factories.

The transport of workers to and from the factories should also be looked after, so that they are least exhausted by travel, and facilities provided for visiting seaside or country by which their vigour may be recuperated. As Mr. Bonar Law said at Shrewsbury, the sons of the so-called idle rich have nobly sacrificed their lives on the battlefield, but we ask how much of this sacrifice may be traced to the neglect of national hygiene.

If failure of the supply of munitions in truth has increased the toll of the dead brave, that failure is due not only to lack of present organization, but to past bad government, which has allowed the unguided exploitation of the land and the building of slum cities. Now the operative is called upon to give his utmost in the time of the nation's need, and while the strength of the best workers is impaired by the

conditions of their daily life—bad housing, lack of open spaces and of amusements other than those provided by the brewer and distiller—the number of wastrels, shirkers, and slackers is the fruit of the culpable neglect in the past of town planning and disciplined physical drill of youth. Let him who sits in his club and abuses the operative perform the operation of putting on his collar and tie once every two minutes for ten hours a day, and for six days a week, then he will have some idea of the monotony of the machinist's daily task. It is done reflexly, and the operative fortunately finds relief in sight of and speech with his fellow workers. But if the work, in spite of its monotony, demands the strict attention of hand and eye, if the operative must not merely mind the machine but work strenuously with and guide it, mark and correct any error made by it, then truly exhausting is the task, and most unwise the demand for overtime.

Physiological need for rest forbids the utilization of overtime to any advantage. The tired worker must go slow, impelled by Nature's call. The Sunday holiday is physiologically right; it is found to pay in reckoning the output of work. The man who is over-driven and nervously exhausted finally breaks down, and takes weeks to recover. Overtime spent in factories badly ventilated and artificially lighted is, we believe, one of the most fruitful sources of phthisis.

In his enlightening book on the *Principles of Scientific Management* Frederick Winslow Taylor tells us that systematic "soldiering," or "ca' tanny," is the cause of the world's output being reduced by one-half of what it might be were every operative to work with his full zeal and power. "The causes of this are," he says, "briefly, that practically all employers determine upon a maximum sum which they feel it is right for each of their classes of employees to earn per day, whether their men work by the day or piece. Each workman soon finds out about what this figure is for his particular case, and he also realizes that when his employer is convinced that a man is capable of doing more work than he has done, he will find, sooner or later, some way of compelling him to do it with little or no increase of pay." If this be true, then it is each man's interest to see that no job is done faster than it has been in the past. If a workman has seen the price per piece of the work he is doing lowered as a result of his having worked harder and increased his output, he will regard his employer as an antagonist. He will have no more "cuts" in the price of piecework if "soldiering" can prevent it. The operative comes to regard the over-zealous quick worker as a traitor to his class, and enforces the reduction of his output to the traditional level.

The whole principle of management and relation of operative to employer seems to be at fault, and by the principles of the modern scientific management, under which no less than 50,000 workers are now working in America, the work of every man is fully planned out by the management at least one day in advance, and each man receives (in most cases) complete written instructions, describing in detail the task which he is to accomplish, as well as the means to be used in doing his work. This task specifies not only what is to be done but how it is to be done and the exact time allowed for doing it. And whenever the workman succeeds in doing his task right, and within the time limit specified, he receives an addition of from 30 to 100 per cent. on his ordinary wages. The tasks are carefully planned, so that both good and careful work are called for in their performance,

† The percentages were as follows:

Working over 80 hours a week	94.37 per 1,000
" 75.80	"	"	"	86.77
" 70.75	"	"	"	177.45
" 65.70	"	"	"	130.0
" 60.65	"	"	"	155.27
" 55.60	"	"	"	100.96

and in no case is the workman called upon to work at a pace which would be injurious to his health. The task is so regulated that the man is well suited to his job and will thrive and grow happier and more prosperous.

Under ordinary management, practically the whole problem is "up to the workman," while under scientific management fully one half the problem is "up to the management"—the choice of the right man for the job, the tools suitable for it, the right use of the tools, the periods of work and of rest, etc.

By the selection of men suitable in temperament and by proper spacing of their work and rest periods, Mr. Taylor, at the Bethlehem Steel Company, raised the work of loading cars with pig-iron from $12\frac{1}{2}$ to $47\frac{1}{2}$ tons per man per diem, and the selected men earned 60 per cent. more wages than before and worked contentedly. The law was worked out that when pig-iron is being handled (each pig weighing 92 lb.) a first-class workman can only be under load 43 per cent. of the day. He must be entirely free from load during 57 per cent. of the day. As the load is made lighter a man can remain a larger percentage of the day under it. Scientific management sees to it that the right periods of load and rest are observed. In the case of shovelling, Mr. Taylor worked out that the right load for each shovelful for effecting the maximum work was 21 lb. Different-shaped shovels were therefore supplied, so that the load should be 21 lb. whatever the material handled. The time period of the act and best way of shovelling were worked out from the observation of first-class workmen and all other workmen trained by the management in their ways.

Scientific management is strikingly seen in the case of girls employed to examine steel balls used for bearings, and picking out defective ones. Mr. Taylor selected those girls who, on testing, showed the shortest reaction time in the recognition of a letter momentarily shown by a moving shutter arrangement. He shortened the length of their shifts and instituted resting periods to avoid eye strain, and set up a system of overlooking to secure accurate work. The result was that 35 girls did the work formerly performed by 120! The girls averaged 80 to 100 per cent. more wages. They worked eight and a half, in place of ten and a half, hours a day, and secured a Saturday half-holiday and four recreation periods during each day. They were even allowed to take two days off at the time of their monthly period. The accuracy of the work done was two-thirds greater, there was a material reduction in the cost of inspection, and most friendly relations established between management and employees, which rendered labour troubles or a strike impossible.

The nation is now in the throes of a cataclysmic war waged with perhaps the most highly organized community of men the world has yet seen. The chief defects in the management and care of the operatives cannot now be righted. Their need for scientific management and garden cities cannot be met. Industrial England has built itself up blindly, guided by little else but the zeal for private gain. The sin of the slums tells heavily against us; biological laws cannot be broken without paying the penalty. The nation must reap as it has sown. When we win through at heavy cost—the penalty of the governing class is the loss of their sons—we must put the national workshop in order under scientific management, and turn the mean streets into garden cities.

MEASLES AND THE PROBLEM OF FILTERABLE VIRUSES.

MEASLES is one of the most mischievous of diseases, not only because it causes annually a large number of deaths, but because it strikes at the foundations of national life; it attacks the young, kills many out of hand, and leaves many others an easy prey to those lymphatic disorders which open the way to tuberculosis, or to a condition of general debility and lack of tone, which means stunted growth. Scarlet fever is only less deadly because it is not quite so limited to childhood and early youth. That measles and scarlet fever are due to a *contagium vivum* no one doubts, but bacteriology has not been able to clear up the etiology of measles, and its results in scarlet fever are doubtful. It has told us little for certain about whooping-cough, another deadly disease for the same reasons that measles is deadly, nor about mumps, nor, finally, about small-pox or chicken-pox.

The Registrar-General in his report for 1913 states that the death-rate from measles in persons under the age of 15 years was 932 per million living, and in children under 5 years of age 2,430; for whooping-cough the rates were 482 and 1,340 respectively. The actual number of deaths from measles was 10,644, and from whooping-cough 5,458. In commenting on these figures Dr. T. H. C. Stevenson, the superintendent of statistics, remarks that, however calculated, the rate for measles in 1913 was a fairly low one; but he adds the significant observation that this was "to be expected from the fact that the rates for the two previous years were both above recent averages." The rate of mortality from whooping-cough was also very much lower than any previously recorded—it was less than half what it was ten years ago. But we have no sort of assurance that this diminished rate will continue.

These diseases—measles, scarlet fever, and whooping-cough—dissimilar as they are in symptoms and severity, have this in common, that ordinary bacteriological methods, which have been so successful in elucidating the etiology of typhoid fever, cholera, and many other diseases, have failed to identify the nature of the living contagion to which the former must be due. But bacteriological methods have given birth to the idea of filterable viruses, of which that of epidemic anterior poliomyelitis is, perhaps, the most familiar. The hint thus afforded has been taken, and many investigations have been made, without, as yet, any conclusive results. A scheme has now been sketched out for an attack on the problem of measles from this direction in a London laboratory.

The memory of Mr. Marcus Beck, surgeon to University College, in whose character and teaching many men of a generation now growing old found inspiration, has been perpetuated very suitably—for he was a pathologist first and a surgeon afterwards—by a laboratory called after him, which is in the charge of the Royal Society of Medicine. When the society built its new home it included in it a well-designed and well-equipped laboratory. The good work which was being done in it was interrupted by the war, the workers being called away to military service. The laboratory has been idle for some months, but this waste of its resources is now to cease and the facilities it provides are to be devoted to a serious attack on the problem of the filterable viruses, beginning with measles, because that disease is, from the social point of view, so serious a menace and because it is always with us, so that the work need never be stopped for want of material.

The Royal Society of Medicine has been fortunate

in securing the services of Sir Ronald Ross as honorary director of the Marcus Beek Laboratory and director of this particular research. He has already enlisted Dr. Cropper as haematologist, but is in want of a bacteriologist, who, owing to the demand for medical men by the War Office, must be a woman. Lady Durning-Lawrence is making an annual contribution to defray the upkeep of the laboratory; and the expenses of this particular research will be borne by the Medical Research Committee, which disposes of the research penny ear-marked under the Insurance Act. The research has a direct bearing upon the war, because experience both at home and in France has proved that the army must expect to have to deal with a large number of cases of measles among the young men recently recruited. Until clear notions as to the nature and natural history of the virus are obtained, methods for checking the spread of measles must remain empirical, and it has to be confessed that they have not hitherto been, either in civil or military life, remarkably successful. It is not, indeed, expected that the problem will be solved very quickly, but it is well that it should be taken in hand without delay, for even experimental science provides its surprises. As has been said, measles is always with us, and the work should not, for this reason, be stopped for want of material; but Sir Ronald Ross appeals for the help of medical men practising within easy reach of the laboratory at the Society's house at No. 1, Wimpole Street, and asks them to let him know of cases of measles which could be used for this intensive study of the disease. We hope that his success in dealing with this new and urgent problem may be as great as that which attended his researches into the causes of malaria and the natural history of the haematozoon to which it is due.

WAR REGISTER FOR THE PROFESSION.

The efforts of the Association to stimulate recruiting for the R.A.M.C. through the medium of its Divisions and Branches have been very successful, thanks to the way in which the honorary secretaries and other local officers have entered into the spirit of the appeal, and to the assistance given by the Scottish Committee of the Association acting in conjunction with the Scottish Medical Emergency Committee. The Special Committee of the Association at its last meeting came to the conclusion that what was now wanted more than anything else was some means of registering every member of the profession in the United Kingdom in his relation or possible relation to the war. In reaching this decision the Committee was helped greatly by the experience of the War Emergency Committee of the Metropolitan Counties Branch, which has for some time been engaged in the collection of information about all the members of the profession in the metropolitan area. Instructions were given to set about the preparation of a register for the rest of the country which would enable a bird's-eye view of the whole profession to be taken and would give a definite answer to the question in which every member of the medical profession must be interested—namely, how far are the members of the profession doing their duty in the great times in which we live? The details which it is proposed to collect will be seen from a paragraph in the Supplementary Report of Council which appears on page 2 of the SUPPLEMENT of this week, and the readers of that paragraph will readily perceive what a valuable document the register will be when completed. We understand that the secretaries of Divisions and of local War Emergency Committees who have been asked to furnish all the information at their disposal have responded in the most encouraging and enthusiastic manner, and the foundations of the register

are being well and truly laid. It will doubtless be necessary, after the local secretaries have done their work, to appeal to the individual members of the profession as to whom no information is at that stage forthcoming, and it is hoped that every member of the profession when applied to will cheerfully and promptly furnish the particulars which will enable the war register of the profession—the first of its kind, we believe—to be an accurate record of what the profession is doing, or is prepared to do, in connexion with the war.

THE SCOTTISH MEDICAL MUSTER ROLL.

The Scottish Medical Service Emergency Committee has now issued the further comprehensive circular letter dealing with the general position in Scotland, the early appearance of which was mentioned in a paragraph on the subject in the SUPPLEMENT for last week (p. 333). The new circular reiterates the intention of the committee to give special attention to offers for whole-time service, believing that arrangements regarding part-time service will best be made and, where necessary, readjusted by those possessing a close knowledge of the circumstances of each individual area. It is hoped to raise in Scotland 400 medical men for whole-time service. It is believed that the graduates and licentiates of July will contribute about 100; of the remaining 300, some will be expected to be ready for duty if required in August, an additional number in September, and a further contingent in October. By thus making successive calls the Emergency Committee hopes that the disorganization of civil practice may be prevented and time allowed for devising adjustments to meet the new conditions. It is intended to make the first call on July 20th, when the number of men required for the August contingent from each Division will be notified. The Committee expresses the opinion that it is neither desirable nor necessary that transfers should be made from the insurance lists of doctors absent on war duty save in very exceptional circumstances, such as have nothing to do with the absence of the practitioner in question. The Committee advises that no practitioner should accept such an application without having previously consulted some local body representative of practitioners in his area. The concluding paragraph of the circular points out that those who cannot serve the country directly with the forces can do so indirectly by placing themselves at the disposal of the Emergency Committee to act as locumtenens. There are young men in remote districts eager to join the R.A.M.C. who are prevented from doing so because they can get no substitute, and can find no neighbour near enough to do their work. If a man, himself too old to serve, will take the place of one of these young men, and thus allow him to go, he will indirectly contribute one to Scotland's 400. The circular has been submitted to and approved by the Director-General. All communications should be addressed to the Convener, Emergency Committee, Royal College of Physicians, Edinburgh.

RESEARCH DEFENCE SOCIETY.

The annual general meeting of members and associates of the Research Defence Society was held at the house of the Royal Society of Medicine on June 30th. In the absence of the President, Lord Lamington, on military service, Major-General Sir Reginald Falbot took the chair. Among those present were Sir William Church, Sir James Reid, Sir John Tweedy, and Sir David Ferrier. The report of the Committee, which was presented by the Chairman, Lord Knutsford, stated that with the help of the War Office they distributed about 350,000 copies of their four-page leaflet, "Protection Against Typhoid Fever." This leaflet had also been translated into French. In October, with the approval of the War Office, they instituted popular lantern lectures to soldiers on wound infection and on the infective diseases, with special reference to the protective treatment

against typhoid fever. These lectures had been very successful. In December the Society presented to the Admiralty for the use of the Fleet, a complete series of 114 lantern slides, with printed catalogue, books of reference, etc. Sir Arthur May, Director-General of the Medical Department of the Royal Navy, kindly arranged for the circulation of these slides, so as to afford one or more special lantern lectures to each battleship. Their opponents, except for the signally unsuccessful attack on the protective treatment against typhoid fever, had been very quiet during the past year. Sir Reginald Talbot, in moving the adoption of the report, paid a glowing tribute to the work of the Royal Army Medical Corps and the civilian doctors among the sick and wounded. The report of the Honorary Treasurer, Dr. F. M. Sandwith, stated that, in spite of a slight falling off of subscriptions, donations, contributions from branches, and sale of literature, doubtless owing to the war, the balance in hand at the close of the year was greater than it had ever been before. Both reports were adopted unanimously. Sir William Osler, in proposing the re-election of the Executive Committee, enumerated the advances in preventive sanitation that had taken place during the last fifty years. He said that never in the history of the British Empire had there been a war in which disease had played so small a part. Among two and a half million men there had only been a thousand cases of typhoid fever. Speaking of preventive inoculation, he said it was impossible to conceive order, baser, and more harmful ignorance than was displayed by those people who were opposing inoculation. He thought the outlook was good so far as disease went in this war. With care they were not going to have the tragedy of the South African War, of the Civil War in America, or of the Napoleonic wars repeated. Sir Alfred Keogh, who was to have spoken, was at the last moment prevented from attending. The motion for the re-election was seconded by Sir Frederick Macmillan and passed unanimously. After the business of the meeting Dr. Andrew Balfour gave a demonstration with the cinematograph on the protective treatment against typhoid fever and cholera.

PERNICIOUS ANAEMIA AND SPINAL DEGENERATION.

DR. BYRON BRAMWELL has recently published¹ an interesting study on the association of pernicious anaemia with subacute combined degeneration of the spinal cord. The occurrence of such degeneration in patients with severe anaemia was noted by Leichtenstern in 1884; it is probable that the "ataxic paraplegia" described by Gowers in 1886 included a number of cases of this condition. The more recent writers on the subject of subacute combined degeneration—Collier, Russell, Oppenheimer, for example—give no clear definition of the anaemia present in these patients, describing it as either primary or secondary, alternatively. Dr. Bramwell has seen and recognized five cases of this peculiar form of spinal degeneration, and he remarks that in all of them the anaemia was pernicious anaemia. In one the nervous signs and symptoms were present for three years before the blood changes characteristic of pernicious anaemia made their appearance, when, apparently as the result of acute intoxication, rapid destruction of the blood took place, and the characteristic clinical features (confirmed by *post-mortem* examination) of pernicious anaemia developed. The degeneration appears to be uncommon in pernicious anaemia; Dr. Bramwell has seen 140 cases of this disease, but only four of them developed subacute combined degeneration. The anaemia, he notes, may either precede, develop coincidentally with, or follow the appearance of the nervous symptoms; and both diseases he holds to be the result of the formation of a toxin (or toxins) in the body.

¹ *Edinburgh Medical Journal*, April, 1915.

From the point of view of differential diagnosis he emphasizes the fact that disseminated sclerosis is commonest between the ages of 20 and 25, and is comparatively rare after 35; whereas subacute combined degeneration has much the same age distribution as pernicious anaemia, and very rarely develops before the age of 35.

EPSOM COLLEGE.

THE annual general meeting of the Governors of Epsom College was held on June 25th. Sir Henry Morris presided and among the governors present were Sir William S. Church, Sir Shirley F. Murphy, Dr. Frederick Taylor, and Dr. Guthrie Rankin. In presenting the annual report and the income and expenditure account Sir Henry Morris stated that four of the masters had taken temporary commissions, and over 400 Old Epsomians were serving with the Forces; amongst them were 290 officers in the Royal Navy, the Regular Army, the Special Reserve, the Territorial Force, or holding temporary commissions. In the roll of honour of Old Epsomians were included 11 who had been killed in action, 2 who had died in hospital, and 19 who had been wounded. Fourteen Old Epsomians had been mentioned in despatches, 1 (since killed) had been awarded the Distinguished Service Order, and 3 had been awarded the Military Cross. In the name of the Governors he thanked the Honorary Local Secretaries and the British Medical Association for the large sums of money they had collected for the Foundation during the past year. The annual report stated that two new pensioners' funds had been founded, one by the late Mrs. Bridget Sarah Greewood, and the other by the late Dr. Burney Yeo. The list of successes at examination showed that the school had well maintained its character for efficiency. Sir James Reid proposed a vote of thanks to Sir Henry Morris for the great services rendered to the College as Treasurer; this was seconded by Sir Frederick Needham, and carried by acclamation.

IN THE BRITISH MEDICAL JOURNAL of May 8th it was announced that the French Académie des Sciences, after considering a report presented to its secret committee by M. Adolphe Carnot, had passed a resolution removing from its membership four of the German "intellectuals" who signed the manifesto which excited such indignation throughout the learned world. Among them were Dr. Wilhelm Waldeyer, professor of anatomy, and Dr. Ernst Fischer, professor of chemistry, in the University of Berlin. The Académie de Médecine has now followed the example of its sister society. At a meeting held *in camera* on June 22nd, a report presented by Professor Blanchard, proposing that all Austro-German associates and correspondents should be deprived of the privileges of membership, was considered. As a result of the deliberations the names of the four German associates, Professors Roentgen of Munich, Behring of Marburg, Fischer of Berlin, and Ehrlich of Frankfurt, were expunged from the list. The question of ten Austro-German correspondents, many of whom are of Slav nationality, was reserved.

Medical Notes in Parliament.

Money, Munitions, and Men.

THE business brought before the House of Commons by the new coalition Government is of enormous importance, but does not call for any extended notice here. Of the new loan it will be sufficient to say that the magnitude of the sum which must be borrowed and the rate of interest make it certain that even if the war were unexpectedly to come to an end before the whole sum now authorized by Parliament is expended, taxation must be for many years heavier than anything to which this country has been accustomed.

Mr. Lloyd George, in introducing the Munitions Bill, made a speech of the utmost gravity; the keynote was struck in the opening sentences, in which he impressed on

the Home and on the country that the toll of life and limb levied by the war, the amount of exhaustion caused by the war, economic and financial, and ultimate victory or defeat depended upon the supply of the munitions which the rival countries could produce to equip their armies in the field. That was the cardinal fact of the situation in this war. The Germans had established a superiority due to a predominance in the materials of war. When they were driving the forces of the Allies before them in any quarter it was due to the same cause, and when the Allies were making progress in any part of the line it was due to the fact that in that sector of the battlefield the Allies had a predominance of munitions of war. This country had an undoubted superiority in men—not merely a superiority in numbers, but in quality. Therefore it was purely a question of equipping them with the necessary amount of material to support their valour. It was stated, he said, on good authority that the Central European Powers were turning out a quarter of a million shells a day, very nearly eight millions a month. The problem of victory was how to equal and surpass that tremendous production. Any obstacle, any mismanagement, any hindrance, any indiscipline, any prejudice, or any delay in the mobilization of our resources at the earliest possible moment must postpone victory. After explaining the provisions of the bill, he said, in the course of an eloquent peroration: "One of the pillars of good government is the security that evil-doing shall be punished. That is equally true in the sphere of international government. Valour alone will not achieve that end. Otherwise our great army would have accomplished it. It is not enough that three millions of young men have offered their lives to their country. It depends upon us at home to support them with skill, strength, and every resource of machinery and organization at our disposal so as to drive the conviction into the hearts of nations for all time to come that those governments who deceive their neighbours to their ruin do so at their peril." Mr. Hodge, speaking on behalf of trade union representatives, said that he had been able to agree with all the proposals. He was followed by Captain Guest (Dorset E., Liberal), who was home on short leave after ten months in France. The nation, he said, still seemed to fail to grasp the meaning, size, and significance of the war. He asked whether the members of the small and-war party of this country imagined that if it did not win the war there would be a civilized British society in which they could air their views and carry on their daily life. Our opponents if they won had no intention of making peace with us, but meant to destroy us as the race they feared most. After Captain Guest, Mr. Asquith intervened to deprecate discussion on compulsory service at that moment. In the course of the debate Mr. Wedgwood (Newcastle-under-Lyme, Liberal), who has come home wounded from the Dardanelles, laid emphasis on the fact that every machine gun saved men's lives. The Germans were holding their trenches with very few men armed with machine guns; when lining trenches it was necessary to have one hundred rifles to equal one machine gun. Other members engaged in criticism of the War Office, and Mr. Lloyd George briefly replied. The debate was resumed on June 23rd, and finally, in response to an appeal by Mr. Asquith, the bill was read a second time without a division.

Mr. Long introduced the bill for national registration under the ten minutes rule on June 29th. The justification for it was, he said, to be found in the language used by the Prime Minister when he said, "We have one paramount duty to perform—to bring to the service of the State the willing and organized help of every class of the community." That, Mr. Long believed, represented the view held by the country and the overwhelming desire of the great majority of the people. The bill proposed compulsory registration of the people, male and female, between the ages of 15 and 65. The registration would be local, conducted by the borough and urban and rural sanitary authorities, under the control of the Local Government Board, with the advice and assistance of the Registrar-General, as in the case of the census. The forms would call for particulars as to age and employment, and each person would be asked to state whether he or she would be prepared to volunteer for any form of labour with which he or she was specially acquainted

other than that in which he or she was engaged. A certificate of registration would be issued, and he hoped and believed that that certificate would be regarded as a badge of honour. After a protest from the incorrigible Mr. Ginnell, who said that he would resist registration if it applied to Ireland, the bill was brought in by Mr. Long, amid general cheers, and read a first time.

The Local Government Board.

The President of the Local Government Board, Mr. Walter Long, on the vote for the Local Government Board on June 24th, made a statement dealing especially with the work the department had done in connexion with the war. Incidentally he said that when he first went to the Board in 1886 its estimates amounted to £174,000, in 1904, the last year in which he had been connected with the Board, they had risen to £220,000; this year they were £360,000, of which £50,000 was a new vote secured by his predecessor for the care of infantile life. Between 1886 and the present time the staff had increased from 400 to 990; of these 200 had volunteered their services and were now serving with the army, either abroad or in this country. The work the Board had been called upon to do in connexion with the war had reference chiefly to sanitary questions, the provision and maintenance of hospitals, and the provision of food supplies; twelve medical inspectors were constantly at work, and had paid 730 visits to nearly 500 different places where troops had been quartered. The object of these visits had been in the first place to prevent undesirable billets being selected; secondly, to secure satisfactory sanitary services in respect of water supply, sewerage, etc., for the troops; and thirdly, to see that there should be adequate hospital accommodation for infectious diseases, and prompt action taken both by the local and military authorities. In the prevention of conditions which might be dangerous to the health of the troops, the Local Government Board, the local authorities, and the War Office had worked cordially together, and as the event showed, with satisfactory results. The department had been instrumental in supplying no fewer than 30,000 beds. Local authorities had done good work not only in the actual provision of beds for the soldiers, whether wounded or sick, but also in many cases, in order to supply accommodation, they had pooled their resources, and had taken in the inmates of establishments in adjoining unions. The War Office had expressed its thanks for the assistance given by the Local Government Board in these directions, and especially for the co-operation which the food inspectors of the medical department had been able to give. After dealing with the necessity for economy in local administration, Mr. Long referred to the special committee to deal with distress arising out of the war, and said that its policy had been guided by the principle that it was its duty to prevent, if possible, suffering as a consequence of the war, rather than to relieve it after it had been created. He believed there was no foundation for the apprehension which had been expressed in some quarters that there had been a sudden increase in infantile mortality due to want of proper nourishment or proper care. It was true that there had been an increase in mortality in the early stage of infant life, but it was traceable to particular diseases—measles and whooping-cough—which seemed to account for it all. In the course of the debate Sir G. Toulmin complained that boards of guardians were slow to adopt matters recommended by the inspectors of the Local Government Board, and asked in how many unions women had been appointed as infant life protection visitors. Mr. Crooks paid a tribute to the marvellous progress made by the Local Government Board in the treatment of pauper children—a matter which had been placed on a sound foundation by Mr. Long himself. Touching on the question of vaccination officers' fees, he expressed a wish that the department would issue an order enabling local authorities to pay them by salary. Sir Godfrey Daving drew attention to the question of what should be done for men permanently incapacitated from serving in the army, and for all except the very lightest employment. The number of men permanently incapacitated was, he believed, already over 2,000, and he hoped the Local Government Board would consider carefully whether these men could not be assisted to obtain employment, perhaps in the way of light

work, in the various great departments of the State. He feared that unless a scheme was carefully devised and carefully administered the problem would be found almost insurmountable. After some further discussion, the Parliamentary Secretary of the Local Government Board (Mr. Hayes Fisher) replied on the debate. The suggestion to pay vaccination officers by salary, he said, commended itself to the President of the Board, but it might not be possible to carry out the suggestion this year. In regard to the care of the health of women and children, he expressed the opinion that economy was necessary, but that much could be effected if encouragement and full scope were given to voluntary efforts.

Duty-free Alcohol in Hospitals.—A most interesting proposal was made by the Chancellor of the Exchequer in a clause in the Finance (No. 2) Bill to allow hospitals to receive duty-free alcohol in the preparation of tinctures and other articles used for medical purposes in the hospital, or to have repaid the amount paid in respect of alcohol contained in, or used in the preparation or manufacture of, tinctures or other articles bought for the purpose of medical articles bought for purpose of medical use in the hospital. On the face of it, this was a concession which the medical profession would naturally, in the absence of any serious drawbacks, have been delighted to welcome. Unfortunately, the Government had not thought it necessary, so far as is known, to consult any bodies representative of the medical and pharmaceutical professions, and when the clause was brought to the notice of the British Medical Association and the Pharmaceutical Society of Great Britain it was seen to be so drafted as to offer opportunities for serious abuse. As is the case with all Government measures at the present moment little time was given for consideration, and the two associations, after consultation, sent letters to the Chancellor of the Exchequer pointing out some of the difficulties they foresaw if the clause went through as drafted, and asking that the matter should be postponed and the whole question of the use of duty-free alcohol in medicine referred to a special committee for consideration and report. The letter of the Association will be found on page 20 of the SUPPLEMENT. Members of the medical profession will hardly need to be told that the Association would not have taken this step if it had not felt that the dangers to the community and to the medical profession more than counterbalanced the gain to the hospitals. The two associations took steps to interest a number of members of the House of Commons in the question, and various amendments were put down on the paper by Sir Philip Magnus, Mr. Glyn-Jones, Mr. King, Mr. Hogg, Mr. Barry, and Mr. Rawlinson, the effect of which, if adopted, would have been, it is believed, materially to diminish the risks of the clause if the Government persisted with it. The clause was debated in the House on Tuesday last, when Mr. Glyn-Jones, in a lucid and convincing speech, which evidently interested the House as the speech of a man who thoroughly knew what he was talking about, detailed the objections of the two associations, and urged that the matter should be postponed until it had been more thoroughly considered. As a result the Chancellor of the Exchequer withdrew the clause, promising to bring it up on the report stage in the hope that in the meantime it would be possible to amend it so as to satisfy the objectors. The chief speech made against postponement came from Sir Henry Craik, who was not convinced by the arguments that had been adduced by the two associations, and thought it rather ungracious on their part to oppose what he thought was a very generous concession on the part of the Government to thoroughly deserving institutions. Sir Henry did not seem to realize that the two associations were compelled by a sense of duty to object, not to the concession, but to the pressing through at very short notice of a clause considered to be of wide-reaching importance, as to which the organized bodies of the two professions chiefly concerned had not been consulted. Opposition also came from Mr. Jonathan Samuel, of Stockton-on-Tees, who, speaking as one interested in hospital management, strongly deprecated the cheapening of alcohol for medicinal purposes. The debate clearly showed that the British Medical Association and the Pharmaceutical Society were thoroughly justified in

asking for delay, and it will also, we hope, have the effect of showing the Government the wisdom, in matters of this kind, of ascertaining beforehand the opinion of bodies which are strongly interested, and which could be relied upon to give the Government the benefit of expert advice.

Royal Army Medical Corps (T.F.).—Mr. Forster informed Sir J. Lonsdale on June 23rd that he was not yet in a position to make a statement with regard to an increase in the pay of officers of the R.A.M.C. (T.F.), so as to make their emoluments correspond with those of the medical officers of the regular and new armies.

Pay of Lieutenants R.A.M.C.—Mr. Horner asked, on June 24th, what was the total pay, with allowances, of a man in the Royal Army Medical Corps holding the temporary rank of lieutenant in the regular army and the pay, with allowances, of a man holding a lieutenant's rank in the Royal Army Medical Corps Special Reserve, and what were the reasons for the difference in pay. Mr. Forster said that the civil surgeon serving under a special contract, with the rank of lieutenant, received 24s. a day, inclusive of all cash allowances. The Special Reserve officer of lieutenant's rank received pay and allowances of 17s. at home and 20s. in the field. The latter was serving on an engagement made in advance, at the pay of the regular officer, as in all other branches of the Special Reserve. The former was engaged on an emergency contract.

Science and the War.—On June 28th the Prime Minister, in answer to Sir Philip Magnus, said that opportunities would arise for the desired discussion on the organization for the purposes of the war of the services of Fellows of the Royal Society and other scientific bodies, and of the professors and staffs of universities and technical schools, and of the scientific and technical resources of the laboratories and workshops of such institutions. In reply to Mr. E. Jones, who on June 23rd asked a question as to chemical laboratories, Mr. Tennant said that the laboratories of the War Office Research Department were available for research in relation to the properties and effects of gases, oils, and dangerous fluids, and that practically all the laboratories in the country had been placed at the disposal of the War Office which had a large chemical staff of highly qualified men. In reply to Sir John Jardine, who asked on the following day whether in order to deal with such matters as poisonous gases, poisoned wells, and new explosives commissions in the army had been given to persons skilled in chemistry, and whether Fellows of the Institute of Chemistry were eligible for such commissions, Mr. Tennant said that arrangements had been made to employ on such duties, both as officers and non-commissioned officers, a number of persons having these qualifications. Fellows of the Institute of Chemistry were eligible for commissions for this purpose.

Optical Instruments.—Sir William Bull asked, on June 21st, whether any application had been made to the Royal Institution for the temporary use of a laboratory in the institution for conducting certain scientific experiments in connexion with the supply of optical instruments for the forces under the direction of a member of the staff of the Northampton Polytechnic Institute, whose services the governors of that institute had agreed to place at the disposal of the War Office; and, if so, whether the managers of the Royal Institution had expressed their willingness to afford facilities for such experiments to be conducted in the laboratories of the institution, as suggested by the War Office? Mr. Tennant said that the facts were substantially as stated in the first part of the question. The communications received from the Royal Institution did not amount to an offer of help or an expression of readiness to lend assistance. Arrangements for the experiments which the War Office had desired to carry out by means of the good offices of the Royal Institution were subsequently made with Dr. Grant Ogilvie, of the Science Museum, South Kensington. In reply to a subsequent question by Sir Philip Magnus, Mr. Tennant said he would have to inquire why it had become necessary to seek some other place for the performance of these experiments than an institution where all the apparatus and equipment existed.

German Attacks on British Towns.—In reply to Mr. Kellaway, on June 24th, Mr. Bruce, Parliamentary Under Secretary, Home Office, said that, as stated in reply to a question on February 22nd, the number of civilians killed and injured in the bombardment of the Hartlepoons, Scarborough, and Whitby by hostile warships was 127 killed and 567 injured. There had been altogether fourteen attacks by hostile aircraft, extending over wide areas, and chiefly directed against undefended towns, villages, and country districts. The total casualties in these raids were: Killed, 56, of whom 24 were men (all of them civilians), 21 women, and 11 children. Wounded (so far as could be ascertained), 138, of whom 86 were men 35 women, and 17 children.

Medical and Surgical Treatment of the Wounded.—On June 24th Mr. Lynch addressed a series of questions to the Under Secretary of State for War with regard to the treatment of wounds. The first related to motor theatres, and asked what objections there were to their employment, and whether the best features of the Belgian system which had given excellent results would be submitted to study with a view to adoption. Mr. Tennant replied that motor operating theatres were not considered necessary, as facilities for carrying out operations were available as near the front as was deemed advisable. The Belgian practice had been duly considered. Mr. Lynch's second question had reference to a discussion in the French Academy of Medicine in the course of which differences of opinion as to the value of antiseptics in infected wounds was shown. Mr. Tennant replied that the discussion in question had been considered by the British consulting surgeons in France, and a report on the result of their experience in the treatment of both infected and non-infected wounds had been prepared for circulation through all military hospitals. Mr. Lynch's third question was whether the mode of treatment proposed by Sir Watson Cheyne by means of cresol paste had given satisfactory results, and if not whether its use had been discontinued in the army service. Mr. Tennant replied that the results obtained by the use of cresol paste had not been satisfactory, and its use had been discontinued. The fourth question was as to the rate of mortality due to abdominal wounds on the western front, and in cases of compound fractures in which it had been found necessary to sacrifice the limb. Mr. Tennant replied that the information was not available.

Colour Blindness (Dr. Edridge-Green's Researches).—Mr. Lynch asked on June 23rd whether Dr. Edridge-Green was at any time requested by the Board of Trade to submit an efficient test for colour blindness; whether, as a result of considerable experimentation and original research, Dr. Edridge-Green devised that form of lantern which was now employed in the official tests in the navy, and which, after slight modifications, was adopted by the Board of Trade; whether the Board offered to Dr. Edridge-Green any reward or acknowledgment of his services; and whether, in view of the importance of the material results which had followed from Dr. Edridge-Green's scientific researches, he would be recommended for a suitable reward. Captain Pretzman (Parliamentary Secretary to the Board of Trade) said that Dr. Edridge-Green was at no time requested by the Board of Trade to submit a test for colour blindness. The lantern adopted by the Board for testing colour vision was not devised by Dr. Edridge-Green, but was devised by a Departmental Committee appointed in 1910 to investigate the question of sight tests. As regards the remainder of the question, the answer was in the negative. Mr. Lynch asked Captain Pretzman to again personally look into the question on the ground that the Board of Trade had simply taken Dr. Edridge-Green's invention and slightly altered it. Since the days of Thomas Young he was the only British man of science who had contributed valuable work in this particular field of research. Captain Pretzman replied that he had that morning looked into the question, and his information did not tally with Mr. Lynch's statement, but he would look into the matter again.

Small-pox Outbreak at Oldham.—Mr. Long stated on June 28th, in reply to Mr. Hodge, that though the first recognized case of small-pox in the recent outbreak at Oldham

was admitted to the hospital on February 25th, it would appear that the first case of the disease, from which all the others could be traced, was in an unvaccinated girl, whose illness was not originally recognized as small-pox. All the cases had mild attacks of the discrete type, and none were fatal, and most of them were in the hospital for comparatively short periods. There was nothing to show that the outbreak was connected with any insanitary condition.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE CENTRAL COMMITTEE.

A MEETING of the Central Committee was held on Thursday, June 24th, when the further details of the proceedings of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés were discussed. The last meeting of the Belgian Committee of which details had been received was that of April 29th, when it may be remembered that the total subscriptions announced amounted to Fr. 65,000 and the total expenditure to about Fr. 34,000, leaving in hand a little over £1,200. At that meeting the proposal to make monthly grants to the indigent was adopted.

The Distribution of Funds in Belgium.

At the meeting on May 6th subscriptions were announced bringing the total receipts up to Fr. 65,803. On that date there remained in hand £800. The interesting announcement was made that Messrs. Elliman and Co. of Slough had authorized M. Delacre to receive on behalf of the Belgian Committee the sum of £304 due to him from a Belgian creditor, and that the creditor had sent the money.

At that meeting the subcommittee presented a report dealing with monthly grants to medical men. The first list included the widow of a doctor who had been shot—she is completely ruined; six medical men at Dinant whose property has been destroyed; three other doctors in different districts in the same condition; and the widow of a doctor who was homeless. The committee unanimously approved monthly grants of 200 francs in all cases. M. Breuglemans reported on two cases, one of a physician and one of a pharmacist, in whose case these grants had already been passed. He reported that the physician was living "as a day labourer, apparently by casual work or by jobs under a manager; in any case, he who once lived in plenty not long ago, is now in a very lonely plight, his family finds shelter under other roofs, and he himself, at an age when the spring is gone out of life, has to exist as a dependant." Notes of similar cases of cruel hardship were furnished, sufficiently proving to what excellent purpose the Belgian Committee is able to put any funds which the British Committee can send to it.

At the meeting of the Belgian Committee of May 20th additional subscriptions brought the total receipts of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés to 75,000 francs. Grants amounting to 4,000 francs had been made during the previous fortnight, leaving in hand about £1,000. Different members of the committee had received letters of gratitude from those helped, and some photographs of the premises of ruined doctors were laid on the table. Dr. Laruelle read a report on four cases of doctors requiring assistance. All had lost their homes, and their furniture and professional plant had been burnt or destroyed; three of them were practising in entirely ruined districts. Dr. Laruelle, in recommending immediate grants, said that it was proposed later on to suggest monthly allocations for these men, as their means of existence would remain precarious. The grants were voted accordingly. Mr. Breuglemans reported on the position of two pharmacists. One of these, having two sons at the war, had, by mortgaging his property, rebuilt his house to prevent it falling down, and had acquired some stock on credit. For the time being he was carrying on business in premises which had been lent to him. The premises of the other had been completely burnt out, and he had to support a wife and child from a business carried on in a ravaged district, where the heads of families had been killed, leaving their dependants to charity. "Medicines are," said M. Breuglemans, "for the

most part supplied on demand, to be paid for after the war, and the medical funds of manufacturing works are no longer running." M. Coppez, who had seen many of the sufferers, said that it was clear that the assistance given was most valuable, and would have to be renewed in most cases after July. Notice, however, would have to be given to those whom it concerned that the grants were for their sustenance, and must not be used, as had happened, to pay insurance premiums. The President of the Belgian Society reaffirmed the necessity of retaining money for urgent cases, and the method of keeping the British Committee informed regularly of the cases helped was set down for future discussion.

A statement of accounts received by the British Committee through Professor Jacobs was read, showing that on June 10th about £700 remained with the Belgian Committee unexpended, from which £200 have to be deducted for purchase and sale of drugs. This statement of accounts, however, was dated on the day on which a further substantial grant was dispatched to Belgium by the British Committee, so that for the time being the Belgian Committee is again in funds.

The Treasurer's Statement.

Dr. Des Voeux announced that the sum of money received by him up to date amounted to £14,893, but all the local funds had not yet reached the central treasurer. A substantial proportion of this sum is on deposit at the bank and is bearing interest, but the Committee recognized that steady and large subsidies would have to be sent to the Aide et Protection aux Médecins et Pharmaciens Sinistrés, so that efforts to collect money must not be relaxed. Moreover, the supply of clothes to the refugee doctors and pharmacists and their wives was an increasing expense, and the need for distribution in this country might become larger.

THE WEEK'S SUBSCRIPTIONS.

Thirty-first List.

£ s. d.		£ s. d.	
Bournemouth Division,		Dr. Buck	1 1 0
B.M.A. (per Dr.		Dr. Dyson	2 2 0

Dr. Burs (collected by)		£3)	1 0 0
Dr. Smiles	2 2 0		

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Mr. Meredith Townsend reported at the last meeting of the Central Committee that two boxes of instruments, received from the Oamaru General Hospital, New Zealand, were ready for dispatch to Belgium, and that it had been ascertained through the National Committee for Relief in Belgium that surgical instruments are much wanted there.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

The late Mr. Bernard Roth left unsettled estate of the gross value of £84,843, of which £62,945 is net personally.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

CASUALTY CLEARING STATIONS.

The Casualty Clearing Stations I have seen are many, and those that I might see are more; but it is useless to put off a description, for what is true of a few will be true to the end. As our composite army grows in size, so, too, grows the number of clearing hospitals. Officially, the latter title is now banned, but, as will be shown by an account that will reach you later, it is not really inappropriate.

There are, I suppose, about a dozen of them, and at one time they were disposed in three narrowing arcs roughly parallel with the fighting line, but they are mobile units, and move, or will, as the army moves.

As distance counts near the trenches they are generally a long way apart, but sometimes there are two or more of them temporarily at the same railroad. There are times when the enemy's long-distance artillery gropes blindly for something to hurt; and if it thinks it has found it at a place where there happens to be a clearing hospital, then the latter must seek new quarters.

But wherever it may go this is never far from the real front. Just now two or three have been left by the tide, say, a dozen miles from the trenches, and others are at intermediate distances. Some are so close that even in "peace time" their occupants can fairly well gauge what is going on merely by the sounds that reach their ears.

In casualty clearing station parlance, it is "peace time" when only ordinary trench fighting, or an intermittent artillery duel, is in progress, and when men with wounds of all degrees of severity arrive at the rate of 90 or 100 a day.

The motor ambulance conveys bring them in from the various head quarters of the field ambulances serving the divisions occupying the section of the line nearest the village where the clearing hospital is established. There is no fixed hour for their arrival, but in "peace times" this is commonly in the hours between reveillé and midday. The convoy loads then represent the whole of the wounded garnered by the field ambulances between daylight that morning and daylight twenty-four hours previously. But there is really no regularity. Often enough a field ambulance will send straight in by its own vehicles a few men who have been wounded so far from the trenches that it has been possible to pick them up forthwith. Often enough, too, it finds that it can send on in the afternoon men who at daybreak seemed too ill to be moved.

It is at field ambulance head quarters that the first winnowing of the wounded takes place; but the mesh of the sieve is very wide. Well it may be, seeing that the clearing hospitals with all their possibilities are so close at hand. When things are at all active it lets through all but those for whom even another hour or less of movement is for the moment out of the question.

At the casualty clearing stations the sifting mesh is closer; as close as the surgeons choose when things are slack, and just close enough during times of "liveliness" to secure that no one shall be moved basewards by a hospital train without having his first-aid dressing replaced, without having any fracture present adequately splinted, without the patient himself having been made comfortable, and to ensure that all shall be detained who are in a state of serious shock or in whom immediate operation is imperative.

But the number that must thus be detained is commonly not large; probably 70 or 80 per cent. of each convoy can be transferred when a hospital train arrives. This is certain to be the case within twenty-four hours, and practically speaking can be almost as soon as the officer in command of the casualty clearing station wishes. A telegram to the D.M.S. of the army to which his unit is attached will promptly bring him, if need be, not one but a whole series of trains.

The foregoing is possibly one of the reasons why the term "casualty clearing station" has been substituted for the original name of these formations. The word "hospital" suggested not more than is really true of them,

but a more ambitious part than is ever theirs on paper. Officially they are entitled to act as hospitals only so long as they have on their hands patients whom they cannot possibly evacuate.

Primarily each of them is a kind of cross between a funnel and a filter, the wide end facing the trenches, the narrow end fitting into the top end of the line of communications and ensuring that the stream of wounded shall take the right direction. In this way they play towards the field ambulances the same part that the latter do towards the regimental aid posts. Whenever a field ambulance wishes to get rid of its sick and wounded the related casualty clearing station must be prepared to take charge of them forthwith. If necessary it must detach part of its personnel and equipment and send it forward to the place which the field ambulance was occupying. Another like portion may also have to be detached and sent rearwards to form an intermediate station if the distance between itself and the nearest railhead is great. This is the official position of casualty clearing stations and obviously it is not one in which the hospital idea can play a conspicuous part.

But their real present position is different. Thanks partly to the sieglike character of the war, but still more largely to the introduction of motor ambulance convoys and to the substitution of automobile vehicles for 70 per cent. of each field ambulance's wagons, the whole situation has been changed. It has been changed, indeed, so thoroughly that it seems likely that the present statements regarding all medical work done in advance of railhead are destined to be entirely recast or will be held to apply only to warfare in countries where motor transport cannot be freely utilized. Meanwhile the net effect is that though the hospital element is still kept officially in the background and the general equipment of a casualty clearing station is still of such a character as to make it a readily moved unit, it can and does in fact do a good deal of hospital work of the very best kind. The latter fact I may perhaps be able to bring out more clearly in a later letter.

MOBILE LABORATORIES.

Two "mobile laboratories" were sent out by the War Office at the beginning of the war; a third and fourth were added soon after Christmas, and I hear that the early arrival of several others is expected. The title which has been applied to them certainly leaves something to be desired in the direction of specificity of description, but I do not know that there is any single epithet by which their character and aim could be precisely indicated. Still the adjective "mobile" is justified, because it does in fact describe one of their more conspicuous attributes with accuracy.

There is no doubt a strong tendency for the work and the apparatus employed to overflow into buildings near which the laboratories are standing, but the nucleus remains unaffected. It consists in each case of a caravan, fitted up with laboratory benches and racks, and mounted on a motor chassis, so that it can be moved at will to any distance along any passable road. A very hurried move might entail the loss of a certain amount of stores, and possibly of one or two pieces of heavy apparatus—say, an autoclave; but if notice to move were given, say at midday, it would not be surprising to find one of these laboratories again at work by tea-time at some village twenty miles distant from that at which one had first seen it. "Mobile" is, therefore, an appropriate adjective.

As for the difficulty of finding a second epithet which shall equally well describe their work, I have heard pathological, bacteriological, chemical, clinical, and hygienic all used in turn, but none of them is satisfactory. The work of the laboratories is not identical, and that of none of them is quite on all-fours with the work done at laboratories to which any of the epithets mentioned are applied in civil life.

Taken as a whole its work lies mainly in the field of preventive medicine, and on it depend most of the measures adopted from time to time for safeguarding the health of the troops at the real front—that is to say, of those who are either actually in the trenches or resting in billets within what the French call the *zone du feu*. The laboratories are supposed to move as the army moves, and meantime they shift their position at the front from time to

time, though not very often. Two of them have now been stationed for several months past at villages which are the head quarters of various army corps, and within four or five miles of the trenches; another—one which has moved fairly often—is about twelve miles away at a place which is at present the head quarters of the second army, and a fourth is at General Headquarters.

One reason why none of these laboratories requires to move very frequently is that attached to each of them is a kind of tender, which can be either dispatched to bring in specimens or used to take the officer in charge to visit some spot where a problem deemed susceptible of solution by laboratory methods is under consideration. The vehicles supplied for this purpose leave nothing to be desired in point of speed, but being of the two-seater or cycle car variety they bump badly when travelling over the cobbled-paved roads of Flanders, however carefully they may be driven. An equally inexpensive or even still cheaper car of heavier build would probably better suit the work required, which includes at times the conveyance of thin glass vessels.

As for the laboratories themselves, the largest and most caravan-like is one to which reference has several times been made in these notes. It is, in fact, an actual caravan, having been originally built and used as a means of visiting races by a well known motor manufacturer, by whom it was handed over to the War Office last autumn, with a view to conversion to its present purposes. The other three furnish about the same floor space as a full-sized ambulance—say, 50 square feet—but have solid wooden walls and probably greater cubic space, since their roofs seem higher. But of course most of the floor space and much of the cubic space is absorbed by benches, shelves, and equipment. Atmospherically, therefore, they are not ideal workshops, either in warm weather or cold. Each of them is mounted on a high-powered chassis, with a relatively short wheelbase. Consequently the body overhangs 3 ft. or 4 ft., and sways a good deal when travelling. In view of these various facts it would not be surprising to find that any other mobile laboratories sent out were mounted on lorry instead of touring-car chassis. While their mobility would not sensibly be diminished, they would be more steady, and the greater amount of elbow-room and breathing-space provided would make them truly self-dependent units.

The internal arrangement of the bodies is much the same in all cases. They are entered from the end like an omnibus, and the worker moves about between two 6 ft. fore-and-aft benches running under the side windows. At the forward end a partition cuts off about two feet of the total available floor space, and thus provides a separate compartment for apparatus requiring use of constant heat. There are cisterns in the roof and electric as well as natural lighting. Their equipment is in three cases bacteriological, and in the fourth is chiefly of the kind to be seen in the laboratories of water examiners.

THE AUSTRALIAN GENERAL HOSPITALS.

The staff of the No. 3 Australian General Hospital reached England in the ss. *Mooltan* on June 27th. The following are the officers:

Colonels.—T. H. Fiaschi, D.S.O., V.D. (N.S.W.), Sir A. W. McCormick (N.S.W.).

Lieutenant-Colonels.—J. A. Dick (N.S.W.), C. T. C. de Crespiqui, Secretary and Registrar, (S.A.), R. Stawell (V.), S. Jamieson (N.S.W.), A. M. Cudmore (S.A.).

Majors.—J. A. H. Sherwin (V.), W. Trethowan (W.A.), J. Morton (N.S.W.), C. Read (N.S.W.), K. Hughes (A.), J. L. Gibson (Q.), W. G. D. Upjohn (V.), H. Harris (N.S.W.), H. J. Stewart (Q.), K. Smith (N.S.W.).

Captains.—E. A. H. Russell (S.A.), W. T. J. Newton (N.S.W.), R. A. P. Wagh (N.S.W.), A. P. Wall (N.S.W.), A. M. Wilson (V.), W. P. Matthews (N.S.W.), F. H. D. B. Lawton (V.), A. H. Gibson (W.A.), T. L. Anderson (W.A.), D. de Witt Henry (V.), E. Fisher (N.S.W.), F. S. MacInre (V.), B. Stewart (V.), A. Brennan (V.), L. A. Hayward (S.A.), J. Hardie (Q.).

Quartermasters.—Captain Mellyn (S.A.), Lieutenant A. S. Stuart (N.S.W.).

Dispenser.—Lieutenant J. R. Hill (N.S.W.).

By the same boat there travelled also a matron and 79 nurses, and 180 N.C.O.'s and orderlies.

Reinforcements for the No. 1 Australian General Hospital were disembarked at Suez. The officers landed were:

Majors.—H. R. Maclean (V.), H. C. Garde (Q.)

Captains.—G. A. W. J. Knight (V.), J. J. Hollywood (N.S.W.), S. Yeatman (S.A.), L. B. Cook (V.), F. MacDonald (Q.), A. Anderson (Q.), H. O. Teague (W.A.), R. E. McClelland (N.S.W.), H. Alsop (N.S.W.), E. R. Stephen (N.S.W.), A. Dunn (N.S.W.), C. R. Palmer (N.S.W.), E. W. Deane (V.), T. G. Leary (V.), R. W. Cunningham (S.A.), A. J. Murphy (Q.), C. J. Cantor (W.A.), R. E. Dunn (T.).

Eighty nurses and 180 N.C.O.'s and orderlies were landed at the same time for this hospital, and, in addition, 50 nurses specially recruited by the R.A.M.C. in Australia for various Egyptian hospitals.

In addition to the officers above enumerated, Captains R. E. Shuter (V.), F. A. Grey (V.), and Clowes (Q.) have reached this country for service at the convalescent depot at Harefield Park; they were accompanied by about 20 nurses and as many N.C.O.'s and orderlies.

HONOURS.

The following names are additional to those published last week upon whom the King has been pleased to approve rewards for services in connexion with operations in the field:

To be Companion of the Bath.

Colonel M. P. C. Holt, D.S.O.

To be Companions of the Distinguished Service Order.

- Lieutenant-Colonel J. Poe, M.B., R.A.M.C.
- Major R. V. Cowie, R.A.M.C.
- Major T. E. Fielding, M.B., R.A.M.C.
- Major F. S. Irvine, M.B., R.A.M.C.
- Surgeon-Major B. Pares, Royal Horse Guards.
- Captain C. G. Browne, R.A.M.C.
- Captain H. StM. Carter, M.D., R.A.M.C.
- Captain (temporary Major) H. A. Chisholm, Canadian A.M.C.
- Captain T. J. Crean, V.C., R.A.M.C. (Reserve of Officers).
- Captain R. Gale, M.B., R.A.M.C.
- Captain F. A. Lloyd Jones, M.B., R.A.M.C.
- Captain T. H. McKillop, Canadian A.M.C.
- Captain O. W. McSheehy, M.B., R.A.M.C.
- Captain J. Taylor, M.B., I.M.S., attached 1st Battalion 39th Garwhal Rifles.
- Temporary Captain O. Richards, M.D., F.R.C.S., R.A.M.C.

Awarded the Military Cross.

- Captain W. Darling, M.B., F.R.C.S., R.A.M.C. Special Reserve.
- Captain G. F. Dawson, M.B., R.A.M.C., attached 2nd Battalion Royal Highlanders.
- Captain P. Dwyer, M.B., R.A.M.C.
- Captain A. K. Haywood, Canadian A.M.C., attached 3rd Canadian Battalion.
- Captain H. L. Howell, R.A.M.C.
- Captain J. B. Jones, M.B., R.A.M.C.
- Captain E. J. Kavanagh, M.B., R.A.M.C.
- Captain J. S. O'Neill, M.B., I.M.S.
- Captain J. W. C. Stubbs, M.B., R.A.M.C.
- Captain H. F. Vellacott, F.R.C.S., R.A.M.C. Special Reserve.
- Captain N. T. Whitehead, M.B., R.A.M.C.
- Captain H. G. Winter, R.A.M.C.
- Lieutenant W. McM. Chesney, M.B., R.A.M.C. Special Reserve.
- Lieutenant R. A. Preston, M.B., R.A.M.C. Special Reserve.
- Temporary Lieutenant D. D. Craig, M.B., R.A.M.C.
- Temporary Lieutenant F. T. Hill, R.A.M.C.
- Temporary Lieutenant H. G. Janion, R.A.M.C.
- Temporary Lieutenant F. W. James, M.D., R.A.M.C.
- Temporary Lieutenant W. H. Lister, R.A.M.C.
- Temporary Lieutenant I. C. Maclean, M.D., R.A.M.C.
- Temporary Lieutenant P. Smith, R.A.M.C.
- Second Class Subassistant Surgeon Ramkrishna Ganpat Shinde, attached 1st Battalion 39th Garwhal Rifles.
- Sergeant-Major G. B. Walker, R.A.M.C.
- Quartermaster and Honorary Lieutenant J. Carr, West Riding R.A.M.C. (T.F.).
- Quartermaster and Honorary Lieutenant H. Dugdale, 3rd East Lancashire Field Ambulance, R.A.M.C. (T.F.).

To be Brevet-Colonels.

- Lieutenant-Colonel H. Ensor, D.S.O., M.B., R.A.M.C. Staff.
- Lieutenant-Colonel M. H. G. Fell, R.A.M.C. Staff.
- Lieutenant-Colonel W. W. White, M.D., I.M.S.

To be Brevet Lieutenant-Colonel.

Major J. S. Bostock, M.B., R.A.M.C.

To be Honorary Majors.

Quartermaster and Honorary Captains W. N. Archibald and A. Lunney, R.A.M.C.

To be Honorary Captain.

Quartermaster and Honorary Lieutenant C. W. Hearn, 3rd Wexsex (attached 26th Field Ambulance) R.A.M.C. (T.F.).

Indian Distinguished Service Medal.
2nd Class Senior Subassistant Surgeon Mahadeo Parshad, I.S.M.D., 1st Gurkhas.
1st Class Subassistant Surgeon Narayan Parshad Sakul, I.S.M.D., 112th Field Ambulance.
Leuco Naik Mangli, Army Bearer Corps, No. 8 Co., 113th Field Ambulance.

Decoration of the Royal Red Cross.

Queen Alexandra's Imperial Military Nursing Service.—Matron Miss F. M. Hodgins, Matron Miss H. W. Reid, Matron Miss G. M. Richards, Sister Miss A. F. Byers (Acting Matron), Sister Miss J. A. Congleton, Dr. Stacey, Miss M. C. Corbishley (Acting Sister), Sister Miss H. Hartigan, Staff Nurse Miss C. MacK. MacRae (Acting Sister), Staff Nurse Miss K. M. Matthews (Acting Sister), Sister Miss G. M. Smith.

Queen Alexandra's Imperial Military Nursing Service (Reserve).—Miss N. Adler, Miss E. G. Barrett, Miss E. M. Hansard, C. Elston, Miss J. Barclay Smith, Miss L. M. Thurling.
Queen Alexandra's Military Nursing Service for India.—Lady Superintendent Miss F. Y. Watt.

Territorial Force Nursing Service.—Miss H. G. Palin, Miss A. H. Ivins, Miss E. A. Jackson, Miss P. M. Morris, Miss C. Webber.

Civil Hospitals Reserve.—Miss I. E. M. Barbier, Royal Infirmary, Bristol; Miss S. C. Mcintosh, Royal Infirmary, Edinburgh; Miss M. Clark, Royal Southern Hospital, Liverpool; Miss M. A. O'Leary, Dr. Stacey's Hospital, Dublin; Miss E. T. Ferguson, Royal Infirmary, Perth; Miss E. Harley St. Thomas's Hospital, London; Miss K. Johnston, City of Dublin Hospital, Dublin; Miss V. M. Kiddle, Guy's Hospital, London; Miss E. M. Le Sneur, University College Hospital, London; Miss M. Oakey, General Hospital, Birmingham; Miss L. O. Peet, Derby Royal Infirmary, Derby; Miss A. Wainwright, The London Hospital, London.

British Red Cross Society.—Principal Matron, Miss N. Fletcher.

Australian Nursing Service.—Matron, Miss I. Greaves.
Canadian Nursing Service.—Matron, Miss E. Campbell.

SIR JOHN FRENCH'S DISPATCH.

The following is a continuation of the list published last week of the names mentioned in Sir John French's dispatch for gallant and distinguished service in the field:

General Head Quarters Staff, etc.

- Colonel S. G. Moores, A.M.S.
- Surgeon-General T. J. O'Donnell, D.S.O., A.M.S.
- Colonel S. Westcott, C.M.G., A.M.S.

1st Life Guards.

Surgeon-Lieutenant E. D. Anderson.

2nd Life Guards.

Surgeon Captain E. J. H. Luxmore.

Medical Service and Royal Army Medical Corps.

- Quartermaster-Sergeant W. Andrews, Acting Sergeant-Major W. Argent, Private P. F. Arnold, Acting Corporal F. Avery, Acting Corporal G. F. Bardswell, Sergeant F. P. Barron, Private F. Batchelor, Private J. F. Benson, Private W. T. Blowitt, Sergeant V. Butler, Sergeant H. G. Boxall, Acting Corporal G. Burdett, Staff Sergeant W. Busby, Acting Corporal G. Butler, Private J. Cartwright, Private S. J. Chase, Acting Corporal A. Clark, Lance-Corporal W. C. Cook, Staff Sergeant A. Dady, Private V. J. Davis, Private J. G. Deakin, Sergeant-Major E. B. Dewberry, Private F. Emmerson, Private A. Evans, Private H. Floyd, Staff Sergeant J. G. A. Forbes, Sergeant-Major G. A. Gibbs, Sergeant-Major J. Gillespie, Corporal F. Gifford, Private H. Greenwood, Sergeant A. O. Gregory, Quartermaster Sergeant T. Gregson, Private W. H. Hamer, Sergeant G. Harris, Private J. Harrison, Private E. W. Hayne, Sergeant G. W. Herbert, Private P. Horrigan, Sergeant W. Hutchings, Staff Sergeant J. R. Ireson, Staff Sergeant (Acting Sergeant-Major) C. Jones, Private J. Jones, Quartermaster-Sergeant F. E. Knipps, Private R. N. Knowles, Sergeant-Major E. Larned, Private W. A. Last, Sergeant A. F. Leaney, Private W. Matchin, Sergeant W. H. Mattison, Sergeant J. N. Mercer, Sergeant-Major W. Merchant, Corporal J. Morrison, Acting Corporal H. F. Mulley, Quartermaster-Sergeant P. H. Musgrave, Staff Sergeant P. J. O'Rourke, Private E. T. J. Owen, Quartermaster-Sergeant E. A. Philbrick, Sergeant R. Pollock, Quartermaster-Sergeant F. Porter, Private A. Foley, Sergeant J. D. Powell, Sergeant H. M. Prince, Quartermaster-Sergeant W. C. Prince, Staff Sergeant G. P. Pursey, Private A. F. Reynolds, Quartermaster-Sergeant C. E. T. Richardson, Corporal R. Roberts, Staff Sergeant W. Robertson, Sergeant H. Russell, Staff Sergeant W. Scott, Sergeant-Major W. H. Scott-Balcock, Sergeant H. W. Seldon, Staff Sergeant E. Sharp, Sergeant-Major F. M. Sharpe, Sergeant E. F. Smith, Sergeant-Major H. Sprinks, Sergeant-Major E. Steele, Staff Sergeant G. P. Steer, Staff Sergeant G. Stubbs, Sergeant H. E. Taylor, Quartermaster-Sergeant J. H. Thomas, Sergeant W. B. Thomas, Private B. P. Thorpe, Staff Sergeant W. S. Tove, Acting Sergeant-Major C. J. Tunn, Staff Sergeant-Major G. B. Walker, Sergeant-Major D. Watt, Staff Sergeant W. Whyte, Private H. Wilkinson.

Q.=Queensland; N.S.W.=New South Wales; V.=Victoria; S.A.=South Australia; W.A.=West Australia; T.=Tasmania.

Royal Army Medical Corps (Territorial Force).

Bickerton, Captain R. E., M.B., 84th Field Ambulance.
Birt, Major E. B., 26th Field Ambulance.
Blackwood, Captain W. M. B., 26th Field Ambulance.
Burgess, Lieutenant R., 24th Field Ambulance.
Cameron, Lieutenant-Colonel D. A., M.B., 86th Field Ambulance.
Clayton, Lieutenant J., 2nd London Sanitary Company.
Draycott, Lieutenant C. N., 1st London (City of London) Sanitary Company.
Fairbank, Captain H. A. T., F.R.C.S., 85th Field Ambulance.
Fisher, Major D. L., M.B., 86th Field Ambulance.
Harrison, Captain W. J., M.B., attached 6th Battalion, Northumberland Fusiliers.
Hearn, Quartermaster and Honorary Lieutenant C. W., 26th Field Ambulance.
Mackay, Major W. B., M.D., attached 7th Battalion, Northumberland Fusiliers.
Price, Lieutenant F. H. N., 2nd London Sanitary Company.
Sharpe, Lieutenant-Colonel W. S., M.D., 84th Field Ambulance.
Sprawson, Captain E. C., 3rd Division.
Waggett, Major E. B., M.B., 85th Field Ambulance.
Wardle, Lieutenant V. H., 86th Field Ambulance.
Whait, Lieutenant-Colonel J. R., M.B., 85th Field Ambulance.

Sergeant C. W. Abnett, 81st Field Ambulance; Private H. Boudry, 24th Field Ambulance; Staff Sergeant J. T. Boyes, Lance-Corporal J. Burvill, 32nd Field Ambulance; Lance-Sergeant J. Dalton, 1st West Lancashire Field Ambulance; Corporal (Acting Sergeant) N. A. Dore, 1st London (City of London) Sanitary Company; Sergeant C. D. Dymond, Welsh Border Mounted Brigade; Staff Sergeant J. C. Caswell, Private H. Dominy, 25th Field Ambulance; Lance-Corporal P. Elcock, 26th Field Ambulance; Staff Sergeant W. G. Gotham, 25th Field Ambulance; Acting Sergeant-Major H. W. Gregory, 26th Field Ambulance; Staff Sergeant W. K. Haddingham, 2nd London Sanitary Company; Corporal W. N. Hodge, 83rd Field Ambulance; Sergeant-Major A. E. R. House, 24th Field Ambulance; Sergeant E. Ingleton, 82nd Field Ambulance; Lance-Corporal E. Meigh, 1st West Lancashire Field Ambulance; Acting Sergeant-Major T. W. Parsons, 25th Field Ambulance; Staff Sergeant S. Pickering, 2nd London Sanitary Company; Staff Sergeant S. C. Pocock, 26th Field Ambulance; Private C. B. Royle, 81st Field Ambulance; Private J. St. John, 3rd Welsh Field Ambulance; Private H. C. Sell; Private H. Stapleton, 83rd Field Ambulance; Acting Sergeant R. M. Watchorn, 3rd Welsh Field Ambulance; Staff Sergeant J. J. Webster; Private A. E. Wright, 81st Field Ambulance.

Australian Army Medical Corps.

Lieutenant-Colonel (temporary Lieutenant-Colonel in army) W. L. E. Eames, C.B.
Sergeant-Major C. R. Williams.
Sergeant P. W. Chapman.

Staff, 1st Canadian Division.

Lieutenant-Colonel (temporary Colonel) G. La F. Foster, Canadian A.M.C.
Captain (temporary Major) H. A. Chisholm, Canadian A.M.C.

Canadian Army Medical Corps.

Ford, Lieutenant-Colonel F. G. L.
McPherson, Lieutenant-Colonel D. W.
Ross, Lieutenant-Colonel A. E.
Shillington, Lieutenant-Colonel A. T.
Watt, Lieutenant-Colonel W. L.
Duval, Major J. L.
Hardy, Major E. B.
Bell, Captain F. C.
Brown, Captain G. B.
Donaldson, Captain A. S.
Fraser, Captain J. J.
McGibbon, Captain R. H.
McKillop, Captain T. H.
McQueen, Captain J. D.
Stone, Captain E. L.
Haywood, Lieutenant A. K., attached 3rd Canadian Battalion.

Quartermaster-Sergeant G. S. Cooke, Staff Sergeant H. G. B. Butt, Staff Sergeant A. J. B., Milborne, Staff Sergeant A. E. Rosey, Sergeant T. M. Brown, Sergeant J. W. McKay (dead), Sergeant W. B. Smith, Lance-Corporal W. McDonald, Private A. Bartley, Private R. W. Chester, Private J. Dalton, Private C. J. E. Farr, Private W. J. Holloway, Private R. L. Head, Private F. J. Lisney, Private W. M. Leishman, Private A. Millen, Private H. G. Stewart, Private G. B. Tompkins, Private E. Trotter, Private J. G. Youldon.

Indian Medical Service.

Anderson, Lieutenant F. J., 11th Indian Field Ambulance.
Atal, Major P. (killed).
Barnfield, Lieutenant-Colonel H. J. K.
Barron, Major R. M., 13th Indian Field Ambulance.

Sheppard, Captain A. L., M.B.
Taylor, Captain John, M.B. (attached 139th Garhwal Rifles).
Trafford, Major W. L., M.B., F.R.C.S.
Wall, Lieutenant-Colonel F.
White, Lieutenant-Colonel W. W., M.D., 128th Indian Field Ambulance.

Indian Subordinate Medical Department.

Macqueen, Senior Assistant Surgeon and Honorary Lieutenant K. G. S.
Holmes, 1st Class Assistant Surgeon J. A. H.
Maine, 1st Class Assistant Surgeon W. J. S.
Rodgers, 2nd Class Assistant Surgeon M. C. R.
Bonche, 3rd Class Assistant Surgeon B. J.
Cummins, 3rd Class Assistant Surgeon A. W.
Fox, 3rd Class Assistant Surgeon H. A.
Fraser, 3rd Class Assistant Surgeon A. G. L.
D'Arcy, 4th Class Assistant Surgeon A. F. J.
Hill, 4th Class Assistant Surgeon E. R.
Perkins, 4th Class Assistant Surgeon J. W.
Gauri Shankar, 1st Class Senior Subassistant Surgeon.
Jasundani, S., 1st Class Subassistant Surgeon S.
Lachmann Das, 1st Class Subassistant Surgeon.
Muhammad Raza Khan, 1st Class Subassistant Surgeon.
Narayan-parshad Sukul, 1st Class Subassistant Surgeon.
Salagram, 1st Class Subassistant Surgeon.
Ganpat Kanooji Rao Rane, 3rd Class Subassistant Surgeon.
Raj Singh, 3rd Class Subassistant Surgeon.
Upendra Kumar Ganguli, 3rd Class Subassistant Surgeon.

Queen Alexandra's Imperial Military Nursing Service.

Matron-in-Chief Miss E. M. McCarthy, R.R.C., Acting Matron Miss A. F. Byers, Matron Miss E. M. Hodgins, Matron Miss H. W. Reid, Matron Miss G. M. Richards, Sister Miss G. M. Allen, Sister Miss S. K. Bills, Sister Miss J. H. Conleton, Acting Sister Miss M. C. Corlishley, Sister Miss H. M. Drage, Sister Miss H. Hartigan, Sister Miss G. A. Howe, Sister Miss E. J. M. Keene, Sister Miss E. M. Lang, Acting Sister Miss C. Mack, MacRae, Acting Sister Miss K. M. Mathews, Sister Miss G. M. Smith, Sister Miss M. Sleenson, Sister Miss M. S. Williams, Staff Nurse Miss D. M. Best, Staff Nurse Miss M. P. Davies, Staff Nurse Miss M. M. Roberts.

Queen Alexandra's Imperial Military Nursing Service (Reserve).

Miss N. Adler, Miss J. Barclay Smith, Miss E. G. Barrett, Miss E. D. Devenish-Reares, Miss C. Elston, Miss E. M. Hansard, Miss B. J. D. Reid, Miss L. M. Thurling.

Territorial Force Nursing Service.

Miss M. A. Brander, Miss H. I. Ivin, Miss E. A. Jackson, Miss P. M. Morris, Miss H. G. Palin, Miss C. Webber.

Civil Hospitals Reserve.

Miss M. W. Bannister (Royal Infirmary, Hull), Miss I. E. M. Barbier (Royal Infirmary, Bristol), Miss M. Clark (Royal Southern Hospital, Liverpool), Miss M. A. Doherty (Dr. Steeve's Hospital, Dublin), Miss E. Fearnley (St. Thomas's Hospital, London) (dead), Miss E. T. Ferguson (Royal Infirmary, Perth), Miss F. Harley (St. Thomas's Hospital, London), Miss A. Healey (Dr. Steeve's Hospital, Dublin), Miss K. Johnston (City of Dublin Hospital, Dublin), Miss V. M. Kiddle (Guy's Hospital, London), Miss M. R. Knight (Westminster Hospital, London), Miss E. M. Le Sneur (University College Hospital, London), Miss S. C. McIntosh (Royal Infirmary, Edinburgh), Miss M. Oakley (General Hospital, Birmingham), Miss L. O. Peet (Derby Royal Infirmary, Derby), Miss A. Wainwright (The London Hospital, London).

British Red Cross Society.

Mr. F. Alexander, Captain E. Daniels, Mr. C. D. Fisher, Principal Matron Miss N. Fletcher, Dr. G. R. Fox, Mrs. Phillips, Miss A. L. Pierce, Dr. J. W. Struthers, Mr. A. C. Valadier, Mr. G. W. Young.

Australian Nursing Service.

Matron Miss I. Greaves.

Canadian Nursing Service.

Matron Miss E. Campbell, Nursing Sister Miss M. P. Richardson.

Queen Alexandra's Military Nursing Service for India.

Lady Superintendent, Miss E. F. Watt, Senior Nursing Sister Miss H. A. M. Rait, Nursing Sister Miss E. Kelsco.

CASUALTIES IN THE MEDICAL SERVICES.

NAVY.

Died of Wounds.

DR. F. H. REES, who died on June 21st from wounds received during the operations in the Dardanelles, was the elder son of Dr. Alfred Rees, of Cardiff. He received his early education at the Cardiff Intermediate School, and after completing his medical studies at University College, London, took the degrees of M.B., B.S. Lond. in 1912. In February he joined the R.A.M.C., but was transferred to the Naval Division at Plymouth as temporary surgeon on February 9th, 1915; after undergoing further training at Blandford he sailed for Malta in April. During the whole of the time he has been in the Dardanelles he was engaged with the land forces amid the desperate fighting which has taken place.

ARMY.

Killed.

Lieutenant Geoffrey Montague Mason Fleming, R.A.M.C., was reported as killed in action in Flanders in the casualty list of June 25th. He took the M.B. and Ch.B. of Dublin University in 1913, and took a temporary commission as lieutenant in the R.A.M.C. from August 16th, 1914.

Died.

Lieutenant Eric Alfred Wright, R.A.M.C., died on June 20th at Alexandria of septic poisoning contracted in attending the wounded, aged 36. He was the only son of Dr. and Mrs. Wright, of Mountsorrel, Romford, and was educated at Felsted School and at Selwyn College, Cambridge, where he took the B.A. in 1899, the M.B. and B.C. in 1904, and the D.P.H. in 1905, also taking the M.R.C.S. and L.R.C.P. in London in 1903. After serving as assistant and senior resident medical officer at the North-West London Hospital, and as house-surgeon of St. Peter's Hospital for Stone, he went into practice at Romford, Essex, where he was medical officer of the Hornchurch Cottage Homes, medical officer to the Post Office, and certifying factory surgeon. He was a sergeant in the London Scottish, went with that corps to France last year, and was with them in their first action at Messines. When their medical officer, the late Captain Angus Macnab, was killed in action, he became surgeon to the battalion. Subsequently he was invalided to England, and took a temporary commission in the R.A.M.C. from December 16th, 1914. In March, 1915, he was sent to Alexandria, where he was serving in the 15th General Hospital.

Wounded.

Lieutenant (temporary) D. Bell, R.A.M.C., Flanders.
Lieutenant W. W. Adamson, R.A.M.C. (T.F.), Flanders.
Lieutenant J. Cowan, R.A.M.C. (Special Reserve), Flanders.
Lieutenant W. H. Shephard, R.A.M.C. (Special Reserve), Flanders.
Lieutenant H. Seddon, R.A.M.C. (T.F.), Dardanelles.
Lieutenant (temporary) A. J. McC. C. Morrison, R.A.M.C., Dardanelles.

Suffering from Gas Poisoning.

Lieutenant R. D. D. Brownson, R.A.M.C. (Special Reserve), Flanders.

SONS OF THE PROFESSION AND MEDICAL STUDENTS.

Second Lieutenant R. B. Buchanan, 5th Battalion Royal Scots Fusiliers, who was recently killed in action in the Dardanelles, was educated at Foyle College, Londonderry, Bedford School, and Edinburgh University, where he began the study of medicine in 1911, and had passed all except the final examination, gaining medals in zoology, practical anatomy, and surgery. He got his commission on October 12th, 1914, and landed at the Dardanelles, with his battalion, on May 30th.

Second Lieutenant Frank Chilton, who was killed at the Dardanelles about June 20th, was the only son of Dr. Charles Chilton, Professor of Biology, Canterbury College, Christchurch, New Zealand. He was a medical student at Edinburgh University, where he was a member of the O.T.C., and, when war broke out, obtained a commission as Second Lieutenant in the 3rd (Reserve) Battalion of the Argyll and Sutherland Highlanders from August 15th, 1914. He went to the Mediterranean on May 20th, attached to the 2nd Battalion, Hampshire Regiment.

Lieutenant Eric K. Colbourne, 1st Berkshire Regiment (of Victoria, British Columbia), died on June 27th of wounds received in action. He was the third son of Dr. and Mrs.

Colbourne of Beckenham, and was 27 years of age. He was gazetted second lieutenant on probation in January last.

Private Wilfred Y. Dawson, 4th Battalion Australian Imperial Force, who was killed in action at the Dardanelles, was the eldest son of Dr. Yelverton Dawson of Southbourne.

Lieutenant Leslie Phillips Jones, of the 9th Royal Berkshire Regiment, died of wounds at the Dardanelles about June 20th, aged 19. He was the third and youngest son of John Phillips Jones of Streatham, and was educated at Mill Hill School, where he was a member of the O.T.C.; at Oriol College, Oxford; and at Bart's, where he was studying medicine. When war broke out he got a commission as Second Lieutenant in the 9th Service Battalion of the Berkshire Regiment from October 17th, 1914; was promoted to Lieutenant on February 8th, 1915; and was sent to the Mediterranean, attached to the 2nd Hampshire Regiment, on May 20th last.

Lieutenant Walter Alfred Leland, 10th Battalion Bedfordshire Regiment, who was killed in action in the Dardanelles, was the eldest son of Dr. and Mrs. Alfred Leland, of Kensington Court, W. He received his lieutenancy last April.

Second Lieutenant Albert Durrell Pank, R.E., died in France on June 20th, aged 19, of wounds received in an accident with a bomb. He was the youngest son of Lieutenant-Colonel Philip Durrell Pank, Bengal Medical Service (retired), and was educated at Wellington, passing from school into the Royal Military Academy, Woolwich. He passed first out of Woolwich in July, 1914, gaining the King's and the Pollock gold medals. He was sent to the Expeditionary Force in France in January, and was attached to the 2nd Field Squadron, 2nd Cavalry Division.

Second Lieutenant Cubitt Noel Rundle, 3rd Battalion South Wales Borderers, was recently killed in action at the Dardanelles. He was the eldest son of Lieutenant-Colonel Cubitt Sindal Rundle, Madras Medical Service (retired), of St. Helier's, Jersey, and was only 19. He got his first commission in the 1st Battalion of the South Wales Borderers on December 23rd, 1914, and was attached to the third (reserve) battalion.

Lieutenant William L. Scott, 25th Battalion Gordon Highlanders, who was killed in France, was a medical student at Aberdeen University. He joined the Gordon Highlanders at Peterhead in December last, when he was appointed a second lieutenant, and left with the battalion in April. Volunteering for foreign service, he went with 15th Battalion to France some months ago, and was promoted to a lieutenancy. He was in his 23rd year, and was the eldest son of Mr. W. L. Scott, solicitor, of Peterhead.

Corporal Geoffrey B. Warde, of the Canadian Contingent, who was killed in France, was the eldest son of Dr. and Mrs. Warde, of Tunbridge Wells. He was 19 years of age.

Charles D. B. Whitty, of the Royal Montreal Regiment, died a prisoner of war at Kersselare from wounds received in action on April 24th. He was the eldest son of Dr. C. J. Whitty of Bath.

NOTES.

THE KING GEORGE HOSPITAL, LONDON.

THE Commandant and Chairman and Committee of the King George Hospital held their first view of the hospital for benefactors and donors on June 30th. The hospital is situated in Stamford Street, next to the Royal Waterloo Hospital for Children and Women, and occupies the building which was designed for the reception of His Majesty's Stationery Office. In his statement of how the hospital came into being, Sir Frederick Treves says that "the building will be memorable not only as a hospital, but also as a record of the sentiment that led to its transformation. It will be a token of the spirit of Red Cross work in England." The scheme arose as the result of co-operation between the War Office and the British Red Cross and St. John Societies. While the War Office has carried out the structural alterations necessary to transform the building into a hospital, the societies have equipped the wards, operating theatres, dispensaries, special departments, chapel, day rooms for the patients, and quarters for the staff; the societies also supply the medical, surgical, and nursing personnel. Thus the hospital, so far as the patient is concerned, is a civilian hospital, equipped and maintained by the generosity of the people of England. The alterations in structure were carried out by the Director of Barrack Construction from plans prepared by Mr. Edwin T. Hall. There are five floors to the building. In the basement are the stores and the x-ray department; on the ground floor are the offices of the commandant and chief officers, waiting rooms, laboratories and dispensaries, barracks which hold nearly 200 orderlies, with a billiard room, reading and writing room, and dining rooms. On this floor also is the chapel, with an altar furnished by Her Majesty Queen Alexandra and Her Royal Highness Princess Victoria. The first floor is devoted to the medical cases; the second, third, and fourth to surgical

cases. There are six operating theatres, each with an anaesthetizing room, sterilizing room, and special stores. The equipment of the hospital was furnished by contributions from various societies and private individuals at the rate of £25 per bed; but this estimate did not include the cost of the operating theatres or the x-ray department and a few other accessories. The theatres and x-ray department were provided by the generosity of the British Farmers' Red Cross Fund. The roof of the building is to be turned into a roof garden, the area of which is about one and a half acres. Here, again, are to be found twenty-four revolving shelters, each capable of seating many men. Undoubtedly the hospital is extremely well equipped, and would suggest a permanent institution rather than one designed for temporary purposes connected with the war. The number of patients to be accommodated will be 1,650; at present only about half the beds are occupied. For this number of patients the actual medical and surgical staff, in addition to the military staff controlling the management, is 149; of these, 14 are on the consulting staff, 33 on the honorary medical and surgical visiting staff, 48 anaesthetists, 4 for the nose and throat department, 13 for the dental, 3 for the x-ray department, 1 for the electro-therapeutic, 4 for the ophthalmic, 4 for the pathological, and 1 clinical photographer. There are 24 resident medical officers. If we may venture to raise one little criticism of the establishment as it stands at present, it is that it would seem to have been constructed on somewhat extravagant lines. It might be suggested that the medical staff, both visiting and resident, could be curtailed without detriment to the patients at a time when there is said to be some shortage of doctors to serve in the army, the more so as it is recognized by those responsible for the institution that in a military hospital the proportion of patients who can sit up and move about is much higher than in a civilian hospital, for the reason that all soldiers, however small the ailment which renders them unfit for duty, are placed in hospital. As regards the equipment of a temporary hospital, it is possible that £4,000 is rather a large sum to spend on the operating theatres and x-ray installation. It is stated that nine and a half acres of linoleum were required for covering the floors; whether this was exactly necessary in the basement and in some of the corridors seems doubtful. The shelters in the roof garden are perhaps a luxury at a time when rigid economy is the order of the day. However, there is no doubt that the needs of the sick and wounded will receive the utmost that science and equipment can give them; and so long as the country can afford it, no one will grudge its soldiers the best that is available.

MILITARY CASES AT BRITISH HEALTH RESORTS.

The honorary secretaries of the special committee of the Section of Balneology and Climatology of the Royal Society of Medicine are issuing a further circular calling the attention of medical practitioners in health resorts in Great Britain to the special Case Record Card, the first issue of which was made by the committee in April. The cards have been approved by the Medical Research Committee, which is charged with the duty of compiling a medical history of the war, and will form part of the statistical records to be used in its preparation. A strong appeal is made to all practitioners, especially those responsible for hospitals and homes for officers and men, to make use of the cards for all military patients, and, in the cases of non-commissioned officers and men, to enter up the regimental number. Further supplies of cards and envelopes can be obtained free of charge on application to Messrs. Adlard and Son, Bartholomew Close, London, E.C. Other communications should be addressed to the honorary secretaries of the committee at 36, Devonshire Place, W. They will be glad to furnish copies of the pamphlet that has been circulated by the War Office and Admiralty, and to receive from local committees or representatives any suggestions which will facilitate the efficient and scientific treatment of war cases at the various British health resorts.

A MOVABLE AMBULANCE HOSPITAL.

Dr. Henri de Rothschild has presented to the French Army Medical Service a movable surgical ambulance hospital consisting of six huts easily put up or taken down. An operating theatre, two wards for twenty-four beds, an isolation ward, and two huts for surgeons and orderlies are provided. The huts are constructed of asbestos sheeting.

INDIA.

Bengal's New Hospital Ship.

The Bengal Volunteer Field Ambulance Corps has provided a shallow draft river barge capable of accommodating 100 beds for river ambulance work on the Shatt-el-Arab, which runs into the Persian Gulf. This is considered at the present moment by the authorities the most useful gift which Bengal can offer as her contribution to the war. The vessel is a two-decker river flat of 400 tons, which was till recently in use as a river transport for troops. It has been converted by the Deputy Director, Indian Marine, into an up-to-date floating hospital, under the direction of the Commandant of the corps, Lieutenant-Colonel A. H. Nott, I.M.S., and the Joint Secretary, Dr. S. P. Savadhikary. On the upper deck there is accommodation for 100 sick and wounded, two fully equipped operation rooms, one for clean cases and the other for septic cases. Between the two there is a sterilizing chamber and an x-ray room fitted with a powerful x-ray apparatus, and contrivances for the electric disinfecting of poisoned wounds. Space is set apart for microscopic examinations, and also for the reception of contagious and infectious cases. On the lower deck are cabins for the Commandant and his officers, accommodation for the men, the electric plant, ice machine, refrigerators, and other conveniences. The motor ambulances will be carried on board as well as a number of stretchers and other means of transporting the sick and wounded. Lifts have been provided for the carriage of loaded stretchers to and from the lower deck. The usual dispensing, dressing, medical, and general store-rooms have been provided. The vessel is lit throughout with electricity, and a number of fans have been fitted up. The vessel carries a full complement of officers and men recruited from the civilian Bengali population, who have been given a thorough training in the military lines at Alipore under the supervision of the Commandant and other military officers deputed by the Government. The cost of equipping and maintaining the unit and hospital will be met entirely from voluntary contributions from the Bengali population. Government, however, is providing the pay of the Commandant and such regular officers as might be lent for the purposes of the unit, and will provide for the transport and rations while on active service. Other officers of the unit will get no pay, but only a small separation allowance for their families, and a life insurance policy for sums varying from Rs.1,000 to Rs.5,000 according to their rank; they will have free uniforms.

St. John Ambulance Red Cross Gifts.

The Indian Council of the St. John Ambulance Association issued recently a special appeal for comforts and articles of clothing which were required for the unit and hospital in the Persian Gulf. Within six days no less than forty-nine cases of these gifts were shipped for the Gulf.

Special Depot Hospitals.

The Indian Council of the St. John Ambulance Association on April 21st addressed a circular letter to all provincial and local centres on the subject of the thirty-one depot hospitals to be provided for sick and wounded Indian soldiers either directly from Bombay or through other selected hospitals, civil and military. The association has already given assistance in the extra equipment of the military "war" hospitals, and it is now asked to assist these depot hospitals with additional articles. Following the procedure adopted in December, it is suggested that each committee of a provincial or local centre might undertake the provision of the units for the depot hospitals. A special grant of Rs. 5 per bed will be made by the association.

ITALY.

Dr. George Sandison Brock, Physician to the British Embassy in Rome, states that it is proposed that British visitors and residents there shall completely equip one or more wards, according to the number raised in the thirty-one hospitals being prepared for the reception of the Italian wounded. The Medical Inspector-General, Lieutenant-General Luigi Ferrero di Cavalerleone, has signified his cordial approval of this suggestion. He will be happy to reserve a special ward, or wards, to be equipped by the British colony. All subscriptions, however small, will be gratefully received by Dr. Brock (6, Corso d'Italia), who will also gladly undertake the application of the sums collected to its intended purpose. Subscriptions may be sent to Mr. E. J. Wallman, care of Messrs. Cook and Son, 54, Piazza Termini, who will duly acknowledge their receipt. The heads of the Italian civil and military health departments have decided to equip a hospital for the treatment of mental disorders caused by the war. The hospital, which will contain 100 beds, is to be established at Treviso.

MONTENEGRO.

The Wounded Allies Relief Committee has received a cable announcing that its typhus hospital units, which left England on June 3rd for Montenegro, are to be stationed at Podgoritz and Niksbich. The units each consist of 100 beds with full equipment for surgical as well as for fever work. The medical staff includes three medical women—Dr. Lillias Hamilton, Dr. Isabel Ormiston, and Dr. Constance B. Slater.

MEDICAL OFFICERS WANTED.

31st Notts and Derby Mounted Brigade Field Ambulance,
R.A.M.C.

There are vacancies for three medical officers in the above unit. Must be willing to learn to ride. Also for a transport officer, who should be a medical man or medical student, and

be able to ride well. The unit is being trained and for some time may be billeted here. Usual outfit, allowances, and pay. Applications to be sent to Captain F. R. M. Heggs, Officer Commanding, St. Jude's Parish Room, Mapperley, Nottingham.

2 1st North Midland Field Ambulance, R.L.M.C.

Three officers are urgently required for foreign service only with this unit. Now under canvas at Dunstable. Apply to Lieutenant-Colonel Dawson, Officer Commanding 2 1st North Midland Field Ambulance, Dunstable.

3 1st North Midland Mounted Brigade Field Ambulance,

R.L.M.C.(T.F.)
A medical officer is required to complete the establishment of this unit. Applications to be sent to Captain Aven, R.A.M.C.(T.F.), Drill Hall, Nineveh Road, Handsworth, Birmingham.

Ireland.

THE HONAN BIOLOGICAL INSTITUTE.

THE new Honan Biological Institute at University College, Cork, has been completed, owing to the generosity of the trustees of the estate of the late Miss Honan, and forms a handsome group of buildings, situated near the plant houses which were the gift of the late William Crawford of Lakelands. As old members of the college will remember, the biological laboratory was a small building, much too cramped for the teaching of the students, much less for the research work which has always been a feature of the college. In the new building ample room has been provided for the study of zoology, botany, and geology. There are junior and senior zoological and botanical laboratories, as well as research rooms, geological and geographical laboratories, and a large semicircular lecture theatre, lit from the roof, and capable of accommodating about 100 students. It must be a great pleasure to Professor Marcus Hartog (now Professor of Zoology, but for many years Professor of Botany as well) to see this department of the college developing so successfully.

CORK MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

FOR the past two years the members of the medical profession in Ireland have been negotiating with the Irish Insurance Commissioners for increased remuneration for medical certification, but quarter after quarter has passed without the least attempt to improve matters. After discussing the situation most carefully the members of the profession in Cork decided, at a largely attended meeting, to decline to certify under the Act for insurance patients in Cork until the Commissioners revised their terms, and signified to the Cork Borough Insurance Committee the intention of not continuing after June 20th, 1915. It appears, however, that the Borough Insurance Committee has made an urgent appeal to the members of the profession who were on the panel to continue in office for one calendar month, so that the Insurance Commissioners may come to a settlement. The following is the text of the resolution sent by the profession to the Cork Borough National Insurance Committee:

In reply to the resolution received from the Cork Borough National Health Insurance Committee, we desire to state that the resignations of the doctors on the Cork panel from certification are in the hands of the Insurance Commissioners. At the urgent request of the Borough Committee we have held a special meeting to consider the matter, and at the request of the Borough Committee we have agreed that the Cork medical men who are on the panel for certification may extend the date of their resignations to a period of one calendar month from the 26th inst., to enable the Insurance Commissioners to come to a settlement satisfactory to the medical profession in Ireland.

SOUTH DUBLIN UNION AND RATIONS.

THE guardians of the South Dublin Union have been considering the present system of ration allowances, according to which many of the officers now draw food rations as portion of their emoluments; it was proposed that the board should substitute for the allowance in kind a cash equivalent, determined on the basis of a standard year. As regards future appointments, a proposal was made to omit the allowance altogether, but an administrative obstacle was found to exist and the proposal was withdrawn. Accordingly, these officers still hold their

title to draw weekly an allowance which includes in some cases at all events—8 lb. of beef, 13 lb. of mutton, 14 quarts of milk, 7 lb. of sugar, 2 lb. of soap, 28 lb. of potatoes, and 5 cwt. of coal. The last item means 13 tons of coal in a year. It would certainly seem to be time that this strangely generous scale of allowances was revised or stopped.

Scotland.

PROVISION FOR SOLDIERS SUFFERING FROM TUBERCULOSIS.

WE understand that towards the end of March the War Office instituted an inquiry as to whether the Insurance Commissioners for Scotland could relieve them of the duty of making arrangements for the treatment of soldiers discharged from the army suffering from tuberculosis, and indicated that it desired that each case should receive a certain period of institutional treatment, and that thereby the return of the soldier to the position of a civilian should be marked by special consideration. The proposal would also secure the relief to some extent of local authorities and Insurance Committees. As a result of communications between the Insurance Commissioners and Dr. Maxwell Williamson, the Medical Officer of Health for Edinburgh, arrangements were made whereby ten beds in the sanatorium were at once set apart; over these the War Office and the Insurance Commissioners had a "call," and others were promised if these should prove insufficient. By April 1st it was possible to report that the ready response of the various authorities in Scotland had enabled the Insurance Commissioners to inform the War Office that, if asked to undertake the work, they were able to do so. Since then the arrangements have been completed, and the scheme has been working smoothly. The plan adopted at Edinburgh has been as follows: Information is forwarded by the military authorities to the Commissioners in regard to a soldier suffering from pulmonary tuberculosis who is to be discharged from the military centre at which he then is; the Insurance Commissioners then telegraph fully this information to Dr. Maxwell Williamson, and indicate that further information regarding the date and hour of his arrival in Edinburgh will be sent to him; another telegram, usually stating the day and hour and station at which the patient will arrive, is sent, and Dr. Williamson dispatches an ambulance to await his arrival. Since the arrangement was entered into nine cases have been admitted and four discharged. The Insurance Commissioners are to be advised at short intervals of the number of beds from time to time available, and thus the cases can be distributed to various institutions with the least disturbance to their other calls. This matter has also been engaging the attention of the public health authorities in Leith, and at the meeting of the Borough Insurance Committee there on June 18th it was reported that the army authorities were anxious to have removed from military hospitals without delay all soldiers discharged from the army suffering from tuberculosis, and that the Insurance Commissioners had arranged that this would be effected, if possible, by the Committee responsible taking immediate charge of the discharged soldiers, or they themselves doing so pending arrangements being made by the Committee concerned. We understand, further, that Dr. William Robertson, the Medical Officer for Leith, is now making arrangements whereby a certain number of beds in the Pilton Hospital are being set aside for such cases just in the same way as has been done in Edinburgh.

South Australia.

(FROM OUR SPECIAL CORRESPONDENT.)

THE WAR.

By the mail which carries this letter some of the members of the Double General Hospital will leave us. It is to be equipped in England and will be under the command of Colonel Fiaschi, D.S.O., of Sydney, a veteran of the Italo-Abyssinian and Boer wars. The Registrar and Secretary is Dr. de Crespigny, of Adelaide, and Dr. A. M. Cudmore, F.R.C.S., will be surgeon, both with the rank of Lieutenant-Colonel. Amongst the juniors will be Drs. Lank Hayward and E. A. H. Russell, and the Quartermaster is Captain

Medlyn, Secretary to the Adelaide Hospital. Sir Alexander MacCormick will join it in England, and it comprises many of the leading men from the other States. Meanwhile our First General Hospital in Egypt is to be doubled, to contend with the casualties likely to come from the Dardanelles, and Drs. C. Yeatman and Cunningham have been appointed to it; a special Convalescent Hospital has also been formed at Harefield Park. As illustrative of the tendency of Australia to adhere to English traditions, I may mention that these officers are required to have maccas jackets with certain trimmings! Shade of Thomas Carlyle! Red tape and circumspection have undoubtedly been imported into this new land, and they seem to flourish. For instance, with regard to the selection of nurses, many of the best we possess, who as matrons have taught generations of probationers, are considered unfit for service because they have not had the inestimable blessing of a training in a general hospital of a certain size. New Zealand refused to send a nurse because she was a native of South Australia and was trained in Sydney; she has gone to England on her own account and hopes to reach the front. Medical men are also taken from their practices and sent down to camp with absolutely no work to do. A camp here of 3,000 men in training had one day no fewer than eleven medical officers, I am told. On the other hand, as regards the selection of men for hospital appointments, Colonel Fetherston, the Acting Director of the Medical Services, seems to have exercised a very wise discretion in selecting the very best men, and in promoting suitable men to important billets.

The Profession.

Meanwhile it would naturally be thought that those who for various reasons were unable to go to the front would be reaping a rich harvest whilst the ranks of the profession are so depleted. Curiously enough, this does not seem to have been the case. Ever since August work has been slack. But the cause of this does not seem to be so much the war as the drought from which we have suffered, and which at the time of writing seems to have broken up. The losses of sheep, cattle, and horses have been enormous, but the farmers are looking forward to a good season now.

The Branch.

We have already sent the Vice-President to the front and the Secretary; now the President himself is going. Staff Surgeon E. W. Morris—we are mostly captains and majors nowadays instead of doctors—accompanies the Naval Bridging Train, and the immediate Past-President (Dr. Poulton) is reigning in his stead.

We rather anticipated His Majesty's views on abstinence, as the following resolution will show:

That in view of the evidence frequently coming before us as medical men of the dangers to our troops from excessive alcoholism, and hoping to exert influence towards temperance among them, members of this Branch of the British Medical Association are of opinion that in the present national emergency all medical men will do well to become and remain total abstainers during the continuance of the war.

It was carried by a two-thirds majority on February 25th. What effect it may have upon the troops remains to be seen, but what is known as the "dry canteen" system in the camp seems only to make the soldiers reel the more when on leave in town.

Belgian Doctors' Relief Fund.

Our list, which includes subscribers in Broken Hill, was hobby-headed by Dr. J. C. Verco with £50, and already £400 had been transmitted to London.

Canada.

KING'S BIRTHDAY HONOURS.

ON the list of the King's Birthday Honours appear the names of the principals of two Canadian universities—Sir William Peterson, K.C.M.G., and the Very Reverend D. M. Gordon, D.D., C.M.G. Sir William Peterson succeeded the late Sir William Dawson as Principal of McGill University in 1895. He was born in Edinburgh, where he attended first the High School, then the University, going thence to Göttingen, and later to Oxford. Twenty years

ago he went from University College, Dundee, to McGill, where he has done splendid service. He is an ardent Imperialist. Dr. Gordon, the Principal of Queen's University, Kingston, is a Canadian by birth, of Scottish descent. He was born in Pictou, Nova Scotia, in 1845; after receiving his early education at the Pictou Academy he entered the University of Glasgow, and from there went to Berlin. He was ordained a minister of the Church of Scotland in 1866, and, after serving as pastor in Ottawa, Winnipeg, and Halifax in 1894, he became Professor of Theology in the Presbyterian College at Halifax. In 1902 he succeeded the late Principal Grant as head of Queen's University. In 1896 Dr. Gordon was Moderator of the General Assembly of the Presbyterian Church of Canada.

Correspondence.

"HYPERTONIC" TREATMENT OF WOUNDS.

SIR,—With reference to Sir Berkeley Moynihan's letter, in the JOURNAL of May 29th, on "hypertonic" treatment of wounds, I should like to indicate shortly the developments in connexion with this method of treatment which have taken place in some hospitals. A great deal of the success attendant on these developments is due to the unremitting efforts of Colonel C. B. Lawson, who was the first to devise the suppository and solid methods and has been the means of stimulating others to research.

At the beginning, the solution of 5 per cent. sodium chloride and $\frac{1}{2}$ per cent. sodium citrate, which Colonel Sir Almaroth Wright recommended years ago for chronic sinuses, was used. The strength of the solution has been increased gradually, with correspondingly improving results. Other lymphagogic agents, such as glycerine (along with 5 to 10 per cent. sodium chloride and $\frac{1}{2}$ per cent. sodium citrate, C. B. Lawson) and carbolyzed glucose (Beckwith Whitehouse) have been tried with satisfactory results.

The latest and, I think, most successful modification of the treatment is the direct insertion of numerous solid tablets into the recesses of any kind of septic wound and into the meshes of wet gauze (5 per cent. saline) which is lightly packed into the cavity of the wound and made flush with the skin. The wound is, of course, previously freely opened up, cleaned and trimmed, and drained in the usual way by a very large tube which reaches through the gauze pack; into it more tablets may be placed if required. A light superficial dressing is applied and changed daily. The deep dressings may be left sometimes for four to six days. The advantages of this are obvious. The "hypertonic" treatment may be given up in favour of antiseptic dressings when the wound is covered with healthy granulations.

I write this letter to give adequate acknowledgement to the workers concerned.—I am, etc.,

H. M. W. GRAY,
Colonel, A.M.S., Consulting Surgeon,
British Expeditionary Force.

June 3rd.

RESIDENTS AT MILITARY HOSPITALS AT HOME.

SIR,—It is an excellent thing that you have been able to publish some details—presumably from an authoritative source—with regard to the residents at the King George Hospital. I am not a believer in Mr. Lloyd George's view that criticism should be silenced during war time, as I consider that only by criticism can efficiency be secured! And while one side to a controversy is perfectly right in raising questions about apparent extravagance, the other should be quite open in explaining the situation. Both sides should be willing, then, to give due weight to the arguments used.

The view is held that the authorities responsible for the King George Hospital have been unduly extravagant at a time when it behoves everyone in this country to practise rigid economy; and I should like to see the arguments used by these authorities to show that extravagance is necessary for the attainment of efficiency. Critics suggest that, no explanation has been given for attaching to this hospital a resident staff at least twice as large as to most other military hospitals. The note you publish does not, of course, answer this criticism.

While the British Red Cross Society and St. John

Ambulance Association are preparing their explanation, may I point out that, on the details you give, the residents may be divided into two classes—

1. Those ineligible for commissions in the army :
 - (a) Physically unfit 6
 - (b) Rejected on account of nationality ... 4
 - (c) English, but no British qualification ... 1
 - (d) Registered in this country, but of foreign birth ... 1

12
- II. Those eligible for commissions :
 - (a) Refused service unless attached to unit of his choice 1
 - (b) Reply of War Office to application for commission delayed too long ... 1
 - (c) No reply yet received from War Office ... 1
 - (d) Only able to offer less than minimum period of service 4
 - (e) Over 40 years of age 2
 - (f) Unable for domestic reasons 3

12

May I suggest that, unless the need for a resident staff twice the size of that ordinarily employed is proved, the twelve men in Class II should reconsider their position in view of the present shortage of doctors, and either take commissions or devote themselves to work which will set free men who might join the army?—I am, etc.,

London, W., June 26th. CHAS. BUTTAR.

THE SUPPLY OF MEDICAL OFFICERS.

SIR,—When "Young G. P." wrote to the BRITISH MEDICAL JOURNAL I had intended making some reply, but before I had time to do so I read "Temporary Lieutenant's" protest in your issue of June 12th.

I may be obsessed by this war, so let it stand for my apology in most heartily siding with all "Temporary Lieutenant" said in his letter. Mine would have been stronger. Now "Captain R.A.M.C. (T.)" jumps in and asks questions about age, pay, and points out what pension one's widow would get.

Again the sordid element. If one did not know that dozens of medical men had given up lucrative practices to go and do their bit, one would blush for the medical profession.

This war has divided mankind (English) into one or more strata:

(a) Those who rushed in the moment the country called. Many had nothing to lose, many had nothing to gain but all to lose. England wanted men, and Kipling's immortal line was their motto, "Who dies if England lives?"

(b) Those not so impetuous, but just as keen, just as good. They wanted to be sure that they were required. And, being satisfied, they also put all thought of gain behind, and went.

(c) Those who are waiting to see how much England is going to pay for their services—good men all, no doubt, but lacking that little quality of pure gold which has run through the best of England's sons for centuries. This is not the stamp of man that makes empires.

(d) The rotter, the hanger-on, who hopes to benefit, who would squeal if the enemy came near.

Naturally one does not like to think that he is losing that which has taken him years to build up. But surely the love of country should transcend all else! How otherwise can one hope for success in the greatest struggle that history has ever witnessed?—I am, etc.,

June 28th. A. M. E.

SIR,—As one of those who did not wait until the war came before offering my services, may I lay before you the following facts? They may serve to illustrate the poor encouragement given to those who have borne "the burden and heat of the day" and "given up their scanty leisure in attending drills, etc." For some years I held the commission of surgeon-captain in a Colonial militia force. I received no remuneration for my services, and had to purchase my own uniform. At the commencement of this war I communicated with the War Office and received the usual reply of my name being noted, etc. I have called several times since to remind them of my application, and received more or less the same

answer. Only a few weeks ago, on my name being put forward by an A.D.M.S., I was informed that I was "too old to serve," having reached the retiring age! This information might surely have been conveyed to me in the first instance without keeping me all these months in a state of uncertainty.

I have repeatedly applied to deputy directors A.M.S. for local work—either whole or part time. From them comes the same answer—namely, my name is noted. Meanwhile, I find the great majority of local appointments have been conferred on civil practitioners, and the question of age not taken into account.

Under these circumstances, can any of your correspondents inform me what is the next course to be taken by one who has already done his gratuitous work, and now when the opportunity occurs of gaining some slight return finds himself "crowded out"?—I am, etc.,

June 28th. DISCOURAGED.

SIR,—Some weeks ago I read an article in the BRITISH MEDICAL JOURNAL calling on medical men to assist the Army Medical Department in giving either whole or part time.

I wish to point out, from my own experience as a member of the West African Medical Staff, and the experience of several of my colleagues, that, although in each instance the whole of our time was offered for periods of three and four months, no real advantage was taken of our services.

The War Office would appear to require at least twelve months' continual service, and apparently will not consider a shorter period. It may not be generally known that medical officers of the West African Staff have as much or more experience of active service conditions as the Army Medical Department. Few of our staff have not been at one time or other on active service, where the conditions are exacting and most trying.

A considerable number of men are continually on leave from the various West African colonies, where fighting has been continuous for the past ten months, and are more than anxious when on leave to be taken seriously. Why could not these men and others suitable be sent to the front to relieve medical officers who must in many instances require rest for short periods as much as combatants?

A continuity of service could easily be set up of experienced men home on leave, the army service would benefit by economizing energy, which could be used in emergencies; and when one hears of the very heavy work done now by individual medical officers at the front, and the congested condition of the various dressing stations, it is amazing that more advantage is not taken of all possible assistance.—I am, etc.,

E. A. CHARTRES, Deputy Principal Medical Officer, Nigeria.

Farnborough, June 25th.

Mr. Percival Turner asks us to state that he does not accept two opinions expressed by correspondents recently. Dr. Sampson's statement that locumtenents are unobtainable except at impossible figures is, Mr. Turner considers, too sweeping, as at present men are available at fees of 6 to 7 guineas a week, which for a practice of over 2,700 panel patients, with private work, is not, he considers, excessive. The other statement is that by "Captain R.A.M.C. (T.)," to the effect that a practice is unsaleable until after the war, buyers being non-existent. Mr. Turner says that though buyers are fewer than usual, practices, he finds, are, considering the circumstances, selling fairly well, many men ineligible for service being willing to take advantage of lower prices to obtain practices.

ON THE CURVE OF THE EPIDEMIC.

SIR,—Dr. Percival gives $y = a \cos^2(mt - a)$ as the solution of Dr. Brownlee's differential equation:

$$\frac{1}{y} \frac{dy}{dt} = \log \left[\frac{CD}{N} \left(N - \int_0^t y \, dt \right) \right]$$

That it is not a solution, however, is seen from the fact that the substitution of $a \cos^2(mt - a)$ for y in the equation

leads to an equation which is not identically true for all values of t , the essential test of a solution.

Owing to a slip in the work of reduction the equation in t obtained by Dr. Percival

$$2m \cot mt = \log CD - \log \frac{a CD}{2N} \left[t - \frac{1}{2m} \sin 2mt \right]$$

is not correct, but in neither its present form nor its amended form is it an identity.—I am, etc.,

Cricklewood, N.W., June 25th.

H. L. TRACHTENBERG.

Medico-Legal.

AN UNREGISTERED DENTIST.

At the Marylebone Police Court on June 22nd, Henry John Goldberg, of 27, New Cavendish Street, W., was summoned by the British Dental Association for taking and using the title of "Dr. Goldberg, Dental Practitioner," implying that he was registered under the Dentists Act, 1878, and also that he was specially qualified to practise dentistry. Mr. H. W. Turner, who appeared for the British Dental Association, said that he proposed to deal only with the offence of using the title "dental practitioner." Goldberg, he said, was unregistered, and, so far as was known, had no dental qualifications recognized in this country. For the last twelve months he had advertised extensively in the leading papers. His claim that he was a dental graduate of the University of Pennsylvania had not been established by official inquiries. Mr. Macdonnell, the solicitor who defended Goldberg, admitted the offence, which, he said, was due to an accident. The defendant was born in Dublin, his father and mother being Russians. The magistrate imposed a penalty of £20, with five guineas costs.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examinations indicated:

SECOND M.B. (*Part I. Human Anatomy and Physiology*).—B. F. Anstey, C. C. Bony, W. L. Berry, P. A. Buxton, A. J. Coe, J. C. Coe, I. H. Coxi, H. V. Edwards, T. Fernandez, H. D. Gardner, S. V. Goldberg, W. N. Goldschmidt, E. F. S. Gordon, F. Gray, N. B. de M. Greenstreet, C. Griffith-Jones, W. E. Heath, S. L. Higgs, H. W. H. Holmes, H. B. Jackson, R. B. F. Lasdow, P. T. Liang, G. T. Lipschutz, P. C. Livingston, E. E. Llewellyn, N. J. Macdonald, J. H. E. Moore, H. Morrison, J. W. McK. Nicholl, F. C. Odling, S. W. Page, A. H. Pearce, A. V. Peggio, A. A. Prichard, H. E. Rhodes, S. Ridgway, N. Rumbold, A. H. J. Smart, H. G. Taylor, D. L. Tucker, E. B. Verney, M. D. Vint, Y. S. Wap, A. T. Westlake, J. Whittingdale, M. Wong.

THIRD M.B. (*Part I. Surgery and Midwifery*).—E. D. Adrian, G. L. Atwater, F. E. Bruce Smith, H. Maschner, H. H. W. Hales, W. Hillbrook, R. W. P. Jackson, P. E. Liang, R. A. Mansell, W. H. Marshall, C. F. Pedley, R. A. Peters, R. A. W. Procter, W. G. A. Schüddokopf, W. J. D. Smyth, G. R. S. Thomas.

UNIVERSITY OF LONDON.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

ON June 24th Princess Alexander of Teck presented the prizes at the London School of Medicine for Women. The Dean, Miss Aldrich-Blake, who was in the chair, spoke of the large number of old students at work among the wounded at home and abroad, and stated that the entries for next October term already far exceeded the fifty-six of last October. She also referred to the rebuilding and extension of the laboratories and to the success of the appeal made on their behalf.

UNIVERSITY OF DURHAM.

THE following were among the degrees conferred at a convocation on June 22nd:

M.D.—S. T. Cochrane, A. G. Dunn, F. Rahitkens, L. L. Westrop.

M.B.—R. A. Hopper, E. E. D. Lau, L. Maseje, A. G. McFarlane, J. E. Meacham, J. D. Prouf, F. B. Robson, G. G. Strachan, A. G. Taylor.

B.S.—E. E. D. Lau, L. Maseje, J. E. Measham, J. D. Prouf, F. B. Robson, C. G. Strachan, A. G. Taylor.

B.V.—A. King.

D.P.H.—A. King.

UNIVERSITY OF SHEFFIELD.

THE following candidates have been approved at the examinations indicated:

THIRD M.B., B.Ch.—F. Gamm, Lydia M. Henry, G. K. E. Inman, Florence E. Millard, W. Sharrard.

FIRST M.B., B.S.—H. E. Finkler, R. E. Ford, Dorothy E. Matthews, R. E. Pleasance, F. Roper, F. L. Smith.

D.P.H.—Hawary B. Beale.

* With distinction in chemistry.

UNIVERSITY OF EDINBURGH.

THE following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B.—J. C. Anderson, J. M. Anderson, J. S. Armstrong, F. W. W. Baillie, T. Y. Barkley, H. J. P. Bruwer, W. M.

Christie, A. G. Clark, T. L. Clark, A. R. F. Clarke, I. A. Clarke, W. A. Cochrane, C. H. Clark, O. Coetzee, M. K. Cooper, M. F. Daniel, M. W. Danzig, D. Dunlop, Henry O. Ferguson, E. L. Gault, A. M. Ghosh, A. W. Gunn, * F. M. Hailey, J. A. S. Henderson, J. Hepburn, Helen G. Hewat, R. M. Hume, E. B. Israel, T. Janakiramiah, O. D. Jarvis, G. G. S. Johnston, C. W. S. D. Jones, D. H. Jones, Mary E. Kerr, A. J. Kenny, W. J. Kirk, N. B. Laughton, E. Law, R. Lawson, A. L. H. Liu, H. L. H. Liu, P. M. D. Little, J. G. Loudon, * J. E. M. McCartney, Helen M. McCall, W. K. McCall, M. K. McIntyre, Marjory Macnaughton, J. W. Malcolm, D. Mallock, Mary Mering, M. F. Mcirling, T. C. S. C. Morton, * J. W. Potter, O. D. Price, W. J. Purdy, A. Ravinini, N. L. Reis, J. W. G. H. Riddell, J. W. Riddoch, J. Rodger, C. Russell, W. Shanks, J. W. Simpson, G. H. Sinclair, F. Solomons, H. Stewart, T. M. J. Stewart, H. Tren, J. Walker, J. W. Watthers, L. H. Verden (B.A.), W. G. Weston, M. E. Willcock, J. M. Wishart, F. G. Wright, C. J. Young.

* Passed with distinction.

UNIVERSITY OF ST. ANDREWS.

THE following candidates have been approved at the examinations indicated:

THIRD M.B., Ch.B. (*Pathology*).—Sheila Bridgford, Annie R. Campbell, Mary I. S. Cuthbert, Kathleen I. David, Mary M. G. Ferguson, D. Fisher, W. A. Fraser, J. Irvine, J. Kincaid, A. M. MacGillivray, C. W. Morrison, Margaret W. Shirlaw, Dora M. Walker.

D.P.H. (*Part II*).—J. C. Robertson.

UNIVERSITY OF MELBOURNE.

AT a meeting of the Teaching Staffs of the University and Affiliated Colleges, held on April 25th, the following resolutions were passed *unanimous contra dicere*:

1. That during the continuance of the war the members of the staff of the university and affiliated colleges pledge themselves to abstain from the use of alcohol, except under medical advice.
2. That the committee to be appointed at this meeting be requested to consider the question whether a university rifle club can be formed with advantage, and whether any other action can be taken in substitution for such a club, or in addition to it; and further, that the members of the teaching staff of the university and the affiliated colleges pledge themselves to encourage volunteering among the members of the university by such means as may be approved by the committee to be formed.
3. Though many special services have already been performed by officers of the university at the invitation of Ministers, it is desirable to make it more definitely understood that such services are available, and therefore that the Council be asked to approach the Federal and State Governments with the suggestion that the members of the staff of the university would be willing to offer their services, as far as compatible with the continuance of university work, to aid or supplement wherever possible, the work of the scientific, technical, or professional branches of the Government departments during the war, on any matters connected with imperial defence, in which their assistance may be useful.
4. That this meeting is of opinion that public lectures under the auspices of the university should be given on the subject of the war, its causes, its importance to Australia, and the political and other problems which will arise from it; and that the council be requested to give its support to this course.
5. That the administration of the above resolutions be placed in the hands of a representative committee, with power to appoint special committees.

Professor Richard J. A. Berry, Honorary Secretary of the Executive University War Committee, adds with respect to the first resolution, that, whilst every member of the staffs was informed of the meeting, which was in consequence largely attended, no attempt was made to force the resolution upon those who were unable to attend.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the subjects indicated:

SCURGERY.—*J. Braun, *A. Butterfield, *F. W. Chamberlain, *E. M. Drott, *G. J. G. Exley, *J. D. Ferguson, *S. C. Ghose-Dastidar, *S. Joubert, *J. C. Lee.

MEDICINE.—*A. Z. Abnshady, *W. Andrew, *L. Baungarten, *J. J. Braun, *F. W. Chamberlain, *G. J. G. Exley, *S. C. Ghose-Dastidar, *S. Joubert, *W. A. Matthews, *A. L. Robinson, *G. C. N. Younger.

* Section I. † Section II.

The diploma of the Society has been granted to Messrs. J. Braun, A. Butterfield, C. J. G. Exley, J. D. Ferguson, S. C. Ghose-Dastidar, S. Joubert, and J. C. Lee.

The Services.

TERRITORIAL FORCE.

EXCHANGE DESIRED.

LIEUTENANT RONALD B. BARRY, M.B., D.P.H., R.A.M.C.(T.F.), 1st North Midland Field Ambulance, Sherwood Foresters Brigade, North Midland Division, British Expeditionary Force, desires to exchange for four months into the sanitary service in this country. The pay and allowances are those of a lieutenant R.A.M.C.T. A junior medical officer with a temporary commission would be accepted.

Obituary.

FREDERICK HOWARD MARSH, M.A. CANTAB. (HONORIS CAUSA), M.C., Sc.D., F.R.C.S. ENG.,

MASTER OF DOWNING COLLEGE, CAMBRIDGE, AND PROFESSOR OF SURGERY IN THE UNIVERSITY; CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

PROFESSOR HOWARD MARSH, Master of Downing College, Cambridge, died at the Lodge in that college early in the morning of Thursday, June 24th. He was born in 1839 at Homersfield, on the Waveney, near Bungay in Suffolk, and was destined to end his days in East Anglia as Master of a Cambridge college, though the greater part of his life was spent in London as a hospital surgeon and teacher.

From the commencement of his professional education, down to the year when he was appointed professor of

surgery to the University of Cambridge, Howard Marsh was continuously associated with St. Bartholomew's Hospital. He signed the students' book on December 8th, 1858, and became M.R.C.S. in June, 1861. He was appointed house-surgeon to Mr. Skey in 1862, and for several years after the expiration of his term of office undertook many useful non-official duties in the medical school, such as the preparation of microscopical specimens for the lecturers. In 1866 he took the diploma of F.R.C.S., and in 1868 was appointed administrator of chloroform at St. Bartholomew's. In the following year he became surgical registrar to the hospital and demonstrator of anatomy and operative surgery to the Medical School. In 1873 Marsh was elected assistant surgeon, and in 1876 demonstrator of practical surgery, an office he resigned in 1879. He undertook the duties of surgeon to the Orthopaedic Department in 1878, a post which he held for four years. He became joint lecturer on anatomy in 1879, and held that chair until 1889, when he was elected joint lecturer on surgery. Promotion to the senior office, owing to purely accidental circumstances, came very late, for Marsh did not become full surgeon till 1891, eighteen years after he first joined the surgical staff. He held the senior office until his resignation in 1903, on his appointment to Cambridge. On his retirement he was appointed consulting surgeon and a governor of St. Bartholomew's Hospital.

In 1867 an institution, then called the Queen Square House of Relief for Children with Chronic Diseases of the Joints, was founded, in great part through the exertions of Miss Perceval, previously on the nursing staff of the Children's Hospital, and afterwards Howard Marsh's first wife. Marsh was appointed surgeon when the hospital was founded, this being the first appointment where beds were at his disposal. In 1871 the institution was renamed The Hospital for Hip Disease in Childhood, and it is now known as the Alexandra Hospital for Children with Hip Disease.

In 1868, the same year in which he became anaesthetist at St. Bartholomew's, Howard Marsh was appointed assistant surgeon to the Hospital for Sick Children, Great Ormond Street, where he had been house-surgeon three years previously, and the profession knows and his writings show the excellent use he made of that appointment. He became full surgeon in 1879 and consulting surgeon in 1888.

Howard Marsh was closely connected with the College of Surgeons from 1889, when he was selected Hunterian professor of pathology and surgery. He was a member of the Court of Examiners from 1892 to 1895, and in 1892 was elected a member of the Council, and, after re-election in 1900, held his seat till 1908, having served two entire terms of office. In 1902 he delivered the Bradshaw lecture. He was twice vice-president—namely, in 1898-9 and in 1901-2. Howard Marsh was an honorary member of the Royal Academy of Medicine of Ireland and a cor-

responding member of the Orthopaedic Association of New York.

Howard Marsh was President of the Metropolitan Branch of the Association in 1903, and in 1904 President of the Section of Surgery at the annual meeting of the Association at Ipswich, when in a short address he turned attention to the importance of the two subjects selected for special discussion, subdiaphragmatic abscess, introduced by Sir Rickman Godlee, and the treatment of simple subcutaneous fractures, introduced by Sir W. H. Bennett. He reminded surgeons that whilst the latter subject was important, since fractures were so common, the former must not be neglected, because, though rare, any doctor might come across a case in the course of his career, and the diagnosis and treatment of this type of abscess were difficult.

In September, 1896, Sir George Humphry, who held the Chair of Surgery at Cambridge, died, and the appointment was left vacant till the summer of 1903,

when Howard Marsh was elected Professor of Surgery. It happened that he was born in 1839, the very year in which Humphry entered St. Bartholomew's Hospital as a student. Marsh resigned his appointment at St. Bartholomew's Hospital and removed to Cambridge. He was made a Fellow of King's College, and in 1907, four years after his appointment as Professor of Surgery, he succeeded Dr. A. Hill as Master of Downing College. Marsh paid much attention to university matters beyond the limits of his official duties. His name was on the electoral roll of the university; he was a university member of Cambridge Town Council, a member of the Watch Committee, and a Justice of the Peace. He also became colonel of the R.A.M.C.(T.), Eastern District, and encouraged the Boy Scout movement. At the same time, consistently with his tastes and habits when young, he took an active interest in university and college games and encouraged the undergraduates by his teaching that learning—especially medical learning—should be manly, and must therefore be fortified by participation in manly sports. He proved most efficient in his purely

professional work, undertaking the fitting and equipment with surgical appliances and instruments of a large room in the new medical schools.

Howard Marsh's talents did not include that skill and high capacity for bold and novel operative measures which distinguished so many of his contemporaries, but his strong point, like that of his teacher Paget, was clinical surgery, especially manifested in his judicious treatment of diseases of the bones and joints. He made free use of those mechanical appliances of other surgeons which he found beneficial in treatment, without troubling much about modifications, but his name came to be associated with the knee splint which he devised, made with lateral steels, jointed so as to prevent rotation, and with a reclining padded mattress, the main feature of which was the firm horsehair cushioned mattress. As a member of the Council of the College of Surgeons, Marsh took part in medico-political business, though he had none of those qualities which make a strong councillor. He was among those men who promoted the admission of women to medical degrees and diplomas, but opposed the medical provisions of the Insurance Act, as he believed that they would encourage inefficient dispensary treatment.

Howard Marsh was an able writer as well as a keen clinical observer. In 1867 there appeared in the third volume of the *St. Bartholomew's Hospital Reports* an admirable monograph "On tracheotomy in children, its methods, its dangers, and its difficulties." He had enjoyed much experience of the operation when he was house-surgeon at the Ormond Street Hospital for Sick Children, and one remarkable feature in this communication was a table showing, not only in figures but also in circles, the relative diameter of the trachea and cricoid in children. He found, from accurate measurements of twenty-nine subjects, that in children the diameter of the cricoid is almost invariably less than that of the trachea, indeed in his series there was but one exception, and in that case the diameters were equal. Marsh's literary work, however, related more to bones and joints than to the surgery of the respiratory tract. Already, a year before the excellent memoir on tracheotomy in children was published, an article by him appeared in the second volume of the same reports, "On the prejudicial effect of inter-articular pressure in joint disease; and the application of continuous extension, by means of a weight, as a remedy for this condition." This paper, like the memoir on tracheotomy, was based on observations made by the writer when he was house-surgeon at the Children's Hospital. It is well worth study by surgeons specially interested in the history of the surgery of hip-joint disease. They will see that Marsh taught the extension treatment when it was far less understood than is the case to-day, and that he based much of his clinical principles on the teachings of *Lectures on Rest and Pain*, which had then recently appeared. They are, we trust, still held as standard surgical literature. The author was John Hilton, who, when Marsh wrote the article in question,

was as deeply admired as a sound teacher of clinical surgery as he was dreaded by candidates as a severe examiner in Lincoln's Inn Fields. Hilton, as we are in a position to know, was admitted by Marsh to be a great inspirer of right principles in the treatment of joint disease, especially through his teachings on the necessity of the separation of the diseased surfaces of the bone by extension. We all know what further developments of hip-joint surgery occurred in the United Kingdom, America, and elsewhere, not many years after the publication of Marsh's article on the evil effects of interarticular pressure. Marsh himself taught and wrote a great deal about the surgery of bones and joints after the appearance of this first-fruits of his knowledge. In the fourth volume of the *Reports* he published notes on diseases of the joints, based chiefly on cases under observation in the hospital during the previous year. He also contributed a paper on manipulation or forcible movement as a means

of surgical treatment (a subject previously much investigated by his master, Sir James Paget) to the fourteenth volume of the *St. Bartholomew's Hospital Reports* (1878). Two interesting papers on bone and joint surgery appeared in the *JOURNAL*. The first was a memoir read in the Section of Surgery at the London meeting of the Association in 1895, on the pathology and clinical history of some rare forms of bony ankylosis, published with some instructive drawings in the *JOURNAL* (1895, vol. ii, p. 1087). The second, which will be found in the *JOURNAL* of 1896, vol. ii, p. 181, was a clinical lecture on displacements and injuries of muscles and tendons. This article, too, is enriched by some good illustrations showing the relation of the peroneus longus and the tibialis posticus to the ankle joint.

In 1889 Howard Marsh, as Hunterian Professor of Pathology and Surgery, delivered at the College of Surgeons three lectures on tuberculosis in some of its surgical aspects,

which appeared in abstract in our second volume for that year. In the third of these lectures he declared that he believed that it was then recognized by most surgeons that, although the immediate result of excision of the knee in children might be all that could be desired, the wound not rarely healing by primary union, the ultimate result was unsatisfactory.

In the Bradshaw Lecture delivered before the Royal College of Surgeons in December, 1902, he dealt with "infective arthritis"—a wise choice, for he was a recognized authority on diseases of the joints; whilst in those very same years when he was in his prime bacteriology had become an established branch of pathological science. Marsh reminded his audience that he was speaking to them just fifty years and one day after Lord Lister became a Fellow of the College. The lecturer insisted on the importance of a discovery made by Weichselbaum in 1888. That authority found that the *Diplococcus lancetatus* of Fraenkel has the power of producing acute inflammation of the joints. This discovery, so interesting in itself from a purely biological point of view, had already

given a great impetus to the study of infective arthritis. Marsh ably reviewed in detail the different types of arthritis associated with typhoid fever, scarlet fever, influenza, erysipelas, glanders, and other serious but far more obscure general disorders.

The substance of the early papers on joints and bones, with the addition of more matter based on later experience, were incorporated into a separate treatise, which first appeared in 1886 under the title *Diseases of the Joints*, and was translated into German by Dr. Kindervater of Leipzig in 1888. In 1895 a new issue was published, entitled *Diseases of the Joints and Spine*, and in 1910 the third edition appeared, revised and enlarged with the collaboration of Mr. Gordon Watson. A volume of *Clinical Essays and Lectures* was completed by Marsh and issued in 1902, and must not be confounded with the second edition of Paget's book bearing a similar title, in the preparation of which Marsh also assisted. The latter work appeared in 1884. Marsh's volume consisted mainly of collected papers on diseases of the bones and joints. He contributed an article on joints to Treves's *Manual of Surgery*, on fractures and hip diseases to Heath's *Dictionary of Surgery*, and on abscesses to Ashhurst's *International Encyclopaedia of Surgery*. Marsh was an active member of the Clinical Society, of which he was president from 1901 to 1903, and amongst his numerous contributions was a good paper on bone-setting, which was read in 1882. Its subject, like manipulation and forcible movement of joints, had already been under the investigation of Paget, Marsh's teacher, who once delivered an instructive lecture on "Cases which bone-setters cure."

Naturally of a cheerful disposition, Howard Marsh loved field sports, and was known to be a keen golfer. He was a very kindly man, with a gentle voice and a pleasant manner which made him popular with colleagues, students, and patients.

Marsh was twice married. His first wife, Miss Jane Perceval, by whom he had a son and a daughter, was the granddaughter of Spencer Perceval, who, when Prime Minister, was shot at the entrance of the lobby of the House of Commons on May 11th, 1812, by Bellingham, a man with a grievance. Marsh's son, Mr. E. H. Marsh, C.M.G., has been for several years private secretary to Mr. Winston Churchill. Marsh's second wife was Violet Susan, daughter of the late Admiral Sir John Dalrymple Hay.

The funeral of Professor Howard Marsh took place on Tuesday, June 29th; the first part of the service was held in the chapel of King's College. The pall-bearers were Mr. Edward Marsh (son), Sir William Dalrymple Hay (brother-in-law), Mr. T. C. Maurice (son-in-law), representing General Maurice, who is at the front, Professor Sir Clifford Allbutt, Professor C. S. Kenny, Professor J. B. Bradbury, Mr. T. W. Danby, and Rev. Dr. T. J. Lawrence (honorary Fellows), the Provost of King's, and Mr. C. E. Grant. Among those present were Sir William Osler, Dr. W. S. A. Griffith, Mr. H. J. Waring, and many other representatives of medical and other bodies. About 500 Boy Scouts lined the quadrangle at Downing. The interment took place at the Brough Cemetery, Newmarket Road.

A memorial service was also held at St. Bartholomew-the-less, West Smithfield, the congregation including Lord Southwark, Mr. Rawlinson, K.C., M.P., Sir Dyce Duckworth, and Sir William Church.

Sir CLIFFORD ALLBUTT, Regius Professor of Physic, Cambridge, sends us the following appreciation of the late Professor Marsh:

The time of the death of a dear friend is hardly the moment to compose a careful appreciation of his life. While now in Cambridge we are feeling keenly the loss of Howard Marsh, our hearts are occupied in silent sorrow. Notwithstanding, it is at this time that men, especially those to whom he was less well known than to ourselves, desire to learn who he was whom we are lamenting, and to receive inspiration from his example.

Among those of us who are now reflecting upon memories of past friendship, our first thoughts will be of the man; our thoughts of the Professor and Master will come in the second place. Howard Marsh was a man of warm and generous affections, and these were so natural to him that he was as little self-conscious of his own goodness of heart

as of his five senses. It was too much a native part of him to be a matter of taking thought. Three or four times in my life Marsh did me great kindnesses with the least ceremony; indeed, our closer intimacy began with his hospitable reception of my wife and myself in Bruton Street on a great occasion when in London hardly a bed was to be heard of. The same simple goodness of heart was apparent, in the same frank and natural manner, not in his particular kindnesses only, but—what was far more—in his steady and modest devotion to public and private beneficence. Although no one could fail to be aware of the devotion of Howard Marsh to those public causes and ends which are set forth in the obituary notices of him, yet until these were published I was in ignorance of some of the chief of them. From himself they would never have been known; and these duties did not consist only in passing efforts or occasional gifts, but, as those knew best who knew him best, in the far harder continual sacrifice of personal ease and gratification for the succour and solace of those in need and suffering.

In public debate Marsh was always on the side of broad views and generous ideas—I will say "progressive" ideas, though to this day I do not know to which political party, if to any, he belonged. He spoke well, with this breadth of view and with conviction, not always academical qualities; and his literary works and addresses were written in English as excellent as their matter. An interesting side of his strong character would appear occasionally when, feeling things keenly as he did, he might seem for a moment a little stubborn; such an attitude in him was always due to imperfect information; after farther explanations, whether he agreed or not, there was an end to all contention. So it was that no colleague could be more reasonable or courteous.

As professor and examiner Howard Marsh was excellent, indeed admirable. I have generally been present, on his invitation, during some part at least of the examination for the Mastership of Surgery, and so had many opportunities of observing his kindly but searching way of getting at the qualities of a candidate. On one occasion more especially I remember this penetration, and his accomplishment as a skilful and intellectual surgeon. A candidate had described a certain local lesion very accurately, so much so that the two examiners were satisfied. But the professor bade the candidate wait a moment, and then proceeded himself to raise the inquiry into the larger sphere of the general pathology and the deeper meanings of the condition. Here the candidate failed to acquit himself so well; he was unable to rise above the narrower technical aspects of experience.

Of Marsh's scientific work, which was chiefly surgical, I am not competent to speak with authority; this appreciation is for others.

As Master of Downing, at a critical period of its growth, Howard Marsh was of great service to the college. Bright and genial in temper, punctual in his duties, well versed in business, familiar with affairs and in touch also with men and things outside academical circles, he carried his colleagues with him, managed its affairs successfully, and represented it effectively. Downing will find it difficult to fill his place, and where we are to look for a like professor of surgery is a still graver question.

Mr. J. H. MORGAN, C.V.O., adds the following notes on the late Professor Howard Marsh: When Howard Marsh was appointed assistant surgeon to the Hospital for Sick Children in 1868 he was already a very busy man. He was holding the same position at St. Bartholomew's, and lecturing at that school. The work of the out-patients' room was not in those days so arduous as it became subsequently, and it was carried out in a small room on the ground floor of the house, which formerly had been inhabited by the celebrated Dr. Mead. His surgical colleagues were Timothy Holmes and Thomas Smith. He remained in the out-patient department for eleven years, when he was promoted to the charge of a ward. His chief interest was in cases of joint disease, and from the first he was opposed to operating in these cases, and developed to a large extent the treatment by rest and splints. These were made of leather softened in warm water and moulded to the limb, and afterward lined with soft white leather. He was opposed to the practice of excision of joints, particularly of the hip, which was so

strongly advocated and practised by Fergusson of King's College and Croft of St. Thomas's. In this he was certainly a pioneer of the methods which are now so successfully followed at such places as the Cripples' Hospital at Alton and at Berck-sur-Mer in France, where an excision is rarely if ever seen.

FRANÇOIS ALBERT DE THIERRY MOUILLOT,

B.A., M.D. DUBL.,

HARROGATE.

By the sudden death of Dr. Mouillot on June 20th, 1915, Harrogate loses one of its leading practitioners and the medical profession an outstanding representative.

Dr. Mouillot had suffered from glycosuria for some years. Twelve months ago symptoms of angina pectoris developed, followed by pericarditis, and he passed through a long illness, from which he appeared to make a good recovery. A term of residence at Duff House, Banffshire, materially improved his condition, and he resumed work, though with diminished activity. To his friends, however, it was obvious that he was gradually failing, but in spite of his disability he worked on pluckily and cheerfully, till the end came in a sudden painless attack of cardiac syncope.

Dr. Mouillot was born in 1858, and was the eldest surviving son of the late Auguste M. C. Mouillot, of Rathfarnham, co. Dublin. His medical education was received at Trinity College, Dublin, where he had a brilliant career, taking the B.A. in 1877, being senior moderator and gold medallist in mental and moral philosophy; his M.B. in 1880, B.Ch. in 1882, and M.D. in 1896. After graduating he became pathologist and registrar in the Birmingham General Hospital, and later settled in practice in Gorey, co. Wexford, where he remained eleven years. In 1894 he removed to Harrogate, took up spa work, and speedily built up an extensive practice which he maintained to the end. He held the appointment of honorary physician to the Yorkshire Hospital for Chronic Diseases. He was a member of the British Medical Association and a past president and active supporter of the local Division. As co-secretary for some years, he took a leading part in the affairs of the Irish Medical Schools' and Graduates' Association, of which he became president, and later on vice-president, an office he held up to the time of his death. One of the earliest members of the Balneological and Climatological Society, he had an active share in its development, holding the office of co-secretary up to the time of fusion with the Royal Society of Medicine; he became, last year, president of the Balneological Section. Since the beginning of the war he had acted as physician to the Grand Duchess George of Russia's hospitals for wounded soldiers in Harrogate, to which he gave much active and willing service.

Dr. Mouillot was not a prolific writer, but from time to time he contributed to the medical journals papers which were invariably marked by shrewd common sense and clinical acumen. As a physician he was able and painstaking; a man of few words to his patients, but of infinite kindness. He set a high standard of professional conduct, and helped not a little by his example and precept towards lifting spa practice from the slough of empiricism to the higher plane of rational therapeutics. In all that pertained to the welfare and development of the health resort in which he practised, he was ever ready with sound advice and assistance in medical matters.

As a man he was a charming companion; genial, full of wit and humour (derived from his Irish associations), and a racy raconteur. Even-tempered and broadminded to a degree, he was never known to speak ill of anyone. His life was one of hard work, with little regard for self; and his loss will be acutely felt by his numerous patients and wide circle of friends.

He leaves a widow, three daughters, and a son who holds a commission in the Indian Army, and is now on active service in Egypt.

SURGEON-MAJOR W. F. MACTIER,

INDIAN MEDICAL SERVICE.

SURGEON-MAJOR WILLIAM FULLERTON MACTIER, Bengal Medical Service (retired), died at Kinnessburn, St. Andrews, on June 19th, aged 92. He was born in Calcutta on October 1st, 1822, the son of Anthony MacTier, of Dunnis House, Aberdeen, first Commissioner of the Court of

Requests in that city; was educated at Edinburgh University, where he took the M.D. in 1843, and entered the Indian Medical Service as assistant surgeon on December 3rd, 1844, on the nomination of Sir R. Campbell. He became surgeon on March 29th, 1858, surgeon-major on December 3rd, 1864, and retired on September 24th, 1866, nearly half a century ago. With the exception of two years, 1853-55, when he was in medical charge of Simla, his whole service was spent in military employ, his last appointment being that of principal medical storekeeper, Calcutta, in 1863-64, after which he went on furlough, and did not return to India. During the Indian Mutiny he was personal surgeon to two successive commanders-in-chief, Generals Anson and Sir Henry Barnard. He had a fine record of war service—first Sikh war, or Sutlej campaign, 1845-46, with 4th Native Infantry, actions of Mudki, Alwal, and Sobraon, medal with two clasps; second Sikh war, or Punjab campaign, 1848-49, actions of Ramnagar, Saidulapur, and Chillianwala, medal with clasp; Indian Mutiny, 1857-58, siege of Delhi, mentioned in dispatches, medal with clasp.

In General Sir Archdall Wilson's general order of November 5th, 1857, published in the *London Gazette* of December 15th, 1857, is stated: "Amongst those medical officers whose unwearied zeal and superior ability have come prominently before me are . . . Assistant Surgeon W. F. MacTier, M.D., on the personal staff of the late Commander-in-Chief."

Surgeon-Major MacTier was the senior officer of the Indian Medical Service retired list, with one possible exception, that of the centenarian, Surgeon-Major H. B. Hinton, who, if he is still alive (and he is still shown in the *Army List* as living), must now be well over 102. One of his sons, Major H. M. MacTier, of the 39th Gharwal Rifles, was killed in action at Neuve Chapelle three months ago; another son, Dr. W. B. MacTier, is in practice at St. Andrews.

Public Health

AND

POOR LAW MEDICAL SERVICES.

ELECTROLYTIC DISINFECTANT.

A REPORT was recently submitted to the Council of the Metropolitan Borough of Poplar by the Medical Officer of Health, Dr. Frederick W. Alexander, in which he gives the following particulars:

The initial cost of the apparatus, building, etc., in 1906 was £583 10s.:

	£	s.	d.
Initial outlay (plant)	325	0	0
Fittings, etc. (Electricity Department)	71	7	11
Sundries, structural (Electricity Department)	6	6	11
Sundries (Electricity Department)	4	6	11
Structure of dépôt (Works Department)	120	6	11
Sundries	32	4	7
Carboys	23	16	9
	583	10	0

On account of the great demand for the electrolytic fluid the dépôt had to be enlarged and an additional new plant, with electric motor for stirring and switchboard, etc., was installed at the beginning of 1910; with alterations to the first plant it cost in round figures £500. Owing to the extension of the electricity works the whole structure and installation had to be dismantled and was re-erected.

During the working of the apparatus—a period of nine years—many improvements for the municipal success of the installation were made. A very important improvement was introduced for the reception of the fluid from the electrolyzers. For the glass receptacles, which were apt to break, and were very costly, specially made cheap metal drums were substituted. A double cell has been constructed of slate, in such a form that the "creeping" of the current (which comes direct from the council's mains) from one cell to another is prevented. This is a most important point; all slate contains metal, and the current in "creeping" from the electrodes in one cell to the electrodes in the other cell causes erosion to take place, and sooner or later a "dead short" happens, and a new double cell is required. The original slate cells were replaced by others of earthenware, which have been

in use for some years. Electricity, on account of moisture, will even creep with an earthenware cell, and efficiency will be lost; moreover, if the partition of the earthenware cell or tank is not properly glazed, it will in course of time become destroyed by the electrical current (240 volts and 20 amperes) acting upon the fluid which soaks into the unglazed earthenware. Earthenware cells take a long time to make (possibly four months), and it is never certain that in the firing of earthenware there will not be defects in the articles when they are taken out of the kilns. A slate double cell can be made in a few days, is cheap, and as now constructed will not permit the current to "creep" and cross to take place; in this way cheapness, safety, and greater efficiency are combined. The current being taken direct from the council's mains, the expense of a "converter" with its consumption of current and necessary skilled attention is saved.

Since the installation of the plant 381,794 gallons of fluid have been manufactured at a cost for electricity of £401 19s. 3d., and for materials of £345 9s. 11d. (under 3d. per gallon).

Not only is the Public Health Department and the various institutions of the Council (the public baths, etc., and the Works Department as required), furnished with the electrolytic disinfectant, but the institutions of the managers of the Sick Asylum and of the board of guardians (within and without the borough), and also some of the London County Council public elementary schools are supplied with an unlimited quantity free.

The output of disinfectants rose from 54,388 gallons in 1912 to 68,795 gallons in 1914. The average expenditure, including wages for the three years ending March 31st, 1914, was £831. It is to be noted that the war has had the effect of greatly increasing the cost of magnesium chloride.

The fluid, as made in Poplar, is stable for an almost indefinite period, and is suitable either for municipal or commercial purposes. The rendering of quantities of hypochlorite of magnesia electrolytic fluid stable for municipal purposes was the difficulty which had to be overcome with the plant erected in Poplar because no plant was in existence prior to the Poplar plant where this had been done on a large scale.

The work of making electrolytic disinfectant, as carried out in Poplar, has attracted attention elsewhere. Plants have been supplied to Gurnsey, Gateshead, Finland, Buenos Aires, and Rangoon. At Portsmouth a plant has been installed for manufacturing the fluid direct from sea water and rendering it stable by the method adopted in Poplar, and recently the Finchley Council placed an order for an installation.

Medical News.

SURGEON-MAJOR S. C. NOBLE, V.D., J.P., Kendal, has been appointed by the Lord Lieutenant a Deputy Lieutenant for the county of Westmorland.

SIR JOHN LENTAIGNE, sometime President of the Royal College of Surgeons in Ireland, left unsettled estate in the United Kingdom valued at £9,869.

The annual general meeting of the West London Medic-Chirurgical Society will be held at the West London Hospital on Friday, July 16th, at 5 p.m. The Council will propose that Dr. Leonard Dobson shall be elected president for 1915-16.

At a convocation of the University of Oxford on June 25th the honorary degree of Master of Arts was conferred on Mr. Horatio P. Symonds, F.R.C.S. Edin., surgeon to the Radcliffe Infirmary, in recognition of his services to the Oxford Medical School.

The administration of Brides-les-Bains, sometimes called the French Carlsbad, offers to British naval and military officers free treatment and the use of the baths and springs. The place is an agreeable summer resort in Upper Savoy and stands at an altitude of about 2,000 ft.

At a sessional meeting of the Royal Sanitary Institute, at Yeovil on July 14th, discussions will be opened on water supplies to rural and small urban areas by Dr. W. G. Savage, M.O.H. Somerset, and on the prevention of minor infectious diseases by Dr. A. E. Remmet Weaver, M.O.H. Yeovil.

On June 24th, at the official residence of the French Minister of War, the British Ambassador presented to M. Millardot two ambulance cars in the name of the boys of Eton. These cars, specially fitted for the service of the Chassens Alps (the "Blue Devils" of the French army), bear silver plates with the following inscription:

"A l'Armée Française les élèves du Collège d'Eton (Angleterre) en témoignage de leur admiration. 1915."

A MOTHERCRAFT and child welfare exhibition will be held at the Passmore Edwards Institute, Tavistock Place, W.C., from July 3rd to July 10th. It will be open free from 2.30 to 8.30 p.m. each day. The exhibits have all been arranged by associations or persons interested in the subject, and there will be no trade exhibits. Among them will be a model day nursery, a dental exhibit, and a fly exhibit arranged by Professor Lefroy. Lectures on flies will be given by Dr. Halford Ross and Dr. King Brown, and one on the protection of children against insect-borne diseases by Dr. Louis Saubon on Wednesday, July 7th, at 4.30.

LIEUTENANT-COLONEL SIR COURTAULD THOMSON has been appointed chief commissioner of the Order of St. John and the British Red Cross Society for Malta and the Near East. The secretary and deputy chief commissioner is Major Stockings. On his arrival at Malta Sir Courtauld, who was accompanied by Sir Frederick Treves, visited most of the hospitals, under the guidance of the D.D.M.S., Colonel Slemán.

An appeal signed by, among others, the Bishops of Stepney and Southwark, the Chief Rabbi, Lady St. Helier, and Mrs. Creighton, has been issued for generous subscriptions this year to the Factory Girls' Country Holiday Fund. Owing to the facts that the railway companies do not see their way to make the usual reduction in fares, and that the charge for board and lodging is necessarily greater, the cost for each girl will be increased, and the committee do not think it right to run into debt. Subscriptions may be sent to the Honorary Treasurer, Factory Girls' Country Holiday Fund, 75, Lamb's Conduit Street, W.C.

SIR RONALD ROSS, the honorary director of the Marcus Beck Laboratory of the Royal Society of Medicine, in addition to the request mentioned elsewhere, addressed to the medical profession practising in the neighbourhood of the society's house, 1, Wimpole Street, to let him know of cases of measles where permission could be obtained to take a specimen of fresh finger blood, asks whether it has been observed that vaccination for small-pox is exceptionally unsuccessful if performed on persons who are suffering from or who have recently suffered from measles of either type, or from scarlet fever. He will also be glad to hear from any persons having special knowledge of the sanitary conditions in the Gallipoli Peninsula and neighbouring parts, as he wishes to make an investigation on this subject.

The Grand Pump Room Hotel at Bath was reopened on June 26th. It stands on the site of the old White Hart, where Mr. Pickwick and his friends put up during the first part of their stay near the baths of Blandford. A large number of medical men from London and the provinces, especially from South Wales, were among the guests at an inaugural luncheon and reception, when they were welcomed by Mr. H. J. Thomas of Cardiff, the guiding spirit of the new enterprise. For some years past the closed and derelict condition of the hostel opposite the pump room colonnade has been a note in the Bathonian eye, but the renovated building is now on a scale of luxury such as would make Angelo Cyrus Bantam, M.C., declare himself more than ever satisfied, and delighted, and overpowered. The hotel contains 120 bedrooms, with 15 private suites. The decorations are chiefly in Adam style, the predominant colour note being a warm crimson, while the white enamelling of the 30 bathrooms and of a large portion of the general building is extremely effective. The kitchens also are said to be the finest outside London. The feature of the hotel which calls chiefly for remark, however, is the direct connexion by means of electric lifts with the New Royal Baths. This portion of the corporation bathing establishment—forming, indeed, the lower part of one wing of the hotel building itself—is now in process of reconstruction by the city council. The invalid visitor will thus find it possible to undergo the various bath treatments at the hot mineral springs without the necessity of making the passage of the street. This direct association of hotel and bathing establishment is not unusual at Continental spas. Speeches were made at the luncheon by Lord Willoughby de Broke, Sir Melville Beachcroft, and others, in which the patriotic emphasis had a distinctly local turn. It was stated that Bath has enjoyed a record season, many thousands of treatments having been given freely to the country's fighters suffering from stiffness after wounds, and students of the local chroniclers have pointed out that the same thing happened after the campaigns of Marlborough and Wellington, and that Nelson also went there for recuperation after one of his naval expeditions.

Letters, Notes, and Answers.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 423, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attingham, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Attingham, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediseca, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

TREATMENT OF CHEIROPOMPHOXY.

"SKIN" asks for suggestions as to treatment of cheiropompholyx, from which he suffers. About every three months vesicles develop on the sides of fingers and thumbs, go on to pustular formation, and become very painful ulcers. He would be glad to know of any treatment which would abort the condition. He has tried painting affected surfaces with silver nitrate in solution but with little benefit. As a holiday is out of the question, he would be glad to know what general lines of dietetic and other treatment might be useful.

LETTERS, NOTES, ETC.

A WARNING.

SOME time ago we had occasion to draw attention to the activities of certain insurance agents who sought to induce doctors to take out a policy with their company, at the same time making a promise, in some shape, that other applicants for policies in the neighbourhood would be referred to the doctor for medical examination. We understand that something of the same kind is now happening in the north of England, and we would advise doctors who may be approached with such suggestion to be on their guard. There is, of course, an ethical side to this matter into which we do not now enter.

RECOGNITION OF CEREBRO-SPINAL FEVER.

DR. ERNEST MILLIGAN, D.P.H. (Long Eaton) writes: I read with great interest the note by Dr. Renault on three cases of cerebro-spinal fever in the issue of the JOURNAL for June 19th, p. 1044, as they confirm the view that cerebro-spinal fever occurs without cerebro-spinal symptoms; in this light the cases published by Dr. Lundlee and his fellow workers are also important. In a thesis written by me shortly after the Belfast epidemic, 1906-8 (see *Practitioner*, June, 1915) I laid stress on this aspect of infection by the meningococcus. The term "cerebro-spinal" applied to the disease is, I believe, misleading, and with a view to the prevention of the disease, I think a less misleading title should be substituted. Some of our leading clinicians could help to this end; such names as "meningococcal infection," "meningococcal fever," "meningococcal meningitis," "meningococcal meningitis," "meningococcal meningitis," or "meningococcal meningitis," or "meningococcal meningitis," would be less likely to result in mistakes in diagnosing this protean disease.

BADGES FOR DOCTORS' CHAUFFEURS.

A. W., who was mobilized in August in connexion with a Voluntary Aid Detachment, and is now working at a hospital conducted by it, suggests by several means should be found of issuing badges to chauffeurs in the employment of doctors in this country, in view of the urgent demand by the military authorities for motor drivers.

LYMPH LAVAGE OF WOUNDS.

DR. ALBERT WILSON (London) writes: The physiological treatment of war wounds by so-called lymph lavage through the use of saline solutions demands attention to the primary principles of osmosis. Three conditions are necessary: (1) The liquids on either side of the partition must be different, but capable of mixing; (2) the liquids must be of different densities; (3) the membrane must be permeable to at least one of the liquids. The formula of "endosmotic equivalents" was established, and expresses by a number some many parts by weight of water pass through the membrane in exchange for one part by weight of the substance. Obviously the use of the water bath does serious mischief, as the endosmosis is then into the tissues, carrying in septic material; while the use of normal salt solution (3 per cent.) is nil, being balanced by the like density of the lymph. If we use a 5 per cent. solution of common salt, there is only a feeble action from the surplus 2 per cent. The endosmotic equivalent of NaCl is 4.3. Epsom salts is preferable, as the equivalent of MgSO₄ is 11.7; copper

is 9.5. Sugar, even, is better than salt; its equivalent is 7 Alcohol is about the same as salt, 4.2. The French have used alcohol for forty years as a surgical application. It is also very cleansing. It is self-evident that more douching effects nothing. There must be constant application of the solution in both or on one's. The surgeon should remember that this action is physical, not chemical; whereas septicæmia and toxæmia are bio-chemical, and demand different methods. Moreover, such treatment is only of value in the pregranulation stage. Granulations do not absorb; the physiological action of the wound is then phagocytic, and lotions arrest this process. Glycerine has recently been advocated as a dressing for war wounds, and has undoubtedly a very high endosmotic equivalent. If applied pure, endosmosis is rapid. I have used it pure in a few cases. If salicylic acid, 2 per cent.; were dissolved in it, the endosmosis would bring this drug into contact, thus destroying all septic organisms, even tetanus. I have for years used this for obstinate ringworm and alopecia; I may say without failure. Its action is that of endosmosis and exosmosis. Glycerine is certainly easy of application to deep, long sinuses, especially down the irregular deep tracks made by shrapnel, which are not always easy to drain. It also soothes pain, and will stand moderate dilution.

DR. JOHN ALCINOR (London) writes: It is generally recognized that salt is a lymphagogue of no small value; douches and gargles containing 5 to 10 per cent. of common salt constitute a useful adjunct in the treatment of catarrhal affections of the nose, mouth, and throat. Glycerine, as Dr. H. J. Holt points out in the BRITISH MEDICAL JOURNAL of June 5th (p. 969), is also a lymphagogue of considerable value. I have used glycerine containing 5 to 10 per cent. carbolic acid or liq. cresol. sap. in a number of cases of endometritis and pelvic cellulitis, with excellent results; a tampon of cotton-wool 3 in. long and 1 in. thick tied in the middle with crochet cotton with loose ends for the purpose of withdrawing it from the vagina, is saturated with this preparation, and inserted through a speculum well up against the os after giving a vaginal douche of 1 in 40 carbolic or liq. cresol. sap. after a period of four to six hours contact, and the discharge ceases, which necessitates the use of diapers; the tampon is changed in twenty-four hours and the treatment continued for eight days. The results of this course of treatment are loss of pain, cessation of purulent discharge, a healthy appearance of the os and surrounding mucosa, and an improved aspect of the patient. It would seem that liq. cresol. sap. is the better anti-septic for the purpose, because of its cleansing properties, its power of inhibiting the multiplication of lymph, and its interference with the powerful osmotic action of the glycerine. As there is a certain similarity between endometritis and pelvic cellulitis on the one hand, and infected gunshot wounds on the other, it would seem that a method of treatment which produces good results in the one class of cases would with appropriate modifications produce equally good results in the other class, inasmuch as the underlying principle, which Sir Almroth Wright so lucidly expounded, is the same in both instances. It is with the hope that resorolized glycerine will be given a trial, both as a preliminary dressing and as a systematic treatment of gunshot wounds, that I venture to put forward the suggestion.

BRITISH HEALTH RESORTS.

WE have received a letter from Dr. T. D. Luke, physician to the Peebles Hydro-Pathic, protesting against the omission of Peebles from the pamphlet entitled *Notes on Hydrological Treatment and a List of British Health Resorts and Spas*, published under the auspices of the Council of the Bacteriological Section of the Royal Society of Medicine. It is, he says, a place of surpassing beauty, noted as a health resort since the time of Queen Mary, and is at this day well patronized.

THE GERMANIZATION OF DICKENS.

WE know the Germans claim Shakespeare as their own; as they admire Dickens, we have no doubt that, in their desire to rule the world, they would like to annex him too. We are sorry that by an unlucky accident the BRITISH MEDICAL JOURNAL should have seen the light as a patriotic contribution to the realization of this scheme. Mr. Crummles was anxious that the British public should know that he was not a Prussian. We are equally anxious to inform our readers that, in spelling the name of Mr. Wemmick as "Wemmick" in our issue of June 26th (p. 1092), we had no desire to Teutonize the author of *Great Expectations*.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 8 0
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-
resistant letters addressed either in initials or numbers.

TREATMENT OF "GUNSHOT WOUNDS" OF
THE KNEE-JOINT.

BY COLONEL H. M. W. GRAY, A.M.S.,

CONSULTING SURGEON, BRITISH EXPEDITIONARY FORCE, FRANCE.

This paper is written in order to draw attention to certain points which have been demonstrated by the surgeons of the British base hospitals in my area—that is, all south of Abbeville—to be of immense importance. In the earlier part of the war the results of the treatment of such injuries left a great deal to be desired. The great majority of such cases as recovered did so with ankylosis. The period of convalescence was usually most painful and precarious.

Such infected injuries were approached with ideas regarding their treatment which, as our experience has shown, are erroneous. The chief of these were: (1) That suppurative infections of the joint demand free and prolonged drainage; (2) that drainage tubes are the best means of procuring this; (3) that these tubes must be large, and must be inserted deeply into the various recesses of the joint, and (4) that strong antiseptic treatment is necessary in order to overcome the infection. These remedies are inimical to a "restitutio ad integrum," because, by their deleterious action, the synovial membrane and cartilages are more or less destroyed, and in most cases the best result that can be hoped for is ankylosis. On the other hand, the importance of certain factors in successful treatment were not grasped sufficiently: (1) That wounds of the knee-joint which are liable to become septic demand immobilization of that joint. Few of such cases arrived at our base hospitals with an efficiently applied splint. Movement of such a knee may turn the scale in favour of sepsis, in two ways—(a) it may favour the entrance of sepsis to a knee previously uninfected, and (b) it may stimulate a virulent, diffuse inflammation instead of a mild, localized one. During after-treatment the splint must be retained for two to three weeks at least. During the later stages gentle passive movement may be made daily. (2) There existed quite a widespread notion that foreign bodies in the joint should be removed "only if they lead to trouble." Fortunately, the fallacy of this view has been demonstrated, and now only those which are imbedded in the bone outside the joint are left alone, if they are not causing trouble. (3) The good effect of excision of the wound of the skin and superficial tissues, or of the whole wound where possible, was not appreciated. This good effect has been well demonstrated in our base hospitals, and, to my mind, the procedure has a profound influence on the subsequent favourable course of the case.

A few amplifying remarks on some of the foregoing points will be allowed.

Foreign Bodies.

The undistorted rifle bullet may perforate the joint without introducing infective material in sufficient amount to overcome the natural resistance of the part, and no inflammation may result. This does not justify neglect to apply a proper splint to the limb in these cases. The broader and more irregular the surface of impact of the foreign body the more likelihood is there of infective material (clothing or skin) being carried in to the depth. Shrapnel bullets, splinters of shell, or distorted rifle bullets may carry distinct "wads" of such material in front of them. The urgency for immediate removal of these foreign bodies increases with their potentiality for carrying in infective material. The size of the foreign body should not be allowed to influence the decision unless in very exceptional cases.

Drainage Tubes.

Since it is so important to remove foreign bodies from the interior of the joint, it seemed a futile proceeding to introduce others, especially when these establish free communication with septic surfaces either of the wound or of the skin, as tubes do. The presence of a tube in the joint, besides exerting a mechanical evil effect on the synovial membrane or cartilages, provides a haven of refuge and a reservoir of pus in which organisms can multiply. "Hypertones" (for example, tablets of sodium chloride and sodium citrate) placed in the tube,

continuous irrigation, or continuous baths, only mitigate—they do not remove—these drawbacks. The tubes should lead down to, but not through, the wound in the synovial membrane, unless the inflammation is so acute that all thought of saving the function of the joint is hopeless. If sepsis in the joint has been acute, it is better to leave the synovial membrane unsutured. This attitude towards the insertion of drainage tubes was stimulated on seeing the results in a few cases of this procedure when carried out at the front, with the object, no doubt, of preventing acute sepsis. In these cases the drains had been inserted with perfect attention to the principles which have been laid down for procuring efficient drainage of the joint, but the results were certainly not satisfactory.

A comparison of the condition in which cases arrived with apparently similar wounds, but which had simply been dressed, made us feel that, if possible, wounds of the knee-joint should not be operated on until they reached a hospital where they could be kept in bed for ten to fourteen days at least after operation.

The Use of Antiseptics.

The opinion is obtaining very firm hold amongst us that any beneficial action which any antiseptic may show in the interior of wounds or of joints is due entirely to its power of inducing "lymph lavage" or "chemiotaxis" or both. The opinion that antiseptics applied to the skin around a wound are of the greatest prophylactic value remains, of course, unshaken. Strong antiseptics in a joint have a deleterious effect on the delicate synovial membrane and on cartilages, which interferes with the resistance and recuperative power of these structures. It is therefore the exception to find that antiseptic dressings or applications in the depths of wounds are used in our base hospitals.

Hypertonic Salt Dressings.

Better and quicker results are found to follow the use of "hypertonic" dressings (see my letter of last week, p. 32). The mode of application varies in different cases. Even hydrogen peroxide is now used practically only to remove very adherent dressings. Regarding the use of injections of formalin-glycerin, iodoforn-ether, or ether into the joints, it cannot be said that any one of these agents is better than the other. They do no harm apparently, and they appear to do good, but hypertonic saline solution seems equally efficient.

It would seem desirable that this well-tried and satisfactory "hypertonic" treatment should be more widely employed. If it were, the provision and transport of medical stores would be simplified enormously.

Excision of Wounds.

The excision of the soiled superficial part of deep wounds or of the whole wound, when possible, cannot be too strongly advocated. In other parts of the body *excisio in toto*, no matter at what stage, followed by immediate suture, has, when technique is perfect, resulted in healing by first intention. The advantages of this are obvious. Contraindications need not be discussed here. I look upon results obtained from this procedure as a measure of the claim which any surgeon can make that his technique is perfect! Primary suture is, of course, out of the question in the wounds we are at present considering—free drainage must be provided, therefore the wounds are left open—but secondary suture, when advisable, can certainly be performed at an earlier stage after excision has been made. Aponeurotic structures especially, unless their removal entails disablement, should be cut away. Their superficial parts at least will slough, and such sloughs take a long time to separate. The ragged, possibly soiled, edges of the wound in the synovial membrane should always be snipped away.

Frequency with which Deep Dressings should be Changed.

As I have pointed out in the letter referred to, the first dressing may frequently be left *in situ* for days. If the joint is "quiet" and the dressing free from pus, there is absolutely no necessity to remove it. The wound in the synovial membrane will thus get a chance to heal. In removing the dressing early it is likely to be torn open.

The feeling is gaining ground that the knee-joint, if given a fair chance, has more recuperative power than it has hitherto received credit for. One cannot, however, while giving it a chance to take care of itself, forget the dire results which may follow if septic infection gains the upper hand. Therefore the cases must be watched with the utmost care, and any untoward symptom be fully investigated. It is rare that a quiet-looking knee is going wrong inside unless a wound exists which communicates directly or indirectly with the joint. In that case there will probably be an amount of discharge in excess of what would be expected from the surface wound. If the knee is at fault, prompt and energetic suitable measures must be taken.

Results.

The recent application of the principles which I have discussed has been followed by a great improvement in results, which must be very gratifying to the surgeons concerned. For purposes of comparison I give the results in 10 cases which were admitted from the Neuve Chapelle fight, and treated by what one might call transition methods—that is, the more recent methods were already being tried in some cases. These cases were unselected, and were similar in severity to those which were admitted to all the hospitals in Rouen during the month previous to May 19th, for which period the surgeons furnished me with returns. I append also a *précis* of the treatment employed.

Synopsis of Treatment.—Excise wound of skin and superficial soiled or necrotic muscle and fascia. Enlarge wound freely if necessary. Remove foreign bodies (previously localized by *x* rays) after possible enlargement of wound in synovial membrane. Flush synovial cavity with 5 per cent. saline solution. Thoroughly remove blood clot. In very acute cases make fresh incision. Trim edges of wound in synovial membrane, suture if sepsis not acute. Insert drainage tube down to but not through wound in synovial membrane. Fill rest of wound fairly firmly with "tablet and gauze" dressing. Inject formalin-glycerin or ether, etc., through fresh puncture. Clean and redisinfect surrounding skin. Superficial dressings, light bandage. Immobilize in suitable splint. If this fails, free arthrotomy, possibly amputation.

Case I.—Second Lieutenant J. Wounded April 25th; admitted April 27th. Temperature 101 F. Lacerated wound 13 in. on the antero-internal aspect of the right knee. Opening in synovial

from joint, containing staphylococci and streptococci. Operation April 27th; synovial membrane not sutured; ether injected. First change of deep dressing on May 2nd. Temperature normal on April 30th and subsequently (see chart). *Result:* Movable joint. Wound practically healed when sent to England on May 12th.

Case 2. Private P. W., 1st Argyle and Sutherland Highlanders. Wounded April 18th; admitted April 20th. Left knee. "Transverse" shrapnel wound, shattering patella; shrapnel bullet lodged to inside of patella. Local severe inflammation and effusion (blood and pus; staphylococci). Temperature 100. Operation April 20th: Fragments of patella left a mistake in presence of sepsis; synovial membrane sutured; formalin-glycerin injected. Temperature 98.4-99 till May 8th, when the patient complained of pain and the temperature rose to 101, and smelly pus exuded from the wound in the synovial membrane. Decided to operate on May 12th. Patella excised; joint washed out; synovial membrane again sutured and formalin-glycerin injected—without success. Joint opened up freely on May 17th. *Prognosis:* Ankylosis.

Case 3. Private L., 1st Somerset Light Infantry. Wounded April 28th; admitted May 1st. Right knee. Temperature 99. Transverse shrapnel wound, suprapatellar pouch; fracture splintering; of lower end of femur; blood and pus (staphylococci) in joint. Operation May 1st. Synovial membrane sutured; injection of formalin-glycerin. Next day temperature 100.4; since then normal. *Result:* Movable joint.

Case 4. Private C., London Rifle Brigade. Wounded May 2nd; admitted May 8th. Has lain out in the open for five days after being wounded. Right knee. *X* rays showed a piece of shell casing in intercondylar notch. Small wound covered by scab on outer side above patella. Local signs of intense inflammation; effusion; very painful on movement. Temperature 103.6. Operation May 9th: Wound excised; joint washed out (full of greivish clotted material, smelling a Gram-positive bacillus found); foreign body removed; synovial membrane sutured; formalin-glycerin injected. The morning and evening temperatures from May 10th to May 14th were as follows:

	Morning.	Evening.
May 10th	100.2	100.8
May 11th	99.4	99.6
May 12th	98.4	99.6
May 13th	98.6	99.0
May 14th	38.0	99.0

On May 17th the wound was painful, and the temperature went up to 102; there was purulent effusion. Lateral incisions were made, anteriorly and posteriorly. On May 20th the condition was steadily subsiding. *Result:* Probable ankylosis.

Case 5. Private K. A large lacerated wound over the outer tuberosity of the tibia; a smaller one over the outer condyle of the femur. Extensive comminution of condyles. Very septic. Pulse 140, temperature 97. Operation: Knee laid open by transverse subpatellar incision. No improvement. Three days later amputation.

Case 6. Private B. Shrapnel wound on outer side of patella; very septic; purulent fluid exuding. Knee much swollen, very painful. *X* rays showed a bullet in the joint near the spine of the tibia. Operation: Wound enlarged after excision; counter opening on inner side of patella. Foreign body removed; joint washed out—iodoform ether. Tube from wound to wound for two days. *Result:* Movable joint.

Case 7. Private S. Left leg amputated at clearing hospital. Small septic wound in right knee, foul pus exuding. Much swelling and pain. Temperature 102. Operation: Shrapnel bullet deeply imbedded in articular surface of tibia. Condyles much eroded. Joint laid open by transverse subpatellar incision. May 16th, patient doing well; temperature normal. *Prognosis:* Ankylosis.

Case 8. Private McG. Transverse shrapnel wound. *X* rays showed grooving of head of tibia. Much swelling and tenderness. Temperature 102. Syringe removed turbid flaky blood-stained fluid. May 16th, patient doing well; temperature normal. *Result:* Movable joint.

Case 9. Private W. Two wounds (machine gun): one perforated condyle of femur and passed out; the other chipped upper surface of tibia and lodged in the tibialis anticus muscle (*x* rays corroborated). Much swelling and tenderness. Temperature 102. Exploring syringe revealed pus. May 16th, patient doing well; temperature normal. *Result:* Movable joint.

Case 10. Private E. C., 3rd Middlesex. Admitted April 27th. Severe, very septic flesh wound in upper third of right thigh (streptococci; thigh wound also contained *B. perfringens*). Conservative measures no use. May 4th, knee-joint and extensive abscess along thigh laid open by transverse subpatellar incision. May 13th, wound clean, covered with healthy granulations. *Prognosis:* Ankylosis.

Case 11. Shrapnel wound; blood and pus in joint (micro-organisms found, nature, shrapnel in joint. Tube left in wound for two days after operation; fourteen days after discharged to England. *Result:* Movable joint.

a, Superficial dressing changed; b, deep dressing changed.

membrane 1 in. Inner condyle split off. Flattened distorted bullet and clothing lying in tissue, which extended up into the medullary cavity of the femur. Sanguinolent pus discharged

Case 12.—Sergeant W. Wounded April 23rd; admitted April 27th. Shrapnel wound; comminution of patella. Operation April 27th: Excision of wound; removal of foreign bodies (bullet and clothing) and fragments of patella; anterior drainage. May 13th, joint gradually settled down; condition very good. *Prognosis:* Ankylosis.

Case 13.—Private S., King's Own Royal Lancashire. Admitted April 22nd. Shrapnel bullet imbedded in inner condyle of femur—left knee—split through articular surface; joint full of blood and pus. Bullet extracted; bone cavity scraped out. Joint washed out with hypertonic saline. Formalin-glycerin. May 13th, patient doing well. *Result:* Movable joint.

Case 14.—Sergeant T., 1st East Surrey. Shrapnel wound in right knee. Synovial membrane torn; bloody pus exuding. Usual operation on April 22nd. On May 7th the patient left for England; wounds clean; no effusion. *Result:* Movable joint.

Cases 15 and 16.—Private R., 1st East Surrey. Shrapnel wounds in both knees; also depressed fracture of skull. Synovial membrane found torn in both knees. April 22nd, usual operation on both knees. May 13th, patient doing well; wounds clean. *Result:* Movable joints.

Case 17.—Private E. G. H., 1st Monmouth (T.F.) Shrapnel wound of left knee. Capsule badly torn. April 24th, usual operation. May 13th, patient doing well; wound clean. *Result:* Movable joint.

Case 18.—Corporal R., Canadian Field Artillery. Shrapnel wound of left knee. Bullet pierced internal condyle and lodged in external. Capsule full of blood clots and pus. April 29th, usual operation; bullet left *in situ*. May 7th, patient left for England; wound nearly healed. *Result:* Movable joint.

Case 19.—Wheeler H., Canadian Field Artillery. Shrapnel wound of right knee.

Case 20.—Private W. S., 4th Yorks. Shrapnel wound of right knee; fragment lodged in head of tibia (fracture into joint).

Case 21.—Bombardier E., Royal Garrison Artillery. Multiple shrapnel in left knee.

Case 22.—Private M., Honourable Artillery Company. Bullet wound of right knee; bullet imbedded in lower end of femur.

In the last four cases it is doubtful if the knee was actually opened. All had much effusion of bloody purulent fluid. All had movable joints when sent to England.

Case 23.—Lance-Corporal D., Canadian Artillery. Gunshot wound of left knee, perforating upper part of joint; no fracture; bloody purulent effusion (Gram-positive cocci). Usual procedure; 10 c.cm. ether injected. *Result:* Movable joint.

Case 24.—Private C., 12th County of London. Shrapnel perforating wound of knee-joint; purulent effusion (Gram-positive cocci). Usual procedure; 10 c.cm. ether injected. *Result:* Movable joint.

Case 25.—Private W., 48th Canadian Highlanders. Perforating gunshot wound of knee-joint; very great effusion; no fracture. Usual procedure; 10 c.cm. ether injected. *Result:* Movable joint.

Case 26.—Corporal L., 2nd D.C. Light Infantry. Perforating gunshot wound of knee-joint; much distension; no fracture. Usual procedure; 10 c.cm. ether injected. *Result:* Movable joint.

Case 27.—Private M., 2nd West Riding. Perforating gunshot wound of knee; no fracture; much distension and severe inflammation around joint; purulent effusion (Gram-positive cocci). Usual procedure; 10 c.cm. ether injected. *Result:* Movable joint.

Note.—In Cases 13-27 I had asked the surgeons of the hospitals concerned to report only those cases which showed signs of acute local inflammation with decided rise of temperature, and which in their opinion would go wrong if not treated according to the method we had worked out. Hence the short notes.

Case 28.—Corporal J. H., 12th London. Admitted May 6th. Shrapnel wound of left knee through ligamentum patellae, with comminuted fracture (T) of head of tibia, communicating with joint; cellulitis in calf. Temperature 104.4. Much distension. Operation May 6th: Aspiration of bloody pus; injection of formalin-glycerin. Abscess in calf opened, and piece of shell $\frac{1}{2}$ in. by $\frac{1}{2}$ in. removed; tube drawn to hole in back of tibia. Anterior wound excised; tube down to hole in tibia; wounds "filled" with hypertonic and gauze. Inflammation gradually subsided. Report on May 14th: Patient looks, eats, and sleeps well; practically no pain; wounds clean; no swelling, no fluid in joint. Knee-joint movable. A similar report was made on May 19th.

Case 29. Private McL., 1st Royal Scots Fusiliers. Wounded May 4th; admitted May 6th. Shrapnel wound of right knee just above patella on antero-external aspect. Temperature 104.7. Much effusion, purulent. Operation May 7th: Fragments of shrapnel removed from joint; usual procedure otherwise; formalin-glycerin injected. Temperature next day 99. His condition gradually improved, and on May 14th there was no effusion, the wound was clean, and the joint movable. May 19th, similar report.

Case 30.—Private M. Admitted May 7th. Fragment of shell (size of hazel nut) removed from above patella. Purulent effusion. Formalin-glycerin injected. May 10th, aspiration, 1 oz. purulent fluid removed. May 14th, no fresh effusion; wound still discharging, but cleaner. May 19th, no recurrence of effusion. (This patient, a few days after the last report, developed purulent effusion again, which ultimately led to free incision treatment, and later amputation. Possibly another injection of formalin-glycerin might have saved the joint.) *Result:* Amputation.

Case 31.—Private L. Piece of shell removed from inner side of left knee—subtarsus bursa. Purulent effusion. Formalin-glycerin injected. Fluid did not collect again. *Result:* Movable joint.

The following four cases were treated: (a) Directly in track of wound, by excision of superficial wounds and superficial part of track; removal of foreign body; free incision on each side of patella and suprapatellar pouch. No tubing inserted; no sutures. Spirit dressing, after swabbing out wounds with 10 per cent. iodine. Posterior knee spint and footpiece. (b) Indirectly when infection occurred after fracture of tibia or condyles of femur. Joint opened and effusion removed at point most remote from surface wounds—along lines laid down.

Case 32.—Lance-Corporal H., 2nd King's Own Yorkshire Light Infantry. Admitted May 2nd, and operated on the same day. Temperature 99. Shrapnel ball in joint; wound on inner side of patella. Great effusion; much clot; condyle fractured (?). Incision on outer side of patella. May 10th, no reaccumulation of fluid; both wounds cleaned well. For the last four days the temperature had not passed 99. Condition of joint seems most satisfactory. May 19th, similar report. *Result:* Movable joint.

Case 33.—Gunner W., 3rd Canadians. Gunshot wound; (shrapnel) wound of right knee; wound on outer side of patellar ligament. Ball removed. Much muco-purulent effusion. Two lateral incisions besides excision of wound. Whole knee swathed in dressing, wet with spirit. May 15th: For ten days temperature varied between 99.8 and 102; patient very ill; locally the knee kept remarkably well; for past three days temperature never above 99. "Looks like making a first-class recovery." May 19th, continued improvement. *Result:* Movable joint. (A periarticular abscess, with stinking pus, developed about June 1st, but caused no trouble in the knee.)

Case 34.—Private M., 2nd Buffs. Admitted May 2nd, with gunshot wound through condyles of left knee. Bone shattered; not marked effusion into joint. Excision of septic wounds—tubes down to site of fractures. Temperature fell gradually. Tubes out on fifth day, when no apparent inflammation in knee-joint. May 19th, condition reported excellent. *Result:* Movable joint.

Case 35.—Lance-Corporal W., Royal Engineers. Gunshot wound (shrapnel) of right knee; septic wound at outer side over head of tibia. Much effusion. Bullet had gone on after opening joint and lodged over external condyle. Usual operation. Bullet not removed at first operation. Tube slung at track removed on fourth day. Bullet removed on May 14th. May 19th, "Perfect recovery seems assured." *Result:* Movable joint.

Case 36.—Sergeant —. This case, which was not fully reported to me, required amputation; hopelessly shattered femur, patella, and tibia—truly an injury of the knee-joint!

There were many other cases of wounds of this joint in the various hospitals in which the effusion gradually subsided without other treatment than rest, with occasionally simple aspiration.

CHALMERS AND O'CONNOR (*Journal of Tropical Medicine and Hygiene*, April 1st, 1915) have described under the name "Pyosis Corletti" a small epidemic of a bullous eruption occurring amongst soldiers at Khartoum. They define the disease as an acute, contagious, bullous pyosis beginning in any region of the body (but not specially affecting the axillary and scroto-crural regions), characterized by the presence of medium-sized and large bullae arising on seemingly healthy skin, and apparently caused by *Aerococcus mollis* (Dyar, 1895). A differential diagnosis must be made between this condition and impetigo contagiosa, dermatitis bullosa plantaris, pemphigus acutus, pyosis mansonii, and Corletti's impetigo contagiosa bullosa. The prognosis is very good, for the disease yields rapidly to vaccine treatment. The authors prepared a vaccine, which was administered in 200 and 450 million doses, with intervals of two to three days between each dose. At the same time local treatment was found useful in expediting the cure. Each blister was pricked, and the exuding fluid caught on swabs dipped in 1 in 1,000 lotio hydrargyri perchloridi. After pricking, the blister should be dusted with some antiseptic powder.

THE PLATING OF GUNSHOT FRACTURES.

BY

NORMAN C. LAKE, M.D., M.S., B.Sc.LOND.,
F.R.C.S.ENG.,

SURGEON, HÔPITAL AUTONOME 6 BIS, NEVERS, FRANCE; ASSISTANT
SURGEON, QUEEN'S HOSPITAL FOR CHILDREN, LONDON.

DURING nine months' experience of large numbers of cases in French base hospitals almost every advocated method of treatment has been given a trial, and of these the method with which this article is concerned has given the best ultimate results. It would be a mistake to say that it was immeasurably superior to all others, for there can be little doubt that every surgeon gets the best results from the method to which he has devoted most time and thought; at the same time, a method which has given good results in some hands may be confidently expected to give good results in others, for there is nothing novel or special about it. Indeed it is so ordinary as to be scarcely worthy of record, yet I have not seen it used in any French military hospital that I have visited, nor heard of its use in any English ones.

Considering the subject from a purely theoretical standpoint, there are two main factors to be dealt with: First, there is the anatomical or mechanical injury; secondly, the infective or inflammatory injury. The ideal treatment would be one which enabled us to deal with each of these separate factors as we wish without interfering in the slightest degree with the treatment of the other.

The importance of obtaining an anatomical result as perfect as possible need not be emphasized. Modern surgery has already appreciated the far-reaching effects of even minor defects in anatomical reconstruction, and how closely the functional result depends upon the anatomical. This relationship is especially marked in the case of fractures, and in the compound comminuted fractures so common in gunshot injuries the great difficulty is to obtain a good anatomical result. The two main unfractured portions of the bone are separated by an interval of 2 or 3 inches, in which there is more or less comminution. In some cases pieces of bone are missing, and in others some of the intervening small fragments die, so that there is actual loss of bony substance. The most perfect anatomical results can only be obtained in such cases if the interval or gap is maintained from the first at its original length, for the consolidation which eventually occurs is frequently very imperfect, and secondary operations to increase the rigidity of the bone are needed. Such secondary operations will only lead to disappointments unless the main fragments have been maintained meanwhile in perfect relative position.

Given, then, some method of assuring a good anatomical result, the second part of the problem—namely, the infection—must be dealt with according to the best accepted methods, whatever they may be. Any method, therefore, of splinting the bone which interferes at all with the practice of the numerous methods of dealing with sepsis, or renders difficult the adoption of those accessory treatments such as massage, so important to good functional results, must be considered imperfect. When it is remembered that among the methods of combating sepsis must be included the Bier's bandage, the antiseptic bath, the drip bath, and others necessitating freedom of the limb, the disadvantage of any method of external splinting becomes apparent; add to this the inconvenience of dressing and nursing when assistance is not so abundant as in peace time, and it will be seen that external splints are by no means perfect. In fact, from the theoretical point of view, the internal splint would appear to be the better; but it must next be considered whether it complies with the other essentials—namely, that it assures perfect anatomical result, and does not interfere in any way with the infective process.

As far as anatomical reconstruction goes, it is possible in the majority of cases to obtain a considerable degree of perfection with a plate; but the problem as to whether its application would not increase the damage by opening up further channels for infection, both in the soft tissues and in the bones (chiefly through screw holes), was one which at first caused a good deal of anxiety. A wide experience,

however, has proved that the fresh infection of soft tissues is negligible in view of the already extensive damage, and that fresh infection of the bone does not occur to any extent worthy of consideration. Indeed, in some cases, chiefly of the smaller bones, a previously septic wound has healed completely over a plate. Such results were unexpected, and may possibly be due to the healthy condition of the tissues previous to the injury, for the screw-holes must frequently open up the medulla beyond the primary limitation of the sepsis, and yet necrosis, except of more or less detached fragments, does not occur. Following logically upon these considerations comes the question whether the plates tend to loosen in the presence of sepsis, and, if so, how quickly such loosening occurs. It has already been mentioned that in some cases complete healing actually occurs over a plate; in the larger number of cases, however, the plates do tend to loosen, although not to the extent that *a priori* reasoning would lead one to expect. This loosening does not occur to a degree sufficient to affect the function of the plate until the fragments have become more or less fixed in position (three or four weeks), and even then it still acts as a most efficient method of extension. Appearing to have little effect upon the septic process, the plates may often be left in position for considerably longer periods, frequently becoming consolidated again.

The chief objections, therefore, to the use of internal splints are rather of theoretical than practical interest; and the ease with which the dressing can be manipulated, and massage, etc., applied to the neighbouring joints and soft tissues, can be attained with few other methods of splinting. In view of recent writings upon the sterilization of these wounds soon after they are inflicted, it must be mentioned that in nearly all the shell wounds seen here twenty-four to forty-eight hours after infliction the infection had already got into the tissues, so that it was impossible to adopt any method of immediate sterilization with success.

Practical Difficulties Met With.

Owing to the comminution the plates on the average have to be longer than those used for clean fractures, in order to get a hold of solid bone, and this increased length sometimes makes their application a matter of difficulty, considering the surrounding sepsis and the inadvisability of opening up fresh channels. On the other hand, in many cases, the increased drainage so obtained is advantageous. In other cases the comminution extends over such a length of bone as to render it impossible to apply a plate. In one or two such cases, where the extent of the comminution was not well shown on the radiograph, the attempt at plating had to be abandoned. These cases are always very serious, and usually give poor results, whatever method of splinting is adopted. Occasionally, too, in cases with much comminution, the hold of the plate on the bone has not been good, and it has been found advisable to apply an external divided splint in addition. For this purpose a divided plaster, having a soft iron connecting piece bent to form a handle for manipulating the limb, has been found most convenient. Even in such cases the application of an internal splint has much to commend it, for it takes the place of an extension (often difficult to apply satisfactorily in compound fractures, especially those of the more distal parts of a limb), and by preventing "sagging" of the fragments makes the use of a wide gap in the plaster practicable, and so facilitates thorough and frequent dressing.

Date and Method of Operating.

The actual plating operation is not usually undertaken for four or five days after admission, which time is spent in clearing up the acute sepsis and having radiographs taken. It is essential to have good radiographs in two planes at right angles, for without them it is impossible to reconstruct the exact position of the bones, the amount of comminution, and the shape of the main ends. Unless a very clear picture of the condition of the bone is held in mind, it will be impossible to judge the best position for the plate. To combat the sepsis no routine method has been used, each case has been treated according to the indications. Of the methods more recently advocated, ether has been used with apparent benefit in many cases; an antiseptic dusting powder composed of benzoic acid 25 grams, salol 5 grams, quinine 25 grams, and magnesium carbonate 25 grams, has

also proved of use in very dirty cases after a preliminary cleaning under an anaesthetic. This powder would appear to possess the additional advantage of being slightly analgesic. Hypertonic saline solutions, both with and without corresponding vaccine treatments, have also been used, but apparently, once the sepsis has been limited, the application of a Bier's bandage, or if possible of a suction cup, is more efficient in causing a flow of lymph; it has been constantly used in the treatment of these cases. Sunbaths have been freely used, and injections of colloid gold (so highly commended by the French) were tried in many cases. In the first two there appeared to be marked improvement, but further use showed that these were probably cases of coincidence, for the average results were not equal to those obtained by the use of antiseptic vaccines.

By the energetic pursuit of these methods the sepsis can be considerably reduced after a few days, and at this period the plating is undertaken. The incision, if one is necessary, is designed, failing anatomical contraindications, so that the plate can be applied to the most satisfactory position on the bone. In many cases the original wound only need be enlarged, but, while opening up as little fresh tissue as possible, it is essential to get good exposure and at the same time to have a thought for the future drainage of the wound. The fragments are now replaced as far as possible so as to restore the continuity of the bone. Such fragments as must obviously die are removed, all others being retained. Where several large pieces are completely missing the gap so caused in the bone is carefully maintained and the plate applied to bridge it over. While this preliminary arrangement is being made, the surrounding structures are carefully examined for injury. It is surprising how frequently injuries are discovered and can be remedied; for instance, in two cases of plating of the humerus the musculo-spiral nerve was found in such a position that it must later certainly have been involved in callus; it was freed and buried in muscle, so preventing the development of pressure symptoms. Many other such cases involving nerves, tendons, muscles, and even vessels, could be instanced. The ends of the main fragments are now exposed, and the periosteum being disturbed as little as possible the plate is applied. The most useful type of plate for comminuted fractures is one having two screw-holes fairly close together at each end, and one or two intermediate ones. This enables one to get a firm hold of the main fragments and also to screw some intervening small fragments into position; not only does this increase the general rigidity, but partially separated fragments often join up again.

The screws in the main fragments should not be placed too close to the fractured end. After drilling the holes we have made it a practice to carbolize them before inserting the screw, although whether this has had any appreciable effect in preventing fresh infection of the medulla there is no definite evidence. Where a fresh incision has been made it can usually be sewn up completely unless needed for drainage. The drainage, however obtained, must be good, and free access for the purposes of dressing maintained. In some cases the wounds are best left absolutely open for the first few days, and partial closure undertaken later. Deep sutures are generally not needed, and ligatures only in few cases; fishing-gut sutures are used for the skin. The application of a tourniquet has rarely been necessary, but where assistance is not easily obtained the use of spinal anaesthesia will be found of advantage, since it releases one pair of hands.

Average temperature chart of six consecutive cases for the first week after plating operations. O, Operation.

first few days, but this is not excessive, as the accompanying average chart, constructed from six consecutive cases, shows.

There is now no restriction; the limb may be treated

almost as one without a fracture, early movements and massage being carried out with ease. At the end of a month the position of things has become fixed, and the plate, if it is much loosened, may be removed. If possible, however, it is retained, and particularly in cases with a gap, for it effectually prevents shortening. At this period, also, one can see what portions of bone will live, and the rest may be removed. The suppuration diminishes almost

Fig. 1.—Showing bismuth paste filling the cavity following on sequestrectomy.

to nothing, although frequently after several more weeks it will be found that there is a sequestrum more or less embedded in a cavity, either of bone or of fibrous tissue; this can easily be extracted and an attempt made to close the wound by any of the recognized methods. The use of bone chips does not appear to be very satisfactory, and usually two or three injections of Beck's bismuth paste have given better results. Before the use of the paste the cavity is sterilized as far as possible by swabbing with pure carbolic, followed by the use of iodotom paste for a few days. Skin grafting has also been freely applied to assist in the rapid closure of the wounds.

Before Grafting.

In many instances this is all that is required, but, on the other hand, a large number of cases remain in which the bone ends are separated by a length of intervening fibrous tissue (sometimes even 3 or 4 inches). In others, with much loss of bone, the separate fragments are connected by thin fibrous tissue, which renders them useless as supporting structures. Such cases can, of course, be fitted with an external support, but the results obtained by bone grafting are such as to render the patient free from this inconvenience. Grafting cannot be undertaken until absolute asepsis can be guaranteed, and that means complete closure of the wound. As explained above, this takes in the earliest cases about three months, and in others as much as six months, so that the secondary operation must be long delayed.

Fig. 2.—Humerus after removal of plate, showing sequestrum. The position of sinus has been marked.

The nature and size of the graft depends entirely upon the use to which it is to be put. A portion of a rib or a strip of the tibia are easiest to obtain, but in many cases the graft can be cut from the same bone, so saving a fresh incision. In this way gaps may be bridged over and fragments consolidated. The grafts invariably "take," but the process is slower than when done on fresh cases, owing

probably to the surrounding fibrosis, which must limit the blood supply. Grafts are best held in position by screws, bone pegs being difficult to cut without special apparatus, but in some cases such rigid fixation is unnecessary. Central grafts placed into the medulla are less suitable in these cases than lateral grafts having larger areas of contact with the bone. In cases of fracture of both bones of a leg, a portion of the fibula split in half forms an excellent graft for the tibia. After a week, when the wound is healed, massage and movements are continued. In three to five weeks the patient may get about in a removable poroplastic or preferably celluloid splint. It is wise to continue the use of this for some time. Emphasis must be laid on the fact that graftings do not require any special set of instruments for their performance, although these render the operation easier. They can be easily performed in any temporary theatre where asepsis can be guaranteed, and which possesses a Hey's or small laminectomy saw.

The short reports which follow are given, not as records, but merely to indicate the type of case in which this method has been applied.

CASE I.—Compound Comminuted Fracture of Tibia and Fibula.

Soldat, 50me Regiment d'Infanterie. Wound of left leg by shrapnel bullet, causing a compound fracture of the tibia and fibula, with extensive comminution over nearly 3 in. There was a large jagged exit wound obviously caused by splinters of bone, for the bullet remained lodged behind the tibia. Upon the day after admission the wound was cleaned up and the bullet removed. Radiographs in two planes were taken, and the sepsis considerably diminished by drip baths of mild antiseptics with dressings of hypertonic saline. Five days later the wound was enlarged, and a plate was applied to the inner aspect of the tibia maintaining the original length between the main fragments; several loose fragments were retained and screwed roughly into position. At this operation the posterior tibial artery was found to be exposed and was buried in muscle. Following this, the limb was placed in a bath of hypertonic saline for some time every day, and movements of the neighbouring joints were commenced.

Within a week secondary hæmorrhage from the posterior tibial occurred, and was dealt with in the usual way. At a third operation six weeks later the plate was removed, together with several small pieces of dead bone; some of the larger fragments had consolidated. The leg was now in good position without shortening, and suppuration had almost ceased.

Within three weeks the wound had healed except for a sinus leading to a small sequestrum. This was removed, the cavity being sterilized with pure carbolic and iodoform paste: three days afterwards injections of bismuth were started, first using the soft paste and later the harder one. The cavity very quickly closed. The radiograph now showed that those of the intervening fragments which had lived had formed a complete bony bridge between the main fragments, and grafting was therefore unnecessary.

FIG. 3.—Case II, six weeks after operation; showing the graft becoming ossified on to the main fragments. The zap, being an oblique one, does not show well in a single radiograph.

FIG. 4. Case II: showing wound of exit and loc of incision for grafting. The latter has been outlined to make it visible.

CASE II. Compound Comminuted Fracture of Tibia.

Soldat, 18me Regiment d'Infanterie. The first portion of this man's history closely resembles that of the previous case. The wound of exit was on the inner side of the leg, about 2½ inches

above the ankle-joint. When healing had eventually occurred there was an oblique gap of about 1½ inches in the bone, and the lower fragments with the foot moved in a somewhat ball-like fashion upon the upper. At the grafting operation a long curved incision was made to expose a considerable length of the anterior border of the tibia. Two strips, about half an inch thick, were cut, one from the upper and one from the lower fragment, the former being about twice the length of the latter. These were now interchanged, so that the long strip formed a bony bridge across the gap between the fragments. It was held in position by screws. A radiograph taken six weeks afterwards shows that the graft is becoming ossified on to the fragments. At present, three months after the grafting, the man is able to walk on the leg without any external support although as a matter of precaution he is made to wear a light case.

CASE III.—Compound Comminuted Fracture of Humerus.

Soldat, 112me Regiment d'Infanterie. Shell wound of the

left arm causing compound fracture of the humerus with considerable comminution. Upon admission there was great displacement, the dressing was exceedingly difficult and painful, and it was found impossible to keep the bones in good position between the dressings. At the plating operation the musculospiral nerve was discovered lying between the bony fragments. It was protected by muscle.

After the plating operation the pain rapidly diminished, dressings were carried out with the greatest of ease, and the limb could be freely moved without fear of disturbing the fragments. Massage and faradism were applied to the forearm immediately, but no signs of musculospiral paralysis developed. A week after the operation the patient was walking about with his arm simply supported in a sling. In this case also there was so little loss of bone that grafting was not required.

FIG. 5.—Case III: showing humerus plated and drainage tube in position.

CASE IV.—Compound Comminuted

Fracture of Radius and Ulna.

Sous-Officier, Chasseurs Alpine. Shell wound of forearm; both bones fractured, the ulna being very little comminuted, but the radius very extensively so with a large portion of the bone missing. The ulna was plated through a fresh incision, the wound healing over the plate. A large raw area over the radius was eventually skin grafted, and when healing had finally occurred the gap was filled by a strip of tibia.

FIG. 6.—Case III, within a short period of operation; showing arm solely supported by sling.

For the radiographs, from which the drawings were made, and for valuable assistance during operations I am indebted to Drs. C. Roberts and C. Cheatle.

THE Hon. Sir Henry Norman MacLaurin, LL.D., M.D., aged 79, of Sydney, N.S.W., formerly a surgeon in the Royal Navy, afterwards President of the Board of Health of New South Wales, later successively Vice-Chancellor and Chancellor of the University of Sydney, left estate valued at £75,348.

A USEFUL SPLINT FOR COMPOUND FRACTURES OF THE LEG.

By CAPTAIN C. H. BARBER, I.M.S.,
SURGICAL SPECIALIST, INDIAN ARMY.

The splint that I am here describing has been of such signal service to me in the treatment of certain compound fractures of the tibia and fibula due to gunshot or shell wounds that I venture to publish it for the use of other surgeons if they think fit.

For simple fractures of the tibia alone, or for compound ones with a small anterior wound and little displacement, the service pattern McIntyre is hard to beat, but in bad compound fractures of both bones, with large and septic wounds fore and aft, none of the ordinary splints is of much use when one is aiming at efficient drainage with early immobilization, and when daily dressing is a necessity. I therefore improvised the following arrangement out of any available pieces of wood; it is designed to provide for any extension necessary in view of overriding of the fragments, to support the leg in a comfortable position, to immobilize the broken bones, and, above all, to allow free access to the wounds without moving the limb. The slings may or may not be necessary according to the amount of extension. One pair of extension straps is bound to the upper part of the leg, and, passing round the central ends of the uprights D, D', is fixed to the screws J, on the outer sides of D, D'; the other, pulling from below, pass through the foot board B, after being attached to a foot-piece, and are tied around one or more pieces, which, acting as a wedge, render increase or decrease of tension possible.

- A, Piece of stout board 6 in. wide, 2 ft. 8 in. long.
- B, Piece of board 7 in. or 8 in. wide, 14 in. high, pierced by two slots, through which pass the extension straps.
- C, C', Two upright pieces of thinner board placed one on each side of the foot and serving (1) to keep the foot in a perpendicular position, if necessary; (2) to support a horizontal heel-piece H; and (3) to strengthen B against the pull of the extension.
- D, D', Pieces of stout board about 9 in. wide, 13 in. high, and 6 in. apart, firmly fixed to A, and supporting between them the double inclined plane E, F, G, made of thinner wood; the slope of F, G, is less marked than that of E, F; F, G, also projects 2 in. or 3 in. from the edge of D.

M from above.

B from below.

- H, A small piece of wood for the support of the heel, though the heel scarcely needs any.
- I, A small block to support E, F, thus allowing A to be a little shorter than would otherwise be necessary, which may be an advantage.
- J, A screw or other means of fastening the upper extension straps after bringing them round the proximal margins of D, D'.

- K, The fastening or knot of the distal extension straps or plaster around a wedge-shaped or straight piece of wood L.
- M, A strip of wood, about 21 in. long, shaped like a T square, attached to B by a screw P, so that it can be turned out of the way when it is desired to apply or remove the splint. The T end rests on the top of D, D', and is attached to them by loose nails or hooks.
- N, From M one or more slings can be hung to support the leg at any point; it also serves to keep D, D', firm.
- O, Foot-piece.

The drawing of a patient with the splint applied I publish by kind permission of Colonel G. B. Irvine, I.M.S., commanding No. 9 Indian General Hospital.

A STAGING TO FACILITATE DRAINAGE AND CONTINUOUS IRRIGATION.

By E. H. WILLOCK, M.R.C.S., L.R.C.P.,
ASSISTANT SURGEON, CROFTON GENERAL HOSPITAL.

In the memorandum on the "Treatment of bacterial infection of projectile wounds" by Colonel F. E. Burghard, A.M.S., and others, published in the JOURNAL of April 24th, a passage at the conclusion of the article reads: "And clearly, so long as a wound is heavily infected, the ideal method of treatment, if only it were always practicable, would be immersion in a bath, or continuous irrigation with some aseptic or mildly antiseptic fluid."

With a view to making continuous irrigation of a wound practicable, no matter in what part of the body that wound may be, the staging now described has been devised. It will be understood that the staging can only be properly utilized if the mattress is so shaped and arranged as to co-operate with the staging.

If a shoulder or leg is to be irrigated a 3 mattress will be required; for the buttocks, pelvis, or back the mattress should be transversely divided. The military mattress in its three sections can be readily adapted to any necessary position. In order to obtain sufficient space underneath the staging it may be necessary to place one mattress on the top of the other.

The staging is made as simple as possible. It consists of an oblong frame resting on four telescopic legs. Movable transverse bars, 2 in. wide, support the part of the body that needs irrigating or draining. For supporting the buttocks special bars are made. These transverse bars are provided with vertical detachable splint bars for the purpose of fixing a limb if necessary. Only one set of splint bars is shown in the sketch. Extension can be applied from the end of the frame.

A deep tray hooks on underneath the frame, and is placed wherever it is required. It is provided with a stopcock, and if the fluid discharged into it is excessive it can then be passed on by means of rubber tubing into a further receptacle under the bed.

The legs rest upon fracture boards, and can be adjusted to enable the frame to be raised or lowered or tilted at an angle.

The advantages claimed for the staging are:

1. Free continued irrigation can be carried on in any part of the body.
2. An entire avoidance of heavy dressings and "pus poultices."
3. Free drainage from dependent parts.

4. Free circulation of air about the wound.
5. Easy dressing.
6. By utilizing it in the transverse position it may be of use in cases of incontinence of urine and feces.

The apparatus is in use at the Royal Herbert Hospital, Woolwich, and Major Spencer, F.R.C.S., R.A.M.C., reports "that it fulfils its purpose admirably, and enables continuous irrigation of a wound in any part of the body to be carried out efficiently and easily without discomfort to the patient or disturbance when dressings are changed, and without risk of leakage into the bed."

Messrs. Down Bros., London, have made the apparatus for me.

The Croonian Lectures

OR

TRYPANOSOMES CAUSING DISEASE IN MAN AND DOMESTIC ANIMALS IN CENTRAL AFRICA.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON,

BY SIR DAVID BRUCE, C.B., F.R.C.P., F.R.S.,

SURGEON-GENERAL, A.M.S.; LATE DIRECTOR OF THE ROYAL
SOCIETY'S COMMISSION ON SLEEPING SICKNESS.

LECTURE III.—TRYPANOSOMA GAMBIENSE AND CONGO SLEEPING SICKNESS.

HISTORICAL.

Trypanosoma gambiense was first seen in the blood of an Englishman who had been employed for some six years as master of a Government boat on the River Gambia in West Africa. He was admitted to the Government Hospital at Bathurst on May 10th, 1901, fourteen years ago. Dr. R. M. Forde, the Colonial Medical Officer in charge, examined his blood and saw actively moving bodies, but was unable to recognize their nature. He therefore asked the late Dr. J. E. Dutton, of the Liverpool School of Tropical Medicine, to come to his help.

In the meantime, however, the patient had been invalided to England, where he was treated in a Liverpool hospital for some time. Thinking himself sufficiently recovered to resume duty, he returned to Bathurst in December, 1901, and on December 15th his blood was submitted to Dr. Dutton for examination. Dr. Dutton saw the parasite, described it, and named it *Trypanosoma gambiense*.

But at this time it did not enter into the minds of any one that this trypanosome was the cause of sleeping sickness. It was looked upon as an almost harmless haematozoon, causing no inconvenience to the native and only a slight ephemeral fever, known as "trypanosoma fever," to the white man.

At the same time the finding of a parasite of this kind for the first time in the blood of man raised a good deal of interest, and Drs. Dutton and Todd were sent out in the following year to investigate the question further.

They arrived at Bathurst on September 2nd, 1902, and proceeded to examine a large number of natives for the presence of trypanosomes in their blood. They examined in all 1,043 natives on the Gambia, and found the parasite only in six cases.

They summed up their report by saying that, taking all the facts into consideration, they believed that trypanosoma fever, as it occurred in natives, was a peculiarly mild one, and they suggested the possibility that the natives might bear the same relation to the Europeans as the wild game of Africa to domestic animals in nagana—the tsetse fly disease; in other words, that the black man was immune to the disease, and merely acted as a reservoir of the virus to the more susceptible white man.

For some time, then, the important pathogenic part this trypanosome plays remained unknown, and it was not until 1903, when sleeping sickness was being investigated in Uganda by the Royal Society Commission, that the discovery was made that *Trypanosoma gambiense* was in truth the cause of sleeping sickness.

GEOGRAPHICAL DISTRIBUTION.

Reference to the map published to illustrate my first lecture will show that this species of trypanosome has a wide distribution in the tropical zone of Africa. It extends on the north from St. Louis at the mouth of the River Senegal to the Bah-el-Ghazal in the Egyptian Soudan; on the east it reaches to the eastern shore of Victoria Nyanza; and on the south to the southern end of Lake Tanganyika, the River Luapula in North-West Rhodesia and Donguela in Portuguese West Africa.

MORPHOLOGY.

When in Nyasaland I received from Dr. Kleine, German East Africa, three monkeys infected with *Trypanosoma gambiense*. These animals had been inoculated with blood from natives suffering from "Congo sleeping sickness" on Lake Tanganyika, and it is from these three strains that this description is taken. We sent for these strains because we wished to have an opportunity of comparing *Trypanosoma gambiense* with the trypanosome causing disease in man in Nyasaland, side by side and under similar conditions. It presents a strong resemblance to the nagana parasite. There are the same short and stumpy, intermediate, and long and slender forms. In size and general appearance these two species so closely resemble each other that one might easily believe them to be varieties of the same species.

Shape.—The shape of the long and intermediate forms is the same as in the nagana parasite, but among the short there is an absence of the blunt-ended forms, which have been seen to be so marked a feature in the Nyasaland trypanosome.

Contents of Cell.—The protoplasm often shows many chromatin granules in its substance.

Nucleus.—In *Trypanosoma brucei*, among the short and stumpy there are large numbers of posterior-nuclear forms. In the Tanganyika strains not a single example of this peculiarity was seen.

Micrococcus.—Small and round, and situated on an average 1.1 microns from the posterior extremity in the short, 1.3 in the intermediate, and 1.8 in the long forms.

Undulating Membrane.—This, as in the other members of this group, is well developed, and thrown into bold folds and undulations.

Flagellum. The flagellum in the long and intermediate forms is free. There is no free flagellum in the short forms.

Length.—In regard to length there is practically no difference between the two species, as will be seen from Table I.

TABLE I.—Showing Length of *Trypanosoma gambiense* Compared with *Trypanosoma brucei*, Zululand, 1913.

Strain.	Average.	Maximum.	Minimum.
<i>T. gambiense</i> , Uganda	22.1	33.0	13.0
<i>T. gambiense</i> , Tanganyika I	22.7	34.0	15.0
<i>T. gambiense</i> , Tanganyika II	25.8	36.0	16.0
<i>T. gambiense</i> , Tanganyika III	21.3	34.0	16.0
<i>T. brucei</i> , Zululand, 1913	21.0	35.0	12.0
Breadth of <i>T. gambiense</i>	2.31	4.75	1.25

Trypanosoma gambiense is therefore very similar in size and shape to *Trypanosoma brucei*, but it would appear to be possible to distinguish them by the presence of the blunt-ended, posterior-nucleated forms which are so common in the blood of animals infected by the nagana parasite and quite absent in animals infected by the other. But as these posterior-nucleated forms are absent or scarce in the blood of man, this method of diagnosis requires the inoculation of experimental animals, and the study of many preparations of their blood. It would appear to be impossible at present to distinguish between the two species by the microscopical examination of preparations made from the blood of man alone.

SUSCEPTIBILITY OF ANIMALS TO TRYPANOSOMA GAMBIENSE.

I now pass to the pathogenic action of this species on various animals. In this it differs markedly from the nagana parasite, which is essentially a trypanosome of the lower animals, seldom attacking man; whereas the reverse is true of the species under consideration, which under natural conditions is almost wholly confined to man.

When *T. gambiense* is taken directly from a patient suffering from sleeping sickness there is often a good deal of difficulty in passing it on to the lower animals—that is to say, it is difficult to infect experimental animals by the inoculation of infected human blood. This is very different from the behaviour of *T. brucei*, which infects most animals with the greatest readiness. It is almost impossible at first to give this disease to goats, monkeys, dogs, and guinea-pigs. The rat is the animal which is least refractory. However, after the trypanosome has become accustomed by several passages through a particular kind of animal, its virulence for this species is heightened. It must also be noted that there is reputed to be a good deal of difference in the virulence of different strains.

This difference in regard to virulence between the two species is shown in Table II, where the average duration in days of the disease caused by *Trypanosoma gambiense*, Tanganyika, is compared with that caused by *Trypanosoma brucei*, Zululand.

TABLE II.

	Monkey.	Dog.	Guinea-pig.	White Rat.
<i>Trypanosoma gambiense</i> ...	159	96	264	137
<i>Trypanosoma brucei</i> ...	26	34	67	30

The disease in animals caused by *T. gambiense* is thus much more chronic than that caused by *T. brucei*, and this character, combined with the morphology already described, affords the surest and safest means of separating these species.

GLOSSINA PALPALIS THE CARRIER OF TRYPANOSOMA GAMBIENSE.

As we have already seen, the carrier of *T. gambiense* is the tsetse fly, *Glossina palpalis*, whose habitat is the wooded shore of lakes and rivers.

When the Royal Society Commission in 1903 had convinced itself that in all probability a trypanosome was the cause of sleeping sickness, naturally, on the analogy of the old nagana work, a tsetse fly was looked for. It is a curious fact that at that time the presence of tsetse flies on Lake Victoria was unsuspected.

I have already described the habits of this species of fly, and shown how very numerous it is in Uganda, swarming on the lake shore in such numbers that our fly boys, who collected about 500 daily for months together from one or two spots, did not seem to make any impression on the supply.

Infectivity of Wild *Glossina palpalis*.

Some of these flies were found to be naturally infected with *T. gambiense*, and I shall therefore, in the first place, consider the natural infection which exists among the wild *Glossina palpalis*.

It will be remembered that the proportion of tsetse flies in Nyasaland infected with Nyasaland sleeping sickness was 1 in 500. It will be interesting, then, to compare the infectivity of the wild tsetse flies in Uganda.

It must be granted that although the shores of Victoria Nyanza and the banks of the Nile and other rivers swarmed with these tsetse flies before 1898, it was only about this time that they became infected with sleeping sickness. Before this time sleeping sickness was unknown in Uganda. It seems probable that the disease was introduced by Emin Pasha's men, who were brought into the country from the Belgian Congo some little time before.

I am sorry that the same method of examination was not used in Uganda as in Nyasaland. In Nyasaland the flies were fed on three different species of animals for nine days. In Uganda the flies were caught on the lake shore, and when brought up to the laboratory were only fed on one species of animal—the monkey. In 1903 at Entebbe, the Government cantonment, the tsetse flies had plenty of opportunity of becoming infected, since they were caught in the vicinity of the hut tax labourers' camp. These men came in thousands to Entebbe to work for Government for one month in lieu of paying hut tax. They lived in rudely built grass huts near the lake shore, and on

examination of their blood some 30 per cent. of them were found to harbour the parasite.

In 1903, while these highly infected labourers were living on the lake shore, the proportion of infective flies was found to be as high as 11.2 per 1,000. The Government removed the hut tax labourers from the vicinity of the lake, which became deserted, and a year afterwards the proportion of infected flies fell to 1.2 per 1,000.

When the Commission returned to Uganda in 1908 and took up camp at Mpumu at the north end of Lake Victoria we found the lake shore flies in the vicinity still infective, although the population had been removed early that year. The examination of 7,200 flies gave a proportion of 1.8 per 1,000.

But we had given the Government to understand that as soon as the natives were removed the flies would become harmless. It was therefore important to find out how long the lake-shore flies remained infective, and why they remained infective. For this purpose they were examined every year until 1912, and the result is given in Table III. It will be seen that although there had been a steady decrease in the proportion of infective flies, a few remained, and these showed no sign of disappearing.

TABLE III.—Infection of Wild *Glossina palpalis*.

Year.	Locality.	No. of Flies Examined.	No. of Flies Infective.	Proportion of Infective Flies per 1,000.	Remarks.
1903	Entebbe	(?)	(?)	11.2	
1904	"	(?)	(?)	1.2	
1908	Mpumu	7,200	11	1.8	1 in 65†
1909	"	18,691	7	0.4	1 in 2,670
1910	"	27,179	4	0.14	1 in 6,795
1911	"	23,899	1	0.04	1 in 23,899
1912	"	28,279	4	0.14	1 in 7,070

The mistake made by the Commission was, first, in believing that the transmission of the *Trypanosoma gambiense* was mechanical, and that a fly lost its power of infection within three days after feeding on an infected animal; and, secondly, in believing that man was the sole reservoir of the virus. It was found that a fly may remain infective for several months, and that man is by no means the only source of the virus.

This prolonged infectivity which some flies possess is due to the fact that in these the trypanosomes do not die off, but proceed to further multiplication, and I must now describe the cycle of development which the parasite passes through in the fly, from its ingestion with the blood until its appearance in the salivary glands of the fly in an infective form. When dealing with *Trypanosoma brucei*, I mentioned that its development in the fly is identical with what takes place in the case of *T. gambiense*, and that it would be more convenient to describe the cycle at this point. I did not describe the development of the nagana parasite in *G. morsitans*, as one description will suffice for both species.

The Cycle of Development of *Trypanosoma gambiense* in *Glossina palpalis*.

It is to Kleine that the honour is due of being the first to show that a tsetse fly could convey the infection some fifty days after the fly had fed on an infected animal, and when we come to consider the difficulties of this observation we must feel that he deserves the very highest credit for making this important advance in our knowledge of trypanosome diseases. He used the tsetse fly, *G. palpalis*, and the nagana trypanosome in his first successful experiment, which was carried out at the end of 1908.

A few months later, in March, 1909, we had our first successful experiment in Uganda with *T. gambiense* and *G. palpalis*.

On March 5th, 1909, sixty *Glossina palpalis* were placed in two cages, thirty in each. The flies were fed on two infected monkeys for two days. They were then starved for 72 hours to get rid of the danger of mechanical transference. The following five days they were fed on a healthy monkey, and every successive period of five days, or thereabouts, on a fresh, healthy

monkey, up to 86 days, when the experiment came to an end. The result was that the first two monkeys remained healthy, and all the following monkeys up to 75 days became infected with sleeping sickness. If five days be deducted for the incubation period, then the flies became infected 20 days after their first feed on the infected animal.

There is some evidence that among the 60 flies only one was infective. Fifty-four days after the beginning of the experiment, each cage was placed on a separate monkey. Up to that time both cages of flies had been fed on the same animal. Cage A contained, after fifty-four days, 11 flies; Cage B, 4 flies. Cage A continued to infect monkeys for twenty-one days more, making a total of seventy-five days. Cage B did not infect. Again, as was natural, the flies gradually died off during the experiment, and as each fly died it was carefully dissected and examined for trypanosomes. Not a single trypanosome of any kind whatever was seen in any dissected fly up to 75 days, when a fly died in Cage A, and on this fly, on examination, was found to be swarming with trypanosomes. After the death of this fly, Cage A ceased to be infective, and when the experiment was stopped the remaining flies were killed off and dissected, but among them not a sign of a trypanosome could be seen. In the same way the flies in the non-infective Cage B were examined, with a similar negative result.

This was a most interesting and successful experiment. It was evident that a single infective fly did all the mischief and by good luck this fly was detected.

Not only did one fly do all the mischief, but judging from the incubation periods it would appear that in all probability it infected each animal on the first day it bit it, showing how dangerous such an infective fly is. When this fly came to be dissected, the gut was found to be crammed with innumerable trypanosomes, and in addition the salivary glands contained large numbers.

This is the first record of these parasites being found in the salivary glands, and led up to the discovery that the invasion of the salivary glands is an integral part in the cycle of development of this group—Group A—of trypanosomes.

After this, numerous experiments were made on the same lines, and with several species of trypanosomes.

The Development of *Trypanosoma gambiense* in Laboratory-bred *Glossina palpalis*.

In 42 experiments performed to ascertain what proportion of laboratory-bred flies become infective when fed on an infected animal, only 8 gave a positive result, as many as 34 were negative. In the 8 positive experiments 371 flies were used, an average of 46; in the 34 negative experiments 1,323, an average of 40. The shortest time which elapsed before a laboratory-bred fly became infective with *T. gambiense* was 27 days, the longest 53 days, and the average 36 days. In the 42 experiments, 1,694 laboratory-bred flies in all were used.

If we consider that in each of the eight positive experiments in only one fly became infective, then only 8 flies in 1,698, or 1 in 212, (0.5 per cent.) became infective. This is a very small proportion and helps to account for the fact that fifteen years elapsed before this cycle of development was discovered. This development of the trypanosome in the fly is somewhat similar to what occurs in the test-tube in artificial cultivation. A thousand tubes are inoculated, let us say with *T. brucei*, the trypanosomes all appear to die off, but twenty days later a peculiarly resistant individual is found in one tube of the thousand, which has adapted itself to the new environment, and soon multiplies into myriads.

But, although it is evident that in these 42 experiments only 8 or 10 flies became infective, a larger number were found in which development had proceeded to some extent—that is to say, the flies had become infected, but not infective. As each fly died it was dissected. In all, 39 flies were found with trypanosomes in the alimentary tract—that is to say, about 2 per cent. We may therefore summarize this series of experiments by saying that 0.5 per cent. become infective and 2 per cent. infected. It must be noted, however, that a good deal of difference exists in different series of experiments, the proportion of infected flies rising sometimes to 8 or 10 per cent.

The Cycle of Development of *Trypanosoma gambiense* in *Glossina palpalis*.

To find out what occurs after a trypanosome has been swallowed by a tsetse fly, we fed laboratory-bred tsetse

flies on an animal whose blood contained numerous trypanosomes, and, at the end of various times, killed the flies and dissected them. This was done for periods of one day, two days, three days, and so on, for fifty-six days.

The flies were examined first in the fresh condition, when the trypanosomes could easily be seen by their movement; afterwards stained specimens, made for more minute examination, were examined day after day, and coloured drawings, at a magnification of 2,000 diameters, made of all the different forms met with. The drawings of the trypanosomes found in the fore-gut, mid-gut, hind-gut, proctodeum, and salivary glands were kept separate, so that a series of drawings of trypanosomes taken from any one part, from the first day of infection to the fifty-sixth day, could be compared. More than 600 drawings were made in this way, so that it seems impossible that any important form could have been left out.

General Consideration regarding the Development of the *Trypanosomes in the Fly.*

For the first three or four days after flies have had a feed of infected blood, trypanosomes are found in them all. These are those originally ingested with the blood, and at the end of six or seven days, when the process of digestion has been completed, they are found to have disappeared from most of the flies; that is to say, it is only in a certain percentage that further development takes place. In one series we saw that this was as low as 2 per cent.; in another it rose to 8 per cent. In other words, in some 95 per cent. of flies which imbibe infected blood, the trypanosomes simply degenerate and die out within the first few days. In some 5 per cent., on the other hand, the trypanosomes find conditions more favourable for development, and increase, filling the whole of the fore-gut, mid-gut, and hind-gut with countless swarms of multiplication furus.

How long this infection of the fly continues is not absolutely known. It is considered probable that in many cases it continues for the rest of the fly's life. In one case a fly was found to retain its infectivity for ninety-six days, but in a few cases there was evidence that an infective fly might in its lifetime lose its infectivity and become harmless.

Types of *Trypanosoma gambiense* found in the Alimentary Canal of the Fly.

It would serve no good purpose to describe separately, day by day, the variously shaped trypanosomes found in the different parts of the alimentary canal, since the different forms or shapes run into each other in such a way as to make any classification of them seem impossible. The results with regard to the number of trypanosomes found in the different parts of the alimentary canal were as follows:

The Proboscis.—In our experience *Trypanosoma gambiense* is never found in the proboscis of the fly, except immediately after an infected feed, when for a short time blood containing trypanosomes may be seen in the lumen of the proboscis.

Proventriculus.—This part of the alimentary canal is sometimes found empty when the remainder of the gut is swarming.

Fore, Mid, and Hind-gut.—It is here that the greatest development of the trypanosomes is found. Among the extraordinary numbers and diversity of type it is difficult or impossible to find one's way. Generally speaking, the trypanosomes found during the first few days are merely degenerated blood forms.

After this there appears a type of trypanosome which remains dominant throughout the whole developmental period. This is a long, moderately broad form, the protoplasm staining well, without granules or vacuoles, having an oval compact nucleus situated in the centre of the body, a small, round micronucleus lying at some distance from the elongated snout-like posterior extremity. The undulating membrane is narrow and simple, and the flagellum proceeds little, if at all, beyond the protoplasm of the cell. The flagellum also appears very frequently to arise from a pink-coloured body situated near the micronucleus, an appearance never seen in the normal blood trypanosomes.

This seems to be the normal developing type in the intestine of the fly. It is seen in all parts of the intestine and at all times.

It forms masses of innumerable individuals alike in size and shape.

When a fresh supply of blood is taken by the fly, this type can be imagined to multiply with extraordinary rapidity. When the blood supply runs low then this type can also be imagined as degenerating and disappearing just as rapidly. The host of divers forms which thus arise

their way by the proboscis and salivary duct or hypopharynx to the glands. They have never been found in the body cavity.

Another curious fact is that as soon as the trypanosomes reach the salivary glands they revert to their original blood form and become infective. What causes or leads up to this reversion to the blood type in the salivary glands is quite unknown, but as we shall see, the *G. palpalis* does not become infective until this invasion of the salivary glands has taken place.

ILLUSTRATIONS OF VARIOUS MODIFICATIONS IN SHAPE OF TRYPANOSOMA GAMBIENSE IN GLOSSINA PALPALIS.

Fig. I.—*Trypanosoma gambiense* in fly.

1, 2, Normal blood parasites (*T. gambiense*), 4, Twenty-four hours after ingestion by the fly. 5 and 6, Forty-eight hours after ingestion by the fly. 7, Ninety-six hours after ingestion by the fly. 1, 7 represent the trypanosomes as they appear in the intestine of *Glossina palpalis* during the first few days. 1-3 are ordinary blood forms, as seen immediately after the fly has fed, and before any change has taken place. 4-7 represent the process of degeneration which takes place during the first four days. The body swells up, the nucleus breaks up, and the cytoplasm becomes vacuolated.

Fig. II.—Developmental forms.

8, *T. gambiense* from fore-gut, eight days after infected feed. 9, *T. gambiense* from proventriculus, fourteen days after infected feed. 10, *T. gambiense* from fore-gut, eighteen days after infected feed. 11, *T. gambiense* from mid-gut, twenty-five days after infected feed. 12, *T. gambiense* from mid-gut, thirty-four days after infected feed. 13, *T. gambiense* from fore-gut, forty-four days after infected feed.

Fig. III.—Part of a mass of *Trypanosoma gambiense* in the mid-gut.

Fig. IV.—Rounded forms.

25, *T. gambiense* from mid-gut, eight days after infected feed. 26, *T. gambiense* from fore-gut, eleven days after infected feed. 27 and 28, *T. gambiense* from mid-gut, sixteen and seventeen days after infected feed. 29, 30, and 31, *T. gambiense* from fore-gut, seventeen and eighteen days after infected feed. 32, *T. gambiense* from hind-gut, twenty days after infected feed. 33 and 34, *T. gambiense* from fore-gut, twenty-four days after infected feed. 35, 36, and 37, *T. gambiense* from mid-gut, twenty-four, forty-four, and forty-six days after infected feed. 38, *T. gambiense* from fore-gut, forty-six days after infected feed.

Fig. V.—Masses of protoplasm.

45, 46, and 47, *T. gambiense* from hind-gut, ten days after infected feed. 48, *T. gambiense* from fore-gut, seventeen days after infected feed. 49, *T. gambiense* from proventriculus, thirty days after infected feed. 50, *T. gambiense* from mid-gut, forty-six days after infected feed. 45-50 represent some of the more exaggerated types of degenerative forms. As will be seen from the drawings, they are huge, misshapen masses of protoplasm, multi-nucleated and, as a rule, in flagellated.

Fig. VI.—Infective forms.

73, *T. gambiense* from salivary glands, thirty-four days after infected feed. 74, *T. gambiense* from salivary glands, forty-two days after infected feed. 75, *T. gambiense* from salivary glands, forty-three days after infected feed. 76, 77, and 78, *T. gambiense* from salivary glands, forty-six days after infected feed. 79 and 80, *T. gambiense* from salivary glands, fifty-six days after infected feed. When alluding, generally, in a previous part of this lecture, to the types of *Trypanosoma gambiense* found in the salivary glands, it was said that in the salivary glands, and here alone, the trypanosomes are found to revert to the normal type found in the blood. 73-80 illustrate this reversion. By comparing them with 1, 2, and 3 (Fig. I), which represent normal blood trypanosomes, it will be seen that they are very similar to the short and stumpy form found in the blood.

beggars description. Some are round or oval in shape, 3 or 4 microns in diameter, with or without flagellum, and from this simple form all shapes and sizes can be seen up to the huge, shapeless mass of protoplasm, multi-nucleated and multi-flagellated.

Salivary Glands.—Trypanosomes did not appear in these glands until the twenty-fifth day, but after this time they were usually present. This invasion of the salivary glands is the most interesting phase in the development of Group A, and brings to mind the development of the malarial parasite in the mosquito. It differs in this, however, that whereas in the latter spores are found, which pass to the salivary glands across the body cavity, in the tsetse fly the trypanosomes apparently find

The salivary glands first become invaded twenty-five days after the infecting feed. In all the salivary glands from flies which gave a positive result, trypanosomes similar to the short blood-type were invariably present.

Experiments to Ascertain if *Trypanosoma gambiense* during its Development within *Glossina palpalis* is Infective.

In Zululand it was observed and at the time it seemed to be an astonishing fact—that when tsetse flies, a short time after feeding on infected animals, were chopped up and injected under the skin of healthy dogs no infection of nagau took place.

It seemed strange that a fly, swollen out with blood in which numberless active trypanosomes could be seen under the microscope, if injected under the skin of a susceptible animal, should not give rise to the disease. As I left Zululand at this time I was unable to follow this observation up, but in Uganda I carried out experiments on the same lines with *T. gambiense* and *G. palpatis*.

If tsetse flies (*Glossina palpatis*) are fed upon an animal whose blood contains trypanosomes, the parasites can be seen living and moving in the contents of the intestines of all the flies for a few days, and in a small percentage (2 per cent. to 8 per cent.) of the flies active trypanosomes may continue to be found swarming in their intestines on any day between the seventh and fiftieth day or even longer.

A series of experiments was undertaken in Uganda to ascertain if *Trypanosoma gambiense* retained its power of causing sleeping sickness when inoculated subcutaneously into monkeys during its period of multiplication within the fly, especially during the interval of some twenty or thirty days in which the bites of infected flies had been proved to be harmless.

The flies were fed upon a monkey whose blood contained many trypanosomes. After a pre-determined time had elapsed the wings and legs of the infected flies were cut off and the bodies were either chopped up or brayed in a mortar with saline solution. In most instances the gut was proved by microscopical examination to be heavily infected with trypanosomes before the whole chopped-up fly or flies were placed under the skin of the experimental animal. Of twenty-nine experiments carried out with *G. palpatis* and *T. gambiense*, eighteen gave a positive result; they were almost uniformly successful up to eighteen hours after the infected feed.

Further experiments proved that this parasite only retains its virulence for a period of about eighteen hours after it has been swallowed by the tsetse fly; it then loses its power of infecting animals for a period of some twenty-two days. This means that during their period of development in the tsetse fly the trypanosomes lose their virulence, and do not regain it until the developmental cycle is completed.

Summary.

Trypanosomes taken into the alimentary canal of tsetse flies retain their shape and infectivity for some eighteen hours. They then degenerate and lose their power of infection, and, as a rule, have disappeared altogether from the majority of the flies by the fifth or sixth day. In a small percentage of flies, male as well as female, the trypanosomes maintain their position; they continue to multiply, and in a short time swarm in the alimentary canal of the fly. These multiplication forms bear little or no resemblance to the original trypanosomes. After some twenty days the developing flagellates find their way into the salivary glands, resume their original blood form and regain their infectivity.

THE RESERVOIR OF TRYPANOSOMA GAMBIENSE (CONGO SLEEPING SICKNESS).

We have seen that in *T. brucei* the cause of "Nyasa-land sleeping sickness," the reservoir of the virus was undoubtedly the wild game, and that in all probability man played a very small part, if any, in its spread. I have already described *T. brucei* as essentially a parasite of animals, and *T. gambiense* as a parasite of man.

In Uganda cases of sleeping sickness were limited to the edge of the lake and the islands; I say "were," because the epidemic has died out. There was formerly a great deal of trade intercourse between the islands and the mainland. Under the shade of the trees, on the shore of the lake, the natives met, and here the fly was thickest. Now we know that in the sleeping sickness area in Uganda anything from 20 to 50 per cent. of the lake shore population had sleeping sickness trypanosomes in their blood, and it therefore appeared extremely probable that the fly conveyed the virus from native to native.

We believed at first (1903) that man was the only reservoir of practical account, and that if he was removed from the fly area, the fly would soon—within a few days—become non-infective. When we returned to Uganda in 1908 we were much surprised to find the fly still infective, although the native population had been removed from the

lake shore for some months. It was evident, therefore, that the fly had some other reservoir from which to draw the virus, and experiments were instituted to throw light on this. The cattle were first examined. These animals, as we have seen, are practically immune to sleeping sickness—that is to say, they show no signs of illness, but it was possible the trypanosome might live in their blood, and be capable of infecting flies without affecting the health of the cattle.

Cattle as a Reservoir.

On September 9th, 1909, an ox was inoculated with a quantity of blood containing large numbers of the parasites. The blood of the ox was examined daily, and eighteen days after the injection was found to contain the trypanosome. Its identity was established by injecting a healthy monkey with some blood from this ox. The monkey showed *T. gambiense* in its blood on the sixth day. Cattle are therefore capable of being infected with sleeping sickness by the injection of infected blood, although they show no signs of illness. Cattle were also infected by the bites of artificially infected flies.

Next, freshly-caught flies, brought up to the laboratory from the lake shore, were fed on healthy cattle. In the first experiment, 2,195 freshly-caught flies were fed on an ox during sixteen days, when the animal was found to be infected. In the second, 1,370 flies, and in the third, 459, gave a positive result.

The next question to be asked was, Is it possible to infect tsetse flies by feeding them on these infected cattle, and afterwards to transmit the disease by means of these flies to healthy animals? Five experiments were carried out. Two of them were positive.

It was therefore proved that laboratory-bred flies can be infected by feeding them on infected cattle, and afterwards the disease can be transmitted to healthy animals by means of these flies.

Finally, it had to be ascertained whether it was possible to find in the sleeping sickness area cattle which had been naturally infected.

Seventeen cattle from various sources were examined with this point in view. Most of them came from places where the tsetse flies were numerous. In one out of the seventeen the parasite was found. This ox came from the island of Kome in Lake Victoria, where sleeping sickness was prevalent and where tsetse flies abound. A small quantity of its blood injected into a healthy monkey gave rise to sleeping sickness in the monkey, and showed that *T. gambiense* was really being dealt with.

The conclusion to the whole matter, then, was that in addition to man, cattle may act as a reservoir of the virus of sleeping sickness.

Antelope as a Reservoir.

We next turned our attention to antelope. At this time, the beginning of 1910, man and his domestic animals had been removed from the lake shore of the mainland for some two years, and from the islands since the previous September. The effect of this depopulation had been to make an area along the northern shore of the lake virtually a game reserve, in which waterbuck, bushbuck, reedbuck, Speke's tragelaphus, hippopotami, wild pig, and other game abound. Before this time we had a strong preconceived idea that cattle and antelope were immune to sleeping sickness, and these preconceived ideas are stubborn things. But after the cattle experiments we set ourselves to ask the same questions regarding antelope.

Eleven antelope in all were employed in this experiment—four bushbuck, six reedbuck, and one waterbuck. A cage of flies which was known to contain an infective fly or flies, was fed on each animal daily for several days. The result was positive in all cases, proving that antelope may be readily infected with sleeping sickness by the bites of infective flies.

The next question was, Can these infected antelope transmit the infection to clean laboratory-bred flies, and if these flies become infected, can they transmit the virus to susceptible animals?

Clean laboratory-bred *Glossina palpatis* were fed for several days on an infected antelope. After an interval of starvation of twenty-four hours or more the flies were transferred to healthy animals and fed daily. When the healthy animal showed *Trypanosoma gambiense* in its

blood the experiment was stopped, and the surviving flies were dissected as soon as possible.

The result of twenty-four experiments carried out on these lines is given in Table IV.

TABLE IV.—Result of Feeding Laboratory-bred Flies on Antelope Infected with Sleeping Sickness.

No. of clean flies used.	Species of antelope flies fed on.	No. of days flies fed on antelope.	No. of days before flies became infective.	Result.	Remarks.
160	Bushbuck 2328	12	29	+	Buck 2328 never showed <i>T. gambiense</i> in blood. In spite of this, flies fed on it became infected 55 days after the buck's infection.
100	"	8	28	+	
100	"	8	39	+	
100	Reedbuck 2357	7	41	+	Buck 2357 showed <i>T. gambiense</i> in its blood for 5 days only.
100	"	8	5	+	
300	Reedbuck 2359	6	44	+	Buck 2359 showed <i>T. gambiense</i> in its blood for 7 days only.
50	Bushbuck 2371	6	29	-	Buck 2371 showed <i>T. gambiense</i> in its blood for 3 days only.
60	"	6		+	
100	Bushbuck 2372	8		-	Buck 2372 showed <i>T. gambiense</i> in its blood for 2 days only.
95	Waterbuck 2378	6	30	+	Buck 2378 never showed <i>T. gambiense</i> in its blood.
60	"	6		+	
50	"	4		-	
110	Reedbuck 2427	6	24	+	Buck 2427 showed <i>T. gambiense</i> in its blood for 4 days only.
60	"	4	35	+	
100	"	6	30	+	
50	Bushbuck 2428	7	28	+	Buck 2428 never showed <i>T. gambiense</i> in its blood.
50	Reedbuck 2429	4	27	+	Buck 2429 showed <i>T. gambiense</i> in its blood for 3 days only.
100	"	6	49	+	
55	Reedbuck 2431	3	28	+	Buck 2431 showed <i>T. gambiense</i> in its blood for 4 days only. In spite of this, flies fed on it became infected 81 days after its infection.
90	"	6	36	+	
100	"	6	43	+	
50	Reedbuck 2445	4		-	Buck 2445 showed <i>T. gambiense</i> in its blood for 6 days only.

The most significant of these experiments is the one in which it is shown that fifty-five days after the last feed of the infected flies on bushbuck 2,328 the blood of the buck was still capable of infecting clean laboratory-bred flies, although *Trypanosoma gambiense* had been so scarce in the blood that they had never been seen microscopically.

These experiments show that antelope of the waterbuck and bushbuck species, when infected with the trypanosome of sleeping sickness, can transmit the infection to clean laboratory-bred *Glossina palpalis*. The infected antelope's blood was in one case capable of giving rise to infection for at least eighty-one days, and in another for at least fifty-five days. These experiments further show that the flies, when infected, are capable of transmitting the disease to susceptible animals.

From these experiments on antelope, the curious fact seems to emerge that a higher proportion of flies become infected by feeding on infected antelope in whose blood the parasites are scanty, than, for example, on infected monkeys, whose blood swarms.

Another curious fact is that even when trypanosomes were never found by microscopical examination in the blood of an antelope, flies fed on that antelope became infected. It would almost lead one to believe that the trypanosomes exist in the blood of these animals in some

other less easy recognizable form than the ordinary adult trypanosome form.

The next thing we set ourselves to do was to find out if the antelope living in the fly area are naturally infected with sleeping sickness. Positive evidence on this point would naturally complete the chain of evidence proving that antelope living in the fly area may act as a reservoir of the virus of sleeping sickness. So far it had only been proved that they were potential hosts.

The easiest method by which it could be proved that they are naturally infected would be the old one of shooting the animals, and at once sending samples of their blood into some healthy area where the blood could be injected into healthy susceptible animals. But those who know the local conditions in Uganda will recognize the difficulty of doing this. The cover is so thick at the edge of the lake that it is exceedingly difficult to see the game. The sun is almost unbearably hot, the country very difficult, and the exposure to the bites of the fly very great.

It may be said at once that we were only able to shoot five antelope on the lake shore. The blood of these, when injected into susceptible animals, gave negative results. A large drive was being organized, which might have thrown the desired light on this subject, but unfortunately the Commission was ordered to leave the country before the drive could take place. It was, therefore, perforce left to a later worker to solve this difficult problem.

In 1911 Dr. H. L. Duke took the question up. Four years had now elapsed since the lake shore had been depopulated, and two years since the islands had been emptied of their population. He chose the uninhabited island of Damba for the experiment. This he did because the Commission had shown in 1910 that the fly on the island were still infective, and again the same result was obtained in May, 1911, by Dr. Carpenter.

With the exception of certain patches of papyrus, practically the whole shore line of the island swarms to a greater or less extent with fly. At one part there is the famous fly beach, from which for several years some thousands of pupae have been brought monthly to the sleeping sickness camp at Mpumu.

The only species of antelope found on the islands of Lake Victoria is the sitatunga (*Tragelaphus spekei*), a species of bushbuck adapted for living in marshes. Dr. Duke shot four sitatunga on the island of Damba, and from these *T. gambiense* was obtained. I cannot say whether all four antelope harboured the parasite, because the blood of the first two was injected into one monkey and the blood of the last two into another. Both monkeys showed the *T. gambiense*. Dr. Duke examined these trypanosomes with meticulous care in order to exclude any possible source of fallacy, and there cannot be any reasonable doubt that the sitatunga on Damba Island were acting at that time as a reservoir of this parasite.

Another proof that the trypanosome found in the sitatunga was really *T. gambiense* has lately been given by Dr. Duke. He states that two of the fly boys who have during the last three years worked with Dr. Carpenter on the islands have developed sleeping sickness of the Uganda type, and trypanosomes have been demonstrated in their glands. These boys have only been exposed to the bite of *G. palpalis*, as they had for eighteen and thirty months respectively resided on the lake shore and islands, where there are no other species of tsetse fly.

This shows conclusively that *T. gambiense* still exists in these lake shore and island flies five years after the removal of the population, and is another striking proof that the antelope are acting as a reservoir.

Taking everything into consideration, then, we may look on it as proved that the antelope on the shores of Lake Victoria act as a reservoir of the virus of sleeping sickness, and that this accounts for the fact that the flies have retained their infectivity in spite of the removal of the native population from the lake shore and the islands.

The prophecy of the Commission that the fly would become harmless shortly after the natives were removed from the lake shore has unfortunately proved wrong, and before the islands are repopulated some other measure will have to be taken to get rid of the fly danger.

A CASE OF CHRONIC INTESTINAL OBSTRUCTION DUE TO TUBERCULOUS CICATRICAL CONSTRICTIONS OF THE JEJUNUM.

BY
STEPHEN H. PUGH, M.B., Ch.B.,
SOUTH TRAVANCORE MEDICAL MISSION, NETTYOOR.

THE patient, a man aged 35, when admitted to hospital on December 26th, 1913, was suffering from intense pain over the greater part of the abdomen, of which the respiratory movements were somewhat restricted. There was no visible peristalsis. On palpation there was some tenderness. No tumour could be felt. The temperature was 101.4° F., and the pulse 120. The only history which could be obtained from the patient was that of occasional fever and great abdominal pain, frequently relieved by vomiting half an hour after food, during the previous six months.

On the morning after admission the temperature was normal and the pulse 100. During the next eight days the temperature varied daily 0.5° F. on either side of the normal line, and the pulse ranged between 100 and 108. On the evening of the following day the temperature ran up to 104.5° F., the pulse reaching 120. Next morning the temperature was normal and the pulse 96, but in the evening the temperature was again 102.5° F., and the pulse 112. During the next two days the temperature was normal, the pulse varying between 114 and 102. Since admission the patient had frequently suffered great abdominal pain, relieved by vomiting, soon after even liquid food.

No diagnosis had as yet been made, but as there was obvious trouble in the abdomen it was decided on the thirteenth day after admission to undertake an exploratory laparotomy. It was at once found that there were five marked cicatrical constrictions of the jejunum about 4 in. apart, the highest constriction being nearly 3 ft. from the upper end of the bowel. The constrictions, which were very hard, were about ½ in. in diameter. The short segments of bowel between the constrictions were remarkably ballooned to over 3 in. in diameter. It was very surprising that the obstruction was not complete. A few only of the mesenteric glands were slightly enlarged. The whole length of the bowel was passed through the fingers, but no other constrictions were found. A lateral anastomosis short-circuiting the bowel above and below the lesions was performed. The patient bore the operation well.

After the operation the vomiting entirely ceased, and the pain was very much relieved. A month after the operation the general condition of the patient was considerably improved, but he had two or three prolonged attacks of distressing hiccough, together with two periods of twelve days each of intermittent fever of the hectic type, the first period beginning thirteen days after the operation. It was not suspected that the patient might be suffering from phthisis until the pathological condition of the bowel was seen. It was thought that the hiccough might be due to irritation by the fermentation of stagnant food, secretions, etc., in the ballooned segments of bowel, and that perhaps the fever was mostly accounted for by toxic absorption from the fermenting material.

Accordingly, six weeks after the first operation, it was decided to resect the 20 in. short-circuited loop of bowel. On opening the abdomen the lateral anastomosis was found to be quite satisfactory, and there were no adhesions to the diseased loop. There was no apparent change in the loop since the first operation. No difficulty was found in performing the resection, and the opened ends of the bowel were closed 1½ in. from the anastomosis. The patient stood the operation extremely well, suffering but slightly from shock, the pulse reaching only 96.

The patient's general condition at once improved rapidly, and he was soon able to eat a large quantity of food without the least discomfort. The hiccough never returned. The temperature remained normal for six days after the operation, when again for two consecutive evenings only the temperature reached 100.5° and 103.5°. During the next four weeks there were daily variations of 0.5° on either side the normal line, the temperature reaching 100° on three occasions only, the pulse varying from 80 to 112. Obviously, in spite of the great general improvement and the complete disappearance of the abdominal symptoms, there was still some active disease

present. Seven weeks after the operation the temperature again became hectic, the evening temperature being about 101°. This fever lasted six days, and then the temperature was normal again for five days, after which the hectic fever again returned, this time with acute pneumonic symptoms, the right upper lobe being consolidated. Cough and copious foul-smelling sputum developed. After thirteen days in this condition the patient died suddenly of a profuse hæmoptysis. Previously to this attack of fever he refused to rest sufficiently and insisted on wandering about the neighbouring village.

This was obviously a case of pulmonary tuberculosis with secondary tuberculous ulceration of the jejunum. Tuberculosis was not suspected till after the first operation, when slight dullness and some bronchial breath sounds were noticed near the right apex. There was very little cough or sputum until the last attack of fever.

STEREOSCOPIC RADIOGRAPHY OF GUNSHOT WOUNDS ON ACTIVE SERVICE.

If my interest those who are acting as radiographers in the field, and, as is often the case, under difficulties, to read of a very simple, quick, and accurate method which I am employing in France for stereoscopically examining gunshot wounds for foreign bodies and fractures, the only apparatus used being the x-ray outfit supplied to the R.A.M.C. on mobilization.

The cumbersome x-ray couch I early discarded, as, owing to the overhead tube holder, it was found impossible to get a stretcher thereon, and I now use a table, the top of which measures 5 ft. 2 in. by 1 ft. 6 in., which fits inside the poles and traverses of any ordinary stretcher, so that the patient, having been comfortably settled in the ward, has not to be disturbed until his return to the ward to be put back to bed, thus saving him pain and myself time.

The method of procedure is as follows:

The patient having been carried to the department by two orderlies, is lifted, stretcher and all, on to the table, which blocks out the canvas, allowing the poles and traverses to fall out of the way. A 15 by 12 black envelope is now placed in position under the part to be examined, and into this is slipped the wrapped plate to be exposed. The exposure made, the plate is easily withdrawn, and No. 2 introduced without any alteration in the position of the patient, the table being moved laterally two inches between the exposures.

The plates are examined by placing them side by side against a window, about 6 inches apart, with a piece of cardboard between, the film side of the left hand radiogram and the glass side of the right hand one being towards the observer, who holds a dark negative (glass side to right) against the right side of his nose, thus blocking out the view of the left hand plate from the right eye. Then, if the observer looks towards the left hand radiogram with both eyes, he will, his right eye accommodating to the reflected image on the surface of the plate thus held, become his own stereoscope and get a perfect vision of the relations of the part under observation.

This is a simplification of the method which I described before the Royal Society of Medicine some years ago, but having now boiled it down to the requirements of field service, where every ounce of apparatus counts in transit, I take the liberty of again describing it with its latest modifications, particularly as I think that there may be some who will be glad to know of a method of examining cases stereoscopically without stereoscopic appliances.

ALFRED J. H. ILES,

Lieutenant, R.A.M.C. (T.F.), Officer in Charge
X-ray Department and Electrical Department,
British Expeditionary Force.

June 8th.

"FATIGUE DYSPEPSIA."

We have received from a correspondent, who prefers that his name should not be published, the following note illustrating the subject dealt with by Dr. Guthrie Rankin in the BRITISH MEDICAL JOURNAL of June 19th, 1915:

Dr. Guthrie Rankin describes a set of conditions which exactly fit a case that has been for many years under my

observation, and the occurrence of so many cases in Dr. Rankin's practice seems to indicate a prevalence that deserves such a distinguishing title as the above to differentiate these cases from others that belong to a broader neurasthenic class.

My patient is a man now aged 56, belonging to a somewhat neurotic family. His father for some years wore an abdominal belt, and died when approaching 70 years of age of chronic pyloric obstruction, apparently non-malignant. My patient, himself always of an energetic disposition, was much subject in his younger days to migrainous headaches. He became an active bicyclist, often riding long distances in a day, and being on the bicycle practically every day. Occasionally after long rides he suffered from some slight burning sensation in the epigastrium when he awoke on the following morning, which proved to be premonitory of what was to follow. He has never been an habitual imbibor of alcoholics though not a total abstainer.

At the age of 44 his health gave way somewhat suddenly. He had recently done a very long bicycle ride over a hilly country, and at the same time was suffering from mental worry in connexion with his private affairs. Severe dyspeptic troubles developed along with circulatory weakness and great irregularity of pulse. The stomach became dilated, and there was more or less stasis of the abdominal contents, including the spleen and left kidney. There was quite an appreciable amount of albuminuria, and some tenderness in the region of the left kidney.

The deficiency of digestive power led to a diminution of the food ingested, and this in turn to emaciation and loss of physical power. He became anxious, and thought he was suffering from cancer, aneurysm, and other complaints, though there was never any definite sign of these or any other organic lesion. The second sound of the heart was slightly duplicated, otherwise there was no heart bruit. The emaciation allowed of easy palpation and percussion of the abdomen, but there was nothing to discover there excepting the displacement downward of the organs and the dilatation of the stomach and colon. There were marked splashing sounds in the stomach, which the patient could easily elicit himself by movement of the abdominal wall.

From time to time the stomach was filled with extremely sour fluid, and the patient learnt to gain relief from the discomfort of this condition by inciting vomiting. Otherwise an acid condition of stomach contents developed during the night, and made itself evident in the early hours of the morning by a burning sensation in the region of the left costal cartilages. The skin covering this part over an area about the size of a crown piece was at such time extremely sensitive to touch, pressure by the fingertips producing a pain resembling that which might be produced by needle points. Thus the patient was awakened by this sharp burning pain, which, if unaffected by copious dilution caused by drinking large draughts of water or by a dose of sodium bicarbonate in water, continued until the stomach had emptied itself through the pylorus, which it did at the end of nine or ten hours instead of within the normal four hours after the last meal. The burning pain was relieved by change of posture, especially to the upright position, and digestion appeared to be more rapid and normal during the day, when the body was upright, than at night.

In the course of a good many months from the onset the complaint passed into a chronic state, with some improvement, and tendency to intermittence and periodic return, and at length became a matter of periodic attack. As the attacks were sometimes separated by long intervals, great improvement of the general body condition was permitted. This was aided by the bicycling being given up, and walking exercise substituted. The albuminuria disappeared entirely, and has not returned. The tongue, which had been furred, resumed its habitual clean state. The stomach became less sensitive, and able to bear a more varied diet, when care was taken as to quantity and avoidance of certain articles. Former weight was regained and exceeded at a later period, when the deposition of a moderate amount of abdominal fat proved advantageous.

Gouty symptoms, however, had supervened, with some swelling of great toe and knuckle joints and tenderness of the soles of the feet, especially in the spring, and the foot

elongated, so that the shoes that had been made for twenty years on the same lasts were now too short. There was also slight local eczema, development of a well marked arcus senilis, and the urine commonly deposited urates on cooling, though always passed quite clear.

The patient was originally blessed with a set of excellent teeth, and still possesses a mouthful, with two or three stopped, but no active caries. Two years ago—that is, ten years after the onset of the stomach symptoms—the lower incisors became loose, and there was a slight pyorrhoea at the junction of the alveoli and the roots of the teeth. There had been, however, some neglect previously in brushing the teeth and tartar had collected in the locality. A disinfectant tooth paste, with more careful brushing, removed the tartar and the pyorrhoea, and the teeth tightened up again and have given no further trouble. This slight pyorrhoea being temporary and long subsequent to the commencement of the stomach attacks, was undoubtedly one of the effects, and not the cause, of the general condition.

After a dozen years the stomach attacks continue, being determined by several circumstances, one of which—and that a prominent one—being physical fatigue or over-exercise, whether mental or muscular. Any great exertion, either prolonged or shorter, if so violent as greatly to increase the pace of the heart beat, is liable to be followed by a stomach attack with the burning sensation in the early morning. Certain articles of food are likely to bring about the same condition. Soedy acid fruit, a hearty plateful of stewed rhubarb, oranges, jellies, are very apt to prove pernicious in this respect; also too much meat, peas, broad beans, or other richly nitrogenous diet, too much hydrocarbon diet, too much milk, and a loaded state of the intestine, whatever the diet, have all the same effect.

Nevertheless, experience has taught that the tendency to these stomach attacks can to a great extent be circumvented by care in avoidance of strain upon the muscular and nervous systems, and by attention to diet as suggested by Dr. Guthrie Rankin, and there need not be any great deprivation either in the matter of agreeable exercise or of eating and drinking. Much time spent in the open air, combined with gentle exercise, such as slow walking or riding in a motor car, has proved in the above described case to be very beneficial. The air of a Scottish moorland, combined with the exercise of fishing the burn, has always proved antagonistic to the complaint and conducive to the healthy development of weight and strength.

THE CAUSE OF THE SHOCK AND COLLAPSE IN COMPLETE INVERSION OF THE UTERUS.

IN the JOURNAL of April 17th I see the record of two cases of complete inversion of the uterus. The profound shock is, to my mind, entirely due to the jamming and mutilation of the ovaries between the brim of the pelvis and the body of the uterus. The injury is analogous to that received by a man on the cricket field who is struck by a cricket ball full on the testicle. He falls instantly—pale, pulseless, with shallow or sighing respirations, and possibly clammy perspiration on forehead. Now, if he is a man with well developed sexual organs, the shock will be all the more severe. Imagine a woman suddenly getting a blow with two cricket balls on right and left ovaries, possibly bursting the delicate organs, with haemorrhage under tense capsules and between layers of broad ligaments; or, possibly again, the Fallopian tubes are torn—can we wonder at the terrible shock and collapse? If she has well-developed ovaries so much the worse for the patient, for big, healthy ovaries stand a bad chance indeed of passing through the pelvic brim. If she is a "scraggy little woman" she may escape with her life, for small ovaries may escape a terrible contusion where big ovaries will not escape. How should we treat such a case? The answer is, just in the same way as you treat the man felled in the cricket field by the cricket ball: (1) Rest with head low and pelvis high; (2) elevate ovaries; (3) foment ovaries; (4) relieve shock by relieving pain. How can we elevate ovaries? Only by plugging the vagina with an aseptic plug, changed often. Would it be risky treatment to give a hypodermic of one-third of a grain of morphine, or should one have the courage to give a whiff of chloroform? Relieve pain and you relieve shock.

Wigan,

H. W. BERNARD, M.B., B.Ch., B.A.O.

Reports of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

At a meeting on May 28th Mr. P. T. CRYMBLE demonstrated a *New x-ray apparatus*. A series of demonstrations on students who had had a bismuth meal at varying periods within the previous twenty-four hours incidentally showed that the rate of progress of the bismuth through the alimentary canal varied with the nature of the food with which it was mixed. Professor SYMINGTON showed a series of *Casts of the endocranium, arachnoid, and brain* to illustrate the degree to which the convolutions and sulci impressed the inner surface of the skull. The Section then separated, one portion adjourning to the Anatomy Theatre, Professor A. F. DIXON presiding. Dr. SYMINGTON read a paper on the *Estimation of the degree of brain development from endocranial casts*. He also showed and described a new method of illustrating cranio-cerebral topography. The method adopted was to make an accurate cast of a coronal section through the head, and then to photograph the section absolutely to scale and place the print on the plaster cast.

In the Physiology Lecture Room, where Professor W. H. THOMPSON presided, Professor T. H. MILROY read a paper on the *Action of rennin*. During the action of this ferment on milk there was no change in the reaction of the milk either in the earlier stage or in the separation of the clot. The addition of alkaline oxalate retarded or inhibited coagulation not only by its removal of soluble calcium, but also from the fall in the hydrogen ion concentration of the milk which it produced. Calcium chloride aided coagulation partly by raising the hydrogen ion concentration and partly by increasing the soluble calcium content. Milk which had been treated showed lowered coagulability, due to the diminished calcium content. The acid precipitation zone of caseinogen lay on the acid side of the ferment *znc*, but the latter was probably simply an extension of the former. Dr. J. E. MAIRWAINE read a paper on the *Electro-cardiographic method of estimating the condition of the heart muscle*, embodying the result of two years' experience. Dr. J. M. GIBSON read a paper on *Heart-block produced by yohimbine and quabachine*. Professor W. H. THOMPSON: A preliminary communication on the *Effects of nicotinic arginin on the excretion of creatine and creatinine*. Arginin was used prepared from herring milk and racemised according to the procedure followed in Kossel's laboratory. Four experiments were performed—three with rabbits and one with a dog. In the latter the addition of 2 grams per day to the food (two days) gave an increase of 2.6 per cent. subcutaneous injection of the same amount, an increase of 195 per cent. to the total output of creatine-creatinine in the urine. The preformed creatinine was not increased, or only to an extent (2 per cent.) which lay within the errors of observation. In the rabbits the increase of urinary creatine was less marked, varying from .04 to .1 mg. per hour during a period of six hours following injection via the jugular vein. There was, however, in two of these (in which the creatine of muscle was determined) an increase of .0341 and .0178 gram per cent. respectively in the fresh muscle. In the latter the increase amounted to .0870 gram per cent. of the dried solids. A control experiment on a rabbit with the same anaesthetic (urethane), but without arginin, gave a decrease in the preformed urinary creatinine of 1 mg. per hour, a decrease in the total urinary creatinine of 0.6 mg. per hour, and a relative increase in the latter of 0.5 mg. per hour. The creatine of the muscle was also increased—namely, to the extent of .0667 gram per cent. for the fresh muscle and .0710 gram per cent. as calculated for the dried solids. The results, so far as they went, pointed to the formation of creatine from laevoarginin in the dog, and did not support the theory of a "wash-out" or expulsion of preformed creatine from muscle. Professor B. J. COLLINGWOOD read a paper on some further observations on a *Uric acid index*. Dr. J. M. O'CONNOR read a paper on *Chemical temperature: regulation in anaesthetized animals*. He said that in anaesthetized cats and rabbits shivering occurred if the body temperature and the subcutaneous temperature were

below a point which was fixed for that particular animal. The oxygen consumed by the animal when not shivering was approximately a simple function of the body temperature. When shivering, more oxygen was consumed than at the same body temperature in the absence of shivering. This excess was directly proportional to the extent to which the subcutaneous temperature had fallen below the fixed point referred to. Dr. J. A. MILROY read a paper on some applications of *Electrolytic reduction*. The following were some of the results obtained: (1) Oxalic acid was reduced successively to glyoxylic acid and glyoxal. (2) In the hope that this reaction might be applicable to other dibasic acids, the reduction of saccharic acid was tried. Only a small amount of a substance which reduced Fehling's solution was formed, and so far the author had not obtained the glycuronic acid which might have been anticipated as the earliest reduction product. (3) Haematin dissolved in 70 per cent. alcohol containing sulphuric acid was transformed first into a pigment resembling haematoporphyrin; later, the solution becomes yellow and has the spectroscopic characters of a solution of urobilin. Still later the solution became practically colourless, but on standing exposed to the air it became yellow. This acidification was more rapid in ammoniacal solution, and the resulting pigment had similar characters to those of urobilin, having a similar spectrum and giving a marked green fluorescence on the addition of ammoniacal zinc hydrate. It might, therefore, be concluded that the final product of reduction was a chromogen of a pigment resembling urobilin.

NORTH STAFFORDSHIRE MEDICAL SOCIETY.

At a clinical meeting on July 1st, Dr. RUSSELL, President, in the chair, Dr. GILL showed an old man with *Molluscum fibrosum*. He was born with a fibrous tumour of the scalp, others appearing shortly afterwards in various parts of the body. A very large tumour was removed twenty-years ago, and many more appeared after the operation; there were some small tumours on the soles of the feet. Dr. MITCHELL SMITH exhibited a child with a *Hairy mole and von Recklinghausen's disease*. Mr. ERIC YOUNG showed a woman with *Molluscum fibrosum*. There were tumours on the palms of the hands and soles of the feet, and she also had a fibroma pendulum of the left buttock; the patient stated that tumours appeared in various parts of the body subsequent to vaccination. A large tumour was removed from the right anterior triangle of the neck in September, 1914, which was reported to be a sarcoma; there was no recurrence. Dr. GILCHRIST and Mr. HARTLEY showed a married woman, aged 27, with one child. She first came under observation in October, 1913, with sacralgia, metrorrhagia, and discharge of seven months' duration, and she was found to be suffering from a large *Ragged ulcer on the posterior lip of the cervix*, and extending on to the posterior vaginal wall. Wertheim's operation was performed by Mr. Hartley. There was no local recurrence, but three months ago she noticed an enlarged gland in the right side of the neck and one in the right groin. Messrs. R. ALCOCK and ERIC YOUNG said it was unfortunate that no microscopical examination of the ulcer had been made. They were of opinion that the swelling in the neck was a breaking down tuberculous gland, and that the original disease might also have been of a tuberculous nature and not malignant. The President, Dr. SHUFFLEBOTHAM, and Mr. WEBSTER also took part in the discussion, and Mr. HARTLEY replied, maintaining that the original disease was malignant. Dr. GOOD and Mr. BLAIR showed a youth upon whom Mr. HARTLEY had operated for *Acute otitis media*, mastoiditis, and lateral sinus infection; the radical mastoid operation, with exposure and division of the internal jugular vein, having been performed. The patient was now quite well. Mr. W. C. ALLARDICE exhibited three patients: (1) A soldier with a *Bullet wound of the humerus*. (2) A soldier with a *Bullet wound of the left chest*, who had been detained in France for nine days after the injury, and on arrival at the North Staffordshire Infirmary was very short of breath, and had a bad colour; there was dullness extending as high as the crest of the scapula, but no displacement of the heart. Some blood was withdrawn by means of an exploring needle, but no further treatment was adopted, and the man had made an

excellent recovery. (3) A young girl, whose hair had been caught in some machinery and the *Scalp completely torn off*. The scalp was cleansed and sutured in position, but sloughed completely; an endeavour was then made to graft with the skin removed from an umbilical hernia, with the same unfortunate result, and it was now decided to graft by means of Thiersch's method. Drs. DAWKS, GILL, HILL, and SMITH discussed these cases. Dr. J. W. DAWKS showed a potter's handler, aged 44, who was first seen in October, 1913, suffering from a persistent brassy cough and slight dyspnoea; he was found to have an *Aneurysm of the arch of the aorta*. For the last eighteen months his condition had remained practically stationary; the blood pressure on the left side was 140, on the right 120. Dr. LIST gave a demonstration of the case in the x-ray department. Dr. G. H. SOWRY showed two sisters, aged 16 and 9, suffering from *Enlargement of lymphatic glands*, marked in the neck, smaller in the axillae and inguinal regions. They were thought to be suffering from Hodgkin's disease, but von Pirquet's reaction was positive in both cases, and there was a very strong family history of tuberculosis. The PRESIDENT also showed two girls with enlargement of the lymphatic glands in the neck, axillae, and inguinal regions. In the younger girl the spleen could be felt, and von Pirquet's reaction was negative in both girls. Dr. McDUGALL drew attention to the importance of a differential blood count in such cases. Mr. CARTER remarked upon the presence of enlarged tonsils in Dr. Sowry's patients and suggested enucleation of the tonsils. Drs. GILL, ROBINSON, and SMITH also took part in the discussion. Dr. SOWRY replied, and commented upon the x-ray treatment of Hodgkin's disease. Dr. DALY showed a man with a *Swelling of the hard palate*, which included the alveolar border and extended to the middle line; this had been present for five years and had altered very little; there was no specific history. Messrs. ALCOCK and CARTER discussed the case and considered the swelling to be of the nature of a granuloma. Dr. MITCHELL SMITH exhibited a cast from a case of *Primary tracheal or bronchial diphtheria*. A girl, aged 13, was discharged from the Isolat on Hospital on June 13th, apparently well, after a severe attack of scarlatina; she was taken ill on the night of the 20th, and was seen on the 21st. The temperature was 102.5, pulse-rate quickened, breathing hurried and shallow, sputa irritable cough, little expectoration, voice very weak and whispering, no stidor; the patient looked very ill, and grey. The throat showed nothing abnormal. Examination of the chest showed diminished air supply; breath sounds on front of right chest practically abolished, on front of left chest greatly diminished, normal at back of chest; resonance on percussion normal over whole of chest. During the night the patient had a severe attack of dyspnoea, with pain below the right clavicle, which lasted until a cast similar to that shown was coughed up. On the 22nd she was very prostrate, breath sounds improved on right side, diminished on left; antidipltheric serum 4,000 units given. On the 23rd, slight general improvement, breathing markedly improved on right chest, worse on left; antidipltheric serum 2,000 units given. Later in the day she had a paroxysm of coughing, with pain below the left clavicle, and the cast shown was coughed up. On the 24th, marked local and general improvement. Report of bacteriological examination positive. The case was discussed by Drs. SHUFFLEBOTHAM, SELWYN-THOMAS, and WEBSTER, and Dr. SMITH replied. Mr. HARTLEY exhibited two pathological specimens: (1) *Multilocular ovarian cystoma*; (2) uterus, cervix, appendages, and portion of vagina, removed by Wertheim's operation on June 3rd, 1915, for *Carcinoma of the cervical canal*.

PROFESSOR H. H. TURNER, F.R.S., has communicated to the Royal Meteorological Society some preliminary results of an investigation on which he has been engaged for some years. He finds that meteorological history is divided into chapters, averaging 6½ years, with abrupt changes (discontinuities), apparently determined by the movement of the earth's axis. He finds that they oscillate about mean positions in a cycle of 40.5 years, which appears in Brückner's collected "cold winters" for 800 years, in Nile flood records for 1,000 years, and in measures of Californian tree rings for 520 years. The chapters are alternately hot and cold, wet and dry, as shown by rainfall and temperature records at Greenwich, Padua, and Adelaide.

Reviews.

MIDDLE AGE AND OLD AGE.

DR. SEYMOUR TAYLOR'S little book on *Health for the Middle Aged*¹ is a contribution to the series which Messrs. Methuen are issuing under the editorship of Mr. Bishop Harman. The title is a happy one, and will no doubt attract many readers, who will not be disappointed, for the volume contains plenty of sound common-sense advice expressed in a genial and readable style. What, precisely, is middle age? Most people, perhaps, would say in two decades—between 40 and 60, but Dr. Taylor inclines to the opinion of the late Dr. Southby, who assigned to middle life the period between 49 and 65. Taking into consideration the changed conditions of modern life, and the improved facilities for postponing the onset of senility, we are disposed to accept this estimate. Middle life is, both for men and for women, a somewhat critical time, and the warnings given by Dr. Taylor on the subject of diet, exercise, etc., are so reasonable and so clearly put that we feel sure they will help many to steer clear of the special dangers to which the author calls attention. Such warnings are by no means superfluous, despite the proverb which asserts that a man of 40 must either be a fool or a physician. For if we may judge by the views frequently expressed on hygienic matters by people of at least that age, to say nothing of their gastronomic exploits, the majority of the middle aged are—not physicians. And these may profit by advice read in a book which they would resent if orally administered.

If, as is suggested, the subject has hitherto been neglected in America, Dr. I. L. NASCHER, in his work on *Geriatrics: the Diseases of Old Age and their Treatment*,² has endeavoured to make up for the deficiency. He complains of the want of attention to senile diseases in the United States, where the general mental attitude towards the aged, according to him, is that "they are useless—a burden to themselves, their families, and to the community at large. Their appearance is generally unaesthetic, their actions objectionable, and their very existence an incubus to those who, in a spirit of humanity or duty, take upon themselves their care." How far this view would be generally endorsed by the Anglo-Saxon part of the American people we will not inquire. An introduction to the book has been written by that eminent veteran, Dr. A. Jacobi, who finds that much the most important contributions to this department of disease have been made by Germans, Germany in this respect having "proved its supremacy as the modern leader in medical science." We had previously supposed that the French had made the more important contributions to the discussion of the subject. Dr. Nascher's book, at any rate, makes no claim to be original. It is frankly a compilation; even its illustrations, with one or two exceptions, are borrowed from other works. It is perhaps the fault of the publisher and not of the author that so many of them are not bound up opposite to the text which refers to them. Thus a drawing illustrating fibrosis of the lung is in the section on the liver; another of the heart in the section on the intestines; while that of enlarged prostate is in the part devoted to senile alopecia. The author shows a good deal of simple faith in the effects of remedies, attaching very considerable remedial powers to the use of phosphorus. He also believes that tannic acid will control hæmorrhage in renal embolism, and he is among the few who still retain any belief in the value of pepsin administered as a drug, while, on the other hand, he is cautious to excess with belladonna and digitalis. He believes that charcoal in 5-grain doses given in a capsule will relieve flatulence, though on what principle he can expect such a result we do not understand. He says (p. 114) that the senile liver is "like the atrophic stage of cirrhosis"; but, except that the two organs may happen to be about the same size, we fail to see any resemblance. There are a good many misprints:

¹ *Health for the Middle Aged*. By S. Taylor, M.D., F.R.C.P. The Health Series, under the editorship of N. Bishop Harman, M.A., M.B., B.C., F.R.C.S., etc. London: Methuen and Co. 1915. Fcap. 8vo. pp. 112, 1s. net.

² *Geriatrics: the Diseases of Old Age and their Treatment*, by I. L. Nascher, M.D. With an Introduction by A. Jacobi, M.D. Philadelphia: P. Blakiston's Son and Co. 1914. (Roy. 8vo. pp. 535; 50 plates; 81 illustrations.)

quite a number of the English names are misspelt. On the obscure and difficult problem of the cause of old age or senile degeneration which so many great thinkers have given up as insoluble, Dr. Nascher ventures the suggestion that it is the result of natural cell evolution; but this is rather like the famous explanation of the sleeping properties of opium, "quia est in eo virtus dormitiva." The author's therapeutic views are generally what would be called sound, and he nowhere lends himself to extreme opinions.

THE SULPHUR MINES OF SICILY.³

The sulphur mines of Sicily give employment to 23,077 men and boys. They afford means of subsistence to upwards of 200,000 persons. Sulphur in its pure form is found in Russia, Poland, Iceland and Spain, and in the United States of America, but the richest mines are in Sicily. They yield one-eighth of the world's production. In the district of Caltanissetta alone there are 377 sulphur mines. The health and physical development of the miners are influenced by the heavy weights carried, the fatiguing and trying position of the body when at work, the absence of light, and the presence of foul air and dust. Gas explosions and landslips in the mines are also a frequent menace to life. Mine owners have been slow in introducing modern improvements. In many places little attention has been paid to hygiene. Although the first to establish a hospital for the study and treatment of occupational disease, Italy has in some respects lagged behind other nations in matters of industrial legislation. Since 1905 the number of sulphur mines has been declining. In that year they numbered 710, five years afterwards they had fallen to 379. The annual production of sulphur is 360,000 tons. The reduction in the amount of sulphur raised in Sicily is largely due to the development of mines in Louisiana. Sicily's greatest competitors are the United States of America and Mexico. Through the utilization of sulphur products in the manufacture of sulphuric acid it is hoped that the industrial prosperity of the island will revive.

Soakage of water through the strata not only causes the mines to be damp, but as the water frequently contains H₂S, it not only becomes an obstacle to work, requiring to be pumped out, but also a risk to health. Absence or deficiency of ventilation is characteristic of the mines. In by far the larger number there are no double shafts whereby air can be made to circulate. The temperature of the mines is high; the men work in many instances without clothing; the work is hard, and gives rise to profuse perspiration, which is followed by considerable physical exhaustion. Owing to the free perspiration the miners suffer much from thirst. At work they drink from 3 to 4 litres of water daily; their pulse-rate is quickened and the heart's action exaggerated, the skin is frequently the seat of erythema and of boils, the teeth decay early, and the gums swell and bleed rapidly. Respiratory and intestinal catarrhs are frequent ailments.

The men who mine the ore are called *piconieri*. The mode of entrance into a mine is by an incline or by a staircase hewn out of the rock. In mining the ore the *piconiere* works in a bad position, he has to stoop considerably, and make great demands upon the muscles of his arms and loins. Many of the men suffer from varicose veins. The *piconiere* usually commences his career in boyhood as a *carusso* or carrier. The *carusso* shares the hardship of the mine with the *piconieri*. He has to carry heavy loads of sulphur on his shoulders up the stairways sometimes almost on all fours. The writer of this review has visited Sicily and been in the mines. He was much impressed with the hard life of the lads and with the risks they had to run. Add to the severity of the toil the circumstances that no stated time is allowed for meals, and that the food is poor in character—salt fish, cheese and onions, eaten when chance offers—and the trials of a sulphur miner's life can be readily imagined. To the housing of the miners little attention has been given. Overcrowding is therefore a prevailing feature. At some of the mines there are barracks; in them men and boys are housed together; they sleep on boards, covered with straw or leaves, with their clothes on. The air of the sleeping room is maldorous, and tends to intensify the

exhaustion from which the men suffer. Nervous diseases are frequent among them; so, too, is insanity. To malaria and ankylostomiasis the Sicilian miner is a frequent victim. GIORDANO attributes much of the ill-health of the men to the excessive use of alcohol and tobacco. Diseases of the lungs are common. These organs become the seat of a form of fibrosis to which Giordano has given the name of "theapneumoconiosis." Owing to the conditions under which the miners work and are housed the lungs become a ready prey to all forms of micro-organisms, including the tubercle bacillus. A large percentage of the cases of pulmonary disease therefore becomes tuberculous. The initial structural changes in the lungs are the result of the irritation caused by the sharp pointed crystals of sulphur which have been inhaled.

Within the last few years the hardships of the sulphur miners have been lightened by obligatory insurance and by mutual help associations. A Royal Decree established ten years ago the Obligatory Insurance Syndicate among employers. For each ton of ore raised which contains 65 per cent. of sulphur one franc and a half must be added to the fund. The Red Cross Society co-operates with this fund. The reviewer can speak most encouragingly of the good effects of the two societies. The numbers of accidents had fallen three years ago from 27.95 per cent. to 17.75. Nursing homes have been established. To M. Pompeo Colojani, brother of the statesman, belongs the credit of the establishment of the Insurance Syndicate and of the introduction of many useful reforms and means for improving the health of the miners. What Colojani has done for the sulphur miners from a social and industrial point of view Giordano of Lerera has done from the medical standpoint. No medical man is more familiar with their ailments or knows more of the diseases from which they suffer. Giordano deserves well of his countrymen, and especially of the particular class with whom through his writings he has made us acquainted. His monograph is interesting and instructive.

TRAINING OF DEFECTIVE CHILDREN.

THE DEPARTMENT of Education, Ontario, publishes from time to time, for public information, pamphlets on educational subjects, and in the seventh of this series Miss HELEN MACMURCHY, M.D., Inspector of Auxiliary Classes for Ontario, gives an excellent summary of what has been done for the training of children with mental and physical defects in Europe and America, in support of her thesis that there is need in Ontario for similar provision. Dealing with the matter on broad social grounds, she points out that in the case of mental defectives not only is instruction in an auxiliary class necessary during school age, but that permanent after-care is essential. It would appear from school census and other returns that the proportion of mental defectives in Ontario is small as compared with other countries—that is, about 1 in every 400 or 500 of the population, against 1 in 250 in England. Yet this mounts up to about 5,000 persons needing provision in the whole province, and the Hospital for Feeble-minded at Orillia seems to be the only institution at present available for the permanent care of such cases. In 1911 an Act was passed by the Provincial Legislature authorizing the establishment of special classes for defectives in connexion with public schools. Two special classes were opened in Toronto in 1910, with an attendance of 32, but the Chief Inspector states that from 250 to 300 require special instruction in that city. Other special classes have been formed at Fort William and at Hamilton.

Interesting hints are given as to the diagnosis of mental defectiveness and of backwardness, and considerable space is given to "word blindness" and "word deafness." The training of teachers for auxiliary classes, the equipment of the special class-rooms, the course of study appropriate for feeble intellects, and the cost of establishing such schools, are subjects dealt with in successive chapters; and the appendices contain memoranda to parents, outlines of scholastic and industrial work, sense exercises, etc., in considerable detail. The pamphlet is of handy size (8vo), well illustrated, and is furnished with an admirable bibliography and index. It is satisfactory to find that the oversea dominions are coming into line with

³ La Fisiopatologia e l'Igiene dei Minatori. Dott. Alfonso Giovinato, Docente d'Igiene Min. nella Regia Università di Palermo. Roma: Tipografia Nazionale di G. Basterio E. C. Via Umbria. 1913.

⁴ Organization and Management of Auxiliary Classes. By Helen MacMurphy, M.D. Department of Education, Ontario, Educational Pamphlets, No. 7, 1915. Ontario: L. K. Cameron. 1915. (Cr. 8vo, pp. 212; illustrated.)

the mother country in their arrangements for mental defectives. In New Zealand a residential special school has been established at Otakeite by Government; it now contains 150 cases, and seems likely to develop into an industrial colony. In Australia "auxiliary" school classes have been organized under the Education Act of 1911 at Melbourne and Sydney, and similar classes are contemplated in Nova Scotia and other parts of Canada. Dr. MacLurely's little volume can be commended as furnishing in small compass much useful information about the feeble-minded class.

NOTES ON BOOKS.

THE third edition of Dr. CAMPBELL'S *Aids to Pathology* includes a considerable amount of additional matter. As a sign of the times let those who were medical students in the Seventies and Eighties of the nineteenth century look into this new issue and see how the beginner must needs know what hormones are and what they mean, whilst if these veterans catch sight of the word "anaphylaxis" they will mostly, we suspect, look up the name at the proper page as indicating something of which they have never heard before. We may hold theories which happen to be current to day as liable to eclipse and extinction to-morrow, but a glance through *Aids to Pathology* will show that many new methods have come to stay. Nearly two pages of small print are, very properly, devoted to the cerebro-spinal fluid. What would Faget and Lionel Beale have thought of lumbar puncture not only described, but taught as a thing to be practised? "The procedure is quite harmless," we are told, and for that and other reasons we find directions how it should be undertaken. Although so much is expected in a publication of this class, the new and old matter are well condensed in this third edition.

The *Proceedings of the Pathological Society of Philadelphia* for last year include instructive papers on rarer forms of disease, such as tumour of the carotid body, endothelioma of the mediastinum, and retroperitoneal sarcoma. Reports on bacteria and parasites will prove of more general interest. Drs. Allen Smith, Middleton, and Barrett issue an abstract of a report on laboratory work on the tonsils as a habitat of oral endamoebae, the complete text of which will be read with interest by experts. Smith and Barrett had previously written on the association of pyrrhloca alveolaris, in many instances, with the amoebic parasites *Endamoeba buccalis* or *gingivialis*, which are found in pyrrhloca pockets. It now appears, as a result of later researches, that the same organisms inhabit the tonsillar crypts in cases of chronic crypt tonsillitis. The authors further dwell on the complications of tonsillitis and their relation to endamoebae and toxins derived from types of symbiotic bacteria. Drs. Rivas and Lucke detected the American hookworm, *Necator americanus*, in the faeces of an East Indian adult. There was double parasitic infestation of the intestine—namely, by *Necator* and by the fluke *Fasciolopsis buskyi*, and eggs of both parasites were detected. The *Fasciolopsis* is an Asiatic, not a New World trematode.

A FRENCH PIONEER IN TROPICAL DISEASES.

IN a thesis presented to the University of Paris in 1914 R. Coville deals with the career and work of C. Dellon, who was a pioneer in the study of tropical diseases. Till the seventeenth century French ships seem to have carried no doctors. When Colbert founded the French East India Company in 1664 part of the organization was a health service on sea and land and in the colonies. When the expedition of Mondeville sailed in 1666 for Madagascar with ten ships carrying 1,700 emigrants, the company engaged three apothecaries and eight surgeons, in addition to those attached to the ships. This was the beginning of the French Naval Medical Service. C. Dellon was a surgeon in the French navy at the time of its foundation, and his name is the only one that has survived from that time. He was probably born in 1649, but the place of his birth and of his studies is unknown. In 1668 he left Port Louis in *La Fosse*, a ship of the India Company, with a crew

of 120 men, which sailed for Madagascar. On September 4th the ship reached Saint Paul in the Ile Bourbon. The heat and the want of water were beginning to make themselves felt, and scurvy broke out among the crew. But the air was so pure and healthy that only four out of eighty of those who contracted the disease died. When the period of his engagement with the company came to an end, he did not return to Europe but settled in the small Portuguese town of Daman. At first he was very successful, but this caused jealousy and he got into trouble with the Inquisition. He was tried for heresy and condemned to five years of the galleys. He was handed over to the secular power for deportation to Portugal, where he was to work out his sentence. On reaching Lisbon, however, he again fell into the clutches of the Inquisition. After many appeals for a new trial he at last succeeded in interesting Dr. Fabre, chief physician to the Queen of Portugal, in his case. The influence of Fabre, together with that of Bossuet, who befriended him, procured him his liberty. He returned to France in 1667 and wrote a narrative of his adventures which was published in Paris in 1685, together with a short treatise on ship diseases and tropical maladies as a sequel. The book went through several editions and was translated into English and German. Dellon's little essay may be regarded as one of the first treatises on the subject. Scurvy naturally holds the chief place, for it was a veritable scourge to all who went down to the sea in ships at that time and for long afterwards. Dellon attributed it to the dry burning air of the sea, to salt meat and bad water, to melancholy caused by long voyages, and to the thirst which had to be endured when in periods of calm and excessive heat the ration of water had to be reduced and the men could not wash themselves. Speaking of the prevention of scurvy, he says that the victuals taken on board must be of the best quality and the biscuit sound and easy to keep. At sea the ship must be kept very clean and "perfumed" several times a week. The sailors and travellers must observe careful hygiene; they must make provision of lemon, verjuice, dried fruit, and particularly prunes. They must avoid every kind of tainted food; they should eat little meat, and only such as had been perfectly freed from salt. Their diet should consist largely of rice, rye, and oatmeal cooked with prunes to keep the bowels reasonably free. Sugar is also recommended as being a marvellous balsam which fortifies the stomach, facilitates the expulsion of urine, and, while neutralizing the acids, softens the whole mass of blood, the thickening of which was, in his opinion, the sole or principal cause of scurvy. In addition to this, Dellon insists on minute attention to bodily cleanliness in order to promote perspiration; a special precaution recommended was carefully to wash the mouth, where the mischief began. He considered that the most important part of colonial medicine was fevers, which he classified summarily into continuous and intermittent. Among the latter the tertian and double tertian were fairly frequent and difficult to cure. He kept patients suffering from fever on low diet, giving them only plain water and *cangé*, prepared by boiling half a pound of rice in four or five pints of water; four or five small spoonfuls of this were given during the day. He makes no mention of bark. After fevers in frequency came affections of the intestine, dysentery being very common in India, contagious, difficult to cure, and often fatal. Dellon noticed that acute gastro-enteritis was common in hot countries. He observed an affection which he calls "Madagascar colic"; he attributes it to the immoderate drinking of a honey wine peculiar to the country, and says the symptoms resemble those of painter's colic. Coville suggests that Dellon may have confused this disease with beri-beri, which is very common on the east coast of Madagascar, and was observed by Bontius at Java in 1642. After referring to the frequency of small-pox in India, and of anaemia in Malabar, and giving an account of snakebite, Dellon concludes by describing *bichos*, of which he said there were three varieties. Two of them, it appears, are caused by parasites, the *Flaria medicinis*, and the chigo, the third being a form of gaeugrous inflammation of the anus. Dellon says nothing about cholera, or about diseases of the liver, the skin, and the eyes. This silence is doubtless due to the fact that he confines himself strictly to affections which had come under his own observation. He was evidently a man who thought for himself, and while not altogether

¹ *Aids to Pathology*, by H. Campbell, M.D., B.S. Lond., F.R.C.P. Third edition. Students' Aid Series. London: Baillière, Tindall, and Cox 1915. (Fcap. 8vo, pp. 255. Cloth, 3s 6d, net; paper, 3s, net.)

² *Proceedings of the Pathological Society of Philadelphia*, New series, vol. xvii, old series, vol. xxxv (January, 1914, to January, 1915). Edited by J. A. Kolmer, M.D. Philadelphia: Wm. J. DeGrua, 1915. (Roy. 8vo, pp. 1002.)

free from the therapeutic prejudices of his day in favour of *purgare, enusula, scignare*, as the sheet anchors of treatment, he used these remedies in moderation. He did not hesitate to take hints from the practice of the native doctors when they seemed to be of any value. It must be said to his credit that he constantly insisted on the importance of hygiene, of personal cleanliness and suitable food.

CHOLERA EPIDEMICS IN BRISTOL IN THE NINETEENTH CENTURY.*

THERE were three notable epidemics of cholera in Bristol in the nineteenth century—namely, in 1832, 1848-9, and 1866.

The following notes on two of these outbreaks, with an account of the means taken to check their spread, the remedies used, and some of the early investigations into the nature of the disease, are, I think, worth recording.

In the autumn of 1831, on the first definite evidence of the arrival of cholera in England, the magistrates met to consider the best means of dealing with the dreaded pest should it reach Bristol; and the mayor, Mr. Charles Pinney (who distinguished himself in the memorable riots of this year), wrote to Dr. Carrick, then senior physician to the Bristol Infirmary, asking his advice. This letter was submitted to the infirmary staff (November 11th), and within twenty-four hours a report was sent to the mayor containing the following practical recommendations:

1. The formation of a "Board of Health," consisting of the chief magistrate and two or three aldermen, the physicians and surgeons of the infirmary, and others, "to receive reports, to give directions, and to communicate with the General Board of Health in London."

2. That a parochial committee be formed in every parish, consisting of the minister, churchwardens, practitioners from the district, etc., to hold daily sittings in the vestry or elsewhere, and to communicate with the Central Board of Health at the Council House.

3. That four or more houses be provided in an open and airy situation, furnished with beds for the reception of cholera patients, together with a staff of nurses and porters.

4. That the magistrates should enforce, as far as possible, the cleansing and whitewashing of the houses of the poor, and "lose no time in removing all manner of filth and nuisances wherever situated."

5. The Board of Health to issue information and directions, and to invite all practitioners to co-operate.

Dr. Howell, physician to the Infirmary, acted as honorary secretary to the "Board of Health," and at once called meetings and issued directions.

By December (1831) many cases had occurred in Sunderland and Newcastle, but the disease did not become generally prevalent until June, 1832. The first cases appeared in Bristol, on July 11th, amongst the inmates of the gaol, and on August 15th there were thirty-three deaths, chiefly in the poorer parts of the city. On October 10th Dr. J. Addington Symonds, who had succeeded Dr. Howell as Secretary to the Board of Health, published from the Council House the welcome news that the plague had much diminished, and by November 8th it had ceased. The cases which came to the knowledge of the Board of Health numbered 1,612; of these 626 died (38.8 per cent.). In crowded places, like St. Peter's Hospital, on which much of the stress fell, the percentage of deaths was over 40. Many suggestions were made, both in the medical and lay press, as to treatment, but nearly every one then considered mercury and opium to be the sheet anchors. Mr. George Rogers, who was inspector of one of the districts, recommended 20 grains of calomel with $\frac{1}{2}$ grain of opium and 5 grains of powdered ginger, the dose to be repeated in a few hours! It seems strange that so large a dose of calomel could be given to a person collapsed from cholera without causing speedy death, but it is certain that some of the patients so treated recovered. Dr. Howell announced that in Holland a preventive against the disease had been found by "Prince Lobhowitz, Governor of Galicia, in Lemberg." This consisted of an oval piece of leather, measuring about 8 by 10 in., smeared with a coat of resin from the fir tree, and applied "warm to the stomach and then to be constantly worn."

"Investigator," in the *Bristol Mirror* of August 10th, 1832, recommended fireworks, especially sky-rockets, as a method of purifying the air, and so destroying the "miasm." This ingenious person founded his argument on the statement that the year before, at the siege of Warsaw, the cholera there ceased after the heavy guns had been fired.

St. Peter's Hospital was crowded with cases of cholera, and as it was "at once the work- or poor-house, the bedlam, and the receptacle for vagrants," its condition at this time may be dimly imagined.

In the cholera-smitten districts the poor were in a state of panic. Unfortunately, there was a widespread prejudice against medical attendance, partly owing to some recent instances of "body-snatching." Early in August, on a Sunday morning, whilst a boy who had died of the disease at St. Peter's was about to be buried,

his mother, accompanied by a considerable mob, insisted on having the coffin opened, on the supposition that the body of her son had been otherwise disposed of. The demand under such circumstances was very properly refused, but no assurances would satisfy her, and, as she persevered in her determination, the coffin was forced open by the mob, when the corpse was exhibited in a very black and putrid state.

No member of the Board of Health (on which J. C. Pritchard, G. Wallis, A. Carrick, Richard Smith, Henry Daniel, and Nathaniel Smith, representing the staff of the infirmary, were very active) got any remuneration for the daily meetings, some of which lasted for three hours, and for the immense trouble they took, or for the danger they encountered. In fact, many of them were considerably out of pocket by the business.

Another bad epidemic of cholera occurred in 1848-9. The disease reached Bristol early in 1849, but did not assume formidable proportions until July, August, and September. The profession in Bristol did its best to stop its spread and to succour those who were stricken down by it. In these days of improved hygienic supervision, with responsible and skilled medical officers in charge of the city's health, it is difficult to conceive the terror inspired by the very name of cholera, which hovered like a black angel of death over the afflicted region. Medical men were appointed to visit the affected districts and to report. I find by some old letters that Dr. J. C. Swayne, Mr. S. H. Swayne, Mr. Wylde, and my father, the late William Smith, were on a committee to investigate and report upon the sanitary condition (or, rather, the insanitary condition) of the Parish of St. George, Brandon Hill. They made visits from house to house, and drew up reports. My father (and I believe one or two others of this small committee) contracted the disease. Mr. J. Williams (brother of the late Dr. Eubulus Williams, and uncle of the present Dr. Watson-Williams), with Mr. Davis and another, went round the districts. They hardly rested day or night. Mr. Williams died of cholera, and the poor people, who now had learnt to appreciate the services of medical men more than in 1832, subscribed from their slender means to honour his memory by a public funeral. His tomb is in Arno's Vale Cemetery, and to those who know of his heroic devotion to duty it is a pathetic and eloquent memorial.

The Bristol Medico-Chirurgical Society (the forerunner of the present society) appointed a "Microscopic Committee" to investigate the disease and endeavour to find its cause. The following medical men served on this committee: Drs. Frederick Brittan, William Budd, and J. C. Pritchard (afterwards physicians to the infirmary), Dr. J. G. Swayne (afterwards physician to the General Hospital), Dr. J. Bernard, and Mr. Neild. They made a careful examination of the evacuations of cholera patients, and came to the conclusion that there were certain crescentic bodies found which were absent in health and in other forms of diarrhoea. Dr. Budd publicly expressed his belief that the disease was due to some minute organism—probably these crescentic bodies. Further research showed that these were not the germs of cholera. The whole investigation showed great skill and patience, and the deductions were prophetic of what was not definitely known until forty years later.†

G. MUNRO SMITH, Lieut.-Col., R.A.M.C.(T.),
Clifton, Bristol.

* The information in this article is derived from letters in my possession, from old Bristol newspapers, and from the Richard Smith MS.

† An interesting account of these crescentic bodies, which were probably partially disorganized red corpuscles, may be found in the BRITISH MEDICAL JOURNAL for March 21st, 1885.

British Medical Journal.

SATURDAY, JULY 10TH, 1915.

WASTE.

RECENTLY the Chancellor of the Exchequer, in the House of Commons, spoke of the duty incumbent upon all citizens to practise a rigid economy at the present time, and deprecated the idea that lavish expenditure was a matter of no immediate importance. Private members enlarged on the text, and even suggested that certain public departments were not free from reproach in this matter. In other quarters the same wholesome doctrine has been preached, and journalists have placed at the disposal of their readers much advice, especially with respect to the subject of food. It will therefore be worth while to scrutinize the administration of one great spending department in this connexion. In our issue of March 20th we dealt at some length with the war rations of the army in the field, and pointed out that the energy value of the food supplied appeared to be quite adequate—a conclusion which has been borne out by practical experience. We did not discuss the feeding of the troops in this country, and we are not precisely informed as to the nature of the issue actually made. It is probable, however, that the provisions of paragraph 28 of the Regulations for the Allowances of the Army, 1914, are in operation. From this paragraph it appears that the daily scale at Home Stations is 1 lb. bread, or $\frac{2}{3}$ lb. biscuit, and $\frac{3}{4}$ lb. fresh or 1 lb. (nominal) preserved meat in barracks or stationary quarters. For men under canvas or (with the approval of the General Officer Commanding) when temporarily accommodated in unequipped buildings the bread ration is the same, but the allowance of fresh meat is 1 lb. We have been informed that this is the meat ration served out to men in billets.

Even if we assume that the above-mentioned articles constitute the whole of the foodstuffs supplied to the army at the public expense, certain reflections inevitably suggest themselves. The first is that all persons who are able to vary the form in which they supply the physiological machine with energy under varying external conditions always do so—that, for instance, the man who regularly consumes a pound of meat a day in the winter is most unlikely to do so throughout the summer. The second is that the proportion of soldiers who are in command of funds permitting them to modify the dietary to a considerable extent is much greater now than on a peace footing. When we further reflect that young soldiers in training are not precisely the persons to exert the supervision over food supplies proverbially associated with the mistress of a boarding house, we shall anticipate that the whole of the food purchased by the nation is not put to the use for which it was intended. But we do think that the public has not yet realized the lengths to which sheer reckless waste has been carried. As generalities are always unsatisfying, we may be permitted to give a concrete illustration. Having been informed by a farmer in the south of England that he fed his pigs on camp swill, we had the curiosity to inspect a barrel of that commodity on his premises. It did not at first sight seem to be an

entirely satisfactory foodstuff for pigs, as it appeared to be a viscid fluid of unpleasant odour, from which bubbles of gas were slowly rising, and we were hardly surprised to learn that many farmers considered that digestive troubles of swine, which might well pave the way for the invasion of the organism by the virus of swine fever, frequently resulted from a diet of camp swill. A further examination of this unsavoury mess revealed the presence of a piece of cheese, which might originally have weighed $\frac{1}{2}$ lb., a large piece of bacon, and several hunks of bread, not to speak of numerous potatoes and the débris one ordinarily associates with table washings. We have no hesitation at all in saying that the barrel must have originally contained solid and palatable food sufficient to supply the energy requirements of an adult for several days.

From inquiries we made we have no reason to suppose that this incident was other than typical of hundreds of farms throughout the country, and we venture to say that such a state of affairs ought not to be allowed to continue. Our national self-esteem has been gratified by the knowledge that the army in the field is a well-fed army, but any undue elation on this account may be checked by the thought that the army is not only well but wastefully fed. According to our information, the system in force is as follows: The commissariat authority has a certain number of men to ration, arrangements are made that each individual receives the prescribed quantity of food, and that is the end of the matter. Whether the soldier actually consumes the food, barter it, or throws it away, is his affair. Let us suppose the case of a tent with eight men and that they receive four 2 lb. loaves; it is quite likely that at the end of the day not much more than half will have been consumed, and if portions remain the men may receive instructions "to clear up that litter," when the bread will promptly vanish, to reappear in the unsavoury swill set before swine.

We are quite alive to the fact that it is one thing to point out an evil and another to offer an adequate remedy; but the first point to apprehend is that nobody, so far as we can ascertain, has made it his business to face the problem. All we can do is to indicate the steps which might conceivably be taken, leaving to those conversant with actual administrative difficulties the task of choosing the right one. In the first place, it might be possible for the men to exchange unused rations for extras at the canteen on some definite scale. The eccentric soldier who desired to substitute, let us say, chocolate for the whole of his bread ration could be defeated by placing a limit on the amount which might be exchanged. We know that in some places in which troops have been billeted the men have exchanged food supplied them for other articles in the grocers' shops, and we believe that official systematization of this practice might help to reduce the present waste. A more drastic step would be to order men to place unused portions of food in a special receptacle, and to punish those who allowed their unconsumed rations to be soiled or rendered unfit for human consumption. Finally, it might be practicable—in view of the number of men unfit for work in the trenches who still desire to serve—to organize a special corps charged with the supervision of broken food. The duty of such a corps would be to see that nothing fit to be eaten by human beings went into the swill tub. Lastly, we think that deliberate waste of food—schoolboy horse-play with pieces of bread, for instance—should be deemed as serious a breach of discipline as the waste of ammunition. A soldier who, not having had occasion

to expend all the cartridges served out to him during the day, fired several rounds in the air at night, would be severely dealt with; he must not waste the ammunition for his rifle, but he is apparently at liberty to waste ammunition for his body to his heart's content.

There is a grim irony in the fact that in the midst of rising food prices, while Cabinet Ministers are exhorting the nation to practise economy, and Government departments appoint committees to report on the best means of increasing the home food supplies, up and down the land this waste is proceeding. Many otherwise intelligent people appear to regard it as matter for a jest—a trait in keeping with the reckless gallantry which should characterize the soldier. In a little country town we were told the story of an old woman who, having a few fowls, asked one or two soldiers to throw any odd crusts they might have into her fowl run, and soon found to her dismay that the fowls were likely to suffer a fate like that of Tarpeia under the avalanche of bread discharged. Cynics will suggest that it may be cheaper to poison pigs with arsenic than with decomposing bread and meat rations. But those medical men who have practised in the poorer quarters of our great cities will fail to see the joke, and will agree with us that prompt measures should be concerted to minimize this great evil.

ENTEROSTASIS.

Our knowledge of the ordered progress of food through the various segments of the alimentary tract has been gained almost entirely during the last twenty years, and by the use of the Roentgen rays. Professor Keith has made a synthesis of our present knowledge, and in his Cavendish Lecture¹ expounds a new theory of the production of stasis in the alimentary tract, or enterostasis. He states that the food normally undergoes a certain delay at a number of fixed points in the alimentary tract, and proceeds to enumerate no less than seven of these points. The first is at the lower end of the oesophagus, the second at the pylorus, the third near the duodeno-jejunal junction, and the fourth at the lower end of the ileum, commonly known as the ileo-colic junction. In the large intestine itself there appear to be three more points at which delay may be regarded as normal. One is near the beginning of the transverse colon, leading to filling of the caecum and ascending colon; the next is at the recto-colic junction; the third, or seventh and last of the whole series, is above the anal canal, and its action leads to the accumulation of faeces in the rectum. The degree to which the stasis of the contents of the alimentary tract takes place at these various points naturally varies somewhat widely in different normal individuals. But Professor Keith argues that after making all allowance for individual variations, there remains a considerable percentage of cases in which the delay at one or more of these points is so long that it must be regarded as pathological. He notes that clinicians have for years spoken of such clinical entities as gastric stasis, duodenal stasis, ileal stasis, stasis in the proximal or distal colon; to these already recognized forms of enterostasis he proposes to add two more, namely, "oesophageal stasis" and "rectal stasis." At each of these seven points we must suppose that some sort of a sphincter mechanism exists, and that each of these seven forms of entero-

stasis is due to abnormal activity of the corresponding sphincter mechanism.

Of what anatomical elements do these sphincter mechanisms consist? Professor Keith gives a full account of the researches made by himself and others in the attempt to answer this question. Without going at all deeply into the details he gives, it is enough to say that he draws a comparison between the "nodal" and "bundle" systems that initiate and regulate the heart's action, and the composite myenteric plexus, known as Auerbach's plexus, in the intestine. He describes this plexus as containing ganglion cells, abundant fine nerve fibres, and peculiar branching intermediate cells that are not connective tissue cells, but have processes uniting with unstriated muscle cells on the one hand, and the true ganglion cells on the other. These intermediate cells, recognized long ago by Kölliker, do not seem to have met with the recognition that is their due at the hands of either histologists, pathologists, or clinicians. Elliott in 1904 recorded the fact that adrenalin has the same effect on the lower ileal tract as stimulation of the splanchnic nerve; in both cases the ileo-colic sphincter contracts, while the rest of the ileal musculature is inhibited. Professor Keith suggests that it is upon these intermediate cells, interspersed between the splanchnic nerve and the muscle fibres, that the adrenalin acts. He gives reasons for believing that the gastro-oesophageal junction contains a nodal centre rich in these intermediate cells, at which the rhythmical peristaltic contractions of the stomach are initiated. Proximal to the entry of the common bile duct is a similar area in the duodenum, with analogous functions; this fact throws light on the observation, often made by skiagraphers, that the first part of the duodenum shows but limited contractility, while peristaltic propulsion waves appear to arise in its second part. The ileo-colic junction is another nodal centre, acting as pacemaker for the peristaltic contractions of the caecum and ascending colon. The large intestine itself, while lacking any special plexus or area of nodal tissue, or tissue rich in intermediate cells, is richly supplied with them throughout; this is particularly the case with the distal part of the transverse colon, the descending and iliac colon, and the rectum. Criticizing Sir William Arbuthnot Lane's view that stasis in the large intestine is mainly a mechanical affair, dependent on the obstruction caused by kinks in the gut, peritoneal bands or adhesions, and the like, Professor Keith points out that skiagrams produce no evidence of obstruction situated at bands or kinks in these regions, and that there is no hypertrophy of the muscular coats above the sites of such kinks or bands. Acute flexures of the bowel produced experimentally do not lead to intestinal stasis; it is, indeed, very difficult to produce obstruction by twisting, coiling, or folding the large bowel.

In summing up the matter, Professor Keith remarks that he does not think that either mechanical conditions or even derangements of sphincteric mechanisms can give an adequate explanation of all the phenomena of enterostasis. The extra factor requisite he describes as a lack of co-ordination between one or more of the nodal points or rhythmical zones of the alimentary tract; points, that is to say, acting as peristaltic pacemakers for the distal segment of the bowel. So far he distinguishes four rhythmical zones in the bowel—namely, a duodenal, a jejuno-colic, a proximal colic, and a distal colic. Though the evidence is at present imperfect there are grounds for presuming two more—an oesophageal and a gastric. The production of

¹ A New Theory of the Causation of Enterostasis. *West London Medical Journal*, July 2nd, 1915. A short abstract appeared in the *BRITISH MEDICAL JOURNAL* of July 3rd, p. 14.

enterostasis is to be compared with the production of heart-block. In each there is a defect or irregular action of either the nodal or the conducting systems, or of both. When such an irregularity or block appears, its effect is naturally to be looked for at the points where one rhythmical zone or area passes into the succeeding zone. It is clear that in order to obtain an orderly propulsion of food along the whole length of the alimentary canal, its various rhythmical zones must be closely co-ordinated in their action by means of a complicated system of reflexes. Disturbance in any one segment upsets the rhythm in all the segments; and this explains how it is that distension of the duodenum, for example, inhibits the action of the ileum, and why a duodenal disturbance further upsets the rhythm of the stomach. Disturbance in the excitability or rhythm of the pacemaker of the caecum will be reflected backwards to the lower ileum, and so stasis in the large intestine may give rise to stasis in the ileum, in the duodenum, and even in the stomach. It is clear that Professor Keith's ambitious scheme for the explanation of enterostasis breaks new ground in a most interesting manner, and is worthy of the attention of both clinicians and the experts in abdominal surgery.

THE ORIGIN OF LIFE QUESTION.

THE recently published number of the *Proceedings of the Royal Society of Medicine* contains an illustrated communication from Dr. Charlton Bastian, F.R.S., entitled "The Importance of Tyrosine as an Aid in the Demonstration of the Present-day *de Novo* Origin of Living Organisms," in which he deals with the effects produced by small quantities of a dilute solution of this synthetic compound when sterilized and added, with the necessary precautions, to tubes containing saline solutions of five different kinds (whose composition is given) which five to ten months previously had been enclosed in hermetically sealed tubes, and then sterilized by boiling for twenty minutes on three successive days. Tyrosine is one of the most powerful of the anxieties whose influence in producing multiplication of cells and of minute amoebae had been shown by some of the McFadden researchers. It was recommended by one of them to Dr. Bastian for use in two ways—first, as an addition to tubes whose contents were ripe for examination; and, secondly, as an addition to the original saline solutions previous to their enclosure within the tubes, in the hope of thereby possibly shortening the long period of probation generally needed before recognizable living organisms can be found within the tubes. The first mode of testing its influence was carried out on a large number of tubes ripe for examination by adding twenty drops of the freshly sterilized tyrosine solution to each tube when it was opened. The tubes were then immediately reclosed and replaced in the incubator for three to four weeks. When the contents of these tubes were re-examined after such an interval, a very considerable growth and multiplication of organisms was found to have taken place, thus tending to disprove the two principal objections which had been urged against the original experiments—namely, (1) that what were found were mere simulacra or pseudo-organisms; or, (2) as others believed, were only dead organisms pre-existing in the solutions. In order to test the second possible influence of tyrosine similar small quantities of the solution were added to a large number of tubes containing some of the same five sets of solutions, freshly prepared, with which other tubes were charged, sealed, and sterilized. After these tubes had been in the incubator for three to four months many of them were examined, but no organisms could be found, and the small deposits were more or less altered in character. This initial use of the tyrosine, far from acting as it was hoped,

seemed therefore to be actually injurious, and to prevent the formation of organisms. But, seeing that the same materials were used in the preparation of the solutions, that the tubes were treated in the same way, and that their contents were examined in the same manner, Dr. Bastian held that other objections (3) urged by some critics were likewise invalidated. The absence of organisms now tended to show that in the first series the organisms found were not likely to have come "from an impure pipette or to have dropped from the atmosphere on to the microscope slide before the cover-glass has been applied"; thus being the only other surmises hitherto adduced by critics.

INVESTIGATION OF COLONIAL AND INDIAN DRUGS.

IN view of the enormous geographical extent of the British Empire, and of the fact that it comprises practically every variety of climate, a systematic investigation of the natural vegetable products of the less developed countries can hardly fail to lead to the utilization of a considerable number at present unknown, and the commercial and economic value of such investigation is very great. A considerable part of the work of the Imperial Institute is devoted to such examination of products from different parts of the empire, and the current number of the *Bulletin*¹ contains summaries of some of the investigations carried out in recent years on drugs from Africa, India, and other parts. In some instances valuable results have been obtained, while in other cases, as was to be expected, they have been negative. Among the former may be mentioned the examination of the rhizome and rootlets of *Podophyllum emodi*, which showed this plant to be a valuable source of the drug podophyllin, and has led to its recognition in the *British Pharmacopoeia*. The present great scarcity of atropine gives special interest to the investigation of the Egyptian plant *Hyoscyamus muticus*, which showed it to be a valuable source of hyoscyamine, from which atropine can be obtained by isomeric conversion. The seeds of *Croton elliotianus*, from East Africa, have been found to contain an oil having purgative properties in quite small doses, but devoid of the vesicating and irritant resinous constituents present in ordinary croton oil (from *C. tiglium*); the physiological action of the oil was investigated by Dr. J. T. Cash and Mr. W. J. Dilling, who regard it as "a body which would be of considerable value as an addition to purgative remedies, for some of the more drastic and irritant of which it would prove a safe and effective substitute." "Native drugs"—that is, products which have a reputation as medicines among the natives of the country of origin—have, as a rule, given disappointing results; not only has chemical examination failed in some cases to detect any constituents to which the reputed activity could be due, but physiological tests carried out with extracts have shown that the drugs do not, in fact, possess the properties ascribed to them. This is, perhaps, not very surprising; but in one case at least—that of the fruit and leaves of the Afon tree (*Treculia africana*) from Lagos—a drug reputed to be poisonous was found to be harmless. The Commissioner of Abeokuta had reported that it was impossible to take horses to certain districts in the colony owing to water-holes and streams being poisoned by its leaves, while the Director of Forests and Agriculture and the Government chemist attributed the poisonous properties to the fruit of the tree; aqueous and alcoholic extracts of fruits and leaves, however, were all found to be non-poisonous to animals. The *Bulletin* contains also several other interesting papers, of less interest from the medical point of view.

¹*Bulletin of the Imperial Institute*. A quarterly record of progress in tropical agriculture and industries and the commercial utilization of the natural resources of the Colonies and India. Edited by the Director and prepared by the scientific and technical staff of the Imperial Institute and by other contributors. Vol. xiii, No. 1, January-March, 1915. London: John Murray, Albemarle Street, W. (Med. Soc. pp. 184. 2s. 6d. net.)

HEMERALOPIA AMONGST SOLDIERS.

SINCE an ophthalmic department was attached to the fourth German army in the middle of January so many cases of hemeralopia occurred that, according to Professor Braunschweig,¹ the disease had assumed epidemic proportions. In a period of only four weeks he observed 23 cases, which were collected from many different sources. Though this number was not striking by itself, it was obvious that when, out of 98 patients treated in hospital for diseases of the eye, 22 suffered from night-blindness, this disease must have been abnormally frequent. The patients complained of inability to see in the dark, of stumbling into pits made by shells, of inability to drive their horses in the dusk, and of a sense of insecurity and helplessness. In most cases several weeks, and even months, had passed before these patients were driven by anxiety and depression to report themselves as unwell. Their ages ranged from 17 to 46, within which limits the disease showed no striking age incidence; nor was there any striking relation between the health and vitality of the patients and their symptoms. A few were weakly, but the majority were robust, and showed no signs of organic disease. In many cases there was slight conjunctivitis or blepharitis, and in about two-thirds of the total there was some error of refraction. When these errors, however slight, were corrected by glasses, the patients felt much better. It seemed, therefore, that the hemeralopia must have been largely provoked by these organic abnormalities of the eye. Bitot's spots were never found in these cases, which was all the more strange as in some forms of hemeralopia observed in times of peace they are invariably present. Many of the patients traced their symptoms to the constant strain on the eyes caused by peering through the darkness in the trenches, and on the roads when driving. This view was probably correct, and the symptoms were, no doubt, aggravated by the great physical and mental strain imposed by the war. Malingering and suggestion were, of course, suspected, but in no case was either definitely detected. As the patients were recruited from numerous companies and over a wide area, and as there were no localities or companies in which the incidence of the disease was disproportionately great, suggestion could hardly have played any part. Only in two cases was malingering a likely cause of the symptoms, the patients complaining of failing eyesight by day as well as by night, although there was no sign to support their assertions. The treatment consisted of correcting errors of refraction, relieving the conjunctivitis and blepharitis, rest in hospital, cod-liver oil, iron, and arsenic given internally, a liberal diet, and uninterrupted sleep. How far this treatment was effective Professor Braunschweig did not venture to say, but he hoped to make his patients fit for active service again in a few weeks, and did not anticipate permanent disablement in the majority of his cases.

"NERVE SHOCK" IN WAR.

A LARGE crop of papers has lately appeared in the German medical press dealing with the organic and functional nervous disorders provoked by modern warfare. Most of the writers agree in refusing to recognize "war psychosis" as a new disease peculiar to modern warfare. It is maintained that the nervous breakdown, which is a common sequel of participation in battles of to-day, is practically confined to persons who are already subject to nervous instability, or in other words, that the strain of modern warfare is merely an exciting cause of "nerve shock," and that many of the sufferers would, under ordinary conditions, have broken down sooner or later. A. Sarbo² has described the organic changes observed in the nervous system as a result of the explosion of shells. The lesions of the brain and cord were, he considered, due partly to

concussion of the cerebro-spinal fluid and partly to concussion of the nerve substance itself. The concussion caused a variety of conditions, ranging from sudden death from diffuse haemorrhage to transitory giddiness or slight staggering. Sarbo describes the two following well-defined groups of symptoms: In the one case the patient suddenly falls down senseless and, on regaining consciousness a little later, notices some deafness on one or both sides, tinnitus and giddiness. In addition to these symptoms, which are primarily due to injury of the auditory centre in the medulla, there are in some cases vague symptoms, such as irregular action of the heart, and bilateral paralysis of the recurrent branch of the vagus. In the other group the patient becomes unconscious, and does not recover consciousness till he is admitted to hospital, where he remembers only incidents preceding the explosion. His speech is slow and laboured, and many words are omitted. There is spastic paralysis of the limbs on one or both sides. Babinski's sign is absent, but the parietal bone is tender on percussion on the paralysed side. These symptoms are due to "micro-organic changes in the parietal convolutions." The prognosis is good in both forms. Sarbo insists that these symptoms are not due to hysteria, and that those who suffer from "nerve shock" require the greatest possible mental and physical rest. Karplus³ has observed 43 cases of injury to the nervous system without macroscopic organic changes. In 16 cases vasomotor symptoms were complicated by neurasthenia, but, with four exceptions, these patients came of nervous stock, and many of them had been under treatment before the war broke out. Karplus attaches far greater importance to the patient's "pre-morbid personality" than to the force of the explosion, and points out that in some cases the symptoms appeared before an explosion; in others, not until some time after the explosion. Many cases were met with showing that explosions did not cause "nerve shock" until the patient was underfed or exhausted. Karplus agrees with Sarbo in giving a favourable prognosis. The same view is held by H. Singer,⁴ who also attaches great importance to exhaustion as a supplementary cause of "nerve shock" following explosions. In the subjects of hysteria he observed giddiness, fits, excitation or stupor, abasia, lassitude, insomnia, and cardio-vascular symptoms. Though the prognosis was good in most cases, the prospect of discharge from the army was apt to delay recovery. Among the subjects of neurasthenia hallucinations were not uncommon after long marches and sentry duty; and many a false alarm was due to visions of houses, airships, lights, etc. Though Singer does not accept "war psychosis" as a new nosological phenomenon, he believes that this war will produce a greater proportion of mental disease than earlier wars, though he qualifies this on the ground that, as the diagnosis of mental diseases is made more readily than it was, this increase may be more apparent than real.

THE PLAGUE OF FLIES.

THE National League for Physical Education and Improvement has organized a national campaign to prevent the spread of epidemics by insects in war time. The inaugural meeting was held at the Mansion House on Monday, July 5th, under the presidency of Bishop Boyd Carpenter. Letters expressing sympathy with the objects of the campaign were received from the Lord Chancellor, Mr. Walter Long, M.P., Sir Edward Carson, M.P., Sir Clifford Allbutt, Sir James Crichton-Browne, Sir Alfred Keogh, Dr. Mary Scharlieb, Sir Thomas Barlow, Sir Lauder Brunton, Sir Rickman Godlee, Dr. Hector Munro, Sir Ronald Ross, and many other well-known persons. On the platform were representatives of the War Office, the Admiralty, the Local Government Board, and the joint committee of the British

Red Cross Society and the Order of St. John of Jerusalem. Sir Frederick Treves, who was to have presided, was prevented from being present by illness. He wrote from his sick bed that in South Africa during the war there were more casualties due to flies than to bullets. "In France the presence of so many unburied dead makes the fly question a very serious one. In Alexandria, owing to the vast number of cavalry horse lines near the town, the trouble of the flies is becoming really distressing. It only wants a definite source of infection to be introduced for an epidemic to run rampant. A fly should be looked upon as nothing but a spreader of disease." Sir Frederick Treves went on to say that when once the people realized what the fly could do, the remedy was easy. Fly-borne disease should cease to exist. Dr. Sambon said flies must be dealt with as Gorgas dealt with the mosquito. The recent outbreak of typhus in Serbia killed more men than did the Austrians. Professor Lefroy said that the house-fly carried summer diarrhoea from child to child, and thus killed from 5,000 to 15,000 children under one year old annually. It also carried typhoid and cholera. This was going to be a fly year. He protested that the open manure heap was a danger and a scandal, and should be prohibited. Dr. F. J. Allan, medical officer of health for the City of Westminster, dwelt on the importance of complete daily collecting of dust and refuse from dwellings where no facilities existed for its sanitary destruction. The keeping of house refuse, etc., in open bins and small buckets that enabled children to play with the garbage they contained, or for the contents to be scattered about in the vicinity of the house, and often, indeed, within some portion of the house itself, was, at this critical period, a grave menace to the country. We most heartily wish the National League for Physical Education and Improvement the fullest success in the campaign it has undertaken.

OXFORD OPHTHALMOLOGICAL CONGRESS.

The next meeting of the Oxford Ophthalmological Congress will be held at Keble College on Thursday, July 15th, and Friday, July 16th. The Master is Mr. Sydney Stephenson; the Deputy Master, Mr. Philip H. Adams; the Honorary Treasurer, Sir Anderson Critchett; the Honorary Secretary, Mr. Bernard Cridland. Mr. Robert W. Dayne is Past-Master. Papers will be read and discussions take place in the Department of Human Anatomy in the University Museum. Scientific and Commercial Museums will also be housed in the same building, which is close to Keble Lodge. On the first day lantern addresses will be given by Lieutenant-Colonel R. H. Elliot on the Indian conchling operation, and by Sir St. Clair Thomson on the surgical anatomy of the nose and its accessory sinuses in relation to the eye and orbit. The following communications will also be presented:—Mr. Harrison Butler: The tragedy of sclerotoxemia, six cases of late infection. Mr. Stephen Mayou: Mooren's ulcer of the cornea. Mr. W. H. H. Jessop: On the papilloedema of vault injuries in the present war. Sir Mackenzie Davidson: The use of the telephone detector for foreign metallic bodies in ocular surgery. Among the demonstrations and exhibits in the Scientific Museum will be the following:—Mr. Sydney Stephenson and Lieutenant-Colonel Elliot: A microscopic demonstration of the results of trephining in animals' eyes. Dr. F. W. Edridge-Green: An apparatus showing the fundamental principles of binocular vision. Mr. W. H. H. Jessop: Skiagrams of orbital and ocular wounds. On the second day a discussion on industrial diseases and accidents will be opened by Dr. Frank Shuffelbotham, of Newcastle-under-Lyne, and will be continued according to the following programme:—Coal-miners' nystagmus: (a) Prognosis: Mr. A. C. Norman (Sunderland); (b) Symptomatology: Mr. Percival J. Hay (Sheffield). Eye

injuries caused by occupation, their prevention and first-aid treatment: Dr. Edgar L. Collis. Industrial cataract: Dr. William Robison. Plumbism as it affects the eye: Dr. S. McMurray. Defects and injuries of the eye caused by steel furnace work: Mr. S. H. Pooley. Some of the rarer industrial diseases and injuries of the eye: Mr. Sydney Stephenson. Dr. John Gray Clegg will also contribute a paper. Full information may be obtained from the Honorary Secretary, Mr. Bernard Cridland, Wolverhampton.

BOSSUET AS A BIOLOGIST.

BOSSUET is probably best known to most students of French literature as a preacher, especially of funeral orations. These gained for him the title of the "Eagle of Meaux," of which he was bishop, and so good a judge as La Bruyère called him the Demosthenes of the pulpit. But he was much more than a Court preacher; he was one of the most conspicuous among the men of genius whom the "Sun King" gathered about his throne, and whose brilliancy cast a reflected lustre on his own commonplace personality. Bossuet was a controversialist of the highest order, and his discourse on universal history had a powerful influence on many generations. It was written to train the mind of the Dauphin, whose tutor Bossuet was for several years. How seriously Bossuet took his duties may be gathered further from the treatise, *De la Connaissance de Dieu et de Soi-Même*, written for the same purpose. It did not see the light till long after the death of the author, when the manuscript was found among the papers of Fénelon, the tutor of that Duke of Burgundy whose untimely death probably changed the course of French history. Bossuet studied anatomy and physiology in no amateurish fashion, but got his knowledge from Nature at first hand with the help of Duverney, author of the first treatise on diseases of the ear written in French, who was associated with him in the teaching of the Dauphin, and of two other distinguished anatomists—Stenson, or Steno, and Winslow—captives of his controversial bow and spear. The late Professor Le Double, of Tours, whose death was a great loss not only to anatomy but to medical history, devoted a solid treatise to Bossuet as an anatomist and physiologist.¹ He says Bossuet's book was the first work on human anatomy and physiology written in French. He shows how firmly Bossuet had grasped the fundamental truth that to understand human nature it is necessary to begin by knowing the constitution of the human body. Bossuet based his psychology on the observation of man, in whom he saw a microcosm in which every kind of mechanism was exemplified. M. Le Double follows him through his accounts of the external senses, the internal senses, the passions, the correlation of soul and body, and the soul of beasts, explaining his author's meaning, illustrating his teaching with sidelights from ancient and modern sources, criticizing and correcting him when necessary, but always treating him in a respectful and sympathetic spirit. Le Double points out that in seeking to reconcile dogma, reason, and science, Bossuet was with Descartes one of the founders of psycho-physiology. It was a bold thing, especially for a bishop, in the reign of Louis XIV to write a book on anatomy and physiology in the vulgar tongue and with the freedom of a philosopher anxious to find a reason for his faith. M. Le Double's work is one that should interest physiologists and anatomists, and especially psychologists. It is a critical review of the physiology of the seventeenth century in the light of modern knowledge, illustrated by much curious learning as to the beliefs and teachings of older times. It may be recommended to lecturers and writers on physiology and anatomy as a storehouse of references and quotations

¹ *Bossuet, Anatomiste et Physiologiste*. Par M. le Professeur A. P. Le Double. Préface en vers par M. H. Henrion. Paris: Vigot (1911). 213s. (Med. Rev. pp. 322; 7 figures, 2 photographs. Fr. 5.)

which may help to relieve the dryness of their subject. It contains well executed portraits of Bossuet himself, of his pupil the Dauphin, and of Winslow, Stenson, Descartes, and others.

HOSPITALS AND DUTY-FREE ALCOHOL.

WE understand that, since the Chancellor of the Exchequer undertook to reconsider his proposal to give duty-free alcohol to hospitals with a view to reintroducing the clause in an amended form on the report stage,¹ communications have taken place between Mr. Bridgeman, Junior Lord of the Treasury, who is well known to be greatly interested in the matter, and representatives of the British Medical Association and the Pharmaceutical Society. It is hoped that as a result of negotiations the concession to the hospitals may be made in a new form not open to the objections taken by the two societies as regards the original clause.

SPIROCHAETES IN THE BRAIN IN PARALYTIC DEMENTIA.

THE demonstration of *Spirochaeta pallida* in the brains of patients dying of general paralysis of the insane, or dementia paralytica, was effected by Noguchi and others in America some little time ago. McIntosh and Fildes² have quite recently published an account of the technique they employed in 1914 for the purpose of this demonstration, noting that hitherto there has been no detailed publication on the subject in this country. The brain substance should be examined fresh, by the method of dark-ground illumination; the most satisfactory illuminator is the parabolic condenser of Zeiss, associated with a $\frac{1}{4}$ in. objective with a correction collar, and a No. 6 compensating ocular. The best source of light is a small arc lamp. A small fragment of cortical grey matter about the size of a pin's head is removed from the specimen and broken up in a drop of saline in a watch-glass; the tissue should not be thoroughly emulsified, since the specimen will then be too opaque for satisfactory examination. A small quantity of the fluid is next placed on a slide and examined for five or ten minutes, and if the examination is then negative a new area of the cortex may be taken in hand. Wherever spirochaetes are found, that portion of the brain may be fixed in formalin and stained by Noguchi's modification of Levaditi's method for demonstrating spirochaetes in sections. It is clear that the dark-ground technique gives no information as to the relation of the organisms to the surrounding tissues; but it very much facilitates the examination of sections, and almost ensures that spirochaetes should be present in the fragment selected for fixing and staining. The detection of spirochaetes in stained sections of the brain is often extremely difficult, as the organisms may be degenerate or atypical, and may be distinguishable from nerve fibrils that chance to have taken up the silver also. It is only when areas are found in which the fibrils are unstained, or when a focus contains typical as well as atypical spirochaetes, that the diagnosis can be made with confidence. McIntosh and Fildes examined the brains of seven cases of paralytic dementia, and by the dark-ground method found spirochaetes in six of them. In addition five cases were examined in which the symptoms suggested the diagnosis of dementia paralytica, but this proved incorrect at the autopsy; in these no spirochaetes were found. All the paralytic cases examined had exhibited relatively acute manifestations before death, and the brains with one exception were not much wasted; the lesions on the whole appeared to be recent. The spirochaetes were always confined to the grey matter; in one case only was a single specimen seen in the meninges. They tend to occur in groups; it is unusual to find a single spirochaete unaccompanied by several others in the

vicinity. They were more or less superficial, and no constant relation between them and the nerve cells or blood vessels could be observed. Some spirochaetes appeared to be applied to nerve cells, but this distribution was not striking. In fact, they seemed to be scattered quite fortuitously about the superficial layers of the cortex, independently of cellular infiltrations. It may be noted that although spirochaetes were found by the dark-ground method in six of the brains, they could only be detected in the cut sections of three of the six. It is clear that the method of staining and section presents greater difficulties than the other, and ensures the detection of the spirochaetes only when they are numerous.

WE regret to announce the death at Bishopston, Renfrewshire, of Dr. Bruce Goff, formerly of Botolphwell, which took place on July 4th, aged 81. Dr. Bruce Goff was a member of the Central Council for many years, and took a prominent part in the conduct of the affairs of the Association. We hope to publish an obituary notice in a later issue.

Medical Notes in Parliament.

Royal Army Medical Corps.—Sir John Lonsdale asked the Under Secretary for War, on July 1st, whether certain lieutenants of the Royal Army Medical Corps Special Reserve serving in France were given to understand some months ago that their names had been noted for transfer to the Regular Royal Army Medical Corps; whether they had been gazetted accordingly, and, if not, when they might expect to be gazetted; whether their transfer on being gazetted would be antedated to the time that they were noted for the change; and whether, as the transfer was entered in some cases before the recent general promotion of Regular Royal Army Medical Corps lieutenants to be captains, those who were noted for transfer prior to the general promotion would be included in the list for captaincy and be gazetted accordingly. Mr. Tennant said that no promise of a transfer to the Regular Royal Army Medical Corps had been given, but a certain number of lieutenants of the Special Reserve and temporary lieutenants had made applications for permanent commissions in the Royal Army Medical Corps, and their requests had been noted for consideration in the event of it being decided to give direct commission instead of, in the usual way, by open competition. The question of the date from which such appointments would take effect and what rank would be given would be for consideration when the matter was settled. Mr. Jowett, on July 1st, asked the Under Secretary for War if he would undertake to refrain from transferring men who enlisted in the Royal Army Medical Corps before the passage of the Army Act Amendment (No. 2) Act from the non-combatant to the combatant branches of the service, having regard to the fact that the men in question enlisted in the belief and, so far as they knew, on the distinct understanding that their services would be utilized for the purpose for which they were volunteered. Mr. Tennant said he could not give any absolute pledge to abstain from using, in the case of men of the Royal Army Medical Corps, the powers conferred by the Act to which he referred, but he thought he could give an assurance that the consideration he urged would be borne fully in mind. Mr. Hogge: Will my right hon. friend at least guarantee that he will give these men a choice? Mr. Tennant said, in reply to subsequent questions by Mr. Hogge, that the War Office always endeavoured to carry out the wishes of the men in the matter of transfer, and that he was looking into the matter regarding the members of the Scottish Royal Army Medical Corps who desired to join the Royal Scots and were not allowed to do so.

Medical Consultants.—Sir J. Lonsdale asked the Secretary to the Admiralty the terms of the new arrangement made with medical consultants at Royal Naval hospitals. Dr. Macnamara, Parliamentary Secretary to the Admiralty, said that the new arrangement was that seven consultants

¹ See BRITISH MEDICAL JOURNAL, July 3rd, p. 23.
² Brain, London, 1915, xxxvii, 401.

should be given temporary commissions as Surgeons-General, with the pay and allowances of that rank—namely:

Full pay	£ 1,300	s. 0	d. 0	per annum
House allowance	70	0	0	..

and two temporary commissions as Fleet Surgeons of ten years' seniority, with the pay and allowances of that rank—namely:

Full pay	£ 638	s. 15	d. 0	per annum
House allowance	50	0	0	..
Hospital allowance	53	0	0	..

As in the case of other naval medical officers, they had been informed that their appointments would not entirely preclude their engaging in private practice, provided it was clearly understood that such practice did not interfere with the performance of their naval duties. Sir J. Lousdale asked if it would not have been better if this practice had been availed of from the beginning instead of having salaries of £5,000. Dr. Macnamara said he could not answer that question, but he desired to say on behalf of these very distinguished gentlemen that they readily acquiesced in this alteration in the most patriotic way. Dr. Macnamara added, in reply to Mr. Watt, that there were seven consultants and then there were two others; the Admiralty had not added to them.

Science and the War.—Mr. Lloyd George stated, in reply to Sir Philip Magnus, on July 1st, that he was fully alive to the great importance of securing the co-operation of scientific workers throughout the country, and of utilizing, so far as practicable, the laboratories and workshops of universities and technical schools for experiments and for the making of munitions of war or parts thereof. He was unable at present to make a detailed statement with regard to the establishment of a central committee or bureau for dealing with inventions and practical scientific questions incidental to the operations of the war. He expressed his appreciation of the valuable help which was already being ungrudgingly given to the Ministry of Munitions by men of science and by scientific authorities and institutions.

Medical Students and the War.—Sir Clement Kinloch-Cooke asked the Under Secretary of State for War on June 30th whether, in view of the necessity of securing the services of as many medical men as possible for the army, he would consider the suggestion of giving the rank of sublieutenant to medical students who have passed their second M.B. examination and were willing to join the Royal Army Medical Corps for the duration of the war? Mr. Tennant said that students of sufficient seniority and medical training to be of use in the army in the way suggested would be better employed if they continued at their medical schools and qualified as medical men as soon as possible. They would then be eligible for commissions in the Royal Army Medical Corps. The services of senior students were required to help in carrying on the work in the large civil hospitals connected with their teaching schools. Nearly all of these hospitals were providing accommodation for sick and wounded soldiers, and their staffs were very hard worked. It was not proposed to admit into the commissioned ranks of the Royal Army Medical Corps any candidates who were not fully qualified medical men. In reply to subsequent questions by Sir Henry Craik, Mr. Tennant said that care would be taken not to give way to any such suggestion as giving a titular name which would imply experience when that experience is not possessed.

Abdominal Wounds.—Mr. Hugh Law asked the Under Secretary of State for War, on July 5th, if he could state approximately the number of men who had died in hospital as the result of abdominal wounds received in the western area of war, and what proportion such cases bore to the total number of men suffering from such wounds. Mr. Tennant said he was afraid this information could not be given without asking the medical authorities in France for a return, and they were already heavily burdened. In reply to a subsequent question, Mr. Tennant said that the Chelsea Commissioners had up to date received reports of

782 cases in which it had been necessary to amputate one or more limbs of men admitted to hospitals at home or in France.

Territorial Force Medical Branch.—Commander Bellairs asked the Under Secretary of State for War, on July 6th, in view of the fact that the medical branch was the only executive branch of the Territorial Force which had a regulation preventing promotion until after three years' service, whether the War Office could see their way to alter the rule so as to induce more medical men to join and as an act of justice to those who had already joined? Mr. Tennant said that the question was already under consideration.

Recruits and Defective Eyesight.—Colonel Yate asked, on July 5th, whether men were now permitted to enlist whose defects of eyesight could be corrected by glasses? Mr. Tennant said that those who wore glasses were not prevented from enlisting unless their eyesight was defective beyond a definite limit; such men were allowed to join the army for certain definite purposes, such as drill instructors, shoeing smiths, Army Veterinary Corps, etc.

Naval and Military Casualties in Dardanelles.—Mr. Joynson-Hicks asked the Prime Minister what is the total number of casualties divided into killed, wounded, and missing in the Dardanelles campaign. The Prime Minister stated, on July 1st, in reply to Mr. Joynson-Hicks, that the total casualties sustained by both naval and military forces up to May 31st were as follows:

	Officers.	Men.
Killed	496	6,927
Wounded	1,134	23,542
Missing	92	6,445
	1,722	36,914
	38,636	

Appointment of Majors.—Colonel Yate asked the Under Secretary for War, on July 5th, whether, in view of the fact that in twelve field ambulances and three casualty stations now at the front, in which by the war establishment strength there should be thirty majors, there were now only two majors actually employed, and these two were doing the work of lieutenant colonels, he would take steps to remedy the deficiency by promoting the requisite number of captains, Royal Army Medical Corps, to the rank of major? Mr. Tennant said that the promotion of a considerable number of captains was already under consideration.

Surgeons and Agents, R.N.—Dr. Macnamara stated, on July 5th, in answer to Commander Bellairs, that the question of giving a distinctive rank to medical men holding the position of surgeon and agent had been carefully considered, but it was not thought necessary to give them such rank; their services were part-time only.

Hospitals and Duty-Free Alcohol.—Mr. King, on July 6th, asked the Chancellor of the Exchequer whether, in reference to the proposal to relieve hospitals from the payment of duty on alcohol used medicinally, he had consulted authorities on the temperance question as to the possible dangers of an increased use of tinctures and other forms of alcohol which must ensue if the cost of such medicines was substantially reduced. The Chancellor of the Exchequer said he had not thought it necessary to take this step, as he had no reason to suppose that the grant of the concession would lead to abuse. The effect of the proposal would be not to relieve hospitals from the payment of duty on all spirits used medicinally—for example, brandy—but only to exempt spirits used in the preparation of tinctures and other articles to be used for medical purposes. Mr. King suggested that, in order to prevent discussions and divisions on the report stage of the Finance Bill, some temperance authority should be consulted. Mr. McKenna replied that Mr. Bridgeman, who had the particular amendment in hand, was consulting various bodies.

Inoculation.—Mr. Tennant stated, on July 1st, in reply to Mr. Chancellor, that in the Expeditionary Force in France there had been up to May 22nd, 1915, 297 cases of paratyphoid, with ten deaths. There were no figures available to show in how many of these cases there had been inoculation against typhoid. Mr. G. Greenwood asked whether paratyphoid was not merely another name for typhoid when it manifested itself in persons who ought not to have it because they had been inoculated? Mr. Tennant said that he was informed that it was a disease wholly distinct from typhoid. In reply to another question by Mr. Chancellor, on July 1st, Mr. Tennant said that in the Expeditionary Force in France there had been up to May 22nd, 1915, 827 cases with 128 deaths. Of these cases 508 occurred amongst the uninoculated, and of these 106 died; of the remaining 319 cases which occurred amongst the inoculated 22 were fatal. The House would be interested to know that the ratio of attacks was fourteen times and of deaths forty-two times greater amongst the uninoculated men. Mr. Chancellor inquired if the figures averaged over the whole period, including the period when the 60 per cent. or 70 per cent. of the men were uninoculated, or merely dealt with the figures relating to the present day? Mr. Tennant replied that he was dealing with the figures for the whole of the campaign—from the beginning of August. Mr. Tennant stated, on July 5th, in reply to Mr. W. Thorne, that men in the Berkshire Regiment were not being refused leave because they were uninoculated; in point of fact, nearly 99 per cent. of the men in question were inoculated. In reply to a supplementary question, Mr. Tennant undertook to treat as private any information on the point supplied to him.

Vaccination.—In replying to Mr. Sutton, on July 1st, the President of the Local Government Board gave the following figures of the number of births registered, the number of certificates of exemption from vaccination received, the percentage of exemptions to births, and the percentage of children ultimately unvaccinated, for the years 1906 to 1914 inclusive.

Year.	No. of Births Registered During the Year.	No. of Exemptions Received During the Year.	Percentage of Exemptions to Births.	Percentage of Children Ultimately Unvaccinated.
1906	935,081	52,391	5.6	16.8
1907	918,042	57,675	6.3	20.4
1908	940,385	152,739	17.3	27.9
1909	914,472	190,689	20.9	32.3
1910	896,962	220,547	25.7	36.3
1911	881,138	248,483	28.2	38.9
1912	872,737	275,229	31.6	42.9
1913	881,890	308,275	35.0	+
1914	878,822	321,280*	36.6*	+

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

The proceedings of the *séance* of May 27th of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés have reached the Honorary Secretary of the Belgian Doctors' and Pharmacists' Relief Fund through Professor Jacobs. The total of subscriptions received was announced as 76,356 francs, new subscriptions of over 1,000 francs having come in during the past week. The transfer of £240 to the Comité National for drugs, two grants of 700 francs each, and a petty cash expenditure of nearly £20 reduced the actual sum in hand to £740. A letter was read from a Belgian doctor in England asking that his grant should be paid into a bank for him, but it was decided that help could only be given to those still on Belgian soil, and the applicant was referred to the British Committee.

M. Coppez reported that the pharmacists were well organized, but that the circular asking for subscriptions from medical men had not reached all whom it concerned.

M. Laruelle reported on several cases of medical men requiring assistance. He gave details of the plight of four medical men, all married men with families, whose houses had been burnt or pillaged, and who had lost furniture, books, instruments, and drugs. As all, however,

had some resources remaining, the Committee decided to make no grants for the present. Of one of these doctors it was stated that he had been forced to march in front of an attacking German force and had received several wounds.

M. Bruegelmans reported on the case of four pharmacists.

1. A. V. M., of L—, has six persons in his family to support from the receipts of a shop started in the neighbourhood of his previous establishment in L—, utterly destroyed. The Committee voted three "mensualities" of 200 francs for the months of June, July, and August.

2. L. L., of D—, has to support a wife and three children. He had previously refused the help of the Committee, but his attempt to carry on business had failed, and a medical friend had recommended his case to the Committee as critical. A grant of 700 francs was made.

3. J. S., of G— R—, was killed during the bombardment of the place, and his premises were much damaged. His brother assumed charge of his affairs, and entered into engagements to preserve and restore the property, which he cannot keep, as he, too, is now ruined. The children and widow are in France. The Committee decided to help the brother's attempt to preserve the property by making monthly allowances of 200 francs for July, August, and September, and by a grant of 700 francs.

4. A. de K., of L—. His premises were burnt, and for several months he was a prisoner in Germany. His physical and mental depression precludes him from earning his living, and until now he has been supported by a generous friend. Mensualities of 200 francs were granted for June, July, and August.

A short discussion followed on the supply of instruments to medical men. M. Jacques proposed that the Committee should endeavour to make purchases to meet the requests for instruments, and M. Coelst thought that grants in money might be made so that the medical man could purchase what he wanted. M. Jacques pointed out that some medical men, though needing instruments to replace what they had lost, were disinclined to approach the Committee. On the motion of M. Laruelle it was proposed to examine all the requests made for instruments and deal with each individually.

THE WEEK'S SUBSCRIPTIONS, Thirty-second List.

	£ s. d.	£ s. d.
Southern Branch, B.M.A. (per Dr. J. Green, Hon. Secretary) (8th donation—total, £82 15s. 6d.)—		Poverty Bay, N.Z., Division, B.M.A. (per Dr. J. Reid, Hon. Secretary)—
Dr. W. A. Simpson ...	0 10 0	Doctors, Dentists, Chemists and Nurses 108 9 0
Bournemouth Branch, B.M.A. (per Dr. F. G. Bond, Hon. Secretary) (5th donation—total, £26 9s. 6d.)—		Dr. H. J. Macvey ...
Dr. C. W. Branson ...	3 0 0	Dr. Geo. E. Finlay ...
Anonymous (per Bank of New Zealand, Timaru Branch) ...	165 0 0	Australasian Pharmaceutical Conference (per the Agent-General for Queensland)—
		Western Australia ...
		Queensland ...
		Victoria ...

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments contributed by the following donors since the publication of the last list:

Dr. Bunting, Sunderland. Dr. T. A. Buek, Ryde.

The proceedings of the Medical Association of the Isthmian Canal Zone for the half year October, 1912, to March, 1913 (vol. v, part ii) contains a series of very interesting papers. Amongst these tropical maladies are fairly numerous—for example, there are reports on Six-day fever, by Dr. W. E. Deeks; The pathological features of a case of bilharziosis of the large bowel in a Martiniquan, by Dr. S. T. Darling; Notes on *Bacillus pestis*, by Dr. H. C. Clark; Leishmaniasis of the nasal mucosa, by Dr. L. B. Bates; Report of a case of cerebral malaria, by Dr. H. R. Carter, jun.; and a review of a clinical study of malarial fever in Panama, by Dr. J. P. Bates. In addition to these, there are also papers on lithiasis, pancreatitis, and sarcomatosis, which are of cosmopolitan interest, and are worthy of study by those interested in the individual subjects. The volume can be consulted in the Library of the British Medical Association.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

VOLUNTARY AID DETACHMENTS.

THERE are now about 120 ladies drawn from various Voluntary Aid Detachments employed in the capacity of nursing probationers in the British army hospitals in France. Their employment is regarded, I am told, as in the nature of an experiment, but if so it must be one as to the results of which considerable confidence is felt. The first appointments were made several months ago, and their number has been increased to the present total comparatively recently.

I have no information as to the exact distribution of these probationers, but gather that they are being sent to hospitals at which the work, though fairly heavy, is regular in its character, and thus allows of arrangements being made for some definite piece of work well within her power to perform being assigned to each newcomer, and for the scope for her energies being increased as her fitness for her occupation becomes apparent. The ladies first sent out were posted to hospitals where the work is habitually of the light-case-long-stay order, and where in consequence it was easy for the sisters to supervise the work of inexperienced assistants. It was on the strength of what was then observed that the subsequent further appointments were made.

All the ladies so far appointed have been nominated, I understand, by a special Voluntary Aid Detachment committee, which does its work under the aegis of the British Red Cross and the St. John Ambulance Societies. They are not free lances, but are engaged for work in France under a definite contract which secures to the War Office the command of their time for not less than six months, if it pleases, and provides for the payment to each probationer of a salary at the rate of £20 a year.

The requirements of the committee of selection include, I am told, the production of a birth certificate, and this fact perhaps accounts for the circumstance that all the members of Voluntary Aid Detachments I have met appear to be women of that indeterminate age which begins about 24 and ends about 40. They have also been young women of the best modern type—that is to say, well set up, healthy-looking individuals, somewhat offhand in manner, but obviously ladies, obviously well educated, and very keen on justifying their existence. Nor do I think I have been mistaken in these conclusions, for they are upborne by what has been said to me by persons of their own sex—namely, the nurses and sisters at hospitals at which they are employed.

The experiment, therefore, if as such it can still be regarded, seems certainly likely to prove a success. It may be added that there are reasons why this might initially be expected. Voluntary Aid Detachments have been in existence for a good many years, and though the part they are expected to play therein is a little vague, they are an officially recognized component of the general system of territorial defence. The units formed by them are semi-independent and their rules vary, but the work required of women members before they can be classed as "efficient" would in all cases seem to be calculated to eliminate individuals of the pillow-smoothing variety. Among other things it includes the passing of examinations in such subjects as cooking, first aid work, and home nursing. Even in peace time it is common, I believe, for enthusiastic members of Voluntary Aid Detachments to acquire some real knowledge of nursing by getting taken on for a time at hospitals and nursing homes; and since the war began the number of these members who have increased their knowledge in this fashion is very large.

There is also the reason that, despite the fact that the army hospitals in France are fully staffed by professional nurses, there must always be plenty of room in them for the labour of women who, however little special knowledge they may possess, are physically strong, mentally level-headed, conscientious in disposition, and ready to do what they are told. To make this evident, it need merely

be recalled that one of the special features of the majority of the hospitals in France is the frequency with which they change their populations. The duration of a patient's stay tends to be numbered by hours rather than by weeks or days, and this means that the amount of bed changing to be done is almost endless. The proportion, too, in the wards of cases which are entirely helpless, is much larger than in civil hospitals at home in ordinary times. For these and other reasons there is never any lack of work than can safely and rightly be given to probationers.

The ladies who are working in the hospitals are not the only representatives of Voluntary Aid Detachments to be seen in France. At one time and another several refreshment buffets or "rest stations" so called have been started by them, and one at least of these is still at work. For enterprises of this order Voluntary Aid Detachments are specially trained, and those organized of them over here were conducted so efficiently yet unobtrusively that it is a great pity that when opportunity for such work increased, it was absorbed by groups of workers less disposed to keep their light under a bushel.

STRETCHER CARRIERS.

A day or two ago an old acquaintance just returned from several months' Red Cross work with the French told me that on the section of the line on which he had been last employed the French depended a good deal on wheeled stretchers for carrying in the wounded from the trenches to the advanced dressing stations. The fact reminds me that several weeks ago at the head quarters of one of the Territorial field ambulances (No. 3 North Midland Field Ambulance, Lieutenant-Colonel Dent in command) I saw a full-sized working model of a new development in the way of appliances of this general order. It was not a wheeled stretcher, such as is used by the metropolitan police, nor a cycle stretcher carrier, such as is often to be seen in hospitals, but something betwixt and between. Its outstanding features were two parallel wire-built pneumatic-tyred wheels, united by an axle each end of which served as a centre point for an elliptic spring. These springs extended to an equal distance before and behind the wheels and their extremities were united by cross bars so shaped that any ordinary stretcher could be fixed firmly on them in a minute. So far the contrivance did not seem to vary materially from others of like kind that I had seen; but on examination it became apparent that it did in fact vary in a very important particular. The centre of the axle and the centres of the cross bars were hinged in such fashion that the whole machine could be closed up concertina-wise. Furthermore, when thus closed it occupied so little space that six like machines could easily be placed inside any ordinary empty ambulance. Consequently they could be brought up to the point where the ambulances would have to await their loads and be sent forward and hasten the arrival of the latter by relieving the stretcher carriers of their burdens.

An experiment shows that the appliance could be opened out and got ready for use by one man in about a minute, that two men could raise and fasten firmly to it a loaded stretcher within another minute, and that when thus loaded with a 14st. passenger, one man could push the whole thing along at a run over a surface resembling a rough field, and including in its course one definite hillock. To carry the same passenger over the same ground by hand proved to be a trying task for the two men who undertook it, and, of course, its completion took a very much longer time. The machine, when I saw it, was not regarded as quite complete. It had been built in haste, and it was thought its construction might perhaps be improved in detail. Possibly this may be the case; but, anyhow, the idea deserves encouragement. To clear a battlefield quickly is always desirable, and when, as in present circumstances, the action is never really at an end, and when the time during which attempts to remove the wounded from the trenches can be made with reasonable safety is extremely limited, any increase in the rapidity with which the task can be performed must be of advantage. It was proposed, I understood, to call the appliance described the "Miller James stretcher carrier," after the officer and non-commissioned officer who respectively suggested and worked out its underlying idea.

CANADIAN ARMY MEDICAL SERVICE.

JUST as Sir Alfred Keogh, when D.G.M.S. during peace time had organized the medical services of the country so successfully that when the great war broke out Territorial and other hospitals and their staffs were ready to stand the strain, so in Canada the present Surgeon-General Carleton Jones had during the last few years organized the medical services in every province. He had repeatedly visited England, had made himself thoroughly conversant with War Office methods, and had developed the Canadian service, so far as possible, along the lines of the R.A.M.C. Thus when the call came the Canadian Army Medical Corps was well prepared to work alongside the British, and, save for the unavoidable delay in procuring ordnance and other supplies, the formation of the various units has proceeded with singular smoothness and enthusiasm. Each province had its divisional service, and everybody and everything fell into line without confusion. Saying this, it has to be realized that conditions in Canada have of necessity introduced certain modifications, making the military organization approximate more nearly to that of the Territorials upon this side. The permanent members of the Army Medical Corps have formed a very small proportion of the whole body. Lieutenant-colonels and majors high up in the service in each province were, with rare exceptions, leading practitioners in one or other large city. But they were men who for years had played an active part in the development of the Army Medical Corps, while not a few had taken out a course at Millbank or Aldershot. When, therefore, Canada despatched her First Contingent, she sent with it not only the medical units of a division but those also for the lines of communication connected therewith, together with reinforcements—namely, 3 field ambulances and 1 clearing hospital, all now at the front; 2 general hospitals of 500 (subsequently upon establishment in France raised to 1,040) beds, 2 stationary hospitals of 200 (now 400) beds. The officer commanding of No. 1 General Hospital is Colonel Murray MacLaren, President of the Canadian Medical Association. To these have subsequently been added the personnel of the Duchess of Connaught's Canadian Red Cross Hospital, Tapiau, manned and, we may add, nursed by the C.A.M.C., for in the Canadian Army Medical Service, unlike the British, the nursing sisters are an integral portion of the service, and not a separate department. This hospital, beginning with 100 beds in the tennis court at Cliveden, put at its disposition by Mr. Waldorf Astor, is now raised to 1,040 beds. Another hospital of 1,000 beds has been established at the Moore Barracks, Shorncliffe. There are, further, a mobile laboratory and sanitary section at the front and two Canadian convalescent hospitals, to which all Canadian patients in British hospitals are eventually drafted—one for 1,000 patients at Monks Horton, near Shorncliffe, the other with 100 beds at Bromley Park, the latter for Canadians from hospitals in the London district.

There has been a similar abundant offering along with the Second Canadian Contingent, so much so that recent graduates granted their degrees this spring entered the corps as privates, and in answer to an appeal from the War Office eighty of them have since arrival in England applied for and been granted commissions as temporary lieutenants in the R.A.M.C. This number does not include the many recent graduates who entered the R.A.M.C. direct. Following the example set by McGill University the hospitals of this contingent have taken on a more distinctively local character. Colonel Birkett, Dean of the Medical Faculty of McGill University, applied for and received permission to offer a general hospital officered by members of the teaching staff of that university, with non-commissioned officers and men largely from the undergraduate body, and nurses from the hospitals associated with the university. This constitutes No. 3 Canadian General Hospital, already established in France. Toronto University rapidly followed suit, and No. 4 General Hospital, under Colonel Roberts, is now at Shorncliffe waiting to embark. Queen's University, Kingston, Ontario, has provided No. 5 Stationary Hospital. Laval University, the French University of Montreal and Quebec, provides the personnel of No. 4 Stationary Hospital. No. 3 Stationary Hospital has been recruited from Western Ontario, and many of its personnel have

been drawn from the Western University of London, Ontario. In addition, there are three Field Ambulances and a Casualty Clearing Station belonging to this Division.

Altogether, therefore, Canada has already provided accommodation and care for between ten and eleven thousand patients.

But this does not exhaust all the offerings. The University of Alberta has offered to supply a hospital of 250 beds, that of Manitoba a stationary hospital for service in France, another offer has been received from the University of Dalhousie, Nova Scotia. The physicians of Vancouver have offered to supply the personnel of a general hospital of 1,040 beds, and their offer has been accepted by the Government. The same is true of Peterborough, Ontario, and its physicians. Lambton County Medical Association (Ontario) offered a unit of 200 beds, the offer being still under consideration, while, lastly, a series of ambulance depôts are in course of organization throughout the Dominion. These will furnish reinforcements for the ambulance corps overseas.

HONOURS.

A SUPPLEMENT to the *London Gazette*, issued on July 3rd, announced that the King has conferred the Military Cross upon the following officers of the R.A.M.C. in recognition of gallantry and devotion to duty whilst serving with the Expeditionary Force:

Temporary Lieutenant John Marchbank Gillispie, M.B., R.A.M.C. On May 24th and 25th, 1915, at Ypres, he displayed conspicuous gallantry in ministering to the wounded under fire. He traversed the ground many times while under heavy shell and rifle fire, and dressed the wounded in the open. On the night of May 25th he went up to a wood near Bellegrave Farm and searched for wounded men close up to the German trenches. In every action his gallantry has been conspicuous.

Temporary Lieutenant John Hart McNichol, M.B., R.A.M.C. On May 24th and 25th, 1915, at Ypres, with untiring energy and gallantry attended to wounded men under heavy rifle and shell fire, saving the lives of many men. On the night of May 25th he searched a wood near Bellegrave for the wounded, attended to them, and had them brought in. This wood was close up to the German trenches. He has shown the greatest courage in attending to the wounded in action.

Assistant Surgeon Edwin Bunkall Messiner, I.S.M.D. For consistent good work, gallant conduct, and devotion to duty when X Battery, Royal Horse Artillery, was in action on May 9th and 10th, 1915. He went under shell fire to assist the wounded, and, although twice wounded, continued to perform his duties after having his wounds dressed.

DARDANELLES.

The following are the acts of gallantry and distinguished services at the Dardanelles for which the Distinguished Service Order has been conferred upon the members of the medical profession mentioned, as announced in the *BRITISH MEDICAL JOURNAL* of June 5th, p. 982:

Major Engine Joseph O'Neill, F.R.C.S., New Zealand M.C. On April 25th and 26th, 1915, during operations near Gaba Tepe, for exceptionally good service and exhibiting initiative and resource in command of a bearer subdivision.

Captain Arthur Graham Butler, Australian A.M.C. (attached 9th Australian Infantry Battalion). During operations in the neighbourhood of Gaba Tepe on April 25th, 1915, and subsequent dates, for conspicuous gallantry and devotion to duty in attending wounded under heavy fire, continuously displaying courage of a high order.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died.

LIEUTENANT WILLIAM REGINALD PRYN, R.A.M.C., is reported to have died in France in the casualty list published on July 7th. He was educated at Guy's, took the M.R.C.S. and L.R.C.P. (Lond.) in 1914, and, after filling the post of house-surgeon of the Royal Surrey County Hospital at Guildford, took a temporary commission in the R.A.M.C. on August 10th, 1914.

Wounded.

Captain H. J. Gorrie, R.A.M.C. (T.F.).
Captain E. D. Gaidner, R.A.M.C. (T.F.), Dardanelles.
Surgeon-Captain R. W. Branchwaite, R.A.M.C. (T.F.), Flanders.
Lieutenant (temporary) H. Pearce, R.A.M.C., Flanders.

SONS OF THE PROFESSION AND MEDICAL STUDENTS.

In addition to the few names which have been given in recent issues of the JOURNAL, the following sons of medical men have been killed. The names given below, however, must be but a small proportion of the total, as all of them, except the two midshipmen, have fallen in the past two months.

Navy.

Geoffrey Charles Harold, midshipman, H.M.S. *Home*, lost when that cruiser was torpedoed in the North Sea on September 22nd, 1914, second son of Dr. Harold, of Harley Street.

Henry P. Lewis Jones, son of the late Dr. Lewis Jones, of St. Bartholomew's, midshipman, H.M.S. *Haecke*, lost when that cruiser was torpedoed in the North Sea on October 15th, 1914.

Lieutenant-Commander R. S. Parsons, R.N., fifth son of Drs. Charles Parsons, of Tunbridge Wells.

Army.

Ackerley, R. H., Lieutenant 3rd (attached 1st) Battalion Royal Welsh Fusiliers, son of Dr. R. Ackerley of Llandinorod Wells, May 17th.

Baddeley, E. L., Major 8th Lancashire Fusiliers, eldest son of the late Dr. Baddeley of Whalley.

Banks, Charles Hunter Donaldson, Second Lieutenant 3rd Battalion Worcester Regiment, elder son of Dr. Charles Banks of Calcutta, died of wounds in Italy last aged 23.

Beattie-Crozier, F., Captain 4th Rajputs, only son of Dr. J. Beattie-Crozier.

Blacker, G. F., Second Lieutenant 12th Gloucester Regiment, attached Northamptonshire Regiment, only son of Dr. A. E. Blacker of Clifton.

Blair, Sidney, Second Lieutenant 3rd (attached 1st) Battalion Royal Warwickshire Regiment, son of Dr. John Blair of Wigan, May 16th.

Bard, T. M., Second Lieutenant 11th South Antrim Battalion, Royal Irish Rifles, son of Major T. M. Bard, attached R.A.M.C.

Campbell, R. C. C., Captain 3rd King's Own Scottish Borderers, attached Highland Light Infantry, son of Colonel R. M. Campbell, C.B., C.I.E., I.M.S. (ret.), May 19th, of wounds received in April.

Chilton, F., Lieutenant 15th Argyll and Sutherland Highlanders, reported killed in the Dardanelles, was the only son of Dr. Charles Chilton, Professor of Biology in Canterbury College, Christchurch, N.Z. He was a student of medicine at Edinburgh University, and a member of the O.T.C. On the outbreak of the war he applied for and received his commission.

Chilton, R. W., Lieutenant 5th Royal Warwickshire Regiment, only son of Dr. R. W. Edginton of Edgbaston, Birmingham.

Empson, R. H. W., Lieutenant 5th Durham Light Infantry, elder son of Dr. J. Empson of Milborne Port, Somerset.

Evans, Eric, Captain 4th Royal Welsh Fusiliers, son of Mr. E. D. Evans of Wrexham, was studying medicine and had nearly completed his course.

Fox, W. V., Lieutenant, 4th South Staffordshire Regiment, son of Dr. G. M. Fox of Walsall.

Frost, E. L., Lieutenant 4th South Lancashire Regiment, only son of Dr. Edmund Frost of Eastbourne.

Garrod, M., Lieutenant 6th Battalion London Regiment, second son of Dr. A. E. Garrod.

Harper, C. G., Lieutenant 6th Gordon Highlanders, eldest son of Dr. J. Harper of Rosary Gardens, London, S.W.

Heffernan, W. P., Second Lieutenant Royal Irish Regiment, second son of Mr. W. K. Heffernan, J.P., of Killeenale, Ireland.

Heywood, T. A., Second Lieutenant 4th East Lancashire Regiment, only son of Dr. T. W. Heywood of Darwin.

Hodges, W. H. W., Second Lieutenant 6th (attached 2nd) Battalion King's Royal Rifle Corps, elder son of Mr. H. T. Hodges of Walton-on-Stone, May 9th.

Hodgson, G. C., Lieutenant 7th Duke of Wellington's West Riding Regiment, elder son of Dr. G. Hodgson of Chertsey.

Maclehose, N. C., Lieutenant 8th Battalion London Regiment, younger son of Dr. N. M. Maclehose of Harley Street.

Mathew, G. C., Captain 2/2nd Gurkha Regiment, youngest son of the late Brigade Surgeon-Lieutenant-Colonel R. C. Mathew, M.A., May 10th.

Miller, J. E. B., Lieutenant Royal Irish Rifles, only son of Dr. J. E. Miller of Londonderry.

Orton, E. H., Second Lieutenant Scottish Rifles, younger son of Dr. G. H. Orton of Kensington, May 9th.

Piggott, Eric John Keeffe Pemberton, Lieutenant Royal Irish Regiment, son of Dr. F. K. Piggott of Shrewsbury, June 24th.

Pollock, F. H., Lance-Corporal 8th Battalion R.F.R.C., who was killed by a shell, was the younger son of Dr. J. Ellery Pollard of Acock's Green, Birmingham. He was 17 years of age.

Riordan, H. de B., Captain Special Reserve, attached 2nd Battalion East Surrey Regiment, only son of Colonel W. E. Riordan, R.A.M.C. (ret.), May 10th.

Shenbrot, P. M., Lieutenant Royal Field Artillery, son of Dr. J. R. B. Robertson, R.A.M.C. (ret.), of Hasling Island.

Scott, T. R. C., Captain Royal Lancaster Regiment, eldest son of Dr. T. R. Scott of Musselburgh, May 10th.

Shaw, R. T., Second Lieutenant Special Reserve, attached 2nd Battalion Royal Sussex Regiment, elder son of Dr. Lamiston Shaw, May 9th.

Shenbrot, P. M., Captain 1st Battalion Essex Regiment, eldest son of Dr. Philip C. Shephard, Aylsham, Norfolk.

Spence, C. B., Lieutenant Royal Field Artillery and Royal

Flying Corps, younger son of Dr. James B. Spence of Burntwood, May 9th.

Slooker, T. F., Second Lieutenant Royal Engineers, elder son of Surgeon-Major E. G. Stocker, Wessex Engineers (I.P.), May 19th.

Thomson, Richard Edward John, Lieutenant 15th Sikhs, eldest son of Lieutenant-Colonel S. J. Thomson, C.I.E., I.M.S. (ret.), May 18th.

Trevor, F. F., Second Lieutenant 3rd Reserve Battalion Duke of Cornwall's Light Infantry, only son of the late Mr. A. T. H. Trevor, of Beaumaris.

Tuke, A. H. S., Second Lieutenant 3rd (attached 2nd) Battalion Northumberland Fusiliers, only son of Dr. T. S. Tuke, of Chiswick, May 9th.

Warren, Percy Soltau, Australian Contingent, eldest son of Dr. Warren, late of Melbourne, Dardanelles.

NOTES.

THE COMPILATION OF CASUALTY LISTS.

AN Eye-Witness present with General Head Quarters in France, after stating that the main duty of the Adjutant-General's Department is the provision of reinforcements, goes on to point out that it is responsible for the duties connected with casualties, discipline, prisoners of war, and sanitation. The office of the Director-General Army Medical Service is a department of the Adjutant-General's office:

A large branch of the work is carried out at one base, where, under the title of the 3rd Echelon, a staff of several hundred officers and men are employed.

"Reinforcements" include complete fresh units and formations of all arms sent out to increase the size of the army, and drafts of the different arms dispatched to fill up the gaps in the units already at the front. The former, as a rule, pass straight through to the front; the drafts form the floating population of the base depôts.

Apart from the work of replenishing the army, there is that of recording and reporting casualties. A proportion of soldiers and officers disappear without leaving any trace of their fate. With regard to the others, before a man's name is sent home as a casualty it is necessary to identify him absolutely, and to ascertain his name, initials, regimental number, and unit, and what has happened to him. This is done at the base by a small staff detached from each unit or branch of the army in the field, which is employed in checking and verifying every piece of information received from the front regarding any member of its own unit and in maintaining a complete record of all its members in the shape of a sort of life-history. In the block of buildings where this work is carried on may be seen several rooms filled with soldier clerks from every unit of the service, British and Indian, working at small tables piled with papers, very much as clerks in a large bank or insurance office at home. Thirty copies of the casualty lists are sent home daily, amounting sometimes to 3,000 sheets of typed matter.

The Adjutant-General's branch is also responsible for the disposal of the effects and the wills of dead men and for their verification and for ascertaining their place of burial. In the latter task it is much assisted by the Graves Registration Commission, which consists of a small body of gentlemen who give their time voluntarily to the work of collecting information about the dead. They also furnish the graves with wooden crosses stencilled with the names of the buried and the date of their death. Finally, a not inconsiderable portion of the Adjutant-General's staff at the base is continuously and solely employed in replying to queries about casualties, of which as many as 200 sometimes come in on one day.

BALTIC AND CORN EXCHANGE HOSPITAL.

The Baltic and Corn Exchange Hospital Unit, the personnel of which is drawn from the R.A.M.C., St. John Ambulance, and British Red Cross Society, has been at work at Calais since last October. A report issued recently shows that Major Stedman, F.R.C.S. (Edin.), the officer commanding, has had the regular assistance of four surgeons, while other members of the profession have been temporarily employed. During the six months ending April 24th, 1915, 1,098 patients were admitted, and a statistical analysis is provided of those cases—747 in number—recorded in the clinical card index. The great majority of the patients were soldiers and officers of the Belgian army arriving from the front at the clearing hospital at the Central Railway Station at Calais or brought down by car from the field hospital of the 6th Belgian Division, and admitted on account of some condition urgently requiring treatment before they could be sent on by the hospital ships to England or Cherbourg, or by the *trains sanitaires* to the base camp in a distant part of France. The statistical tables which form the bulk of the report have been prepared by Dr. Lionel J. Pictou, registrar of the hospital. A glance at them shows how various were the conditions with which the staff had

to deal, ranging from all kinds of injury due to projectiles to carcinoma of the sigmoid and appendicitis (12 cases). Cases of typhoid numbering 69 were treated in an annex hospital; of these, 14 died. Of 25 cases among vaccinated persons, 3 died, while of 44 unvaccinated 11 died.

The report includes reprints of two papers on α -ray work by Lieutenant J. R. Caldwell, a member of the staff, which have appeared in the *Lancet*.

Those responsible are to be congratulated on the amount of valuable service disclosed, and we see that, since the conclusion of the period dealt with, a sudden and great increase in the number of wounded arriving at Calais has placed a further strain upon the resources of the hospital, and involved the opening of three new wards.

ARRIVAL OF HOSPITAL SHIP IN DUBLIN.

Early last week the hospital ship *Ozfordshire* arrived in Dublin with 673 wounded soldiers, of whom 226 were cot cases. Of the total number, 300 men were dispatched to Belfast in two trains, one from the Great Northern Railway and the other from the Great Southern and Western. Sixteen cot cases were taken in the Great Northern train and 20 in the other. Unfortunately, a wounded soldier died of internal haemorrhage while he was being lifted from his cot to be brought ashore. The 373 cases were distributed among the various Dublin hospitals. The arrangements for conveying the wounded were entirely in the hands of the Irish Automobile Club, and fifteen of the club's ambulances were in use. As usual on these occasions, the men of the R.A.M.C. were assisted in disembarking patients by St. John Ambulance orderlies and Red Cross and Voluntary Aid Detachments. At the North Wall, where the patients were disembarked, were 50 St. John men and 8 Red Cross orderlies, while the patients were transferred from the ambulances to the hospital wards by 125 St. John Ambulance orderlies and 18 Red Cross orderlies. One hundred of the less severely injured cases were sent to the Dublin Castle Red Cross Hospital. Out of the 373 wounded allotted to Dublin, 192 were lying-down cases and 181 were sitting-up cases. The men all came from Flanders, and the majority of the wounds appear to have been inflicted with shrapnel.

WOUNDED ALLIES RELIEF FUND.

Hospital Work in France.

Since its acquisition by the Wounded Allies Relief Committee in February the Hôpital Militaire Anglais at Limoges has received well over two hundred surgical cases, specially selected by the French authorities as being particularly severe and complicated. In the same space of time there have been only eight deaths. At the Hôpital Militaire, 37A, Dieppe, the death-rate since February is only 0.5 per cent. This hospital receives the more slightly wounded and keeps most of its patients from within two or three days of their being wounded until they are completely cured. The administrator writes:

During the month of June Dieppe has gradually been emptied, according to a new regulation, which is that wounded are to be sent to certain sections of the country till they are full, leaving others to work off their cases. At the end of May there was not a bed to be had in Dieppe, now we have nearly a thousand, and are next on the list to be filled.

THE FRENCH RED CROSS.

Mr. James Donelan, M.Ch., M.B., Medical Referee, Comité de Londres, 2, Knightsbridge, Hyde Park Corner, S.W., writes: "The generous response of the profession to the appeal you were good enough to allow me to make in the *JOURNAL* of April 24th (p. 740) tempts me to beg again your kind assistance. A number of hospitals that previously made their own arrangements for their surgical staffs, owing to new regulations by the authorities, have now to be supplied through this organization. Vacancies now occur and will continue to do so for some months. I should, therefore, feel greatly obliged to any of my *confères* desiring to offer their services for a month or more if they would write to me for application forms or any other information on this subject. If they should wish a personal interview, as I am doing this work in the intervals of practice, I must ask them to write for an appointment. There are a very few paid appointments for good operators willing to go for three or more months.

In the case of American surgeons, I am instructed to say that their co-operation is heartily welcome and most

valued. In order, however, that American surgery should be as worthily represented as it deserves, and in view of the fact that we have scarcely any criterion of the value of many diplomas, evidence of actual hospital appointments and of surgical work done therein will be required. Surgeons who have served with the American Red Cross in any but the hospitals of our allies are not eligible."

TYPHUS IN A GERMAN PRISON CAMP.

The Wounded Allies Relief Committee has received a letter from a trustworthy source in Switzerland stating that the camp for prisoners of war at Soltan, Germany, is in quarantine as the result of an epidemic of typhus fever. It is permitted to write and to send parcels to the prisoners, but they are, of course, not allowed to reply. The letter goes on to say that all necessary sanitary measures have been taken to stem the epidemic.

INDIA.

Bengal's Hospital Ship.

In the *JOURNAL* of July 3rd (p. 30) an account was given of the hospital ship, or rather flat, *Bengali*, fitted out for service in the river Tigris by the Bengal Volunteer Field Ambulance Corps. Unfortunately she has been at the bottom of the sea for nearly two months. An account of her loss is given in the *Pioneer Mail* of May 28th and June 4th. She left Calcutta on May 15th, in tow of the transport *Sikh*, the intention being to tow her from Calcutta to Bombay, and thence to the Persian Gulf. Bad weather was encountered soon after leaving the Sandheads, and she foundered in the Bay of Bengal, about 260 miles east of Madras, on May 17th. Fortunately her medical personnel were not on board at the time, intending to join her at Bombay, so when lost she had only a small working crew on board, who were all saved by the *Sikh*, no lives being lost. The medical staff, under Lieutenant-Colonel A. H. Nott, I.M.S., will go to the Persian Gulf for employment there as an ordinary land field ambulance.

SERBIA.

According to the *Morning Post* Professor Reiss, of Lausanne, has written from Kragjevatz, stating that, thanks to the timely assistance of the British and French Red Cross Missions, the health of the Serbian army is now very good, and the epidemic of typhus has been stamped out. Owing to vaccination on an extensive scale he thinks the danger of cholera may now be regarded as non-existent.

The *Daily Telegraph* of July 3rd contained a message from Mr. Granville Fortescue, stating that he had just returned from a ten days' tour in Serbia, where the sanitary condition showed a vast improvement. Typhus, he says, is rapidly dying out, in spite of the difficulty of instilling the simplest hygienic principles in the minds of the peasants. Foreign doctors and nurses find their progress checked by the indifference of the Serbian to medical supervision. The only danger that threatens is typhoid. Cholera he thinks a remote possibility. The Austrian prison camps are well organized, but the latrines are described as highly insanitary. In view of the myriads of flies, that increase as the summer advances, this constitutes a serious danger.

MONTENEGRO.

The two typhus units of the Wounded Allies Relief Committee for Montenegro will shortly be established at Nikshic and Podgoritza. The two Belgian doctors in charge of the Committee's hospital at Kragjevatz, Serbia, have been appointed lieutenants in the Serbian army. Subscriptions towards any part of this work will be gratefully received by the Committee's Honorary Treasurer, T. O. Roberts, Esq. (Manager), London County and Westminster Bank, 27, Strand, W.C.

MEDICAL OFFICERS WANTED.

Wanted, two good fox-hunting doctors, to join a Mounted Brigade Field Ambulance. Must take imperial service obligation. Pay and allowances as R.A.M.C. Applications to Captain Edwards, Hampshire Carabiniers, Bowood Camp, Calne, Wilts.

The late Dr. Samuel Herbert Habershon left unsettled property valued at £7,869.

DR. WILLIAM ARTHUR BRAILEY (consulting ophthalmic surgeon to Guy's Hospital) left estate valued at £10,003.

DR. DANIEL CARMICHAEL, of Newcastle-on-Tyne, late medical officer of health for Bedlington, left estate valued at £8,857 gross, with net personally £3,060.

The Lyons City Library is collecting, under the title of "Bibliothèque de la Guerre," documents of all kinds relating to the war. They include the medicine and surgery of the war, hygiene and epidemiology, hospital administration, the relations of the war to public health, legal medicine, veterinary science—in short, all branches of medical science which have a direct bearing on present events. To Professor Lesieur, physician to the Lyons hospitals, has been entrusted the chief direction of the work.

England and Wales.

LONDON.

Teachers for Mentally Defective Children.

THE Education Committee of the London County Council reported to the meeting of the Council, on June 29th, that they had had under consideration the desirability of making provision for the training of teachers for mentally defective children, in view of the need for such teachers which would be produced by the Elementary Education (Defective and Epileptic Children) Act, 1914. The Board of Education, it was stated, are prepared to approve and pay grants for the establishment of a one-year course of such training for trained certificated teachers and graduates, and it was felt that the Council have special facilities for providing a course of this kind, the special schools of London being larger in number, and probably superior in quality, to those of any other area of equal size. The Committee recommended that persons who already hold certain educational qualifications should be accepted as resident students at the Council's training college at Furzedown (Wandsworth) for a special course of training for teaching in schools for the mentally defective.

The recommendation was adopted by the Council.

Ambulance Service for London.

The ambulance scheme for London is gradually taking shape. The special committee on the establishment of this service reported to the Council that a new ambulance station in Shoreditch, equipped with two motor ambulances, was opened on June 21st, and that new stations in Southwark, Bloomsbury, Brixton, and Lee, would be successively available during the next two months. It was also stated that, an essential feature of the ambulance scheme for London being the use by police constables of private telephones, some 350 telephones were at present available in various parts of the county, but it was hoped that this wholly inadequate number would be greatly increased shortly. To secure an efficient service, telephonic facilities should be available at intervals of not more than 440 yards in every one of the more important streets and roads.

Asylums' Expenditure on Drugs.

The accepted tenders for the London County Asylums for the four months from July to October included an expenditure on drugs of £1,505, on druggists' sundries of £107, and on bandages and dressings of £325.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN LIVERPOOL.

Dr. Hope, M.O.H. for the city of Liverpool, in his annual report giving details of the work done by the school medical inspectors, states that 38,709 children were examined, of whom 19,289 were entrants and the remainder between the ages of 12 and 13. The head teachers in a large number of cases materially contributed to the efficiency of inspection by drawing the attention of the school medical officers to children requiring examination. It is worthy of notice that children absent from school were not overlooked but medically examined when illness was put forward as an excuse for non-attendance. There were 5,397 eye cases, including 4,973 instances of defective vision. Of the remainder there were only 2 cases of trachoma. Of affections of the mouth, nose, and throat there were 1,416 cases, defective teeth claimed 308, tonsils and adenoids and mouth breathing 200 cases. There were 411 cases of ear defects; of these 199 were cases of deafness and 180 cases of otorrhoea. There were 136 cases in which the organs of the chest were involved; heart disease 65, bronchitis 75 cases. Tuberculosis accounted for 72 cases, phthisis 47, of which 15 cases were dubious; tuberculous glands 14, tuberculosis of bones and joints 2, and other forms of tuberculosis 9. Of general diseases there were 362 cases, including anaemia and eclampsia 279, malnutrition 47, rheumatism 20, rickets 9, cretinism 6, haemophilia 1. The number of infectious and skin diseases was 368 cases, including measles 3, whooping-cough 3, mumps 23, influenza 2, ringworm of the scalp 76, ringworm of the body 35, scabies 21, impetigo 147, alopecia 16, eczema 17, and other skin affections 23. There were

80 cases of nervous disease—chorea 20, epilepsy 21, infantile paralysis 10, and other untabulated affections 29. The treatment of these children has not yet been so well organized as their inspection. The Education Committee has provided for efficient eye treatment by paying for the services of ophthalmologists. There is also x-ray treatment for obstinate cases of ringworm of the scalp. But the bulk of skin affections is left to the charitable institutions of the city. At present the Education Committee is considering measures to ensure treatment of those children suffering from mouth, nose, and throat affections. In time, no doubt, the school authorities will awaken to their responsibility of fulfilling the corollary of efficient medical inspection by providing efficient medical treatment. It is not right that this should be left to charitable institutions. Now more than ever is the child a valuable asset to the State. The health of its future citizens should not be jeopardized by procrastination and by failure to provide an efficient and competent service for the treatment of school children.

THE SALFORD SCHEME FOR THE PREVENTION OF EXCESSIVE PRESCRIBING.

At the monthly meeting of the Salford Insurance Committee on June 17th a report was read from the Medical Benefit Subcommittee dealing with the disparity in the number and cost of prescriptions for the year 1914 as compared with 1913. It appears that in 1913 the charges on the drug fund were so heavy that the chemists only received about two-thirds of their accounts, the total deficiency being about £3,680, while in 1914 there will be a very substantial surplus in the fund. The amount of surcharge claimed by the Pharmaceutical Committee for excessive prescribing in 1913 amounts to about £1,100, and sixteen of the panel practitioners are implicated. So far, however, the Insurance Committee has not come to any decision. In order to prevent as far as possible any tendency to excessive prescribing in 1914, an arrangement was made between the Panel and Pharmaceutical Committees by which the general pool for the panel practitioners was to be credited on paper with the whole of the 8s. 6d. available for medical benefit, while each practitioner was then to be debited with the cost of his own prescriptions, it being understood that in no case would the chemists receive more than 2s. or less than 1s. 6d. per insured person. It thus became the direct interest of each practitioner to reduce the cost of his prescriptions. The effect of this arrangement was seen even at the beginning of 1914; there was a large decrease in the charges for drugs and appliances, the cost per script falling from about 7d. to 5d., and the number of scripts being also lessened. In some cases the reduction was so great that a fear began to be expressed in the Insurance Committee that insured persons might possibly not be receiving adequate drugs and appliances. Only one definite charge, however, was brought forward. This came from the lady superintendent of the district nurses' home, and was to the effect that in a number of cases patients had not been supplied with adequate dressings. An inquiry was therefore made by the Medical Benefit Subcommittee, and in its course it came out that in many cases the doctors had been giving their patients medicines out of their own surgeries free of charge, instead of giving prescriptions, mainly in order to save themselves being debited with the dispensing fees of 2d. a bottle. Though no complaints had been made by patients of inadequate medicines, the Medical Benefit Subcommittee considered that such a practice was undesirable and that the arrangement might possibly lead itself to some abuses, such as those alleged in the case of dressings. The Subcommittee accordingly passed the following resolutions:

1. That no evidence has been adduced that would satisfy this Subcommittee that insured persons in Salford have not received adequate medical attendance and treatment during the year 1914.
2. That this Subcommittee is of opinion that the disparity in the number and cost of prescriptions for the year 1914, as compared with 1913, has resulted from the arrangement made between the Panel and Pharmaceutical Committees at the beginning of 1914 for the repression of excessive prescribing, which arrangement has now been discontinued.

The whole matter had previously been referred for the consideration of the Panel Committee, which agreed with the subcommittee that the arrangement had not proved

satisfactory. When it was made it had been definitely stated by the Commissioners that it was simply an arrangement between the Panel and Pharmaceutical Committees not requiring the consent of the Insurance Committee, whose business was simply to see that the insured received adequate drugs and appliances. At the same time, any expression of opinion by the Insurance Committee was bound to have weight, and the two resolutions of the Medical Benefit Subcommittee were carried unanimously by the Insurance Committee. It was explained that the Panel Committee had anticipated this by informing the panel practitioners that the arrangement would be considered to have ended with the year 1914, and that the drug fund would now be dealt with in the usual way, with the special safeguard that the chemists will, every month, scrutinize all scripts, and refer to the Panel Committee any that are considered extravagant. The Panel Committee will then investigate each case as it arises, in accordance with Regulation 40, with a view to saying whether any surcharge is to be recommended; it is hoped that in this way the long delay that occurred in 1913 may be avoided.

A letter was also read from the Panel Committee calling attention to the hardship inflicted on the sixteen practitioners who were alleged to have prescribed extravagantly in 1913, owing to the fact that, pending the settlement of the question of surcharge, sums of money had been withheld from them considerably in excess of the sums claimed by the Pharmaceutical Committee as surcharge. It was stated that this had been done in consequence of advice from the Commissioners stating that no final settlement should be made with these practitioners until the question of surcharge had been determined. After some discussion, it was proposed by Dr. Taylor that any amounts owing to these practitioners in excess of the amounts claimed by the Pharmaceutical Committee as surcharge for over-prescribing should at once be paid. Dr. Taylor said that though he had spoken strongly on several occasions against excessive prescribing, and thought it should be punished if no satisfactory explanations were forthcoming, he could not regard it as fair to withhold, say, £10 from a doctor when the utmost surcharge claimed was only about £3. The motion was seconded by Mr. Gill, who represents the chemists on the Insurance Committee, and was carried unanimously. This still leaves a final settlement to be made with these practitioners when the question of surcharge is settled.

The Clerk stated that the number of patients treated during the month of April was 13,291, and the average cost for drugs and appliances was 8.9d. a patient. The number of prescriptions dispensed was 26,515—that is, about 2 per patient, the average cost per prescription being 4.4d. The number of insured persons in the area is somewhere about 90,000. It is fully expected, now that the arrangement for debiting the doctors with the cost of their own prescriptions has been ended, that the charge on the drug fund will rise considerably as compared with 1914, as there will be no further likelihood of medicines being given by the doctors out of their own stocks. At the same time, with the experience that the panel doctors have now had in economical prescribing, and with the monthly scrutiny of scripts, which will avoid the long delay that occurred in 1913, it is fully expected that extravagant prescribing will be reduced to a minimum.

Scotland.

TOWN PLANNING.

IN his annual report Dr. A. J. Macgregor, M.O.H., Dunfermline, discusses the town planning scheme at Rosyth, which is a short distance outside the burgh boundaries, and to which the works connected with the Forth naval base are attracting a large population. Dr. Macgregor says: "A town planning scheme is at the root of a sanitary measure, its main object being to improve the conditions of living along health-giving lines, and not merely to improve the amenities of a district. It seeks to establish a standard of housing, and so comprehensive is the Act in its application that it not only defines the units for present and future housing, but also takes under its control all building operations within the prescribed area

undertaken during the preparation of the scheme. This power of retrospective control has in the case of Dunfermline exercised an inhibitory and most prejudicial influence on building operations, and the house famine that has prevailed throughout the burgh for the last three years has been more acute than ever. Our hope of relief lies either in the acceptance of our town-planning scheme by the Local Government Board, or, failing such acceptance, by the abandonment of the principle of retrospective control until our scheme can be so modified as to enable it to receive the necessary official sanction. The sanitary authorities are prohibited from making use of their statutory powers in regard to housing accommodation so long as the condemning of property only means turning out families in the street. In the altered conditions prevailing since the war broke out it is hopeless meantime to look to a municipal housing scheme, and our future welfare, so far as housing is concerned, must centre round the fate of our town-planning scheme."

HEALTH OF LEITH.

IN his fourteenth annual report Dr. William Robertson, M.O.H. Leith, states that the death-rate of the burgh in 1914 was 15.4 per 1,000 of the population. The total number of deaths was 1,234. Of this total, phthisis, pneumonia, bronchitis, and other pulmonary diseases accounted for 282, whilst other forms of tuberculosis, excluding phthisis, caused 60. Tuberculosis in all its forms was to be blamed for 144 deaths, and cancer claimed 96 victims. By slow degrees the contest against tuberculosis of the lungs was being successfully carried on; but all the sanatoriums and dispensaries were like whitewash applied to a disease which could only be arrested by having houses well ventilated and well lighted. Fresh air in dwellings would save the local authorities much expense everywhere. An open-air school was much needed in Leith. Heart disease had caused 131 deaths, and from non-defined causes there had been as many as 305. There had been no fewer than 700 cases of scarlet fever, and of these 569 were removed into hospital; but the disease had fortunately been of a mild type, and the average stay in hospital had been only thirty days; and 131 cases had been treated at home by the Milne method. Through the shorter stay in hospital and the Milne method of treatment Dr. Robertson calculated that £1,848 had been saved to the rates. There had been only three cases of typhoid fever (all imported); there had, however, been seven cases of typhus fever, but the outbreak had been promptly and successfully dealt with. The medical officers of health throughout the country, although they had all been eager and willing to assist or advise during the war, had so far been very little utilized.

Ireland.

RED CROSS HOSPITAL AT BRAY.

IT is stated that Her Royal Highness Princess Patricia of Connaught has graciously consented to allow the auxiliary hospital for wounded soldiers at Bray to be called "The Princess Patricia Hospital." This hospital is being organized and financed by the joint committee of the County Dublin Branch of the British Red Cross Society and the St. John Ambulance Association, and will contain over 200 beds. It is estimated that a sum of £8 will be sufficient to equip a bed. The superintendent of the Queen Victoria Jubilee Institute for Nurses in Ireland, who has been granted special leave for the period of the war, has been appointed matron of the hospital, and the work of preparation is being pushed forward with all speed. At the present time the capacity of the large general hospitals in Ireland to receive wounded soldiers from the front has reached its limit; practically every bed is occupied. Many of these patients have been in hospital for a considerable time; some are convalescent, and others, though still requiring careful treatment and nursing, have so far recovered as not to require the special treatment that can only be given at a large surgical hospital. It is intended therefore to remove the convalescent and slightly wounded cases from the general hospitals so as to provide accommodation for the more seriously wounded cases.

ENFORCING THE VACCINATION ACTS.

Dr. Brendan McCarthy, Local Government Board Medical Inspector, appeared before the Fermoy Board of Guardians, who have for some years allowed compulsory vaccination to lapse. Dr. McCarthy explained the dangers to the public that might result from the action of the guardians, and the great tendency there was in times past following great wars to epidemics of small-pox. The guardians, after some discussion, decided by a majority to enforce the Vaccination Acts in the district.

TYRONE COUNTY HOSPITAL.

Dr. Edward Thompson, F.R.C.S.L., presented to the members of the Joint Committee of Management the medical and surgical report of the Tyrone County Hospital for the year 1914. The expenditure for the year amounted to £2,979. The average number of beds occupied was 52.5, and the cost of each occupied bed came to £51 16s. and of each patient discharged £3 16s. 3½d. During the year 779 patients from all parts of the county were admitted. Dr. Thompson stated in his report that when he was appointed, forty years ago, as surgeon to the hospital the number of operations was about 60 each year. For the year 1914 the number of operations amounted to 307, which showed how much the work had increased during this period and how necessary and what a boon such an institution was to the well-being of the county Tyrone. During the latter part of the past year and up to the present time a large number of wounded soldiers from the British Expeditionary Force had received medical and surgical treatment in the wards of the hospital; they were admitted without charge and had been treated, as they well deserved to be, as honoured guests.

During the year there were performed, among other operations, 10 appendectomies, 45 excisions of adenoids and tonsils, 20 radical cures for hernia, 4 ovariectomies, 5 extractions of bullets, 30 gynaecological cases.

The staff consists of Dr. Thompson, who is empowered to summon extern assistance in major surgical operations to be performed by him. In addition to the 307 major operations performed during the year, there were 597 minor operations.

The development in recent years of provincial hospitals, like the County Tyrone Hospital, is a marked feature of medical practice in Ireland.

Correspondence.

REMOVAL OF BULLETS FROM WOUNDS.

SIR,—I have found the following plan of much service to me in dealing with the removal of bullets and foreign bodies in the hospitals here. The bullet is very often distant from the supposed site. Mark on the skin with ink or aniline pencil where the foreign body is supposed to be, and on that mark place a very small piece of lead foil, and over both a bit of strapping. The x-ray plate will show the relative positions of the skin mark and the bullet. I then place the "pilot lead" over the position of the metal and have another exposure made, and have not failed by this means to locate the exact position of the bullet. The only question is that of depth. Although I have thought this out, I do not suppose there is any originality about the idea, but it may serve to be useful to some surgeons who are trying to be of service to their wounded brethren.—I am, etc.,

C. L. FRASER, F.R.C.S. Edin., etc.,

Lieutenant-Colonel, R.A.M.C.(T.), Medical Officer in Charge
Improvised Hospitals,
Berwick-upon-Tweed, July 4th.

NERVE SUTURE FOR BULLET WOUNDS.

SIR,—Permit me to point out a serious error in a paper appearing in your issue of July 3rd, p. 10, entitled "Nerve suture for bullet wounds." In this paper Messrs. Stoney and Meade report (see Case 1) that within two months of the operation of suture of the ulnar nerve, at about 2 in. below the elbow, "there was good voluntary power of contraction of the flexor carpi ulnaris."

Recovery of muscular power in a muscle whose nerve has been divided two months previously being an impossibility, some explanation of this reported phenomenon

must be sought for, and it is easily found in Cunningham's *Anatomy*, second edition, 1906, p. 629, where you will see this sentence:

The muscular branches of the ulnar nerve in the forearm arise as soon as the nerve enters the forearm.

The severance of the ulnar nerve in this case evidently took place below the point at which the branch to the flexor carpi ulnaris is given off; there was paresis of the muscle due, to disuse or to concussion of its nerve branch, which cleared up after treatment by suitable means. The recovery had nothing to do with the operation.

It is of great importance that a thorough knowledge of these cases be grasped by operating surgeons, otherwise disasters and disappointment will result. I say disasters, because a surgeon who believed a peripheral nerve could regenerate in two months would often be willing to excise a nerve scar where another, surgeon would wisely stay his hand.

Perhaps I may also be permitted to point out that Messrs. Stoney and Meade's third conclusion, at the end of their paper, may have a misleading effect. They say:

The sooner an operation for its suture is performed, the easier it is, and the greater the likelihood of an early cure. In cases, however, where the wound is septic, it may be advisable to allow time for the wound to heal. (The italics are mine.)

It is not merely advisable; it is essential.

I beg to refer Messrs. Stoney and Meade, and others of your readers who may be interested, to my short note on this subject in the *Journal of the Royal Army Medical Corps* for March of this year.—I am, etc.,

PAUL BERNARD ROTH,
Captain R.A.M.C. (S.R.).

Military Hospital, Hamstead, July 5th.

LOCALIZATION OF FOREIGN BODIES BY
X RAYS.

SIR,—Commenting on the method of finding the position of a foreign body by x-rays, where two exposures with movement of x-ray tube have to be made, Professor C. Niven, of Aberdeen University, in a letter to me suggests that it is possible for a good glass-blower to make an x-ray tube with two centres of emission, so as to give two images on the screen at the same time, thus obviating all movement of the x-ray tube, and simplifying the procedure.—I am, etc.,

Birmingham, July 5th.

JOHN W. DUNCAN, M.B., Ch.B.

BRITISH AND FRENCH SALVARSAN PRODUCTS.

SIR,—In the annotation in the *JOURNAL* of June 26th, concerning British and French salvarsan products, it is stated that the unfortunate results and deaths following the use of the German preparation were not fully explained, the chief explanations being impurity of the water used and idiosyncrasy of the patient. Other explanations put forward were the liberation of endotoxins caused by the destruction of spirochaetes and the use of too acid or too alkaline solutions. It is now known that none of these explanations, with the possible exception of idiosyncrasy, holds good. The endotoxin theory was disproved by the fact that similar unfortunate results followed the use of salvarsan in non-syphilitic cases; the acid or alkaline theory was disproved by their occurrence when a neutral solution was used; the theory of chemical or bacterial impurities in the distilled water or saline solution was disproved by the fact that water containing such impurities did not produce such results when used alone, but did when salvarsan was added. In fact, all these excuses for salvarsan were made by the Germans, and mask the real explanation, which, in most of the severe and fatal cases, more especially those of haemorrhagic encephalitis, is simply arsenical intoxication. Indeed, Ehrlich himself, after the excuses for salvarsan reached the point of absurdity, admitted that the formation of an oxidation product of salvarsan was a factor in the causation of haemorrhagic encephalitis.

Whether English salvarsan is more or less toxic than the German product is immaterial, considering that this drug is not essential in the treatment of syphilis. The labour and ingenuity expended on its manufacture would be better applied in the production of high explosives or

poisonous gases, or any other means to rid us of German "culture," which has for so long hypocritized and contaminated the civilized world.—I am, etc.,

London, W., June 30th.

C. F. MARSHALL.

TREATMENT OF THE SYMPTOMS ARISING FROM INHALATION OF IRRITANT GASES AND VAPOURS.

SIR.—I have read with great interest the article by Mr. Symes on the above subject in the *JOURNAL* of July 3rd. As I carried out some experiments on the same subject myself a short time ago (*Lancet*, May 29th, 1915) with quite different results, it would be at least interesting to compare the different results and if possible suggest some cause to account for the discrepancy.

My experiments were confined to the use of atropine as a remedial agent. Briefly, I "gassed" a series of rabbits, which were intact and unanaesthetized, some with bromine vapour and some with chlorine; after exposure to these irritant vapours the animals were treated with atropine by intravenous and subcutaneous injection. In every case the animals treated with atropine showed distinct and marked improvement as compared with controls which received no atropine. Symes, on the other hand, states that "atropine sulphate in intravenous doses ranging from 0.5 mg. to 10 mg. has been without effect."

It has been demonstrated by Dixon and Ransom (*Journal of Physiology*, 1912, xlv, 5, 413) that atropine by intravenous injection dilates the bronchioles, and further, that so long as an animal remains under the influence of this drug so long will the bronchioles remain in a state of maximal dilatation.

In order to account for his negative results after intravenous injections of atropine, Symes suggests that "the bronchial circulation was largely, if not completely, arrested by the bromine vapour." If the bronchial circulation is thus occluded I fail to understand the mechanism whereby the bronchorrhoea is produced. Whether the bronchorrhoea be of the nature of an inflammatory exudate or a secretion from bronchial mucous glands, surely the presence of an active circulation is necessary.

However this may be, the treatment of "gassed" patients, both at home and abroad, by atropine, given as a rule subcutaneously, has produced beneficial results in many cases. It may be that in the very early stages of the worst cases the bronchial circulation is actually occluded, and that in such cases atropine injected into the circulation is unavailing. In such a state the inhalation of stramonium fumes might well produce an effect which intravenous injection fails to produce. On the other hand, when bronchorrhoea is established (and the bronchial circulation presumably acting), intravenous or subcutaneous injections of atropine do without doubt produce a dilatation of the bronchioles, which dilatation is both maximal and lasting.

It is, of course, for those in charge of the "gassed" patients to decide which method of administration to adopt in any given case; when all is said the chief active principle of stramonium is atropine. One point in particular, however, seems worthy of comment. Is it desirable to give the patient the benefit of the central stimulant action of atropine or not? If such central stimulant action is desirable, presumably it will be more pronounced if the drug is given by injection. I am, etc.,

Pharmacological Laboratory,
Cambridge, July 5th.

DOUGLAS COW.

SIR.—Dr. Cow has kindly given me the opportunity of replying to his letter.

Dr. Cow's animals (rabbits) were "gassed" via nares, my own via tracheal cannula. My bronchial (and bronchiolar) effects were therefore the more severe. My drugs were tested immediately on cessation of the "gassing," and at intervals for one to three hours afterwards.

We agree that atropine gives relief. With Dr. Cow injections were successful, but whether from their central nervous or bronchial effects is not in evidence.

In my hands (encephalon destroyed) injections failed, whilst inhalations succeeded. Here the effects could not have been central nervous—must therefore have been bronchial.

The source of the bronchorrhoea was, presumably, in great part, the pulmonary alveoli.

I would add that our knowledge of the broncho-dilator effects of atropine is to be dated many years anterior to 1912.—I am, etc.,

Teddington, July 5th.

W. L. SYMES.

THE BOARD OF TRADE AND DR. EDRIDGE GREEN.

SIR.—In the *BRITISH MEDICAL JOURNAL* of July 3rd, in the Medical Notes in Parliament, Captain Prelyman is reported to have stated, on behalf of the Board of Trade, in reply to a question by Dr. A. Lynch:

Dr. Edridge-Green was at no time requested by the Board of Trade to submit a test for colour-blindness.

As a matter of fact, the original of the lantern which is now the official test of the navy for colour-blindness was constructed at the request of and for the Board of Trade. Owing to the intervention of the Royal Society, the wool test was adopted, and my connexion with the Board of Trade ceased.

The following is a copy of the minute appointing me a member of the International Code of Signals Committee, dated May 14th, 1889, and signed by Sir Michael E. Hicks-Beach:

The Board of Trade are also pleased to appoint F. W. Edridge-Green, Esq., M.B., to be a member of the Committee with special reference to the consideration of the subject of colour-blindness and eyesight.

—I am, etc.,

London, N.W., July 3rd.

F. W. EDRIDGE GREEN.

EMERGENCY BILL FOR MENTAL TREATMENT.

SIR, In your issue of June 19th, p. 1069, Earl Russell states that the treatment contemplated in the bill which he introduced on July 22nd, 1914, is "voluntary in every respect." This authoritative statement is very valuable, and may be taken in conjunction with another noteworthy pronouncement, namely, that made by Mr. C. Harmsworth in the House of Commons on May 13th last, to the effect that his bill for mental treatment "did not involve compulsory detention." Dr. G. M. Robertson, on the other hand, admits that compulsory detention is provided by Section 13 of the Scottish Act, 1866. I must consequently, with apologies to Earl Russell and Mr. Harmsworth, rearrange the measures in the order of compulsory merit, giving the palm to the Scottish Act. It is not denied, however, that the English bills include reception of the patient into an institution for lunatics.

What strikes one as curious is why bills which are voluntary in every respect should be worth bringing in at all, since hospital treatment is admittedly not prohibited by the Lunacy Act, and the "patient," as long as he is "uncertifiable," is a free agent and competent to give his consent to hospital treatment without being assisted thereto by a bill.

Mr. R. Burrows (drafter of Earl Russell's bill) complains that Section 315 of our Lunacy Act inflicts a penalty on a person who takes charge of an "alleged lunatic" without being aware that lunacy has been alleged. There is, however, another point of view of even greater importance than that from which Mr. Burrows regards the question—namely, that of the person who is about to be taken in charge. Where lunacy has been alleged, it is a vital matter that the allegation should be sifted before the person is taken in charge, because he may not be insane. He has his rights, and ought to be confronted with the allegation made. It is too much the custom to take it for granted that the individual is already affected to such an extent as to make his statements unreliable, whereas that is the very point at issue, and it ought not to be accepted as a foregone conclusion that he is incapable of self-defence. It is in order to guard against unscrupulous dealings on the part of those who may wish to take charge of the "patient" for profit that Section 315 was framed, and it has often proved of use in this respect, since numbers of persons take charge of such cases for profit.

If Earl Russell desires to free his bill from ambiguity, he would do well to insert in it a proviso making it obligatory at the outset to obtain the consent of the patient in writing, and that a notice should be also given to him in writing to the effect that he cannot subsequently be detained against his will.

In the letter to which Dr. G. M. Robertson replied in your issue of June 12th, I did not mean to infer that Dr. Robertson does not apply excellent medical treatment to those cases whom he detains compulsorily; and I quite agree with him that nursing homes are chiefly run for the reception of the well-to-do, and also for profit. The alternatives which I meant to contrast, in dealing with "uncertifiable" cases, were:

1. Treatment by compulsory detention in Scotland under Section 13.

2. Treatment on a voluntary footing at a stage when the patient is capable of entering a hospital of his own accord, and of recognizing that it is for his good to do so.

What I have been trying throughout to emphasize is the great gain to be derived from providing hospitals dissociated from lunacy and from compulsion—that is, places where recent and uncertifiable cases (more especially among the less well-to-do) will not be afraid to come for early treatment, so that the beginnings of insanity may be checked. This is a great need. Such cases have a not unnatural dread of entering any place connected with lunacy, lest, having entered, they may not get out again. It is encouraging to hear that Scotland has now three hospitals which receive uncertifiable mental cases. When last in Edinburgh I was told that there was in the Royal Infirmary a small department intended for such cases. I asked: "How many beds?" and was told "Three," my informant adding: "But you know, that is quite enough for Edinburgh."

English law insists that where a man's freedom is taken away, he has a right to appeal to judicial intervention. I was not aware till now that Scotland did not recognize any right of the kind in this case, and must confess, all things considered, to a feeling of thankfulness at being domiciled on this side of the border.

Dr. Robertson cites as a proof of how well the ends of justice are secured without any need of this "privilege" in Scotland, that out of 150,000 persons certified as insane only one action for illegal detention was brought into court. Does Dr. Robertson seriously think that this proves his contention that there have never been any instances of unjust or unnecessary commitment? He who is so alive to the brand associated with the suspicion of having once been placed on the lunacy register cannot but be aware of the dread of publicity which deters action, as well as the expense, the reluctance to involve relatives, and the doubtfulness of the issue with the weight of lunacy authority and organization thrown into the scale against the plaintiff. It must also be taken into consideration that up to the moment of a fortunate release no "patient" is allowed an inkling of the allegations made against him, and that what he states is often regarded as delusional; so the ground is cut from beneath his feet and he is powerless to make use of any means of effecting his own rescue.

No doubt the Scottish board is desirous of exercising its unlimited prerogatives with loyalty and gives ear to the representations made to it, but those under certificate are not in a position to put forward their own case effectively. Reforms in this direction are far more imperatively necessary than is the introduction of Section 13 of the Scottish Act into the statute book which guarantees our English liberty.—I am, etc.,

London, W., June 26th.

S. E. WHITE, M.B.LOND.

ON THE CURVE OF THE EPIDEMIC.

SIR,—On seeing Mr. H. L. Trachtenberg's letter in your last issue I at once wrote the following letter to him:

17, Claremont Place, Newcastle-on-Tyne,
July 3rd, 1915.

Dear Sir,—I shall be interested to hear what you consider wrong with my solution of Dr. Brownlee's equation, and what slip I have made in the work of reduction in my letter of June 12th.

As stated in my expression,

$$2m \cot mt = \log CD - \log \frac{a CD}{2N} \left[t - \frac{1}{2m} \sin 2mt \right]$$

is true when certain conditions are satisfied, these conditions being that when $t=0$, $y=0$, and consequently then $y=a \sin^2 mt$.—Yours truly,

A. S. PERCIVAL.

As he has not replied as yet to me privately, I must ask him to substantiate his statements in the JOURNAL.

It is necessary for him to show that

$$-2m \tan (mt - a) = \log CD - \log \frac{a CD}{2N} \left[t + \frac{1}{m} \sin mt \cdot \cos \overline{mt - 2a} \right]$$

is not an identity when $y = a \cos^2 (mt - a)$; and, further, what slip I have made "in the work of reduction" when the conditions are such, that when $t=0$, there are no cases of the epidemic, or $y=0$. Under these conditions, of course, $y = a \sin^2 mt$, as $a = \frac{\pi}{2}$.

It will be noticed that Mr. Trachtenberg confines himself to accusing me of inaccuracy; he does not venture to give a solution himself, or even to correct the alleged inaccuracy.

To an epidemiologist I might point out that when observations are taken from the time before the onset of the epidemic, the simple expression,

$$2m \cot mt = \log CD - \log \frac{a CD}{2N} \left[t - \frac{1}{2m} (\sin 2mt) \right]$$

is true, and, if preferred, it may be written in the form:

$$2m \sqrt{\frac{a}{y} - 1} - \log CD - \log \frac{a CD}{2N} \left[t - \frac{y}{am} \sqrt{\frac{a}{y} - 1} \right]$$

—I am, etc.,

Newcastle-on-Tyne, July 7th.

A. S. PERCIVAL.

Obituary.

RICHARD CLEMENT LUCAS, M.B., B.S.LOND.,
F.R.C.S.,

CONSULTING SURGEON, GUY'S HOSPITAL AND EVELINA HOSPITAL FOR SICK CHILDREN.

By the death of Richard Clement Lucas the profession has lost an eminent surgeon and a remarkable man. His was a distinct personality which cannot be ignored when the surgery of the late Victorian era is under review, and his name will be always associated with the early development of renal surgery, a subject in which he took a continued interest. The son of the late Mr. William Lucas of Oaklands, Midhurst, Sussex, he was born on April 16th, 1846, and was thus in his 70th year. Educated at Queenwood College, Stockbridge, Hants, he afterwards entered as a student at Guy's Hospital in 1863, and had a distinguished academic career at the University of London, taking the M.B. gold medal in 1871. He qualified as M.R.C.S. and L.R.C.P. in 1868, and became a Fellow of the College of Surgeons in 1871.

Lucas served Guy's Hospital for nearly half a century, distinguishing himself in all the appointments which he held. In 1872 he became assistant demonstrator of anatomy, the senior demonstratorship being awarded to him in 1874. In 1877 he was made demonstrator of practical surgery. In 1875, while he was holding these appointments in the medical school, he was elected assistant surgeon to the hospital, and thirteen years later, in 1888, he attained the rank of surgeon, retiring in 1906. From 1888 to 1900 he was lecturer on anatomy, and in later years he became lecturer on surgery to the hospital, holding the latter lectureship from 1900 till his retirement. Lucas devoted an enormous amount of time and energy not only to his hospital duties but also to the education of the students, in every one of whom he took a great personal interest. Quite a number of his colleagues owe their success in life to the stimulus which he applied to them by his interest and advice in the early stages of their careers. He used to ask the first year's men to meet him in order that he might discuss with them collectively and individually the best course for each to pursue in his work, and few who were present at one of those talks will forget the strong impression that he made upon the young student. Full of ambition himself, and indefatigable in work, he certainly possessed a wonderful power of inducing energy in others.

In his prime he was a masterly operator, bold, rapid, and certain. Nothing pleased him more than a deep and extensive dissection in the neck, in which his dexterity and anatomical knowledge had full play. In his work he was always teaching the student, and the interest of his

lectures was notably enhanced by the excellent lightning sketches with which he illustrated them.

Lucas wrote a large number of papers on anatomical and surgical subjects, in many of which he displayed remarkable originality. Needless to say, a man of this calibre does not go through life without encountering much opposition. An interesting example of this is worth recording because of its surgical interest. Early in 1880, when the relations between the governors and staff of Guy's Hospital were at a considerable tension, Lucas, then an assistant surgeon, had as a patient a man who was very ill with a tuberculous kidney and a discharging sinus in the loin. Lucas proposed to remove the kidney—an operation which at that time had rarely been attempted, and never, so far as we know, successfully. The governors refused to sanction the operation, but Lucas denied their right to interfere between his patient and himself, and in the presence of the superintendent, whom the governors had deputed to represent them, he operated with a most successful result, as the patient was shown more than twenty years afterwards.

Among the students as a whole Lucas was always to the fore as a patron of sport. For many years he was president of the Students' Athletic Club, and he founded the "tag-of-war," which became such a popular institution at Guy's. His love of sport also made him a prominent figure in the hunting field, where he was a well-known follower of Lord Leonfield's hounds, rarely missing a Saturday meet.

In 1901 Clement Lucas was elected a member of Council of the Royal College of Surgeons, retaining his seat till 1914. He was vice-president of the College from 1909 to 1911, and, in the latter year, Bradshaw Lecturer.

Mr. Lucas married Miss Kathleen Emma Pelly, daughter of Surgeon-General Saville Marriott Pelly, C.B. There were two sons of the marriage, one of whom is now serving as a second lieutenant in the Royal Field Artillery.

W. A. L.

On December 9th, 1911, Clement Lucas delivered the Bradshaw Lecture before the Royal College of Surgeons. The subject was "Some Points in Heredity." He noted how the word "diathesis" was falling into disuse as the true microbic cause of disease after disease was becoming unravell'd. He held it libellous to continue to speak of John Hunter as of the strumous arthritic diathesis with a nervous element, yet such was the description given of that great man by Professor Laycock as recently as in 1862. Fallacies concerning tuberculosis, syphilis, leprosy, malaria, and cancer were exposed. He reviewed the Mendelian and Galtonian schools, and turned to those undoubted evidences of heredity where physical deformities, not constitutional diseases, were transmitted. Clement Lucas declared on the ground of personal observation, that deformities tend to increase in succeeding generations. The crooked little-finger, which the Mendelians treated as a matter of small account, could easily be shown to be persistently hereditary, and the lecturer reported an instance in which he observed its development in three generations. An ill-developed lateral incisor tooth foretold hare-lip and cleft palate in the offspring. The tenacity of the development of deformity, as Clement Lucas aptly called it, was illustrated by cases of this kind observed in the course of his own experience. Much was said about twins, and the lecturer made out that the one-yeck, or "identical twins," were not necessarily degenerate. One of the pair may undergo prejudicial changes in uterine life, and both may fuse and become double monsters; but on the other hand, both may grow up strong in body, and in some instances strong and "identical" in mind. Lucas quoted the marks gained by twin brothers who passed at the same date the examinations at the Royal Colleges and London University.

DR. THOMAS SMAILES, of Honley, Huddersfield, who died on June 24th after a brief illness, was the oldest doctor in active practice in the Huddersfield district. He was born at Wesleyham Ferrers, Northlants, in 1849, the eldest son of a Wesleyan Methodist minister, and after an early training as a chemist he took up medical studies at the Leeds School of Medicine and the General Infirmary, qualifying as M.R.C.S. Eng. in 1875. He subsequently became L.R.C.P. and L.M. Edin. (1876), L.S. Sc. Durh. (1891),

and M.D. St. Andrews in 1892. After acting for a short time as assistant, he settled at Honley, where he acquired a high reputation as a skilful practitioner. He also became well known by his public work as member of the local board and urban district council for about twenty-nine years, and as its chairman for ten years. He acted for over thirty years as medical officer of health for South Crosland, and for three years as medical superintendent of the Colnet Holmes Fever Hospital, a scheme in which he was greatly interested from its foundation. He was a valued member and "father" of the West Riding Local Medical and Panel Committees, the local treasurer for the War Relief and Belgian Refugee Funds, and the President on two occasions of the Huddersfield Medical Society. Whilst taking an active interest in local government, he also found time for church work. Having released his son for military duties, he took on the full burden of a heavy practice in January last, and the strain brought on an attack of acute pneumonia, which proved too much for him. His loss is widely mourned by a large circle of friends and patients, amongst whom he had practised for a period of forty years.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Michael F. Gavin, formerly professor of clinical surgery at Boston Polyclinic, aged 72; Dr. Bernard G. Macredlein, formerly professor of oral surgery in the Milwaukee Medical College, of which he was one of the founders, and later professor of the same subject in the Marquette University School of Medicine, aged 67; Dr. Léon Maire, surgeon to the Hotel-Dieu of Vichy; Dr. John Hildreth McCollom, professor of contagious diseases at Harvard and author of numerous writings on diphtheria, scarlet fever, measles, small pox, and other contagious affections, and for many years medical superintendent and director of the Boston City Hospital, aged 72; Dr. Alfred Mitchell, emeritus professor of internal medicine in the Medical School of Maine, Portland, and for many years Dean of the school, aged 78; Dr. Gabriel Pichardó, Alcalde of Santa Clara, and a prominent figure in the medical profession of Havana; and Dr. Samuel Baldwin Ward, Dean of the Albany Medical College and professor of the theory and practice of medicine since 1864, aged 73.

THE LATE PROFESSOR HOWARD MARSH.—We have been informed by the Secretary of the Hospital for Sick Children, Great Ormond Street, that the late Professor Howard Marsh held the appointment of house-surgeon to that institution as early as in 1862, before he became Mr. Skey's house-surgeon in October of that year at St. Bartholomew's Hospital. He was elected assistant surgeon to the Children's Hospital in 1868.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

The following degrees have been conferred:

M.D.—A. G. Atkins, on D. H. Fraser, E. Mellanby.
 THESIS M.B. *Perit. U. M. Uterine, Pathology, and Therapeutics*.—The following candidates have passed: E. D. Adrian, F. H. Brice Smith, H. Gardiner Hill, W. Hillbrook, T. J. H. Holden, L. M. Ingle, R. W. P. Jackson, R. A. Mansell, W. H. Marshall, W. New, R. A. Peters, C. M. Ryley, G. R. S. Thomas.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on June 16th.

Election of Vice-Chancellor.

Sir Alfred Pearce Gould, K.C.V.O., M.S., was elected Vice-Chancellor for the year 1915-16 in succession to Sir Wilmot Herringham, C.B., M.D., to whom the thanks of the Senate were accorded for the services rendered during his tenure of office.

Recognition of Teachers.

The following were recognized as teachers of the university in the subjects and at the institutions indicated:

London Hospital Medical School: Dr. F. J. Smith (Hygiene).
 Middlesex Hospital Medical School: Dr. E. A. Young (Clinical Medicine).
 London (R.F.H.) School of Medicine for Women: Mr. A. G. B. Foulerton (Hygiene).

Appointments.

Dr. Frederick Taylor has been elected Chairman of the Committee of Medical Members of the Senate.
 Dr. T. G. Brodie, F.R.S., was appointed one of the representatives of the university at the hundredth anniversary

celebration of the founding of Alleghany College, held at Meadville, Pennsylvania.

Brown Animal Sanatory Institution.

The annual report of the Superintendent of the Brown Institution for 1914 was presented. It showed that 5,865 animals had been taken to the institution, of which 508 were in-patients at the hospital. The commonest diseases had been mange and scabies in dogs, and lameness in horses. Treatment of a number of animals had been refused on the ground that the owners could afford to pay the proper fees of veterinary surgeons. Of the 508 in-patients 478 were cured or relieved, 10 died, and 20 were destroyed as incurable. The five lectures required under the will of the late Mr. Brown were delivered during November by the Superintendent, the subject selected being the Biology of acid-fast bacilli. The report also contained particular details of investigations carried out in the laboratory by different workers.

UNIVERSITY OF DURHAM.

The following candidates have been approved at the examinations indicated:

- FIRST M.B.—G. Bartell, P. C. Arnold, C. N. Armstrong, F. J. Armstrong, O. Colville, C. C. Carr, R. A. McK. Dickson, R. Davison, J. M. de Lacey, S. Foskett, W. D. Forrest, F. T. Gass, A. S. Graham, A. Hanson, G. Hall, J. Hetherington, H. Kameel, F. N. Y. Lott, R. E. Pratt, S. C. Smith, A. H. W. Whyte.
- SECOND M.B. (*Anatomy and Physiology*).—D. G. P. Bell, W. E. M. Wardill, W. A. Freedman, A. T. Harrison, D. E. Hearn, Mary F. Henegan, W. A. James, W. I. F. Powell.
- THIRD M.B. (*Materia Medica, Pharmacology and Pharmacy, Public Health, Medical Jurisprudence, Pathology and Elementary Bacteriology*).—H. M. Leete, E. C. Dunlop, J. A. Heron, N. Brantwaite, W. Dunca, Stephanie P. L. H. T. Dunch, M. J. Erdberg, B. Hunter, J. D. Johnson, M. C. Joint, Freda Newman, R. R. Scott, T. W. Shaw, K. I. Shalaby.

* Passed with second-class honours.

VICTORIA UNIVERSITY OF MANCHESTER.

The following candidates have been approved at the examinations indicated:

- FIRST M.B., CH.B.—J. S. Chorlton, A. T. Gibb, E. Granger, H. M. von Mengershausen, J. Rigby, H. H. Stones, F. Varne, H. Willan. (*Medicine*): W. Halliwell. (*Forensic Medicine and Toxicology*): J. H. Albinton, H. W. Bennett, W. Christopher, R. Colley, E. W. Fish, E. R. Gilmere, Eva L. Glasier, G. Lapsage, B. L. Lloyd, E. L. Jewell, F. C. Ormrod, Nestie H. Perry, Dorothy Potts, C. R. Sandford, W. Stansfield, G. B. Wild.

Awarded second-class honours.

Awarded distinctions in Surgery and Medicine.

- THIRD M.B., CH.B. (*Pharmacology and Therapeutics and Hygiene*).—F. H. Anderson, F. E. Archer, W. T. G. Boyd, Hilda R. Brade, Frances G. Bullough, C. E. J. Carruthers, Kathleen L. Cass, Ruth E. Conway, W. C. C. Easton, J. Holker, N. Kleiz, E. N. P. Mercland, J. S. Stenson, A. B. Platt, Elizabeth C. Powell, J. Schloberg, D. M. Sutbeyand, H. Taylor, H. Tomlinson. (*Hygiene*): R. T. Fiddes.
- FIRST M.B. and CH.B. (*Part II, Organic Chemistry and Biochemistry*).—Mary E. Boulton, G. H. Buckley, T. H. S. Bullough, F. J. Coops, G. Cunningham, Kathleen Doyle, Georgiana M. Duthie, Olive M. Gimson, A. Heris, F. C. Jones, S. Kells, J. N. Laird, P. McCormick, J. A. Marriott, W. E. Mason, P. B. Mumford, J. G. Nolan, E. R. Ormerod, Olga M. Payne, H. D. Preston, Ethne Ratner, W. Reikan, A. H. Seick, H. Stafford, Dorris M. R. Tompkin, Ruth A. Wilson.

UNIVERSITY OF BRISTOL.

The following candidates have been approved at the examination indicated:

- FIRST M.B., CH.B.—Hilda Mary Brown, J. R. Duerden, A. J. Keevil, T. H. A. Pinniger, Marjorie South Neville.

UNIVERSITY OF ST. ANDREWS.

The following candidates have been approved at the examinations indicated:

- FIRST M.B., CH.B.—Margaret A. Alexander, Agnes W. Andrew, M. A. McJan Lamb, Beryl, A. C. Cassells, D. Dempster, M. A. Margaret, Faith, G. M. Grant, C. B. McDonald, M. A. W. McDonough, M. A. Monahan, Chand, Madhok, D. H. Murray, M. A. D.P.H. Second Examination.—J. C. Robertson.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE COUNCIL OF THE COLLEGE OF SURGEONS.

THE annual election of Fellows into the Council took place on Thursday, July 1st. Sir Frederic Eve, Vice-President, in the chair, presided over the meeting. Mr. W. H. Jones, Mr. W. H. Jones, and Mr. H. J. Price acted as scrutineers; 767 Fellows voted, 758 sending their ballot papers through the post and 9 voting in person.

The result was declared by the Vice-President as follows:

MR. R. L. LILL	... 449 votes.
MR. J. C. BATES SYMONDS	... 443 "
MR. H. F. WALTERHOUSE	... 417 "
MR. J. F. FIFEHEAD	... 251 "
MR. WALTER G. SPINLER	... 300 "
MR. J. B. LAYFORD	... 264 "
MR. T. H. OPENSLAW	... 249 "
MR. H. B. ROBINSON	... 196 "
MR. P. M. YEARSLEY	... 80 "

Mr. Bingham, being fourth on the poll, becomes substitute

member of Council for Sir Rickman Godlee until 1921 and Mr. Walter Spencer, being fifth, becomes substitute member for the late Mr. Lockwood until 1918.

Mr. Ryall and Mr. Symonds were declared July re-elected and Mr. Waterhouse, Mr. Bingham, and Mr. Walter Spencer duly elected members of Council.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, IRELAND.

Reuben Harvey Memorial Prize.

THE Reuben Harvey Memorial Prize for the year 1915 has been awarded to Mr. Bryan A. McSwiney, of Kingstown, co. Dublin, for a thesis entitled "Creatine and Creatinine."

Medical News.

DR. JOHN SHEARWOOD ROBERTS, of Sheffield, has left estate valued at £78,164.

THE next meeting of the Society for the Study of Inebriety will be held in the rooms of the Medical Society of London, Chandos Street, Cavendish Square, W., on Tuesday, July 13th, at 4 p.m., when Major Leonard Darwin, President of the Eugenics Education Society, will open a discussion on alcoholism and eugenics.

THE following is a list of recently elected Honorary Fellows of the Royal Society of Medicine:—*British*: Sir R. Douglas Powell, Lord Moulton, Sir John MacFadyen, Sir Francis Darwin, Robert Bridges, Lieutenant Colonel Sir David Prain, T. Pridgin Teale, Sir John Williams, Professor E. G. Browne, Professor S. G. Shattock. *Foreign*: Professors J. Babinski, A. Chauffard, Jules Dejerine, M. T. Tuffier (Paris), and Paul Heger (Bremen).

THE seventy-fourth annual meeting of the Medical-Psychological Association of Great Britain and Ireland will be held at 11, Chandos Street, Cavendish Square, W., under the presidency of Dr. David G. Thomson, at 3 p.m., on Thursday, July 22nd. The business will include the election of officers, council, and standing committees, the reception of reports of committees, and the consideration of a resolution empowering the council, should it think fit, to make grants in aid of original research on the recommendation of the research committee.

ON June 25th the annual meeting of subscribers to the British Hospital for Mothers and Babies and Training School for District Midwives was held at the residence of Countess Brassey in Park Lane. The Countess of Stamford presided in the absence, owing to indisposition, of the Princess Louise Duchess of Argyll. The report of the Committee of Management stated that the home at Woolwich had been amalgamated with the British Lying-in Hospital. The sum of £25,000 was being raised for a new hospital, and about half the amount had been subscribed, including £1,500 by King Edward's Hospital Fund. Lord Sydenham referred to the great wastage in infant life, and expressed himself as strongly in favour of making the Notification of Births Act universal and compulsory, and was glad the new President of the Local Government Board had promised to take this subject in hand. Sir Francis Champneys, Chairman of the Central Midwives Board, said the Board had inaugurated a scheme by which the training of midwives would be extended from three to six months. The Queen and Princess Louise Duchess of Argyll have consented to become patrons of the hospital, and Princess Christian has consented to act as president.

ON July 3rd the Mothercraft and Child Welfare Exhibition at the Passmore Edwards Settlement in Tavistock Place was opened by Muriel Viscountess Helmsey, Chairman of the National Society of Day Nurseries. The object of the exhibition is to spread knowledge whereby the mothers of this country shall be helped to rear healthy children. It will be open daily from 2.30 to 8.30 p.m. till July 10th. Health talks, lectures, and demonstrations are to be given every day by Dr. Eric Pritchard, Miss Florence Petry, Dr. Alice Benham, Dr. Halford Ross, Dr. H. Cameron, Dr. Louis Simonson, and Dr. Langmead, and it is hoped that the exhibition may be of practical assistance to health visitors and social workers in different parts of the country in their task of endeavouring to improve the health of the community. It is intended that this exhibition shall be a permanent one, moving from place to place, and requests for the exhibition to visit particular centres will be received by the Secretary, Mothercraft and Child Welfare Exhibition, 7, Hanover Square, London, W. The exhibits include models of rooms, an artificial feeding exhibit, model clothes, model of a day nursery, a dental exhibit, house-wifery and cooking, and a fly exhibit, illustrating how flies carry disease and how they may be kept away from houses.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attingham, Westrand, London*; telephone, 2653. General, (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2656. General, (3) MEDICAL SECRETARY, *Medicera, Westrand, London*; telephone, 2634. General. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Correspondents, answers, and communications relating to subjects in which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

COLONEL G. F. ROWCROFT (Barton-on-Sea writes: With reference to Mr. W. H. Martindale's caution (May 29th, p. 956) against inhaling (volatile) oil of mustard, as recommended in your previous issue of May 8th, he is undoubtedly right. How is it to be done? Is the process recommended useless, or is there something further in it that has not been explained?

PREGNANCY AFTER REMOVAL OF BOTH FALLOPIAN TUBES.
DR. C. SHEAHAN (Carcroft, Doncaster writes: A patient of mine, aged 43, underwent removal of both Fallopian tubes, subject to salpingitis, at the Jessop Hospital for Women, Sheffield, in November, 1913. After the operation she continued to menstruate and became pregnant, being delivered of a fully developed male child on June 10th. The infant, however, was stillborn, the patient suffering from chronic Bright's disease, with a large quantity of albumin in the urine. I should like to know if many such cases have been recorded, and how such an occurrence can be explained.

The stumps of the Fallopian tubes do occasionally manage to get rid of their ligatures, so that the canals become pervious and capable of transmitting ova. Morris of Boston, U.S.A., amputated both ovaries and tubes for inflammatory disease quite close to the uterine in July, 1898. As in our correspondent's case, menstruation returned, and then the patient became pregnant and was delivered of a live child in September, 1899. Similar cases have been recorded. The ligature probably ulcerates through the tube, which leads behind it without any stricture of the canal. This also accounts for the failure of many attempts to sterilize patients with contracted pelvis by division and ligation of the tubes. As for small inflamed ovaries when removed with the tubes, since the pedicle is always very short, a piece of ovarian tissue is almost necessarily left behind on the ovarian ligament, just below the stump of the tube. This explains how conception occurred in Morris's case. See "Pregnancy after Removal of both Ovaries for Cystic Tumour," by Alban Doran, *Trans. Obstet. Soc.*, vol. xlv, 1903, p. 231, with an instructive discussion, in which Sir J. Bland-Sutton, Professor Herbert Spencer, Dr. Amund Routh, and other authorities related their experiences. An abstract of the paper and discussion will be found in the JOURNAL, vol. i, 1902, p. 1476, and further notes on "Pregnancy with Deficient Tubes and Ovaries" appeared in vol. i, 1904, p. 743, and on "Pregnancy after Removal of the Fallopian Tubes" in vol. ii, 1910, pp. 1648 and 1891.

ANSWERS.

TREATMENT OF CHEIROPOMPHOXY.

DR. G. LEWIN writes, in reply to "Skin," that he has found a solution of picric acid useful in some cases, and suggests that there would be no harm (beyond the staining) in trying it.

SERUM TEST FOR GONORRHOEAL INFECTION.

"R. R." will find all about the serum test for gonorrhoea in the following: Original articles by Schwartz and McNeil, *American Journ. Med. Sciences*, May, 1911. Textbooks: *Gonorrhoea and its Complications in the Male and Female*, by D. Watson, M.B., C.M. London: H. Kington, 1914. Price 15s. net. *Syphilis and Venereal Diseases*, by C. F. Marshall, M.D., M.Sc., F.R.C.S., third edition. London: Baillière, Tindall, and Cox, 1914. Price 10s. 6d. net.

LETTERS, NOTES, ETC.

THE "NAUHEIM" TREATMENT IN LONDON.

CYANOTIC writes: As it is not possible for patients suffering from cardiac and circulatory disorders to go to Naheim for treatment at the present time, I thought it would interest your readers to have my experience of a course of "Naheim" baths in London. I have suffered from malarial fever in India, and had two severe attacks of influenza. About a year ago I began to suffer from dyspnoea on the slightest exertion; this symptom increased so much that I was obliged to have a motor car in order to attend to my practice; hitherto I had

been able to walk. The dyspnoea increased, and I was absolutely fagged out at the end of a day's work. About five months ago my legs became oedematous, and for four months I had been unable to go to bed on account of the dyspnoea, but had to sleep reclining in an easy chair. Then I sought medical advice from a West End consulting physician, and under his treatment with cardiac tonics, taking as much rest as possible, etc., my condition improved for a time; but I found I was again going downhill, so I consulted the leading authority in this country on the "Naheim" treatment, and on his advice and under his care took a course of "Naheim" baths in London. After a week's treatment I was able to lie down to sleep. Before the treatment my heart was greatly dilated, the area of cardiac dullness measuring 7 in. across at the nipple level; my blood pressure was 100 to 245 mm. Hg. I had great dyspnoea and cyanosis, my calf measured 15 in. (oedema). I was not able to do anything, and could not sleep. After four weeks' treatment the area of cardiac dullness measured 5 in. across, my dyspnoea diminished very markedly, so also did the cyanosis and oedema; the calf now measured 14 in. I feel a different man and fit for work. A day or two ago I walked a mile with comparative comfort—a thing I have not done since last December. My blood pressure now is 90 to 120 mm. Hg. I feel that I should like to bring before my fellow medical men the marvellous results of a course of "Naheim" baths in London, as I do not think that the fact that this treatment can be given in England is sufficiently known. I would end with a warning that the treatment should always be taken under careful medical supervision, and not at a bathing "institution."

"LIFE, ITS ORIGIN AND ENERGY MECHANISM."

"JADROO" writes: May I be permitted to make a brief reply to the notice of my pamphlet you were good enough to insert in the BRITISH MEDICAL JOURNAL of June 26th?

Your reviewer has two points to make against my theory—the one is that "nerve impulse travels at an enormously slower rate than electricity," and the other that "muscular contractions are energized by the electrical nature of a combusive nature in the non-nitrogenous element of the constituent molecules." Regarding the first: If there were a direct course through from station to station—that is, from the cerebro-spinal system whence the impulse originates, to the muscle to be energized, the point your reviewer endeavours to make would be effective, but as there are stations and stopping places on the way—relay stations, in fact—there must necessarily be, when in one originating impulse has in some cases to energize simultaneously a dozen muscles or more, and has to be divided up for the purpose, considerable delays. This is, as I hold, the almost obvious explanation.

Although your reviewer objects to analogies, the position resembles London telegraphing to move troops in Edinburgh, Glasgow, Inverness, Wick, and the Shetland Islands, and half a dozen other places simultaneously. The messages cannot reach all the places at the velocity of electricity. Regarding the second point: If he had said that muscular contractions are accompanied or followed by chemical changes, etc., no objection could have been made to it. As expressed, however, I do not think that any evidence can be produced for his statement. I have carefully sought for such evidence, but have never been able to find any in any standard work on physiology, or biology, or elsewhere.

I have with much interest read what you write, the chief medical journal could advance against my theory, and am pleased to see there is so little.

EPSOM COLLEGE ELECTION.

MRS. DOROTHY MILWARD (5, Glossop Road, Cardiff writes: May I, through the medium of the JOURNAL, thank all those who have been so good as to send me a vote of sympathy at Epsom College for my son Wilmet? I would specially thank the Association and its Branches and Divisions which have been so largely instrumental in gaining for my boy the proud position of head of the poll by 780 votes. The heartiness of the support given is a tribute to the esteem in which my husband was held by members of his profession, and, as such, I would very gratefully acknowledge it. I trust that my son may prove himself worthy of the support which has been given him.

GERMANIZATION OF DICKENS.

M.D. suggests that the next step will be to change the name of Mr. Wemmick's employer, "Mr. Jaggers," to "Mr. Jäger."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 425, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-remittance letters addressed either in initials or numbers.

BRITISH HEALTH RESORTS IN PEACE AND WAR.

BEING THE THIRD CHADWICK LECTURE, DELIVERED AT THE
ROYAL SOCIETY OF MEDICINE, JUNE 10TH, 1915.

BY R. FORTESCUE FOX, M.D., M.R.C.P.,
F.R.MET. SOC.

The remedial use of water may be said to rest upon the two bases of history and experiment. In my first lecture I recalled the long history and tradition connected with this branch of treatment, and showed that whilst it has survived all changes of medical doctrine, it has flourished most when men's minds were turned from vain speculations and occultism to the observation and study of natural processes. In the second lecture I examined the experimental basis of the subject, and endeavoured to show that the use of baths in particular was agreeable to ascertained physiological law, and that their proved effect upon the body was such as to make them remedies of no mean value.

I propose now to consider the British health resorts in which waters and baths of various kinds are employed. Some of them have been in popular or medical use for many centuries, others only for a few years. Some are large towns, others small villages. Some are warm places in the plain or valleys, others cool, on the moorland or hillside. Their medical value consists in the means of treatment they afford. In this respect some resorts, in virtue of their natural endowment, enjoy a wider application than others. These have, perhaps, a stronger individuality and their application is more limited, but by no means less valuable.

Formerly the chief consideration in the choice of a spa was that one possessed larger establishments than another, or was more modern or amusing, the presumption being that the same treatment could be obtained everywhere. This idea has found support from the practice at some resorts of introducing all the methods of treatment belonging to other places. In the endeavour to create a universal provider there is, however, a danger lest the original virtue of the place, perhaps the waters, by which its reputation was first established, should be in the new development neglected and forgotten.

The serious study of medical hydrology in recent years has shed new light upon the true value of waters. And not only has the hydrologist to consider what are the particular properties and actions of the waters and baths, but what is the influence of the place as a whole, including, above all, the influence of the climate upon the sensitive organization of invalids. In the best type of health resorts the specific action of the waters and baths is promoted and reinforced by the general action of the place.

National Health Resorts.

The health resorts of a country are a national asset. Their utilization and development may be a matter of national concern. It was so under the Roman Empire, when baths were more widely and scientifically employed than at any period in history. It is so now in France, Italy, Germany, and other Continental countries. In those countries the Governments have for many years made themselves responsible in one way or another for the national spas. Medicinal waters, like other mineral resources, are considered of sufficient importance to warrant their conservation by law, and their development is assisted by Government oversight and legal provision. They are thereby protected against the risks that otherwise attach to private ownership, both in the way of neglect on the one hand and unwise exploitation on the other.

Owing to the European war British invalids are almost entirely precluded from availing themselves of the Continental spas, which have enjoyed hitherto perhaps an undue share of British favour. This favourable notice was, no doubt, chiefly due to the high state of development they have reached under the encouragement and supervision of their Governments. If one nation be compared with another, the Frenchman goes to the French resorts, the Italians to those of Italy, the Germans to those of Germany. But the British have in great numbers

gone far afield, and many of the spas of other countries owe much of their prosperity to this fact.

Another reason for seriously examining the resources of our own country is that large numbers of war invalids are now leaving the hospitals who are not fit to return to the front nor yet to go to their own homes. We know from long experience in civil life that the maladies and disabilities from which these men suffer can be greatly relieved and often cured by the ministrations of the health resort.

The General Characters of British Health Resorts.

An island climate on the north-west of Europe has given to the British health resorts a certain character which differs widely from the Continental type. They are situated five to ten degrees nearer to the polar circle than the great spas of France and Germany. The more northerly summer is cool and fresh, with frequent changes of temperature. The North Atlantic current may be 6° or 8° F. cooler than the sea at Dover, and nearly 20° cooler than the Mediterranean. No such tempering influences mitigate the heat of the Continental summer. Since the action of baths is different in different climates, and especially varies with altitude and with temperature, the choice of a bathing station is sometimes a matter of climate. Thermal treatment may be well borne by a delicate subject in a cool or dry air, but might be intolerable and even dangerous in a hot and humid valley.

SCALE OF THERMALITY OF BATHING RESORTS. (Mean Temperature of July in degrees Fahr.)

78. Castellammare, Bay of Naples.
- 77.
76. Salsomaggiore (altitude 520 ft.).
75. Levico (1,700 ft.).
- 74.
- 73.
72. Bex, Switzerland (1,400 ft.).
- 71.
- 70.
69. Naubeim, Homburg, and the Rhine Spas.
68. Aix-les-Bains (860 ft.).
67. Evians-les-Bains (1,240 ft.). Vichy (736 ft.).
66. Spa, Belgium (1,000 ft.). Luchon, Pyrenees (2,030 ft.).
65. Contrexéville (1,150 ft.).
64. Plombières (1,300 ft.).
63. BATH (100 ft.). DROITWICH (200 ft.). LEAMINGTON (200 ft.). CHELTENHAM (150 ft.).
62. BUXTON (1,000 ft.). LLANDRINDOD (700 ft.). WOODHALL SPA (37 ft.).
61. HARRGATE (500 ft.). Bormio, Italy (4,500 ft.).
60. Cauterets, Pyrenees (3,200 ft.).
- 59.
58. STRATHPEPPER (200 ft.).
57. Leukerbad, Switzerland (4,600 ft.).
- 56.
55. St. Moritz, Switzerland (5,800 ft.).
- 54.
- 53.
52. BATH, in the spring months.

There are certain disorders and constitutions for which health resorts high on the scale of thermality are helpful and appropriate. At the hot end of the scale are most but not all of the Continental spas. Most of the British spas will be found in the cooler part of the scale. The coolest spas are those of high altitude and of northern latitude. Some invalids require treatment in the warmth and shelter of valleys, or in warm summer climates, such as can be obtained in England at Bath, Leamington, or Woodhall Spa. Others do better on the moorland or hillside, as at Buxton or Harrogate; others again at mountain resorts, such as the great French spas in the Auvergne; and others at northern stations, as in Scotland.

The difference in summer heat between the cooler British spas and those of the Continental plains is quite enough to affect the result of treatment. Buxton is 8° F. cooler than Naubeim and the Rhine, and Strathpepper as much as 12° F. cooler. In weakness of the heart and circulation cool treatments are preferable, or at most a carefully limited and guarded thermal influence.

Thermal Debility.

It follows that the British spas are less liable than their rivals to the chief danger that attends upon the use of hot

baths—namely, the condition that has been described as "thermal debility." Many persons to avoid this undesirable result of treatment are very properly advised to take an "after-cure" in bracing air. If this is neglected, and sometimes in spite of all precautions, an insidious weakness may be experienced, which is in proportion to the heat to which the patient has been subjected, both in the bath and in the climate. In the cooler British stations this danger is minimized.

Northern British Resorts.

Many of the stimulating effects belonging to high altitudes may be obtained at the northern British resorts, at or near the level of the sea. The cool summers of the north, like those of high altitudes, make a greater call upon the activity of the tissues than warm summers, but do not make the same demand upon the heart and breathing. Consequently, the northern cold is better borne than the same degree of cold in the mountains, especially by elderly persons and those in whom the breathing and circulation are embarrassed. The long summer days give a character of their own to northern stations, and the extreme translucence of the air, as in the mountains, is evidenced not only by the feeling of warmth, but by the power of the actinic rays. It is also remarkably free from dust. The atmosphere has more humidity than in the Alps, and is therefore more sedative.

It will be observed that many varieties of stimulant and sedative influence are blended in the health resorts of the north. For example, in the north-east of Scotland a marine air is often combined with that of the moorland, and at an elevation of a few hundred feet the atmosphere has a fresh and invigorating quality with which a sedative influence is subtly mingled. The baths and climates of northern health resorts are especially helpful in nervous and mental fatigue, in circulatory disturbance, insomnia, and premature age. The Norwegian spas Larvik and Sandefjord, and the famous Swedish baths of Modum, should be placed in this category.

British Thermal and Subthermal Waters.

Bath stands highest in the scale of thermaity of all the British spas, and the warm climate accentuates and reinforces the sedative effect of the baths. The climate of Buxton, like the waters, is of lower temperature and more tonic. The two places represent two widely differing types of treatment, both of great value in their proper application. Bath is a health resort of very large application, since the treatment can be given throughout the year. It is therefore a spa of two thermalities. For some constitutions and maladies the baths are most efficacious in summer, whilst others require the cooler regimen of winter and spring. No better example could be adduced of the fact that the climate for the time being powerfully affects the results of bath treatment. The baths of Buxton have a stimulant effect in those rheumatic and gouty disorders for which warmer treatments may be injurious; but over and above the effects of temperature Buxton waters exert a definite action in many cases of rheumatism. The less frequented waters of Matlock Bath in Derbyshire, of Clifton, and of Mallow in county Cork, belong to the same valuable class of naturally warm waters.

Sulphur Waters.

Sulphur waters are well represented in the British Islands. In what form is this element presented in natural waters? For the most part as a volatile gas, antiseptic, absorbed by the skin, rapidly diffused throughout the body. In its effect upon some chronic disorders it approaches to a true specific. Its exhibition in such cases often aggravates symptoms before relieving them. The hydric and alkaline sulphides exist nearly alone or combined with lime salts in what have been called "pure" sulphur waters, like those of Stratheffer in Scotland, Llanwrtyd in Wales, and Lisdoonvarna in Ireland. In another group the sulphides are combined with chlorides, forming a "muriated sulphur" water, as at Harrogate, Llandrindod, and Moffat. The lime salts and chlorides are respectively diuretic and aperient, but modify also in other ways the actions and uses of sulphur waters. For example, one of the sources at Llandrindod is nearly isotonic with the blood, and, following the French hydrologists, might be called a "natural serum."

Hot sulphur springs, which are associated with volcanic action, are not found in Great Britain. But there are

within the empire many remarkable waters of this class, notably in the Punjab and other parts of India, and in New Zealand, not to mention Helwan in Egypt.

Salt Waters.

Droitwich, the premier British salt spa, has a saturated brine, radio-active, containing about ten times as much salt as sea water. It is well adapted for stimulating surface treatments at different temperatures (see *infra*, rheumatism and cardio-vascular affections). The other salt or muriated waters of Britain can be used both for drinking and bathing. Here again the secondary and modifying elements in the water alter its whole effect. For this reason the salt spas are possessed of strong individuality, and are widely different in their actions and uses. The group includes Woodhall Spa, Bridge of Allan, Leamington, Cheltenham, and Llangammar in Wales.

Treatment of Rheumatism and Gout.

In some cases the high thermaity of the Continental spas (Aix-les-Bains, Vichy) is to be preferred to the cooler range of island resorts. But it should be remembered that rheumatic persons, and still more sufferers from gout, are sensitive to heat, and therefore prone to suffer from thermal debility after bath treatments. For this reason the hydrologist will often prefer the cooler treatments of the British spas, particularly in atonic states of the cardio-vascular system. A cure is dearly bought at the expense of the heart.

It has sometimes been argued with a show of reason that since all the spas claim to benefit rheumatism, therefore no particular water is better than another. The truth is that at all well appointed spas a similar kind of bath treatment is employed, namely, heat in various degrees and forms, with douching and massage. These external applications are sometimes described as "thermal treatment," and can be, within limits, given anywhere. For rheumatism and gout, as for other maladies, the spas therefore offer a twofold provision—the remedy of heat and thermal treatment, in which they agree; and the remedy of waters, in which they differ. Undoubtedly rheumatism is treated with success at most well appointed spas, for the reason that it receives at all of them a similar thermal treatment.

But altogether apart from baths and other surface treatment, there are certain waters which have a curative value in rheumatism and gout, and after a rather long experience I am not disposed to say whether the baths or the waters are the more valuable.

England offers for these maladies the thermal water of Bath and the subthermal water of Buxton. Both of these, within their own class, are unsurpassed and of the first value. Then there are the brines of Droitwich and Nantwich, affording one of the most effectual forms of external treatment. Lastly, there is the important group of sulphur waters, for drinking and bathing, which in their effect upon the body approach to a specific action in these maladies.

Treatment of Nervous Affections.

As regards nervous affections, the loss of the Continent will be difficult to make good. The physician often relies upon a complete change of scene and atmosphere, of habits and people, even of country and language, in order to recreate wearied and irritated nerve centres, or to overcome old habits of invalidism.

With reference to bath treatment, it may be noted that in nervous disorders for which health resorts are appropriate: (1) Both irritation and depression are usually present, and therefore a sedative as well as a stimulant action are required; (2) that cool and "subthermal" treatments combine a sedative with a stimulant action, and that, on the whole, hot or thermal bath treatments are injurious in nervous maladies; (3) that rest is often an urgent requisite, and that therefore many small and tranquil spas in a rather sedative climate may be in some cases preferable to other resorts that are recommended as having "every treatment, the finest hotels and the best music"; (4) that in the summer and autumn seasons moorland and especially northern air, with or without tonic bath treatments, are especially helpful for these subjects.

Treatment of Circulatory Disorders.

An acknowledgement is due to the foreign physicians who have called attention to the good effect of cooling

baths in heart affections. For many years the fact had been occasionally noted at the spas, both in the British Islands and in Italy and France, but those observations were neglected or forgotten until the claim was recently put forward in connexion with a particular Continental health resort. In truth, equally good results have been obtained at many places from baths of a certain temperature with or without effervescence. There is nothing specific in what has been loosely called the "Nauheim bath."

The British health resorts, in consequence of the island climate, are well adapted to the bath treatment of cardiovascular cases. No persons are so liable to thermal debility as those who suffer from circulatory troubles. In their case during the summer season both hot baths and hot climates are best avoided. Moreover, for the greater number of such persons the fatigues of foreign travel, as well as the abrupt change of habits, may be prejudicial. There is in the British Islands a wide choice of localities where baths of this description are given with sufficient precision. It must be confessed that no bath requires greater care, and accuracy of observation of its effects from day to day; and in no other kind of disorder is the reaction to baths so curiously variable.

During the summer season cardio-vascular patients may be treated in the relative warmth of Droitwich or Woodhall Spa; or, in an atmosphere of ascending tonicity, at Llangamarch, Llandrindod, Harrogate, Buxton, Strathpeffer. All of these places, although very different, may be described as resorts for circulatory disorders. In winter time baths of the same kind may often be taken with advantage at coast resorts like Sidmouth or Torquay, or in adequate bath establishments in the town.

Undeveloped British Spas.

Besides certain spas already mentioned, there are two British waters, once much resorted to, and still of great potential value. These are the chalybeate water of Tunbridge Wells and the St. Anne's Well at Malvern. Although possessing a minimum of "mineral" constituents, Malvern is a true "medicinal" water, with an action best described as *eliminant*. It takes rank with Evians on the Lake of Geneva, and there is, in my opinion, no reason why Malvern in time to come should not occupy as important a position among the health resorts of England.

War Service of the British Spas.

It is well known that for many years the Continental spas have been widely and successfully used for the after-treatment of soldiers in connexion with European wars. After the South African war many military cases were treated with advantage at the British spas, but, unfortunately, no systematic records were kept. The matter was discussed by the Section of Balneology in the Royal Society of Medicine, with the conclusion that, from the evidence available in this country, supported by the much more extensive evidence of other countries, valuable results might be anticipated from similar treatment at the present time if efficiently and systematically carried out. That is to say, that a great many injured and disabled men, for whom all that is possible had been done by surgical skill and ordinary hospital treatment, would obtain relief or cure from suitable treatment by baths and waters, which would be otherwise unattainable. In short, that there is in war time a great scope for after-treatment at bathing health resorts.

In view of these facts, and of the great numbers of men invalided from the field, the Section determined to draw the attention of the authorities to the matter. Early in the year a committee was formed, upon which the War Office and the Royal Society of Medicine were represented. Local committees and representatives were forthwith appointed at the British health resorts and the facilities for treatment inquired into and organized. A widespread absence of information was encountered, and a pamphlet prepared setting forth the various conditions, surgical and medical, which could be submitted to bath treatment with advantage, with a schedule of the health resorts and the treatment which they offered. This was circulated by the War Office among the military hospitals, and also supplied to the Admiralty. A full statement of the available accommodation, both for officers and men, at the principal resorts was also prepared.

The health resorts without exception showed every willingness to co-operate in this war service. Already very large numbers of free baths have been given, free accommodation has been often availed of, and spa practitioners have given their services in all necessitous cases. Private bath establishments and "hydropathics" in the less favourable situations have for the emergency of the war placed their facilities for bath treatment freely at the disposal of the local medical men for military cases.

The Committee were anxious to promote not only a sufficient but an efficient after-treatment. A system of case record cards was organized. These have been officially approved, and will form part of the Government statistics in the medical history of the war. About 7,000 cards have been already issued.

Perhaps the most serious difficulty is the proper selection of cases for the different localities. On the one hand are the men, hundreds or thousands, ready to leave the hospitals or homes, but not yet cured. On the other hand, there is offered for their relief or cure a wide and various provision of waters, baths, and climates all over the country. The problem is how to bridge this gap, so as to secure for each man the best choice of locality and treatment. Only by careful selection in the hospitals, or in some kind of clearing station, and by expert distribution of cases can favourable results be obtained. The same care and pains that are taken in advising ordinary invalids ought to be applied to the distribution of military cases.

Medical Baths in Towns.

A large number of these men could be treated at a good medical bath establishment in town or country, as well as or better than at a spa. Medical baths have been for many years in use in Continental cities, with similar installations in the civil and military hospitals. The hydrotherapy thus provided is found adequate for a certain proportion of cases, and much expense avoided. In time of war many of the most useful treatments can be thus applied, under skilled medical direction, in the vicinity of the great hospitals, and large numbers of patients can be easily handled with a modest installation of baths.

In the British Islands baths have been hitherto but little used in connexion with the hospitals, but good medical baths have been erected of late years in London, Bradford, and other towns, where treatment is adequately given. New needs have now to be met. The Committee has included in its recommendations that approved establishments should be made available for military use, and that bath treatment should be attached to some of the military hospitals.

Future of British Hydrology.

No one who has followed the growth of medical hydrology in this and other countries during the last few years can fail to realize that it has taken a place among the medical sciences, and that at the present day the art or practice of hydrology affects the welfare of many thousands of persons. How important in the public interest that this branch of treatment should be well-informed and scientific, and that a wise, and not unwise, use should be made of the British waters and baths!

What better means could be taken to these ends than to set up systematic instruction in hydrology? And what better place than London to possess an institute of hydrology? At such an institute, under right auspices, not only could teaching be given, but a clinic established, and, most vital of all, investigation and research carried on, that English physicians should no longer subsist on knowledge borrowed from other countries, but that we should substantiate our practice upon our own soil. Only so in any country can any art permanently flourish.

If our view be extended a little further—from London to the outlying parts of the empire, to South Africa, India, New Zealand, Canada—the British hydrologist has work to do. India alone is richly endowed with medicinal waters of every description. No scientific report has ever, admittedly, been made upon them. There and elsewhere much remains to be done to investigate, make known, and utilize these natural resources of the empire.

[The lecture concluded with an account of the arrangements for soldiers at the British spas, illustrated by lantern slides.]

THE
DIAGNOSIS, PROGNOSIS, AND TREATMENT OF
NERVE AND MUSCLE INJURIES RESULT-
ING FROM GUNSHOT WOUNDS:

WITH ESPECIAL REFERENCE TO THE USE OF THE
LEWIS JONES CONDENSER APPARATUS.

By FRANCIS HERMAN-JOHNSON, M.D.,

CAPTAIN (TEMPORARY) R.A.M.C.; SENIOR MEDICAL OFFICER TO THE
X-RAY AND ELECTRICAL DEPARTMENT, AND LECTURER ON
MILITARY RADIOLOGY, CAMBRIDGE HOSPITAL, ALDERSHOT;
CONSULTING RADIOLOGIST TO MILITARY HOSPITALS
IN ALDERSHOT COMMAND.

IMPORTANT as is the X-ray work of a large military base hospital in war time, it is necessarily somewhat one-sided. Diagnosis bulks large; Roentgen treatment is called for only to a very limited extent. But the activities of the electrical department are not—or, at any rate, should not be—confined solely to radiography. Provided that intelligent lay assistants are available, much of the actual taking of plates may safely be left in their hands. The medical officer in charge should see every plate and every patient, and should himself write all reports; but the time which would be occupied in routine work may be more profitably employed in another field.

As a result of injuries sustained on active service—for example, bullet wounds in the neighbourhood of nerve trunks—the number of cases of paralysis of limbs is great. To decide upon the exact lesion present in each case, and to sort out those which, if curable at all, are curable only by operation, from those in which treatment by non-surgical measures ought to be tried, is a task calling for all the diagnostic skill which can be brought to bear upon it. When the most severe cases have been handed over to the surgeon, there remains a large number whose only hope of a restoration to usefulness must lie in those means of treatment which are at the disposal of the electro-therapist.

Diagnosis and Prognosis.

The introduction by the late Dr. Lewis Jones of an apparatus known as a "condenser testing set" has proved of the utmost value.¹ In the early days of the war I applied for, and obtained, one of these sets, and all nerve and muscle testing has been done by its aid. With it electrical impulses varying in length from $\frac{1}{1000}$ up to $\frac{1}{2}$ of a second in length can be thrown into a muscle.² A choice of twelve is given by the existing instrument.³ Only absolutely normal muscles will respond to the first two. On the other hand (when the limb is warm), response only to the last two values on the scale—when these are reinforced in a manner specially provided—is considered in the light of our experience here to be an indication for operative interference. Exploration has shown either a mechanically divided nerve or one strangled by fibrous tissue. It is our usual practice to wait a month after the first test before resorting to operation, and to search anxiously for any sign of spontaneous improvement. Where, however, sensation is also completely lost there can be no excuse for delay.

Muscular reaction confined to condenser impulses of the order $\frac{1}{10}$ of a second is a most valuable guide in determining the necessity for an operation. If the nerve, when exposed, is found to be actually severed it is, of course, certain that the patient will not recover the full use of his limb for a long time; but if the lesion is merely a strangulation, the original condenser test does not in itself furnish sufficient ground for a definite prognosis. The test may be relied on to show that a *physiological* block has existed for some time, but does not necessarily mean that the axis cylinders distal to the lesion are injured beyond power of

recovery. This limitation fortunately detracts but little from the practical utility of the test. Operation apart, its prognostic significance is most unfavourable.

Muscles requiring from 3 to 8 on the condenser scale to throw them into contraction will all respond more or less to faradism, the only difference being that some require a stronger current than others. It is true that nearly all lower segment lesions in which, after some weeks, a fair faradic response can be obtained tend to recover either spontaneously or under proper treatment; but the time and care necessary vary greatly as between case and case. Two patients, each of whom has had an injury to the leg, may both be equally unable to move the corresponding foot. Yet one is cured in a few weeks, while the other requires careful attention for months. The muscles in each case react to faradism, the response being somewhat less brisk in the one case than in the other. If these cases be tried with the condenser test, it will be found that the first reacts to No. 3 or 4; the second, only to 7 or 8.

The average faradic coil gives individual impulses lasting—effectively—about $\frac{1}{10}$ of a second. The normal muscle can react to impulses lasting less than one-twentieth of this time, and therefore a muscle whose nerve supply has been very considerably impaired may still respond well to coil currents. One has frequently heard it stated in courts of law that because the claimant—for example, in a workman's compensation case—stated that he could not freely use a limb, whereas all its muscles responded well to faradism, it was therefore strongly to be presumed that he was malingering; or, at least, greatly exaggerating his symptoms. Medical witnesses for the defence did not go so far as to assert that good faradic reactions could not exist coincidentally with loss of voluntary power in lower segment lesions, but gave it as their opinion that such cases were extremely rare. I will admit that I formerly had some leanings to such a view; but the experience of the last six months has convinced me that, while complete loss of will control is unusual when faradic response is preserved, impairment is very common. This takes the form of feeble action, or, more characteristically, of sluggish movement resembling that of involuntary muscle.

In the condenser testing set we have a means of gauging objectively the seriousness or otherwise of the various cases which in former days would simply have been noted as responding to faradism—with, perhaps, the further note that the response was brisk, moderate, or feeble. The condenser set furnishes us with seven or eight definite impulses, all lying within the faradic range, but differing the one from the other in such degree that an injured muscle will not twitch until a particular stud is reached. A faradic test can never be repeated exactly as it was made; the impulse of a condenser of known capacity charged at a definite voltage is always the same.⁴ The possibility of personal error in electrical testing is thus greatly reduced, and one is usually able to give a prognosis with very considerable confidence.

Two types of cases in which complete loss of voluntary power may exist react to the lowest condenser discharges: paralysis due to disuse, and paralysis due to psychical trauma. The amount of disability which can result from simple disuse, and which may sometimes persist in spite of massage and passive movement, must be seen to be believed. I refer to the case of limbs which have been kept on splints as a result of wounds, but in which no specific damage has been done to nerves and muscles. Yet it may safely be prophesied that full voluntary control can be re-established in a month or less. Paralysis due to psychical trauma must be carefully distinguished from the above, though the condenser results are identical. The history is nearly always that of an injury under dramatic circumstances—often the bursting of a shell which has killed several men near to the patient. Generally he has himself been slightly wounded in the neighbourhood of the paralysed member. In civil practice such cases would be dubbed "hysterical palsy," but the use of such a term appears to be inappropriate under present circumstances. Many of the victims of this form of paralysis are men of proved bravery, and there is no ground for assuming that they are necessarily of unbalanced mentality. Skin

¹His description was published in the *Proceedings of the Royal Society of Medicine*, vol. vi, 1913 (Elect. Therap. Sect.).

²The instrument in use here is one made by Mr. Leslie Miller, the original model having been constructed under the supervision of Dr. Lewis Jones. It is used nominally at 100 volts, and the twelfth stud then gives rise to an impulse lasting $\frac{1}{2}$ second. An arrangement is provided, however, by which the last three studs may be used over again through a resistance at a voltage of 200. We are thus able to get impulses lasting approximately $\frac{1}{10}$, $\frac{1}{5}$, and $\frac{1}{2}$ second. This makes 15 gradations in all, and muscles are reported on as responding somewhere between 1 and 15. "Lewis Jones condenser scale"; or, briefly, thus: "Tib. anticus, 13, c.a." (condenser scale). Both electrodes are always placed on the muscle.

⁴The resistance also counts, but that of the human body may be regarded, for condenser testing purposes, as a constant.

anaesthesia following the distribution of no cutaneous nerve or nerves is a common accompaniment, and aids in the diagnosis. The majority of such patients recover in a week or two under appropriate treatment, but a favourable prognosis cannot be given with certainty at first, as cases with a neurotic taint may prove most obstinate.

In the types of paralysis above discussed there is no injury to nerve trunks. Where such injury has occurred, but without the abolition of all faradic response, condenser studs ranging from No. 4 to No. 8 will be required to provoke reaction. The prognosis in such cases cannot be given even approximately as the result of a single test. They must be appropriately treated, and examined electrically from time to time. Some will improve rapidly in a week or so; in them a speedy restoration may be looked for. On the other hand, others will show no change for the better even in two months. In a few instances paresis gradually passes into paralysis, in spite of treatment; this is due, in most cases, to a gradually contracting fibrous band. The latter class should be operated on as soon as it is certain that they are retrogressing. In the "no change" type it is also probably best to operate, although some patients undoubtedly begin to improve even after two months, and in others the lesion may not be such as can be benefited by surgery. In cases of fibrous stricture, however, the chances of surgical success are so much lessened by delay that a reasonable probability of its presence justifies exploration. Provided that the operation is skilfully done, practically the only risk which the patient runs is that inseparable from the administration of an anaesthetic.

The same remarks apply to cases just beyond the faradic range, but the prognosis becomes progressively more unfavourable as the higher condenser numbers are approached. Strictly speaking, all cases in which it is decided to wait should be given the benefit of treatment in the interval, but in practice it is not usually possible to find time for this when the probability is very strong that operation will ultimately be required.

Down to the end of February, 13 cases were recommended for operation, constituting about one-fifth of the total number examined. Of those explored, the nerve was found to be severed in one, almost severed in a second, and constricted in the remaining eleven. It may, of course, be objected that some of the latter would have recovered without operation, but the surgeon was not of this opinion. On the other hand, the cases in which a favourable prognosis was given have for the most part done well. The kind of exception which is most likely to occur is that in an apparently severe case nothing definite is discovered at operation, and complete recovery subsequently occurs. So long, however, as it is found possible to prophesy correctly in two out of every three cases, the value of the condenser test will not be seriously impaired.

The foregoing remarks are intended to refer chiefly to gunshot injuries of nerve trunks. The principles of treatment immediately to be laid down apply, however, equally well to lower segment palsies, however caused. Injury to the circumflex nerve as a result of dislocation, paralysis following a toxic neuritis, and disabilities due to anterior poliomyelitis, are cases in point.

TREATMENT.

The cases treated in the electrical department may have been operated on or not. In the former instance a divided nerve may have been found or merely a strangulation. Again, the condenser test may show the muscular reaction to be within the limits of the normal; or, while still capable of faradic response, the muscles may require abnormally long condenser discharges to excite them; or, again, the injury to the nerve-muscle combination may be so serious as to require the longest possible impulses. In some instances there will be no voluntary power; in others, it will remain considerable. Finally, passive movement may be free or greatly restricted either by adhesions or contractures. Each of the above calls for some special modifications in the treatment applied, but certain general rules may be laid down which are more or less applicable to all cases.

1. Necessity for Free Passive Movement.

On first seeing a case we should determine whether any adhesions are present. The mere fact that a joint cannot be moved freely does not, of course, prove that it is limited

by fibrous tissue. Limitation may also be due to (a) tendon shortening, (b) contracture of muscles, (c) simple muscular spasm. The joint and as much of the limb as possible should be immersed in hot water—as hot as the patient can bear. After a few minutes it will often be found that a much greater range of passive movement can be obtained. In simple spasm the muscle does not tend to recontract while under the hot water. In contracture the limb can generally be more or less straightened by gradual pressure, but tends to resume its old position immediately. In tendon shortening and fibrous adhesions it cannot be straightened at all. The former condition can be recognized by feeling the tendons stand out when the limb is moved in opposition to them. The diagnosis of fibrous adhesion is arrived at by a process of exclusion. It is assumed that an x-ray examination has shown that no bony ankylosis is present.

Massage can do something to alleviate all the foregoing conditions, but its maximum effect is often very quickly reached, and further dependence upon it alone becomes a mistake. As soon as definite improvement week by week ceases to occur under massage, other therapeutic measures must be used. Fibrous adhesions can often be overcome by the use of the continuous current; or, if the expression is preferred, by chlorine ionization. Tendon shortening is the result of a faulty position during the healing of a wound, and may, in bad cases, have to be dealt with surgically.

Contracture of muscles is due to paralysis or paresis of their opponents, and, if recognized early and combated by suitable splints, need never become serious. If already present in marked degree, a splint must be applied of such a shape as to relax the parietic muscle or muscles. Where the contracted muscles are otherwise normal, the matter is simple, but where they are themselves only less damaged than their opponents the exact amount of extension and the time during which the splint should be worn are matters calling for the exercise of careful judgement. We must also beware of trusting to relaxation alone to cure a damaged muscle. In many cases it will; but, even so, if electrical stimulation be added, the time required is shortened by one-half to two-thirds. And there are instances in which nothing other than the electrical stimulus has power to set the damaged neuro-muscular machinery again in motion.

The point of the foregoing remarks is that direct stimulation of muscles and motor nerves is useless unless proper mechanical conditions have first been established.

2. Importance of Warmth.

The preliminary treatment just discussed may occupy days or weeks, but there is a further preparation, which it may be necessary to attend to at the commencement of each individual sitting. To attempt the electrical stimulation of cold and clammy limbs is futile. The affected parts should be immersed in hot water for some minutes, and if diathermy is available, it is desirable to apply it also.

3. Direct Application of Electricity to Nerves.

The transverse passage of large galvanic currents through the site of injury of a nerve trunk is often advantageous. Large pads are placed opposite to one another, so that the limb is almost encircled. The absorption of blood-clot and fibrous tissue is promoted, and local healing generally accelerated. It is also useful, when the limb is in the before-mentioned hot bath, to pass a mild sinusoidal current; it should not be heavy enough to cause any visible muscular contraction. If definite movements are produced the healthy muscles are apt to benefit more than the injured, and the tendency to unbalanced action is thus increased. Much discredit has been brought upon electrotherapy by the indiscriminate use of baths by ignorant persons.

4. Stimulation of Individual Muscles by Interrupted Currents or Condenser Discharges.

This is the sheet anchor in the treatment of nerve-muscle injuries. It needs much skill and practice, and cannot be successfully accomplished merely by propping up in front of one a diagram showing motor points. A skilful operator learns to play upon a limb as on an instrument, and is able to produce any desired movement or combination of movements at will.

Upon the first occasion the movements of the paretic muscles should be provoked at intervals of a few seconds until definite fatigue appears—that is, until the response is obviously weaker. The object of this is to obtain necessary data. Upon the next occasion only half the previous amount of stimulation must be given, so as to avoid all possibility of overting the muscles. The amount of stimulation at each sitting should not be increased until it is reasonably certain that more can be tolerated without fatigue. In order that the information obtained at one sitting may be usefully applied at the next, it is necessary to be able to repeat or modify all the conditions as desired. With a faradic coil this cannot be done with any approach to nicety, though practice and experience will enable one to obtain very fair results. The most accurate instrument for the purpose is a modification of the condenser testing apparatus, in which a mercury break takes the place of the metronome, and any selected length of condenser impulse may be thrown into a muscle a given number of times per second. A speedometer should be attached to the motor of the break, and the patient's circuit should be interrupted by some mechanical device which can be set for any given speed. If a metronome is used, the mercury in the cups may be so adjusted as to cause each tetanization to last any desired space of time. With a little adaptation, the same metronome may be used either for charging and discharging condensers in nerve testing, or to interrupt rhythmically any form of current which is being passed into the patient. Generally speaking, the individual contraction should only be of brief duration.

The instrument has the additional advantages that muscles injured beyond the faradic range may be rhythmically tetanized if desired, and that the progress of a case in either direction may be ganged without special tests, owing to the muscles requiring a higher or a lower stud to excite them.*

5. Exercises.

The value of exercises when any voluntary power is present is well known, but the method of resistance to graduated pressure (or weight) does not seem to have been as widely used as it deserves. Such control often returns long before ordinary movements can be performed, and gives great confidence to the patient. The movement of otherwise helpless limbs is often possible in a full bath. Great care should be taken not to ask patients to perform any given movement unless there is a good prospect of their being able to do so; failure often causes great depression.

It will be objected to this that many apparently fruitless efforts may be necessary before success can be obtained. This is true, but the well-known good effects of utilizing the will may be obtained without risk of mental upset. Patients should be told to make a mental effort at the same time as a contraction of the muscle is about to be provoked electrically. The metronome is a great aid to this, as the patient soon learns to know exactly when the stimulus is coming. A sliding resistance is also an advantage, as the operator can by its aid make fine adjustments in the strength of the current according to the amount of voluntary effort put forth by the patient. Even if at first no appreciable lessening of the required electrical stimulus is produced by the patient's voluntary efforts, these should be persisted in; as a result of such persistence, cases which are curable will be cured the more quickly.

Cases in which the psychical element enters need especially tactful handling. They are of two kinds. The mental trauma may be wholly responsible for the disability. But it is a great mistake to tell such patients that there is really nothing the matter with them. They should be shown that their muscles are all capable of vigorous movement under electrical stimulus, and informed that all they need is proper treatment to put them right in a week or two. The judicious holding out of the prospect of furlough "as soon as the power returns" also has a good effect. Harshness may easily render an otherwise readily curable disability lengthy or even permanent.

* The electrical stimulation of muscles just described must not be regarded merely as a means of keeping them in order while their nerves are spontaneously recovering. By conduction and reflex action the whole of the lower segment neuron is favourably affected, and not merely its terminations in the muscle.

Again, we may have to deal with a definite organic injury in itself curable, but accompanied by an emotional instability due to shock. Patients affected thus are apt to weep, and declare their hopelessness of cure in the face of obvious local improvement. It is no use dealing sternly with them in these circumstances. If they have good homes, they are best sent to them for a week or two with a clear intimation that they are to use the respite to "pull themselves together." On their return it is time enough to lecture them upon their foolishness. Some patients of this type, although able to get about and apparently well in body, cannot be satisfactorily treated as out-patients. The discipline of a hospital is essential to their cure.

Electrical Treatment after Operation on Nerve Trunks.

When a nerve has been merely freed from a constricting band, electrical treatment should be begun after a reasonable period—say a fortnight. It should be very gentle at first, but should in other respects follow the same lines as if no operation had been done. When a nerve has been sutured the matter is not so simple. I have not personally treated any cases of this kind for more than a few weeks before losing sight of them; but Bailey of Brighton, who made elaborate experiments on himself extending over a year, is of opinion that electricity is of great assistance.

Cases of ascending degeneration, fortunately rare, appear to be very hopeless. Care must be taken not to diagnose ascending degeneration when the paralysis is due in reality to cut tendons. The distinction is not easily made in all cases. The wound may produce some sensory disturbance in its neighbourhood, and it is not always possible to be sure that a particular muscle responds normally to electricity; one is deprived of the most useful guide—namely, the tautening of the tendon beneath one's finger.

In giving a prognosis in a case of nerve injury, one should be sure that one is dealing with a pure lower segment lesion. A shell wound in the neck at close quarters may produce a mixed lesion, slightly damaging lower neuron cells controlling the arms, and at the same time (by the force of the explosion) causing haemorrhage in the motor area of one or both sides. Slight facial palsy of upper neuron type, not noticeable unless looked for, will sometimes furnish the key to a lack of progress beyond a certain point. I am far from suggesting that electrical treatment is useless in brain lesions, but the brilliant results which are often obtained in lower segment paralysis cannot be looked for. Cerebral galvanization, as recommended by Professor Leduc, may be given a trial in addition to stimulation of muscles, but it is a procedure calling for great perfection of apparatus and skill on the part of the physician. In unpractised hands it has dangerous and even fatal possibilities.

The sum total of suffering which can be relieved by electro-therapy is not less than that which can be dealt with by surgery itself. But the right use of the elaborate electrical paraphernalia which modern science has provided calls for skill, experience, wide medical knowledge, and a well-balanced judgement. To leave such work wholly or chiefly in the hands of lay assistants, however intelligent, is no more rational than it would be to permit operating-room attendants to perform abdominal section or excise tumours from the brain.

THE Commissioner of Patents at Ottawa has recently granted a licence to Mr. E. Neil Macallum and Mr. Newton Candee, both graduates of the University of Toronto and synthetic chemists of special training and experience, to manufacture salvarsan under the name of "Diarsenol," as since the war began it has become very scarce in Canada. Mr. Macallum studied for several years under Professor Schultz in Munich and Professor Perkins in Manchester and Oxford, and is well qualified to undertake this work. In order that the Canadian product may be equal in every respect to the German, arrangements have been made with the University of Toronto to test and standardize every quantity of salvarsan made, before it is permitted to be used; these biological tests are being carried out in the pathological laboratories of the university and in the Toronto General Hospital. The price of the compound has been fixed by the Commissioner of Patents; it includes a royalty to the German patentees, and is only slightly in advance of the wholesale price current before last August. The Synthetic Drug Company of Toronto will undertake to place neo-salvarsan on the market as soon as it has been able to manufacture a supply of diarsenol sufficient to meet the present demand.

SUGGESTIONS FOR THOSE INTERESTED IN WAR DÉPÔTS AT HOME.

By JAMES HOSSACK, F.R.C.S.E.D.,

BURTON, IPSWICH HOSPITAL; LATE BURTON AT ST. JOHN'S
HOSPITAL, MOA, ST. MALO.

The experiences of a surgeon who has served for nearly eight months in a St. John's Hospital in St. Malo may be of considerable use, especially to those of us who may be asked to assist in the management of what are called dépôts in England. To Ipswich dépôt—I believe the first of such organizations—I am infinitely indebted for the magnificent way they kept me supplied with all sorts of surgical and other necessities. It is admirably managed and organized, and is under a trained nurse, as all such dépôts should be.

As the wounded in this war do not fall into line according to modern books on surgery, neither do the supplies sent from the dépôts in general quite fulfil the requirements. Economy is essential, and I am convinced that if some sort of standardization were adopted by all dépôts, much money might be saved. It is with this view that I propose to offer certain criticisms that I hope may be of use, and certain suggestions that may be, I hope, of greater use.

Swabs.

Swabs, I believe, can be improved from an economical point of view without losing efficiency. I received many beautifully done up and sterilized. Ideal—but yet not economic. Practically every case admitted to hospital was septic, and most of them very septic indeed. The swabs were made by cutting up squares of gauze, a small handful of cotton-wool was put in the middle of the gauze, and the four corners tied; 500 were then enclosed in a jaconet bag and sterilized. This is theoretically admirable, but practically I may point out defects. First of all, these swabs, about the size of a pigeon's egg, were far too small, especially when wet and squeezed dry. I like a swab to be about the size of a hen's egg, and so do most surgeons. The jaconet bag was beautifully made, with a tape run round the mouth, but to a certain extent this was a waste of labour. A packet of 30 swabs tied up in a muslin bag, and 20 such muslin bags enclosed in a wrapping of jaconet fastened with a pin is all that is required. The jaconet wrapping with pin attached come in very handy for fumigations. Thirty swabs is usually enough for most operations. The remaining 19 packets can remain in their covering till wanted, almost certainly during the day. In big cavities the smallness of the swabs became an absolute danger—there was always present to the surgeon's mind the possibility of losing one. In an emergency with secondary hæmorrhage (a not infrequent occurrence), one packed in 6 or 8 or 10 of these swabs, and one was constantly harassed with the idea that perhaps one was left behind. The known number of 30 saves counting when rushed. Dr. Griffith, discussing this question with me, made the admirable suggestion that squares of Turkish towelling, double or treble thickness, 6 to 8 in. square, should be sewn along their edges and a tag of tape, about 6 in. long, sewn to each at the corner; they cannot be lost because of the tape, and after use can be washed, boiled, and kept in 1 in 40 carbolic solution in glass jars in the theatre, and could be used over and over again, whereas a swab once used is done for. Sponges are old-fashioned, no doubt, but, if properly looked after, are by no means to be despised; they must be good and their care and storage understood.

Sterilization.

Sterilization is certainly admirable, but is not necessary in nine-tenths of the cases from a surgical point of view, but there is one important point that must never be lost sight of. Scattered over England to-day there are various centres where scarlet fever, measles, and diphtheria are known to exist. Many of the bandages sent out are made in schools by school children, other articles are made in homes, others in dépôts by lady workers. The sources, then, of infection are numerous. For this reason, to prevent any infectious disease being sent out, all dressings, bandages, and I would say everything possible, should be sterilized. It would never do to have an outbreak of either measles or scarlet fever in a base or any hospital owing to neglect of this. If it could be brought home to

goods sent out by dépôts, it would, I fear, be a serious blow to them. Hence one necessity of a trained nurse at the head of affairs to keep an eye on these details. I am a firm believer in carbolic acid, and, without exception, all my cases were treated antiseptically as against aseptically. All swabs, sterilized or not, were wrung in 1 in 40. We had only one theatre and antiseptics were *de rigueur*, so that it is essential to have plenty of carbolic acid.

Lint and Gauze.

Boric lint is a necessity, and it can never be wrong to send it out in quantities.

Small packets of gauze about 2 yards are best; larger packets are liable to become soiled. I would suggest that the gauze be cut up into squares of about 6 to 8 in. Packets of a dozen such squares should be wrapped up in waxed paper before being sent out. Long strips of gauze about 2 in. to 5 in. wide, rolled up like a bandage, are extremely useful, and can be packed in the same way.

Splints.

Splints were sent to me which were absolute works of art in the way of padding and so forth, but, to my mind, extravagant again. The wood was covered with corrosive wool padding, and this was held in position by cotton sewn across and across the back. In twenty-four hours the padding was saturated, the wood itself soaked with pus—and alas for the work of art!

I suggest that the wood should be painted first with creosote, and when dry enamelled. This will prevent pus and fluids soaking into the wood. The splint can be used time and again by sponging it over with an antiseptic, instead of getting a new one and burning the old. My advice is not to pad. No limb is perfectly flat; each has its own curves and bends, and each splint should be padded to fit its own limb. I found padding the splint with ordinary cheap wool to fit the contour of the limb, then to slip on a piece of jaconet to cover the whole splint, tying it in position by strips of bandage, saved time and money and fitted the patient best. The cheap wool was burnt, the splint sponged, the jaconet boiled and dried, and so practically there was no waste. No splint yet invented will ever meet every case, no matter how well padded. Many will not agree with this, but it is my personal experience. I found that a piece of board from a packing case, a saw, a few French nails to fasten on a footpiece, and a tin of enamel made the most satisfactory splint. For leg cases I always allowed the T-piece at the bottom to be sufficiently high to act as a support for the foot to be bandaged and to take off the weight of the bed-clothes: the under half of the T was left about 4 in. long to elevate the limb and make an inclined plane. Almost all fractures are compound, comminuted, and pouring with pus, so that soiled padding is inevitable. Lengths and breadths of splints must be assorted; 4½ in. is a good average width for leg splints.

For arms I can recommend a waterproof paper splint resembling gouch, sold in rolls by Cuxon, Garard, and Co., Birmingham. It can be cut as required by any pocket knife, or a strong pair of scissors. It can be sponged or burnt.

Wool.

For sopping up discharges there is nothing to equal wool-wool, and for dressing wounds outside the gauze, both in the theatre and wards, it is ideal.

I do not like cellulose wadding. It clings to the skin and is difficult to remove, does not absorb pus well, and easily disintegrates and clogs up syringes. In peace times ordinary corrosive absorbent wool is best, but wool-wool is better and cheaper for wounds discharging much foul pus. In the theatre there must always be white absorbent wool.

Pine Sawdust Dressing.

This is in many ways admirable, cheap, and to a certain degree efficient, but uncomfortable. When sodden with pus it gets heavy, and acts like an old-fashioned linseed-meal poultice. I have doubts, too, of its antiseptic properties; sterile they may be, but not satisfactory on the whole.

Drainage Tubes.

I know of no substitute to equal drainage tubes, but they should be big; the index finger or thumb is not a bad guide for size. Let the walls be thick and fairly stiff, so that

when the tube is run through a limb and round the bone it will not kink and be useless, but remain round and a tube. The tubing should not be cut up into lengths; this should be left to the surgeon.

Bandages.

The varieties of sizes and material were legion. Cheap cotton ones are extravagant because the material of which they are made is ruined in the first washing. They do not iron out, and cannot be fitted on to lie flat after washing. Usually their first use was the last. Let the cotton bandages are made of be good; it is cheapest. Far and away the best bandage is made of flannelette; care should be taken to see that it is not inflammable. For many-tailed bandages it is admirable, as good as domette and cheaper. These bandages can be washed, ironed, and are as good as new, and can be used time and again. It is astonishing, too, how often one uses many-tailed bandages made of flannelette for arms, legs, chest, abdomen, etc. Slip the bandage under the limb and the rest is easy—much quicker for the surgeon and easier for the patient, when every movement causes pain, than putting on a roller.

For chest cases the many-tailed bandage has a tendency to slip down, not up. To prevent this I had sewn on to the back top part of each chest many-tailed bandage two strips that came over the shoulders, crossed on the chest, and were pinned to the bandage in front, braces in fact, and found them very useful. Many-tailed bandages should be rolled in the following way: Take two long pieces of stiff paper, 6 inches longer than the depth of the bandage, and commence at each end rolling the many tails towards the centre. The result is two sausages as it were of bandage rolled on paper, meeting at the middle. This can be slipped on under anything, and when unwound the paper removed everything is finished with, the tails all flat and no rucks.

Three sizes of bandages are sufficient—2½, 3½, and 6 in. are all that are required. With a sharp table knife the 6 in. can be cut if desired to any breadth, 1 in. upward to 5 in.; it must be cut squarely to avoid scalloped edges. Most bandages are far too long. Bits are torn off and thrown away; 4 to 5 yards is enough, instead of 6 yards.

All kinds of arm slings were sent us—patent leather looking things, khaki coloured with buckles and what not. There is nothing to equal the triangular sling, and a colour other than white would be welcome—black or slaty-blue to match the uniform, or khaki. A safety pin (black) should be put in each sling. The standard St. John sling is correct for size.

For irrigating wounds there is nothing to equal a Higginson syringe, with a glass nozzle, but a piece of gauze should be tied on to the other end to prevent bits of wool getting in and blocking the valves. The whole thing can be boiled, and lasts for weeks, or even months. I prefer them as handier than an irrigator with long rubber tubing. Glass syringes, whether hypodermic, exploring, or what not, are always being broken, either in boiling, by accident, or carelessness; all metal is best in the long run. Ordinary 6-inch probes are almost useless. I had made for me probes varying from 1 ft. to 18 in. long. I have seen cases in which bullets have entered at the buttock, and been removed from the back of the neck. Stout copper wire silvered, with a blunt point at one end and an eye at the other, I found admirable; they can be bent to any curve, and are cheap and everlasting.

Drugs.

The tablet form is best, and a great variety is not needed. Calomel, aspirin, morphine, and salol are in constant demand.

Antitetanus serum is essential, but, alas! not always to be relied on. A reliable mark should be got from a reputable firm, and I strongly urge that samples should be submitted to a bacteriological test before sending out. This is most important; certain samples proved to be inert. I found a most practical way of putting up these was a method used by Parke, Davis, and Co. It consists of a round glass container, made with glass tips at each end. Inside this container was the serum, with a plunger at one end. Enclosed in each packet was a sterile needle and a rod. By breaking off one end the needle fitted on, and by doing the same to the other end, and screwing the

rod on to the plunger inside, the syringe was complete. I gave many of these away to young officers going to the front, confident the risk of contamination in such an appliance was reduced to nil, even in the hands of an amateur.

Clothing.

All sorts of strange garments were sent to us by kind souls, who enclosed no name and no address. We never knew what some were—whether socks, mittens, or night-caps. Bed jackets of splendid flannel and exquisite workmanship made so narrow across the back that no ordinary man could get into them. All these had to be altered, and three jackets were frequently used to make two good ones. Shirts, again, have arrived with neck bands so tight as would have throttled anybody who tried to fasten them; the bands had to be taken off and bits let in, and so on. All this means want of some central supervision. They had not been examined at any dépôt, and were sent out by well-meaning people, who had probably never made shirts or bed jackets in their lives before. Standardization is required, and would mean economy. Then there were strange and wonderful garments with tapes up the backs, down the sides, down the front, up the arms, the result of patient work—all very admirable, but in nine cases out of ten not needed, except in paralysed cases the result of injury to the spine. It is not comfortable to be on a string of knots, and patients complained of cold backs. The simpler the garment the better: it should be big enough, but not too big; the wrist bands should let a man's fist through, and the neck be big enough to button. Pyjamas are not much used in hospital wards, but ward suits for patients to walk about the wards and grounds are a necessity. Each hospital should, if possible, have the same pattern in colours and arrangements, or at least each ward or floor.

Various sizes of coats and trousers are necessary for big men and little men. The jackets should have three pockets—two at the sides, and one for the handkerchief. Those known as patch pockets are best and easiest to make. Pockets in the trousers do not much matter. The material of which these suits are made should be washable and not liable to shrink.

Buttons are a great nuisance, and were frequently missing. An excellent button can be got consisting of a metal disc with a central hole, and a separate shank shaped like a collar stud. A small slit was made where the missing button came off, the head of the stud passed through and the disc snapped on. It is easy to do, and makes an admirable job.

French soldiers had no slippers; their hobnailed boots in the wards ruined the floors, and the clip-clop they made was irritating. Slippers of felt are essential, should be big enough to put on a bandaged foot if necessary, and of all sizes. Any ingenious woman can make them cheaply.

Tobacco.

A tremendous amount of money is frittered away in tobacco and cigarettes that could be infinitely better used in other ways. When I left St. Malo at the beginning of June I should think I left behind a couple of hundred-weight of tobacco and cigarettes, sent to us by all sorts and conditions of people and societies. This was due to overlapping from want of organization.

French soldiers are careless with their matches and cigarette ends. They finish the cigarette, and drop it with the spent match by the bedside. Tin ash trays to stand by the bedside are a necessity, yet, except in our hospital, I never saw any.

Ward Appliances.

The best basins for the wards for washing patients I came across were papier-mâché ones sent from Ipswich. They were enamelled inside and out. They tumbled about, and had no end of rough usage, but they never broke, never chipped, or, if they did, a 6d. tin of enamel was all they wanted to look and be like new. Earthenware or tin basins very soon got broken, or bashed, or dented. For dressing wounds enamelled ware basins, bowls, and big kidney dishes are a necessity. Kidney dishes can be got in papier-mâché, are cheaper than the enamel ware, and do not chip.

The most expensive item we had to deal with was mackintosh. In regard to this, the cheapest is the

dearest: give a good price for a good article. No substitute that I know of equals good mackintosh. It is an absolute necessity. We had many different things to try, but always returned to mackintosh.

Such things as razors and shaving brushes we were always hard up for. Usually the men arrived with nothing but what they lay in. As for trouser braces, nobody ever thought of sending us these useful articles till they were asked for.

There is no need to send crutches. All these are supplied locally, and made by any carpenter. Ordinary unscented antiseptic soap is a godsend for washing the men, who arrive in a filthy condition.

All parcels should be sent out in cases: 3 ft. by 1½ ft. by 1½ ft. is one handy size. The lid should be hinged at the side, screwed down, and a partition should divide the case into two. When stood on end it makes a capital bedside table, cheap, efficient, very necessary, and far better than an orange box. The screws are an advantage for opening and come in handy for fastening foot pieces on to splints, and in many other ways. These boxes are useful, too, for storing x-ray negatives, and when placed side by side one tier above another become handy lockers for boots, caps, belts, and so on.

Bigger boxes should be about the height of a table when on their ends. Three or four placed together and covered with a sheet of American cloth make an excellent ward table. If the partitions are put in and the lids hinged they act as cupboards as well, to keep the thousand and one things necessary in a ward. Placed in the linen room they make excellent cupboards for sheets, towels, pillow cases, etc.

It is desirable to have the wood planed, for then it comes in also very handy for many splints. They must have the Red Cross label pasted on, and I like a list of contents tacked on to each box, both in French and English. It saves bother with the Customs. Much worry can be saved by getting the signature of Sir Wm. Garstin at the Red Cross offices, Pall Mall, also to tack on. It acts like a charm on Customs officers. The arrangements may now be different, but the St. John Ambulance Association or the Red Cross will always advise in this matter.

Need for Organization.

It is a great pity that there is not some central organization to deal with overlapping. I would suggest that a central dépôt or committee be authorized to deal with these matters, and that model garments, model bandages, splints, etc., be given to the dépôts throughout the land where charitable people who want to make things and do things in this terrible crisis can see what is required, and have pointed out to them certain faults they must avoid. The money and the will is here, but much is wasted through isolated but well meant unorganized effort. I understand the Marlbon dépôt is attempting such co-ordination. I heartily endorse such action, and wish it success.

In this article I am discussing matters as they appeared to me at St. Malo. I cannot speak of what happened further up near the firing line.

FURTHER INVESTIGATIONS INTO LATENT DYSENTERY AND INTESTINAL PARASITISM IN SARAWAK, BORNEO.

By W. LEDINGHAM CHRISTIE, M.D.,

F.R.C.S.ENG.,

SURGEON TO THE BORNEO COMPANY, LIMITED.

In a previous paper I stated: (1) That many people, European and native, were found to carry what we believed to be *Amoeba histolytica*, without complaining of acute or chronic dysentery, but that they were mostly pale and weak, while many, indeed most, of the same persons had also ankylostomiasis. (2) That in the cleared portions of this country malaria was not common, yet the tradition that every feeling of languor or heat was considered to be "a touch of fever" was so common that quinine was used extensively. After calomel and saline were substituted, great improvement resulted, because the

septic state of the alimentary canal, associated with constipation, was so usual, that "constipation fever" would have been a truer description. (3) I gave a list of 100 unselected cases of all kinds, among Tamils, Javanese, Chinese, Dyaks, Malays, and Europeans, who came into hospital, and I stated that amoebae were found in 34 per cent., ankylostomiasis in 40 per cent., whip-worm in 44 per cent., round-worm in 24 per cent., and monads in 13 per cent. These patients, however, had occasionally been treated for these conditions, and as I wished to find the main reservoir of intestinal parasitism, I set to work to test 100 Malays living on the banks of the Sarawak River in their usual fashion, in palm leaf houses on high piles on the edge of the river.

None were selected or pressed, and few had been treated. These patients often try to get santonin, but the hospital is distant, and we may consider their ailments as practically untreated, the native remedies being of little use. Most people are probably now aware that Malays let all their sewage run into their river. They squat for defaecation in it, and drink from near the same spot, trusting to the current and tide for cleansing. They love their river, are always bathing, swimming, boating, drinking, or fishing in it. To the casual observer they appear as a happy, clean family sporting beneath their cocoanut palms and fruit trees. They are fond of gong-beating and dances on every possible occasion. They dislike any work, save boating and gathering jungle produce in the forest. Yet in reality the average Malay seems sad and sooty when not *en fête* or excited. Careful examination will show that debility must result from the very great amount of parasitism from which they suffer. One of our Malays manages to struggle through his work as boatman and carpenter with filaria in his blood, amoebae, ankylostoma, round-worm and whip-worm in his alimentary canal, having already become immune to malaria, which is found more frequently in the young. He was, on the other hand, an ardent advocate of beta naphthol and santonin among his compatriots, and it was he who went and explained the reason why their stools should be examined. With no small effort, and by sending this man and a laboratory assistant up and down the river, we managed to get good specimens of faeces in Petri dishes, carefully labelled, from 100 Malays—men, women, and children—in the order in which they offered, without any reference to present or past illnesses. The women were somewhat shy, and are therefore in the minority. Four slides were examined, and amoebae were chiefly searched for. Only moving specimens, or those well stained by neutral red, were counted. They had the eccentric nucleus, blunt pseudopodia, and other characters of *Amoeba histolytica*. The differences of size, amount of activity, and tendency to be quiescent we considered to be due to the warmth or coldness, liquidity or otherwise of the stools, and the time intervening between voidings and examination. The work was done by myself, or assistants under my supervision, in a well-equipped laboratory.

The result was as follows: *Amoeba histolytica* was found in 59 per cent. of the samples; *Ankylostoma duodenale* (or *americanum*) in 59 per cent.; monads (*Trichomonas*, 63 per cent., *Cercomonas*, 3 per cent.), 66 per cent.; round-worm (*Ascaris lumbricoides*), 79 per cent.; whip-worm (*Trichocephalus dispar*), 84 per cent. Each person had several sorts at once—in fact, in 17 per cent. five were observed on the same slide, namely, ankylostoma, amoeba, monads, round-worm and whip-worm. The figures are well under the mark, for in twenty cases which were previously negative, where we got a second specimen, we found amoeba in 50 per cent.

These Malays who came to Sejjik Hospital afterwards for medicine did not complain of any symptoms, but some looked pale and thin, while others, who appeared normal, were not up to a fighting or athletic standard of vigour. On inquiry among 83 whom we were able to meet, we found that of those in whom amoeba had been found, 34 could remember having had dysentery, 26 could not, while of the negative cases, 10 had had dysentery and 13 had not. It may be argued that much of the languor described is due to tropical anaemia after ankylostomiasis or malaria. There is some truth in this, but none said anything about malaria which they knew well; and the following cases will show that those who had amoebae

apparently non-pathogenic, had later on acute dysentery with an amoeba to all appearance the very same.

Typical Cases.

There are few records at present of Malay cases, but the following from our case-book may show that other nationalities suggest that the same amoeba may be pathogenic at one time and apparently non-pathogenic at another.

1. S., Malay boy, aged 16 years, Sejjak. Admitted July 7th, 1914, for poisoned wound on leg. Amoebae found July 12th, 1914. No symptoms of dysentery. History showed that he had had acute dysentery when about 6 years old. He then had blood in stools, and became wasted. His mother had dysentery three months ago.

2. N. K., Tamil girl, about 11 years. Admitted February 27th, 1913, as a visitor with mother and younger brother, who had acute dysentery. She was not ill, had no diarrhoea, no colic, no blood in stool. She had ankyllostoma, mounds, and amoeba, which persisted till May 18th, 1913. Amoebae were found moving about at the examinations on forty-seven occasions, although twelve 4-grain injections of emetine were given, and salol, beta naphthol, quinine, and irrigation were tried. She was readmitted on July 3rd, 1914, with acute dysentery, severe colic, and blood in stools. Amoeba of the same species was found daily until the 10th, when she was discharged well after emetine and saline. When a carrier, I could not see any difference between her amoebae and those of her brother, nor did the amoeba she had at first differ from that she had when acutely attacked.

3. M., Tamil woman, about 20. Admitted December 16th, 1912. Diarrhoea, blood in stools, and acute colic. Amoeba found. Emetine and saline given. Discharged well December 26th, 1912. Readmitted January 25th, 1913. Acute dysentery as before. Amoeba found daily up to February 18th, 1913. Discharged February 25th, 1913. Again admitted July 3rd, 1914. Acute dysentery as before. Amoeba found. Discharged July 10th, 1914.

4. A., Tamil woman, about 25. Admitted January 31st, 1913, with bronchitis, but stools found to contain amoebae and active colic. No diarrhoea, nor blood in stools. Readmitted November 6th, 1913, with acute dysentery, severe abdominal pain. Amoeba found as before, also ankyllostoma and whip-worm. After treatment with emetine and saline, amoebae ceased to appear on December 1st, 1913. Discharged December 3rd, 1913. Again admitted April 4th, 1914, with otorrhoea. Amoeba found, also ankyllostoma. No diarrhoea nor other intestinal symptoms. Amoebae persisted till April 11th, 1914, when discharged. Admitted fourth time July 2nd, 1914, with acute dysentery, diarrhoea, severe colic, and rectitis. After emetine and saline treatment no amoeba found on July 10th, 1914. Discharged July 13th, 1914.

5. K., Javanese man, about 35, a coolie who had not been in hospital for seven years previously. He had cut his shin with his parang, and severe sepsis had set in, with a large abscess as the result. Admitted June 24th, 1914. Amoeba was found on June 25th, 1914. Patient had had no diarrhoea nor colic, but on July 7th, 1914, acute dysentery began. He had emetine twice, but refused further injections. Saline was given freely and he recovered, but amoebae were still found. Gingivitis and stomatitis became very acute, but, though very weak for many days, he is now gaining strength.

6. S., Tamil female. Admitted October 10th, 1913, with acute dysentery. Amoeba found till the 12th. Discharged October 17th, 1913. Readmitted on January 6th, 1914, with pleurisy. Amoebae found, no diarrhoea, no blood, no colic. Amoebae found up to date of discharge.

7. S., Javanese man, aged from Java May 30th, 1914. He looked very weak and thin, with prominent eyes and a slight cough. He had ankyllostoma, round-worm, whip-worm, and Trichostrongylus. He absconded on June 21st, 1914, and was caught after wandering about without proper food or shelter for five days. He was sent from the estate to hospital on July 13th, 1914, with acute dysentery. Amoeba was found, also blood corpuscles and broken-down epithelial cells. He died on July 27th, 1914. The post-mortem examination showed that 11 ft. of the lower bowel and ileum were ulcerated. The lower part of the colon was soft and the mucous membrane appeared to be melting away. The serous coat was exposed in places. The lower ileum was much injected and ulcerated. The mesenteric glands were enlarged and yellow, almost caseous. There were purulent nodules in the lungs; the pleurae were not adherent. This case shows the ravages of dysentery when debility and starvation, with concurrent disease, have their effect.

8. M., Javanese woman. Admitted November 8th, 1914. She died in a few hours of acute dysentery. She had been delivered of a 7-months child the day before, and had had haemorrhage. Probably latent dysentery had pre-existed.

Conclusions.

(1) That amoebic dysentery is endemic among the Malays of the Sarawak River; that some immunity seems to exist against very severe attacks or epidemics, but that some educational and remedial campaign would be beneficial. (2) If Case 1 as a carrier had a non-pathogenic amoeba, why did he not get a fresh

infection from the acute attack of dysentery to which his mother had been subject? The suggestion is that both amoebae are alike. (3) If in Case 2 the girl carrier had a non-pathogenic amoeba, why not at once get infected with the pathogenic one of her brother? As no difference could be seen, the suggestion is that both amoebae were alike, one acting in a latent way till able to produce severe symptoms at a favourable time. (4) Case 4 leads to the conclusion that a person may have latent dysentery alternating with acute, and no difference be seen between the amoebae. (5) Case 5 would indicate that amoebiasis caused acute dysentery when cocci were in the blood and the resistance was low. (6) Case 6 indicates amoebiasis following acute dysentery, and the amoebae appeared the same as during the acute stage. (7) Cases 7 and 8 show the virulence of the amoeba, latent at first, after exposure, starvation, and tubercle in the one case, and after haemorrhage and chillbirth in the other. (8) Although the picture seems dark, yet ordinary hygienic cleanliness and care, with freedom from intimate association with natives, will usually protect Europeans from danger of death from amoebic dysentery.

THE "ELASTIC TISSUE" ENIGMA;

A SUGGESTION FOR ITS POST-MORTEM STUDY, IN ARTERIES KEPT PERMANENTLY ELASTIC, AND IN THE "ROOSEVELT ELASTIC LUNG."

BY

WILLIAM EWART, M.D., F.R.C.P.,
CONSULTING PHYSICIAN, ST. GEORGE'S HOSPITAL.

I. Its Biotics.

The natural history of the elastic fibre is a standing problem which the inferior elasticity of indiarubber does not help us to solve. We perceive how it is destroyed in the lung by overstrain in emphysema and by disuse in obesity, and how readily it is then disposed of by phagocytosis. The mystery is its surprising normal "endurance." This would almost seem to be a function of its mechanical exercise, even more than of its nutrition. Facts have been recorded which demonstrate a patchy local "regeneration." But of its "alimentation" we know nothing, except that the fibre can be stained. And yet, if we assume that it grows, like the length and breadth of our muscular and of our tendinous fibres, it should be, at any rate at that stage, receptive of nourishment. On the other hand, the following facts would suggest that, when full grown, its vital exchanges are of a minimal order; and its viability and function largely dependent upon motile and hygroscopic factors, whilst apparently independent of direct innervation.

The work of Alexis Carrel has opened up a new era in surgery—that of transplantation—by demonstrating the persistence, for appreciable periods after somatic death, of some degree of "vegetative" cellular vitality in the simple tissues, rendering them capable of a revival of their nutritional activity when implanted into vigorous living tissues, and also the facultative prolongation by low temperatures of that suspended animation; nay, more, the persistence, after successful transplantation, of the functional capacity of some of the organs, when "isolated" *in vivo*.

The lung is hitherto the isolated instance of a dead organ capable of preservation for indefinite periods in a state of fitness for discharging its "passive" motile function almost as well as during life, thanks to the survival of some degree of elasticity in all its textures. It affords the unique example of one of our tissues, the elastic fibre, preserving indefinitely, without any vital nutrition, the fullness of its own simple function, which seems to be limited to passive movement. I might venture to suggest that this strange instance of a relative "artificial immortality of function" should be associated with the name of the distinguished physician, my lamented friend the late John West Roosevelt of New York, to whom we owe its demonstration.

The only published account of his method which I can trace is that which he gave to the New York Pathological Society, of which he was then president, at its meeting of December 10th, 1890. In his own words, "The lung exhibited was removed on January 11th, 1890. It retains very nearly the normal colour of a freshly removed lung.

It expands and contracts in an apparently normal manner. The vesicular murmur can be plainly heard in it, and percussion gives the same note as obtained from fresh lungs. The process will be seen to be a modification of the old glycerine-carbolic method, well known and often used to preserve anatomical specimens in an elastic condition. The modifications are important, however; and the results far better than any obtained in the old way. The idea of the method is, first, to fix the tissues by the chromic and acetic acid solution, then to introduce the glycerine-carbolic solution, and, finally, to get rid of this, and practically to make an 'oil-tanned' lung.

The composition of the three solutions and the mode of using them are then given. It does not appear that, at that time, he had prepared any specimen of both lungs, or that he subsequently exhibited, or published any description of, any such. That which he prepared (by his new method) to present to me at New York in the spring of 1892 may perhaps have been the first. These lungs were slightly pathological. They did not remain in efficient working much more than a year: partly, perhaps, owing to insufficient exercising. Meanwhile, in the early summer of 1892, I prepared, according to his latest directions, a perfectly normal and complete specimen of both lungs with trachea. This was a complete success. It was long used for demonstration at St. George's Hospital; and it still preserves its elasticity after the lapse of nearly twenty-three years. Unhappily, through a preventable accident, it has quite recently developed a bad "puncture" which now disables it, though it is still inflatable, for any complete and lasting inflation. That long record, and the fear lest, owing to his untimely death, the value of his latest method might otherwise be lost to science, make me anxious to publish those simple directions which enabled me to secure that success, without the help of any actual demonstration of his technique, or of any knowledge of the published details of his earlier method.

Improved Method for Preparing Lungs in order to Preserve their Elasticity and Gross Anatomical Appearance.—The lungs must be removed intact, and the pulmonary blood vessels cut as close to the heart as possible. If it is intended to prepare both lungs the trachea should be cut as high as possible. If only one is prepared, cut the bronchus at its junction with the trachea. Insert and tie as large a cannula as possible in the bronchus or trachea, and in the pulmonary artery.

"1. Take of Müller's fluid 1,000 and of acetic acid 75. Fill the lungs through the air passages, and suspend them in solution for twenty-four or forty-eight hours; height of funnel not more than 3 ft. 2. Inject through the artery a mixture of glycerine 4, carbolic acid 1. 3. Dry as well as possible by suction applied to the air passages, then inject through the artery, under pressure of 5 or 6 ft. of water, cotton-seed oil 100, oil of origanum 10. Dry as well as possible, and keep in a crock."

II. Its Physiology.

The "Roosevelt elastic lung" is therefore remarkable for its durability as a whole; but much more so for that of its elastic fibre and of the elastic function in it. A striking contrast is displayed between the pathological history of the fibre in life and its artificial history under preservation in death. As shown by emphysema and by obesity, it is more prone than most living tissues to mechanical destruction by overuse or disuse. As shown by arterial degeneration, and by vascular syphilis, it is also exceedingly liable to destruction by microbes and by phagocytosis. This is doubtless correlated with an extremely low coefficient of nutritive activity and requirement; which is fully demonstrated by its endurance, when it is adequately protected against the scavengers of death.

We know little about it. But we do know that it is the last to die; and that it is also our *ultimum movens*, when, by a final vital recoil, the all-pervading "elastic skeleton of configuration" restores our normal lineaments after their muscular rigidity. That enigma, the last we have approached, might well hold our solution for another problem, not the least important of those yet to be solved—"the mechanics of our biomorphology." If, as it appears, the elastic fibre has in its mechanical keeping our individual polyorganic architecture, might it not conceivably be itself the builder; and, if so, the missing link between our physics and our vital energy? Adam's striking conception of "fibrogenesis" as a linear intraplasmatic

crystallization along each line of movement and of stress is suggestive of a great mechanical antithesis. Our "rigid" skeleton of support is mineralized through "rest"; our "pulsatile" elastic skeleton of organic architecture and nutrition would be the direct mechanical product from the individual. In vital "work," too, might possibly lie the true explanation for our chief clinical puzzle. The extreme diversity in our "normal" individual "splyngnopiesis" might be but an expression of the diversity in our "physical" or elastic coefficient, as the invariable or irreducible individual factor in our vital "dynamic equation" between the nervo-muscular heart and the neuromyo-elastic artery.

The Croonian Lectures

ON

TRYPANOSOMES CAUSING DISEASE IN MAN AND DOMESTIC ANIMALS IN CENTRAL AFRICA.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON,

BY SIR DAVID BRUCE, C.B., F.R.C.P., F.R.S.,

Surgeon-General, A.M.S.; Late Director of the Royal
Society's Commission on Sleeping Sickness.

LECTURE IV.

In this concluding lecture I intend to sketch briefly the outstanding features of the trypanosomes belonging to Groups B and C. As far as we are aware, none of the trypanosomes attack man. They are, therefore, of less interest to us than the two species already described.

GROUP B.—THE TRYPANOSOMA PECORUM GROUP.

I. TRYPANOSOMA PECORUM.

The first of this small group, which only consists of two species, is *Trypanosoma pecorum*. It is probably the most important trypanosome disease of domestic animals in Central Africa.

Morphology.

Fig. 1 shows its general appearance. It is the smallest of all the African pathogenic trypanosomes, varying from 9 to 18 microns in length, with an average of 14 microns.

Fig. 1.—*Trypanosoma pecorum*.

Its breadth averages 1.96. This species is monomorphic, and short and stout in form. The contents of the cell are generally homogeneous. The nucleus is oval in shape, and situated about the middle of the body. The micronucleus is small and round, and situated near to, but not at the posterior extremity, and often appears to project beyond the edge of the trypanosome. The undulating membrane is simple, but fairly well developed, and there is no free flagellum.

There ought to be no difficulty in recognizing this species from morphology alone. If one or two hundred are drawn and measured, the average length would separate it from its neighbour *Trypanosoma simiae*. Another small trypanosome, *Trypanosoma uniforme*, differs in shape and in having a free flagellum.

Animals Susceptible to *Trypanosoma pecorum*.

Next in regard to the animals attacked by this trypanosome. This is essentially a disease of the herds. Horses, donkeys, oxen, goats, sheep, and pigs all fall victims.

One peculiarity about *Trypanosoma pecorum* is that it readily loses its virulence for certain animals by passage through certain other animals. For example, if this species—which is usually more or less infective to the monkey, dog, and rat—lives for some time in the blood of

the goat, it loses its power of infecting the former animals. This has given rise to the erroneous idea that a species, *Trypanosoma nanum*, exists. *Trypanosoma nanum* is in truth nothing but a strain of *Trypanosoma pecorum* which has lost its virulence for the other animals by its passage through the goat or allied species.

TABLE I.

Average Duration of Life, in Days, of Various Animals Infected by *Trypanosoma pecorum*.

Animal	Average Duration in Days.	No. of Animals Employed.
Donkey ...	87.75	1
Cattle ...	121.75	4
Goat ...	55	59
Pig ...	21	1
Monkey ...	1.7	11
Dog ...	43	57
Guinea-pig ...	41	5
Rat ...	33	10

Percentage of Recoveries in Various Animals from *Trypanosoma pecorum* Infection.

Animal	Percentages.	No of Animals Employed.
Donkey ...	80	5
Cattle ...	35	17
Goat ...	12	70
Pig ...	0	1
Monkey ...	0	11
Dog ...	1	63
Guinea-pig ...	0	5
Rat ...	0	10

This trypanosome does not seem to be very fatal to horses, mules, or donkeys. In Nyasaland there was no opportunity of testing it on horses, but out of five donkeys four recovered. Two-thirds of the cattle, and seven-eighths of the goats, succumbed.

The Carrier of *Trypanosoma pecorum*.

The chief carrier of *Trypanosoma pecorum* is *Glossina morsitans*. I am not aware of this trypanosome ever having been found in Nature in *Glossina palpalis*. In Uganda, where we made many feeding experiments with the wild *Glossina palpalis*, in not a single instance did a *Trypanosoma pecorum* infection take place. In Nyasaland, on the other hand, this parasite was the commonest of the trypanosomes with which *Glossina morsitans* was infected, as the following table will show.

TABLE II.—Proportion of Tsetse Flies (*Glossina morsitans*) Naturally Infective with *Trypanosoma pecorum* in Nyasaland.

" 13	50	—	—	—	" 16	113	+	+	+

It will be seen from Table II that there were 56 experiments, and 10,081 tsetse flies (*Glossina morsitans*) were employed. In the 56 experiments *Trypanosoma pecorum* was found 46 times, more than twice as often as *Trypanosoma brucei*.

Nine monkeys, 34 dogs, and 35 goats were infected.

This gives a proportion of 4.6 per 1,000 flies infective with *Trypanosoma pecorum*. It is therefore abundantly evident that *Glossina morsitans* is a carrier of this trypanosome under natural conditions. But when once this disease has infected a herd there is some circumstantial evidence available to show that the infection may be spread by means of the ordinary cattle or buffalo flies, the Tabanidae.

The ordinary horse-fly of England belongs to this genus, and it is a matter of common experience that these flies give a severe bite or stab, as a rule drawing blood.

These Tabanidae are in their habits and distribution quite different from the tsetse flies. At a particular place for the greater part of the year they may be absent or rare, but at certain times they suddenly appear in enormous numbers, only to disappear again in a few weeks. When swarming in this way they are a veritable pest to cattle. The flies feed mostly at the hottest time of the day, and the cattle to protect themselves crowd together, so as to expose as small a surface of their bodies as possible. If there are any infected animals in the herd the conditions could not be more favourable for mechanical transmission. The infected animals are close beside the healthy, and the flies pass from one to another almost instantaneously.

In Uganda we had an opportunity of studying a sudden epidemic of this disease in a herd of milch cattle. In the course of two months 34 of the cows died out of a herd of 300. The evidence was all against this epidemic having been caused by tsetse flies.

For four months we had as many as 100 fly boys scouring the district for biting flies, but not a single tsetse fly was captured. We therefore came to the conclusion that one or more infected animals having got accidentally into the herd, the infection was spread by one of these swarms of Tabanidae. As soon as the affected animals were removed from the herd the epidemic ceased.

Another example of the same kind occurred among our experimental cattle at Mpumu in Uganda. The Tabanidae, which had been rare, suddenly appeared in swarms. They were first seen in the valley to the west of the hill in September, 1909, and a month later in the valley to the east. Soon after this the cattle, which had shown no signs of disease during the previous year, were found to be suffering from *Trypanosoma pecorum*. Those which grazed in the valley to the west were first affected, and afterwards those which grazed to the east of the hill.

Another writer, George E. Owen, has come to the same conclusion. He states that between 1908 and 1913 some 2,500 to 3,000 head of cattle died from trypanosome disease in the Barotse Reserve of Northern Rhodesia, though this district is free from *Glossina morsitans*. The mortality began each year in February and practically ceased after June. December and March are the months when flies are most numerous.

In 1912 Mr. Owen was sent to investigate, and was able to keep a herd of 800 without loss through 1813. The animals were carefully watched for six months during the season when the flies were scarce, and all the infected or suspected cattle removed before the flies again became numerous.

It may therefore, I think, be concluded with a fair degree of certainty that the trypanosome disease caused by *Trypanosoma pecorum* can be carried from sick to healthy animals by biting flies other than *Glossina*. What happens, probably, is this. One or more oxen previously exposed to the bites of tsetse are introduced into the herd living in a tsetse free district, and from these few infected animals the disease is spread by the Tabanidae.

I must apologize for discussing this point at such a length, but it is an important one, and shows how necessary it is that cattle owners living outside tsetse areas should keep strict watch on their herds in order to prevent the presence of trypanosome-infected cattle among them. They should include a microscope in their outfit.

The Cycle of Development of *Trypanosoma pecorum* in *Glossina morsitans*.

This trypanosome belongs to Group B, in which development takes place first in the gut and then passes forward into the labial cavity of the proboscis, and finally reaches the salivary duct or hypopharynx, where the trypanosomes revert to the original blood form and become infective. There is no infection of the salivary glands.

TABLE III.—Development of *T. pecorum* in *G. morsitans*.

Date.	Expt.	No. of Flies Used.	Experiment Positive or Negative.	No. of Infected Flies Found.	No. of Days before Flies became Infective.	Mean Temperature.
1912.						
May 16 ...	546	22	+	4	53	69° F. (20.5° C.).
July 2 ...	524	30	+	2	37	65° F. (18.3° C.).
1913.						
Jan. 3 ...	1732	60	—	0	—	84° F. (28.8° C.).
Jan. 7 ...	1737	40	+	3	19	84° F. (28.8° C.).
Feb. 12 ...	1853	25	+	5	24	84° F. (28.8° C.).
Feb. 24 ...	1950	33	+	6	21	84° F. (28.8° C.).
April 29 ...	2115	40	—	4	—	84° F. (28.8° C.).

Seven experiments were carried out with laboratory-bred flies. Five were positive and two negative.

Two hundred and forty flies were used, and twenty-four infected flies found (10 per cent.). The first two experiments were carried out at the ordinary temperature of the laboratory; in the others the flies were kept in the incubator.

It would appear from these five positive experiments that a period of from nineteen to fifty-three days may elapse before the cycle of development of *Trypanosoma pecorum* in *Glossina morsitans* is complete and the fly becomes infective.

Fig. 2.—*Trypanosoma pecorum* from proboscis.

Result of the Dissection of the Infected Flies.

Table IV gives the result of the dissection of the twenty infected flies found in the positive experiments. The second column gives the number of days between the first feed of the fly and its death and dissection.

2115	9	+	—	+	—	+	++	++	—
2115	11	—	—	+	—	+	++	+	—

In Experiments 546 and 524 there was no separate examination of the hypopharynx; it is included in the general term "proboscis." It was only when the importance of the hypopharynx became evident that an examination of the separate parts of the proboscis was made.

In not a single fly was any invasion of the salivary glands noted, but it will be seen that in every positive experiment trypanosomes are found in the hypopharynx.

So much for the positive experiments; let us see what is the result of the dissection of the infected flies in the negative experiments. In none of the infected flies had development reached the hypopharynx, and consequently none of the flies had become infective.

Labrum: early infection.

Labrum. Hypopharynx. Fig. 3.—*Trypanosoma pecorum*: Development in proboscis.

From the consideration of these tables it will be seen that in *Trypanosoma pecorum* the development takes place at first in the intestine, then passes forward into the labial cavity, and finally invades the hypopharynx, and there is completed.

The Type of *Trypanosoma* found in the Infected Flies.

Fig. 2 represents the developmental forms of *Trypanosoma pecorum* found in the labial cavity of *Glossina morsitans*.

In regard to the forms found in the intestine, it may be said that these are indistinguishable from the developmental forms of other pathogenic trypanosomes.

The first seven figures represent early forms in the labial cavity. These were seen adhering singly by their flagella to the labrum.

The next group are the ordinary forms found clinging by their flagella ends to the labrum. It will be seen that they have assumed the cribridial stage—a stage which seems to be a *sine qua non* in the final stages of the cycle of development of all the pathogenic trypanosomes, and the interpretation of which is still obscure.

The small blood forms are from the hypopharynx of dead infective flies, and also from living infective flies induced to salivate on a cover-glass. They represent the final stage in the cycle of development, and are the only infective forms.

In Fig. 3 are seen drawings, at a magnification of 250 diameters, of the labrum and hypopharynx of a fly infected with this trypanosome. While the labial cavity

is seen to contain clusters of large ribbon-like trypanosomes, the hypopharynx is swarming with the small infective forms. From these drawings the ease and facility with which a tsetse fly can infect an animal will be readily understood.

Another way of showing how easy it is for a fly to infect an animal is to induce an infected fly to salivate on a cover-glass. If a hungry fly is placed on a large cover-glass, which covers a man's finger, the fly will attempt to bite through the glass, and in so doing will smear it with its saliva. If this is then stained and examined under a microscope, thousands of trypanosomes will be seen.

The Reservoir of *Trypanosoma pecorum*.

Table VI represents the number of times *Trypanosoma pecorum* was found among the 180 wild animals examined in Nyasaland and the species of game which harboured it.

TABLE VI.—Showing the Species of Animals Dealt with, the Total Number Examined, the Number found Infected, and the Species of Trypanosome by which they were Infected.

Animal.	No. Examined.	No. Found Infected.	Tripp. brucei.	Tripp. pecorum.	Tripp. simiae.	Tripp. caprae.
Eland ...	10	6	0	6	0	1
Sable ...	5	0	0	0	0	0
Waterbuck ...	13	9	3	1	0	8
Koodoo ...	3	2	0	2	0	0
Bushbuck ...	10	7	0	7	0	1
Hartebeeste ...	35	6	5	1	0	0
Reedbuck ...	19	12	3	1	0	9
Orobi ...	26	4	1	1	0	1
Duiker ...	7	2	1	0	0	0
Buffalo ...	9	2	0	2	0	0
Lion ...	1	0	0	0	0	0
Hyaena ...	3	2	0	2	0	0
Warthog ...	33	7	1	3	3	0
Elephant ...	2	0	0	0	0	0
Wild cat ...	3	0	0	0	0	0
Porcupine ...	1	0	0	0	0	0
Total ...	180	59	14	26	3	20

It will be seen that 26 animals among the 180 harboured this parasite (14.4 per cent.), and the eland, the koodoo, the bushbuck, and the buffalo were the greatest sinners; 60 per cent. of the eland, 66 per cent. of the koodoo, 70 per cent. of the bushbuck, and 22 per cent. of the buffalo having *Trypanosoma pecorum* in their blood.

It is rather curious that *Trypanosoma pecorum* has picked out the animals in whose blood *Trypanosoma brucei* was absent.

2. TRYPANOSOMA SIMIAE.

This species of trypanosome is remarkable for the virulence it displays towards the monkey and the domestic pig, killing these animals in an incredibly short period of time, whereas it is harmless to oxen, antelope, dogs, and the smaller experimental animals. Curiously enough it affects goats and sheep, although oxen and antelope escape.

Trypanosoma simiae is similar to *Trypanosoma pecorum* in the rapidity with which its virulence becomes modified. If a cage containing wild tsetse flies (*Glossina morsitans*) infected with this parasite is placed on a monkey or a goat, both animals take the disease and the monkey in such an acute form that the average duration of disease is only a few days.

But if the attempt is made to pass this species of trypanosome from an infected goat to a healthy monkey, by the inoculation of the goat's blood, the experiment usually fails, showing that a short sojourn in the blood of the goat has almost nullified the virulence of the parasite for the monkey.

Another interesting point in regard to this species is, that as far as is known, the warthog is the only animal among the wild game which harbours it. It is probable

that it will also be found in the blood of the bush-pig, but that has not been done yet.

Morphology.

If Fig. 4 be compared with Fig. 1, it will be seen that *Trypanosoma simiae* is longer than *Trypanosoma pecorum*. It is monomorphic, varying from 14 to 24 microns in length—average 18. The trypanosomes are fairly uniform in shape. The body is elongated, undulating, and frequently extends in a straight line. The contents of the cell are clear and free from granules. The nucleus is oval,

Fig. 4.—*Trypanosoma simiae*.

and situated about the middle of the body. The micronucleus is small and round, situated almost invariably about 1½ microns from the posterior extremity. The undulating membrane is well developed and thrown into bold undulations.

It is difficult to say whether this species has a free flagellum or not. By careful staining and good illumination it would seem in most cases as if the undulating membrane extended to the tip of the flagellum. In some preparations, however, the last two or three microns of the flagella appear to be free.

Susceptibility of Animals.

Table VII shows the average duration of life in various animals infected by *Trypanosoma simiae*, also the percentages of recoveries from the disease.

TABLE VII.

Average Duration of Life in Various Animals Infected by *T. simiae*, Nyasaland. Mixed Infections are not included. (The letter R stands for refractory.)

Animal	Average Duration in Days.	No. of Animals Employed.
Ox R ...	4
Antelope R ...	5
Goat and Sheep 46.6 ...	5
Pig 5.3 ...	9
Baboon R ...	3
Monkey 10.8 ...	24
Dog R ...	21
Rabbit R ...	10
Guinea-pig R ...	5
Rat R ...	5

Percentages of Recoveries in Various Animals from *T. simiae* Infection. Mixed Infections are included.

Animal	Percentages.	No. of Animals Employed.
Ox R ...	4
Antelope R ...	5
Goat and Sheep 37.5 ...	32
Pig 0.0 ...	13
Baboon R ...	3
Monkey 14.3 ...	35
Dog R ...	21
Rabbit R ...	10
Guinea-pig R ...	5
Rat R ...	5

It will be seen that the ox, antelope, baboon, dog, rabbit, guinea-pig, and rat are refractory.

In the whole range of the trypanosome diseases of animals there is surely nothing so striking as the rapidly fatal action of *Trypanosoma simiae* on the domestic pig. In nine experiments the average duration was only 5.3 days. This, not from the time of the appearance of the trypanosome in the blood, but from the date of the infection. Further, this rapid action is not the result of an exaltation of virulence by numerous passages through the pig, but natural to the trypanosome.

The Carrier of *Trypanosoma simiae*.

The carrier of *Trypanosoma simiae* in Nyasaland is *Glossina morsitans*. Table VIII gives the proportion of flies naturally infected with this parasite.

TABLE VIII.—Proportion of Tsetse Flies (*Glossina morsitans*) Naturally Infective with *Trypanosoma simiae* in Nyasaland.

.. 9	130	—	—	—	.. 11	156	—	—	—
.. 13	50	—	+	—	.. 16	213	+	—	—

As will be seen from this table, there were 56 experiments, and 10,081 tsetse flies were employed. In the 56 experiments *Trypanosoma simiae* was found 34 times (60.7 per cent.). Twenty-six monkeys and seventeen goats were infected. This gives a proportion of 3.4 per 1,000 flies infective with *Trypanosoma simiae*. It must be noted that warthogs were numerous in the sleeping sickness area, Nyasaland, which accounts for the fairly high proportion of infected flies.

The Cycle of Development of Trypanosoma simiae in Glossina morsitans.

This species belongs to Group B, and the cycle of development is similar to that which has already been described as occurring in *Trypanosoma pecorum*.

The Reservoir of Trypanosoma simiae.

In Table VI is shown the number of times *Trypanosoma simiae* was found among the 180 wild animals examined in Nyasaland, and the species of game which harboured it.

It will be seen that only 3 animals among the 180 harboured this parasite (1.7 per cent.). This was, of course, due to the fact that it is only the warthog among the wild game which acts as a reservoir; 30 warthogs were examined and 3 found infected (9 per cent.).

GROUP C.—THE TRYPANOSOMA VIVAX GROUP.

The three species forming this group have a strong family resemblance, and but for size might almost be included in one species.

1. TRYPANOSOMA VIVAX.

This is the cause of one of the most important diseases of cattle in Uganda. We did not meet with it in Nyasaland, where its place seems to be taken by *Trypanosoma caprae*. It is, however, widely distributed in Central Africa. It has been reported from Senegal and the Sudan

Fig. 5.—*Trypanosoma vivax*, Ziemann.

in the north to Rhodesia in the south. It is easily recognized on account of its extreme activity during life, its characteristic morphology in stained specimens, and the fact that it only affects horses, cattle, goats, and sheep, while monkeys, dogs, rabbits, guinea-pigs, rats, and mice are refractory.

In Uganda the tsetse flies on the lake shore were found to be infected with it, and it was also found in the

of a bushbuck shot at the same place at which the flies were collected.

2. TRYPANOSOMA UNIFORME.

This trypanosome resembles *Trypanosoma vivax* very closely except that it is smaller. Up to the present it has

Fig. 6.—*Trypanosoma uniforme*.

only been found in Uganda. Its carrier there is *Glossina palpalis*, and its reservoir the wild game on the lake shore.

3. TRYPANOSOMA CAPRAE.

This species has only been reported up to the present from Lake Tanganyika and Nyasaland. It, like the other two species belonging to this group, only affects cattle, sheep, and goats. Monkeys, dogs, and the smaller experimental animals are immune.

Morphology.

Fig. 7 shows its general appearance. During life this trypanosome, like the other members of the group, is characterized by its extreme mobility.

Fig. 7.—*Trypanosoma caprae*, Kleine.

It is a monomorphic species, varying from 18 to 32 microns in length, the greatest number of individuals being 25 microns long. Measured across the broadest part, *Trypanosoma caprae* averages 3 microns in breadth (maximum 4.25, minimum 1.75). It differs from *Trypanosoma vivax* in that it is heavier built and altogether has a larger and clumsier appearance. The posterior half is swollen, and its end is bluntly angular or rounded. The anterior extremity is narrower and pointed. The contents of the cell are clear, with a delicate alveolar structure and free from vacuoles and granules. The nucleus is oval, compact, and lying about the middle of the body. The micronucleus is large and round, situated as a rule close to the posterior extremity; the undulating membrane is more developed than in *Trypanosoma vivax* and thrown into bolder folds and undulations. There is a well-marked free flagellum which averages 6.5 microns in length (maximum 9.4, minimum 4).

Susceptibility of Animals to Trypanosoma caprae.

Table IX gives the average duration of the disease, and the percentages of recoveries in various experimental animals.

this species is not pathogenic to the monkey or dog, of course it was found only in the experimental goats. This gives a proportion of 3.5 per 1,000 flies infected with *Trypanosoma caprac*.

The Cycle of Development of Trypanosoma caprac in Glossina morsitans.

Trypanosoma caprac belongs to the *Virax* group, in which the development of the trypanosome is restricted to the proboscis.

TABLE XI.—Development of *T. caprac* in *G. morsitans*.

Date.	Expt.	No. of Flies Used.	Experiment Positive or Negative.	No. of Infected Flies Found.	No. of Days before Flies became Infective.	Mean Temperature.

Jan. 16 ...	1777	35	+	11	19	84° F. (28.8° C.).
Jan. 22 ...	1784	35	+	20	19	84° F. (28.8° C.).
April 1 ...	2046	33	+	13	20	84° F. (28.8° C.).

Six experiments were made with laboratory-bred flies; 5 were positive and 1 negative.

One hundred and seventy laboratory bred flies were used and 46 infected flies were found (27.1 per cent.). The first three experiments were carried out at the ordinary temperature of the laboratory: in the last three the cages containing the flies were kept in an incubator. It is difficult to understand the difference in the number of infected flies found. In Experiments 444 and 1215 only 8 and 5 per cent. respectively of the flies became infected, whereas in the last three experiments an average of more than 40 per cent. was found. The flies in the second group were kept, it is true, at a temperature similar to that which they would find in summer in their native haunts in the low country, while the last three experiments were done in winter, and at the ordinary temperature of the laboratory. This would no doubt explain the difference to some extent. Again, goats and sheep infected with *Trypanosoma caprac* are unsatisfactory animals to feed flies on. One day the

trypanosomes are present in small numbers in the blood, the next day it may be impossible to find any; very seldom are they in large numbers. It is possible, then, that flies may feed on an infected goat or sheep without taking in a single trypanosome.

It would appear from the five positive experiments that an average period of nineteen days elapses before the cycle of development of this parasite is complete in *Glossina morsitans*, and the fly becomes infective.

Now 46 infected flies were found among 170 used, and the next table gives the result of the dissection of these flies.

It will be seen from Table XII that it was not until the last experiment that the labial cavity and hypopharynx were examined separately. In the previous experiments the presence or absence of trypanosomes in the proboscis as a whole was noted.

In the first two experiments only a single infected fly was found in each. In Experiment 1777 eleven, and in 1784 as many as twenty were found.

In regard to the number of trypanosomes in the labial cavity this may vary greatly. Sometimes the lumen of the tube will be seen to be densely crowded; at other times a single colony will be seen. For example, in Experiment 1777 the first infected fly, dissected on the twenty-first day, is noted to have had the lumen of the proboscis swarming with clusters of torpedo-shaped flagellates attached to the labrum by their flagellar ends, a few swimming free. In the seventh infected fly, dissected on the thirtieth day, only three colonies are noted. In the same way, at one time the hypopharynx may contain few, at another time it is seen to be densely packed with swarms of actively moving trypanosomes. In unstained specimens the difference in size and shape between the trypanosomes in the labial cavity and those in the hypopharynx is quite manifest.

From this table the broad facts stand out boldly—that in this group of trypanosomes the development is confined to the labial cavity and hypopharynx, and does not take place in any other part of the fly.

The Type of Trypanosomes found in the Infected Flies.

No attempt was made by the Commission to study the development of *Trypanosoma caprae* in *Glossina morsitans* in the earliest stages. This can only be done if a large number of laboratory-bred flies are available, and this was not the case in Nyassaland.

In Figs. 8 and 9 are represented some of the developmental forms found in the labial cavity and hypopharynx of infected flies. It will be seen that most of the flagellates found attached to the labrum are criethidial in type, with well defined nuclei, micronuclei, and free flagella. Some are ribbon shaped, others have elongated posterior extremities, and again others are torpedo-shaped.

The last three rows are from the hypopharynx, and have been obtained, as a rule, by causing the fly to salivate on the cover-glass. They represent the final stage in the cycle of development, the reversion to the infective or blood form. They are rather smaller than those found in the blood of the vertebrate host, but resemble them closely in every other way.

Fig. 8.—*Trypanosoma caprae* from proboscis.

may be said to be, first, that some order is beginning to reign in what was lately chaos in regard to the classification of the pathogenic trypanosomes. They may all now be referred to three groups, and nine species.

In regard to the transference of the virus from sick to healthy animals by the fly, this has been made clearer and easier of comprehension by the discovery of the part the salivary glands and hypopharynx play in the various modes of development which the trypanosomes undergo in the fly. It results that it would almost appear impossible for an infective fly to pierce even momentarily the skin of a healthy susceptible animal without causing infection.

Another important feature is the proof brought forward that *Trypanosoma brucei* and *Trypanosoma rhodesiense* are the same.

Finally, in regard to the prevention of these trypanosome diseases of man and domestic animals. We have seen that the wild game in the fly country is heavily infected. It is impossible to doubt that they are the reservoir and source of many of these diseases. There can be little

Fig. 9.—*Trypanosoma caprae*: Development in proboscis.

The Reservoir of Trypanosoma caprae.

Among the 180 wild animals examined in Nyassaland 20 harboured *Trypanosoma caprae* (11.1 per cent.); 61 per cent. of the waterbuck and 47 per cent. of the reedbuck acted as reservoirs.

CONCLUSION.

This concludes the Croonian Lectures on the trypanosomes causing disease in man and animals in Central Africa. These lectures deal with but a small part of the subject, which has in the course of the last twenty years grown to huge proportions. Nothing has been said about medicinal treatment, and even measures of prevention have been left a good deal to the imagination. Taking a look back over the whole field, the outstanding features

doubt that if the wild game were driven out of the fly country, trypanosome diseases such as those caused by *Trypanosoma brucei* and *Trypanosoma pecorum* would disappear.

In regard to the measures of prevention against the most important of all the trypanosome diseases—Congo sleeping sickness—it has been shown by experience that the removal of the natives from the fly area is a simple and efficacious way of stopping an epidemic.

In these sparsely inhabited countries where spare land and food are easily obtained, there is as a rule no difficulty in effecting this migration.

If it is desired to go a step further and render the sleeping sickness area inhabitable, then clearing and cultivation must be resorted to. By these means in all probability *Glossina palpalis* will be driven away, and with it the disease.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF RIGID OS UTERI.

I HAVE read with interest Dr. John A. Irvine's communication on this subject in the JOURNAL of June 12th, p. 1002. The administration of tartar emetic successfully rectified the uterine complication. The effects of antimony, however, are far from pleasant to the patient, and liable to cause dangerous depression. There is, in my opinion, a better way by which the relaxation of the rigid os uteri may be effected *cito, tuto, et jucunde*.

As I have pointed out in my book *Clinical Memoranda* (Baillière and Co.), the application of a tampon of lint or absorbent cotton-wool, soaked in a solution of cocaine, or β eucaine (10 grains to the ounce of boric acid solution), to, or into, the os and cervix, acts like a charm.

The irritated nerves and muscular fibres are anaesthetized, and the spasm relaxes directly—even within five minutes—the os dilating widely. On many occasions I

have had cause to bless this precious drug which has never failed me.

Not only does the cocaine relieve the spasm of the os, but, as the solution spreads all over the vagina, it also anaesthetizes the mucous membrane, permitting the head to pass through the outlet with a minimum of discomfort.

Driffield, E. Yorks.

A. T. BEARD, M.D.

RECURRENT VESICULAR RASH.

I HAVE at present a young married woman under my care who has a blister which appeared spontaneously over the lower end of the nina. About nine months ago a somewhat smaller blister arose over the big toe. I then thought a shoe must have wrung her feet. She had a patch of zoster over the glutei in the winter, and when the ulna blister appeared there was a fresh patch of zoster. All these manifestations were on the left side. She is quite healthy otherwise except for slight grating in some joints and slight occasional asthma. I regard the whole as a manifestation of fibrositis.

GEORGE MAHOMED.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

At a meeting on July 1st, Dr. W. S. A. GRIFFITH in the chair, Mr. J. D. MALCOLM showed (1) *Papilliferous carcinoma of the ovary associated with adenomyoma of the uterus*, (2) *Fibromyoma free from attachments in a pelvic abscess*. Mr. E. A. BARTON read a paper on the *Condition of the larynx and trachea in stillborn infants*. As a result of a number of post-mortem examinations on stillborn infants that had never made any attempt to breathe, it was shown that in all cases the glottis was closed, and in a majority the lower half of the trachea was also occluded, the posterior muscular wall being folded into the lumen and the cartilage rings sharply flattened and incurved, so that the trachea presented on section a very flattened oval. A deep sulcus formed by the interval between the ends of the incurved cartilages ran vertically down the posterior surface of the trachea. It was also suggested that an outward elastic tension of the ribs might further aid the initial inspiration. The bearing of these observations on artificial respiration of the stillborn flaccid infant went to show that, until the glottis was opened mechanically and the trachea was made patent, it was useless to attempt any postural or other means to inflate the lungs, and that this first separation of closed surfaces was best attained by mouth to mouth aspiration. Remarks were made by the PRESIDENT, Dr. AMAND ROUTH, Dr. EARDLEY HOLLAND, Dr. RUSSELL ANDREWS, Dr. HANDFIELD JONES, and Dr. HERBERT SPENCER. Mr. T. G. STEVENS read a paper on *Adenomyoma of the recto-vaginal septum*. He described six cases, the first of which was described before the Section in 1909. The other five cases all came under his care in the last six months. In two cases the growth was accidentally discovered in patients who complained of sterility; in the other three the growth was discovered during the performance of hysterectomy. In all the cases the growth was in the loose tissue just behind the posterior fornix, and except in the first cases was attached to the back of the cervix uteri. In four cases the growth had involved the rectal muscle, and in one of these had penetrated to the submucous tissue of the rectum. In these four cases the peritoneum was closely fixed to the growth. In none of the cases could the symptoms complained of be ascribed to the growth; they were due to some intercurrent uterine lesion. The histology of the growths in every case was that of a diffuse adenomyoma as commonly seen in the body of the uterus. The diagnosis, prognosis, and operative technique were discussed. The origin of the growths might be from: (1) The endometrium; (2) Mullerian remnants; (3) Wolffian remnants; (4) the peritoneal endothelium. The first was proved to be the source of origin of most adenomyomata, but in the case of tumours at a distance from the endometrium any connexion between the two was difficult to demonstrate. The other three possibilities were based on theoretical considerations only, and were incapable of proof. Dr. WALTER S. A. GRIFFITH delivered his presidential address, taking for his subject, *The causes which determine the "lie" of the fetus in utero*. Reference was made to the views of some early writers as to the position and presentation of the fetus, and as to the causes which they considered efficient, showing the gradual development of the gravity theory, which, however, owing to insufficient and often incorrect data, had not yet been actually proved. He had therefore determined to investigate the subject *de novo*, and presented his work under the following headings: (a) *The fetus*. The fetus, which was a body of varying and not uniform density, was immersed in fluid in a closed cavity of more or less corresponding shape, and was for a time freely movable in it. Later, as its size more nearly approximated that of the uterine cavity, its mobility was more and more restricted. Investigations had been directed to the following points: (1) The specific gravity of the fetus at different periods of development, and of its most important parts; (2) the specific gravity of hydrocephalic and anencephalic fetuses, and especially of the head, in these cases; (3) the centre of gravity of the fetus, (b) *The liquor amnii*. This was a fluid of uniform density in each specimen. (4) The varying specific gravity of different specimens; (5) the

relative specific gravity of the fetus and the liquor amnii; (6) the metacentre, or centre of buoyancy. This was the centre of gravity of the fluid displaced by the fetus—that was, the centre of gravity of a substance of uniform density exactly corresponding in shape and size with the fetus. This was the centre through which the resistance to the descent of the fetus, whatever its position *in utero*, must act in a vertical direction. (7) The relative positions of the centre of gravity of the fetus and the metacentre. (c) *Movements disturbing the fetus at rest*. (8) Fetal movements; (9) uterine movements—that is, contractions; (10) maternal movements. The specific gravity of the fetus was illustrated by tables giving the details of forty-six fetuses from the second month onwards, and from these were drawn the following conclusions: That in no instance did the specific gravity of the head exceed that of the remainder of the body before the end of the sixth month. It was generally lower, and in only one case of the sixth month was it equal to that of the body. In three only out of nine normal fetuses of the seventh month was the specific gravity of the head higher than that of the body. In two of the eighth month, the only ones of this month Dr. Griffith had examined, the specific gravity of the head was lower than that of the rest of the body. In sixteen full-term fetuses the specific gravity of the head was considerably higher in thirteen than the body, equal in two, lower in one. It was also demonstrated that up to the end of the sixth month of pregnancy the difference of specific gravity of the three great divisions of the fetus—namely, its head, thorax with the arms, abdomen with the legs, was very slight. During the seventh and eighth months the thoracic portion was the highest, and it was only in the last month that the head was constantly higher than the rest of the body. It was also seen that the relative specific gravity of the head to the body had no necessary relation to the lie of the fetus, whether when quite fresh or in various degrees of maceration *in utero*; maceration hardly affected the specific gravity of the fetus. Two matters of interest were demonstrated in these tables, matters which were of much importance in the rival contentions of Matthews Duncan and Sir J. Y. Simpson. The examination of hydrocephalic and anencephalic fetuses showed that the theoretical opinions and arguments of Matthews Duncan were correct. The specific gravity of the two hydrocephalic fetal heads was very low, as low as in normal fetuses of the fifth month—namely, (1) 1.037, (2) 1.039. The head of the anencephalic fetus of the seventh month was very high for the period of development—namely, 1.061. It consisted chiefly of bone. The specific gravity of full term normal male fetuses varied between 1.049 and 1.060, of female between 1.049 and 1.056; the average in 9 males 1.055, in 7 females 1.053. The specific gravity of the umbilical cord was 1.020, considerably higher than that of the liquor amnii, and it therefore sank when lying free in it. *The specific gravity of the liquor amnii*. The tables illustrating this comprised 112 specimens varying from 1.002 to 1.016, with an average of 1.007, and showed that the specific gravity of the liquor amnii varied but little during pregnancy, and was independent of the sex, weight and length of the fetus, of the age of the mother, and the number of her pregnancies. They also showed that the fetus had a higher specific gravity which increased throughout pregnancy, and that the fetus must always sink to the most dependent part of the uterus. The forces which disturbed the fetus at rest were then discussed, and the conclusion was drawn that the cumulative effects of the natural forces acted by assisting, while the fetus was freely movable, the only dominant and always present force, gravity, to act efficiently, until the position of the fetus became stable. The centre of gravity of the fetus was illustrated by tables of fourteen fetuses, from the fourth month onwards, leading to the following conclusions: The centre of gravity was found at all periods to be within the pericardium close to the right auricle, but by measurement of the distance from the centre of gravity from the vertex and breech respectively it appeared gradually to move nearer to the breech than the vertex. It was nearer the vertex than the breech in the specimen of the fourth month only; in the five specimens of the fifth and sixth months it was practically midway, and in the seven specimens of the eighth and ninth months it was nearer the breech end. This apparent but important displacement of the centre of gravity was considered to be

due to a greater development of the body below the diaphragm than above it. The principle involved, and the methods of determining the position of the centre of gravity and the metacentre, were then described. And two wax models used in this, the most difficult part of the investigation, were exhibited, and it was shown that the metacentre being situated on the breech side of the centre of gravity the effect of gravity was to continually pull the cephalic end down and push the breech end up. Dr. Griffith hoped to be able to bring before the Section at a less strenuous time a report on the examination of the relative position of the two centres in fetuses of the earlier and middle months. He had avoided criticism of the views and writings of others, being of the opinion that an accurate examination of the factors would be of more value in the avoidance of errors in the future than criticism of theories and statements founded for the most part on crude and often erroneous data.

Reviews.

DISORDERS OF THE HEART.

DR. LEWIS has recently published, under the title *Lectures on the Heart*,¹ some lectures he delivered last autumn in America—one in New York and three at Baltimore, and an address to the Faculty of Medicine at McGill University, Montreal. The book merits perusal by all who are interested in modern cardiology, as it presents, in readable and easily accessible form, the results of certain investigations made by the author and other workers in his laboratory.

The first lecture deals with the excitation wave in the heart. It is shown that if the electrical condition of the surface of the auricles is examined during natural contraction the part over the sino-auricular node is with each contraction primarily negative to every other part, so that we may assume that the contraction starts from this point. The same conclusion is reached by exciting different spots on the surface of the auricle artificially when it is found that the nearer the spot excited is to the sino-auricular node the more closely does the electrocardiogram of the resulting contraction approach the normal type. By taking electrocardiograms simultaneously from a standard lead and two points on the surface of the auricle, it is possible to measure the time the wave of negativity, and therefore of excitation, takes to pass from one point of the auricular surface to another, and hence to trace its course. The conclusion reached is that the excitation wave has its origin in the sino-auricular node, and spreads at rates ranging about a metre a second along the chief muscular tracts, which radiate from its neighbourhood, courses through the whole auricular tissue up to its ending on the chief veins and down the septum to the auricular ventricular node.

By a similar method of investigation Dr. Lewis reaches the conclusion that the wave of excitation having passed through the auricular ventricular bundle and the Purkinje system, spreads through the ventricular muscle from within outwards, from the endocardial to the epicardial surface, and that the rate at which it appears at any point on the surface depends mainly on the thickness of muscle it has to traverse, as the rate of conduction through Purkinje substance is approximately at least five times as fast as through ventricular muscle.

The second lecture deals with matters familiar to most of those interested in electro-cardiography. The third lecture—on the relation of the auricular systole to heart sounds—after describing the method of recording heart sounds and murmurs graphically by the string galvanometer, describes and discusses various phonograms. It is suggested that the auricular sound heard in some cases of complete heart-block consists of two factors—one due to the contraction of the auricular muscle, the other attributable to the cessation of flow from auricle to ventricle, and consequent closure of the auricular ventricular valves. Canter rhythm is of two kinds: in the commoner type the additional sound occurs immediately before the natural first sound, in the second in early or

mid-diastole. The first variety is held to be due to a double closure of the auricular ventricular valves, the first closure resulting from the wane of the auricular systole blood. The second sort of canter rhythm is thought to be produced by a vibration of the valves from quick filling of the ventricle and their consequent closure, just as Thayer and Hirschfelder have suggested in describing the third sound of the normal heart. The periodic accentuation of the first sound and reduplication of the first and second in complete heart-block and the various murmurs of mitral stenosis are then dealt with.

The fourth lecture gives an account of the work of the author with Mr. Barcroft and others on cases of dyspnoea in which there is little or no cyanosis. The suggestion is thrown out that dyspnoea resulting from the presence of non-volatile acids in the blood is a far commoner phenomenon than is usually supposed.

In the address on cardiac syncope delivered in Canada, the author treats of syncope from general slowing of the whole heart as the result of vagal stimulation, from slowing of the ventricles in heart-block of various grades, from fibrillation of the ventricle, and from accelerated heart action causing lessened cardiac output, with consequent fall of arterial pressure and hence cerebral anaemia.

INFANT MORTALITY.

THE study of the causes and means of controlling infant mortality is of such interest to sanitarians that the editors of the Cambridge Public Health Series did well to include among their manuals a work devoted to it. Dr. HENRY ASHBY'S *Infant Mortality*² contains a great deal of useful information based upon personal experience, and its perusal will be of value to all who are engaged in the task of attempting to provide better conditions for the children of the poor. The chapters which deal with the duties and qualifications of health visitors, the organization of infant consultations and dinners for mothers, and the care and preparation of food are particularly worthy of commendation. While so much is good, it may seem a little ungracious to call attention to shortcomings, but we are bound to say that Dr. Ashby's book does not entirely fulfil the rather ambitious programme outlined in the editors' preface. The editors assert that the volumes in the series "include the latest scientific and practical information, offered in a manner which is not too technical. The bibliographies contain references to the literature of each subject, which will ensure their utility to the specialist." It is, perhaps, sufficient commentary upon the latter statement to remark that Dr. Ashby nowhere cites the work of such investigators as Westergaard, Mombert, Gauzen-Müller, and Vertijn Stuart, nor does he seem to be acquainted with the important monographs of Sallet and Falkenburg and of Groth and Halm. The author's want of familiarity with the literature is indeed amusingly illustrated by the naive remark that "the fact came to light from vital statistics in Ireland and in the different counties of England that a high birth-rate is generally associated with a high rate of infant mortality" (p. 16). It must also be said that the attribution to Dr. Newsholme of a demonstration that "it is by no means true that it is the weaklings who die off," hardly corresponds to the facts of the case. In our opinion the question whether infant mortality is or is not "selective" is not one with which the sanitarian, *qua* sanitarian, need concern himself. If a writer wishes to discuss the problem, he would do well to make himself acquainted with the numerous papers, such as those published by Professor Karl Pearson and his fellow-workers, which at least make it plain that the statistical difficulties involved are not to be overcome without the aid of delicate and precise instruments of research. Dr. Ashby would have done better to confine himself to the discussion of actual administrative measures, since the sketchy and inadequate treatment of the general problems of infant mortality which occupies the first quarter of his book is not a good introduction to the part really based upon wide experience, and therefore of scientific value. We hope that when a second edition is called for Dr. Ashby will subject the earlier chapters of his book to a drastic revision.

¹ *Lectures on the Heart*. By T. Lewis, M.D., F.R.C.P., D.Sc. London: Shaw and Sons, New York: F. B. Hoeber, 1915. (Demy 8vo, pp. 124; 85 figures. 6s. 6d. net.)

² *Infant Mortality*. By H. T. Ashby, B.A., M.D., B.C. Camb., M.R.C.P. Lond. Cambridge Public Health Series, under the editorship of G. S. Graham-Smith, M.D., and J. E. Furvis, M.A. Cambridge: The University Press, 1915. (Demy 8vo, pp. 229; 9 figures, 10s. 6d. net.)

CANCER.

Dr. DUNCAN BULKLEY will meet with the assent of many of his readers when he observes that, from the enormous work which has been done on cancer with the microscope and test tube, it would seem sometimes that research workers have become somewhat myopic, and are still not sufficiently far-sighted to recognize the true value of statistical studies and clinical observations. The thesis of his book, *Cancer, Its Cause and Treatment*,³ is that the earlier the morbid process leading to the development of the neoplasm is met by dietetic, hygienic, and medicinal measures, the greater the promise and expectation of permanent success. Dr. Bulkley boldly declares that for the proper treatment of cancer, and for the prevention of its occurrence and recurrence, a vegetarian diet is necessary. He would even exclude eggs and milk; yet he admits that the yolk of eggs may sometimes be taken with advantage, and also milk alone, at the body temperature, about an hour before eating. The vegetable diet should be so arranged as to give the requisite quantity of calories, from a proper proportion of vegetable protein, carbohydrates, and fats. He has a great belief in fats, and allows a quarter of a pound of butter daily. Dr. Bulkley, speaking of treatment, lays much stress on moderate purgation. Sir Arbuthnot Lane, he reminds the reader, has emphasized the fact that cancer may be one of the terminal results of intestinal stasis. Dr. Bulkley has observed that imperfect intestinal excretion is frequently recorded in the history of persons subject to cancer, and believes that this stasis plays an important part in the auto-intoxication which, he considers, precedes malignant disease. A hormone therapy of cancer is at present in its infancy, though thyroid secretion has been shown, by clinical experience, to exercise sometimes a definitely beneficial effect on cancer. Like all other writers on the treatment of cancer, Dr. Bulkley finds that certain special local dressings act in a satisfactory manner, even after the onset of ulceration. Dr. Bulkley condemns not only meat and alcohol, but likewise tea and coffee. He quotes from a report to the House of Commons the information that Holland, known to be the largest consumer *per capita* of coffee of any country in Europe, had in 1905 a cancer death-rate among the highest, while Hungary, the smallest consumer of that pleasant beverage, had a cancer mortality in 1903 of only 39 per 100,000, or a little over one-third that of Holland. He quotes from another writer the statement that the people of the United States consume one-third of the total coffee produced, or more than Germany, Austria-Hungary, France, and the United Kingdom combined. On the other hand, England and her colonies consume one-half of the world's output of tea, and the United States but one-fifth of it. Dr. Bulkley then notes how many of the working class consume enormous amounts of tea which is kept brewing all day. The last six words are an important qualification of the evils of tea drinking long recognized by our readers.

Dr. Bulkley admits that he cannot show precisely how unfavourable hygienic and dietetic causes set up cancer, and admits that no single cause of malignant disease has yet been demonstrated. While the bio-chemistry of cancer throws little light upon its true nature, enough is known. Dr. Bulkley considers, to prove that the morbid changes in the cells are largely associated with deranged metabolism, and, as above indicated, his teachings on treatment are based on that fact. Unfortunately, wide though the association with deranged metabolism may be, science has not yet reached the truth, and the author concludes that the long continuation of many baneful causes has produced such a degeneration of tissue in the human race that, even when the reformed dietary has been established, it will take a generation or more of proper living to make the beneficial impression on the general incidence of cancer which is so ardently desired by humanity.

NOTES ON BOOKS.

THE *Archives of the Middlesex Hospital (Clinical Series, No. XI)*,⁴ edited by Mr. W. SAMPSON HANDBLEY and Dr. VICTOR BONNEY, includes two cases of bronchiectasis following operation for the removal of tonsils and adenoids, by Dr. Cockayne; three cases of acute intraocular

³*Cancer; Its Cause and Treatment*. By L. Duncan Bulkley, A.M., M.D. New York: P. B. Hoeber, 1915. (Cr. 8vo, pp. 230, \$1.50 net.)

⁴*Archives of the Middlesex Hospital (Clinical Series No. XI)*. Being the Thirty-Second Volume of the Archives. Edited by W. S. Handbley and V. Bonney. London: Macmillan and Co., Ltd. 1914. (Duo. 8vo, pp. 32; 15 figures.)

inflammation treated with sensitized vaccines, by Mr. B. T. Lang; a paper on the after-history of patients in whom the operation of gastro-jejunostomy has been performed for malignant disease, by Mr. C. H. S. Webb; and an inquiry into the radiographic appearances of the stomach after gastro-jejunostomy, by the same author and Mr. W. N. Kingsbury. There are also papers on the investigation of cardiac irregularity by means of the polygraph, by Dr. George Ward; and on lactic acid in *Bacillus coli* infections, by Mr. I. H. Lloyd-Williams.

MEDICAL AND SURGICAL APPLIANCES.

The Salmon-Ody Truss.

THE ball-and-socket joint was first adopted in the manufacture of trusses by the firm of Salmon, Ody and Co. over a century ago, and the apparatus which bears its name is still much favoured by surgeons. The latest improvement, which has proved to be of high service, is the addition of a small spring, secreted within the ball of the joint, which presses the ball against its socket. This contrivance prevents the cup and ball from working loosely and renders the truss less liable to displacement, more convenient for adjustment, and efficient and enduring when in wear. The truss is supplied by Messrs. Salmon, Ody and Co., of New Oxford Street.

INTERNATIONAL MEDICAL AMENITIES.

A NORWEGIAN physician, Dr. Monrad-Krohn, has written to us about the remarks on international medical amenities published in the *JOURNAL* for March 6th, 27th, and April 3rd. In his opinion Mr. Murray is right in saying that the Scandinavians have a leaning to the German in preference to the English language, and, as far as medical books are concerned, Dr. Monrad-Krohn gives the following explanation for this preference: When a Norwegian student begins his medical career he starts reading anatomy and physiology. Now, the booksellers all have a large stock of German textbooks on these subjects, whereas it often takes two or three weeks to get a corresponding English book. This is very often enough to make the young student decide upon the book which he can get at once. He starts reading it, and, once having become more familiar with the German language than with the English, he also buys German books on pathology, surgery, etc. Meanwhile he gradually forgets much of the English he learnt at school. Dr. Monrad-Krohn accordingly suggests that, to bring English and Scandinavians into closer touch on medical subjects, English publishers should see that the Norwegian booksellers have a large supply of medical textbooks in stock, particularly on the subjects of anatomy and physiology. This object would be promoted by the early reviews of new editions of English textbooks in the Norwegian medical press.

Dr. Monrad-Krohn pays a generous tribute to the courtesy with which he has been met by his colleagues in England, where, he says, excellent opportunities have been given him for the clinical study of medicine. He suggests that a medical guide to London would make things easier for the foreign visitors, and would "add considerably to the organization of London as a medical educational centre, whose unequalled clinical material ought to place it far above Paris, Vienna, and Berlin."

THE committee of Queen Mary's Convalescent Auxiliary Hospitals wishes it to be known that an exhibition of artificial limbs will be opened at Queen Mary's Convalescent Auxiliary Hospitals, Roehampton House, Roehampton Lane, S.W., on July 20th, and will remain open until July 23rd inclusive. Full particulars may be obtained on application to the honorary secretary, Mr. C. H. Kenderdine, at St. Stephen's House, Westminster, S.W. A conference in connexion with the exhibition will be held at Roehampton House on Thursday, July 22nd, at 3 o'clock p.m. to enable a committee of orthopaedic surgeons and the Directors-General of the Navy and Army Medical Services to confer with the artificial limb makers as to the best way of dealing with the problem of the supply of artificial limbs to sailors and soldiers who have lost limbs in the war. Any members of the medical profession who wish to attend will be welcome. With the approval of the Directors-General of the Navy and Army Medical Services gold and silver medals will be given as well as diplomas for the best exhibits, which will be judged by a committee of English, Scottish, and Irish orthopaedic surgeons.

British Medical Journal.

SATURDAY, JULY 17TH, 1915.

LEGISLATION FOR THE EXPECTANT MOTHER AND HER UNBORN INFANT.

UNDETERRED by Cicero's well-known adage, *Silent enim leges inter arma*, a deputation from the Women's Co-operative Guild—an association which has already done yoman service in the cause of the expectant mother and her expected baby—waited on the President of the Local Government Board last month to urge the amendment of the law so as to give power to local authorities to develop their work on behalf of maternity and infancy. The opinion was expressed on behalf of the Guild that the country would heartily endorse such an amendment of the law as was necessary to make this valuable department of the public health service more effective.

The Women's Co-operative Guild has a right to speak on this matter, for it is a self-governing organization of 32,000 married non-wage-earning women, and it has concerned itself with the national care of maternity ever since the introduction of the Insurance Act. Its members also have had personal experience of the need for improved conditions, and have been cognizant of the sufferings which have arisen from poverty, out of work, short time, and the lack of opportunity for obtaining the knowledge, treatment, and conditions considered essential at these times by all women of the middle class. The Guild stated in a memorandum it presented that among the most urgent needs is the provision of skilled advice and treatment before, at, and after childbirth, such as is supplied by health visitors, maternity centres, maternity homes, and hospitals; it was also pointed out that, while the 700,000 insured women receive free doctor, pregnancy sickness benefit, double maternity benefit, and sickness benefit in the event of prolonged illness after childbirth, the six million non-wage-earning married women receive nothing but single maternity benefit, and are therefore justified in looking to the nation for the provision now recommended by the Local Government Board in the interest of the country. Before the outbreak of the war the Guild had largely devoted itself to rousing public health committees and relief committees to the urgency of providing for the care of mothers and infants; and the results of that campaign, in which many other women's and labour organizations co-operated, had been striking; conferences and deputations to local authorities had been held in numerous towns, and as a consequence of the Local Government Board circular of July, 1914 (making the care of maternity a national responsibility) and the activity of the Guild, more than 140 public health committees were considering the matter or had begun or had increased their work since August. The Guild maintained, however, that the present state of the law hindered the carrying out of the whole service of health for expectant and nursing mothers, and children up to school age. Public health authorities have had to rely upon certain clauses in the Public Health Act of 1875, which did not fully meet

the case, and an excuse for inaction was thus given to unprogressive councils. Again, the lack of power on the part of county councils, because technically they were not public health authorities, hindered action in rural and small urban districts, where there was great need for advice to mothers, and for the early supervision of the health of infants.

The following facts were submitted with regard to specific spheres of action: First, with regard to the employment of health visitors for antenatal and infant visiting, the Local Government Board held that health visitors might be appointed to enable the local authority to make use of the information obtained through the Notification of Births Act, which, though not of universal application, it was open to any county councils or public health authority to adopt. The Board, however, found it difficult to hold that local authorities, whether county councils or public health authorities, had an implied power to employ health visitors for antenatal visiting. Secondly, as to maternity and infant welfare centres for medical advice and treatment for expectant and nursing mothers and children under five years, the county councils had no powers; and although the public health authorities had power to provide hospitals for the reception of the sick under Section 131 of the Public Health Act, 1875, it could not be said that all the women and all the children whom it was desirable to get to the centre for advice were "sick." Thirdly, as to hospital provision for complicated cases of pregnancy (the prematernity work in which this JOURNAL has always interested itself), for the confinement of sick women, and for complications after parturition in mother and infant, the county councils once more had no powers; and whilst the public health authorities again had power to provide hospitals for the reception of the sick under Section 131 of the Public Health Act, 1875, they might not provide hospital accommodation for ordinary maternity cases. Fourthly, with respect to the provision of a doctor or midwife in the home when the person was too poor to pay for these services, the county councils had no powers; the public health authorities might, with the Board's consent, provide "a temporary supply of medical assistance for the poorer inhabitants of their district" under Section 133 of the Public Health Act, 1875, and the Board had taken this to include the provision in necessitous cases of a midwife and doctor when called in by a midwife. It was urged that it would be economical to empower county councils to act, and that it was the only way by which much-needed care in rural districts could be secured, and, finally, that the public health authorities needed legal power to provide antenatal advice and treatment and to carry on preventive health work among children.

Mr. Long's reply to the deputation was sympathetic and encouraging, and he has already carried out his promise to introduce legislation to make the Notification of Births Act compulsory all over the country. The bill was read a third time in the House of Commons on July 13th, and its second clause, as it now stands, authorizes any local authority, whether a sanitary authority or not, to exercise for the purposes of the care of expectant mothers, nursing mothers, and young children any powers which a sanitary authority has under the Public Health Acts, 1875-1907, or the Public Health (London) Act, as the case requires. By Clause 3 the application of the Act is extended to Scotland and Ireland. Mr. Long said that his predecessor (Mr. Samuel) had been successful in obtaining a grant in respect of the expenditure from the Treasury, and that the

balance that would fall on local authorities and on the rates would be small. The Local Government Board and the Board of Education have issued a joint memorandum defining the conditions under which grants in aid of maternity centres and schools for mothers, will be made, and the Board of Education has published a memorandum on class instruction at schools for mothers, prepared by Dr. Janet M. Campbell, one of the Board's senior medical officers, designed to assist those engaged in the work of such schools in organizing class instruction in the way most suitable to the needs and circumstances of the school.

CORONERS' LAW.

FROM reports published in the *Western Morning News* on dates July 5th and July 6th of an inquest held by Mr. Hacker, H.M. Coroner for the Totnes District of Devonshire, on the body of one William Lancey, it would appear that he holds opinions as to his powers which the Coroners Act does not authorize nor permit. The case was quite simple, and the evidence as reported does not make apparent the necessity for an inquest being held at all. An insured person was under treatment by his panel practitioner for some months, and the diagnosis was not easy. Several medical men had been consulted, both locally and at the hospital at Exeter. A diagnosis of gastritis and cardiac insufficiency had been made and due and proper treatment prescribed. Dr. Patterson, the panel practitioner, treated the patient up to the day before he died, and when death took place suggested to the relatives that, in order to verify the diagnosis, it would be advisable to make a *post-mortem* examination. No objection was made; the examination confirmed the diagnosis and the usual death certificate was given by Dr. Patterson, accepted by the Registrar, and the burial order made out. Before the burial could take place the coroner was informed of the death and issued an order for a second *post-mortem* examination and an inquest.

At the first inquiry the coroner is reported to have made the following statement: "It is illegal to give a certificate of a case of sudden death when the cause is unknown. It must be reported to the coroner. . . . I go further," he added, "and say the fact of making a *post-mortem* examination without reporting to the coroner and without obtaining at an inquest a proper order for such an examination is going very near committing an indictable misdemeanour in interfering with the proper course of justice and exposing the body in such a way as to prevent an inquest." This ruling of the coroner was at once challenged by Mr. Dell, the solicitor who attended the inquest on behalf of the two doctors concerned, and after taking some formal evidence the inquiry was adjourned.

At the adjournment Dr. Patterson and Dr. Morton Palmer, the practitioners whose procedure the coroner had attacked, were represented by Mr. Hempson, solicitor for the Medical Defence Union, and the coroner then stated that it was quite clear by the Act of Parliament and also by common law that this being a case of sudden death, of which the cause was unknown, an inquest became necessary. Dr. Patterson should have known that; all doctors knew it. His duty on finding that death had taken place was to tell Lancey's friends to report the case to the coroner. . . . When a medical man could not give a certificate, the ordinary practice was to at once report the case. Dr. Patterson expostulated, and explained that he knew that death was due to natural causes, and that there was nothing to conceal. Mr. Hempson

disputed the coroner's ruling, and protested firmly against the branding by the coroner of the medical practitioners with conspiracy, and his statement that they were practically guilty of an indictable offence. Mr. Hempson was about to make further protests, but the coroner directed him to resume his seat. The coroner, in his summing up, said that after Dr. Patterson's explanation and candid statement, the jury would probably think that there was not much ground for complaint; after a few minutes' deliberation, the jury returned a verdict of death from natural causes, thereby justifying to the full both the treatment and diagnosis of Dr. Patterson.

It is difficult to imagine why the cumbersome machinery of the coroner's law was set in motion in this case and why the county was put to the unnecessary expense of an inquest. The procedure adopted by Dr. Patterson in asking for, and, after gaining permission, making a *post-mortem* examination in order to verify his diagnosis and enable him to give a correct death certificate, was, we have no hesitation in affirming, quite legal, right, and proper. A similar course is adopted in every hospital every week, and is quite common in general practice. To affirm that where an absolute diagnosis cannot be made in cases involving no suspicious circumstances a *post-mortem* examination cannot be made without an order from a coroner is absurd. A coroner has no power to order a *post-mortem* examination without holding an inquest, and to hold that the law insists upon an inquest whenever the coroner desires, is an illegal assumption of authority.

It is true that if a case be reported to him it is his duty to make inquiries, but if such inquiries satisfy a reasonable mind that the death arose from illness it would be quite irregular for him to hold an inquest. Lord Selborne laid down the authority of the coroner as follows: A coroner has not an absolute right to hold an inquest in every case in which he choose so to do, nor is it in general the duty of coroners voluntarily to obtrude themselves into private houses. Such officious interference would be in many cases a censurable excess of duty. If notice of the death is accompanied, or followed, by information that it was probably due to such cause as apoplexy or other visitation of God, so as to show that an inquest is not necessary, the coroner may reasonably exercise his discretion by not holding an inquest. In this case not only was there no suspicion of foul play, but a certificate of death had been issued in accordance with statute law, signed by a registered medical practitioner, and the actual cause of death as previously diagnosed confirmed by a *post-mortem* examination. As a matter of law it is not the duty of any one to make a report to the coroner or to inform him of anything relating to a death, however sudden. We are aware, of course, that some coroners, though they know or ought to know this, try to invent a duty under the common law; but as a matter of fact there is no legal authority to enforce this. If there were such a common law duty, indictment could follow a breach of it, but this is not the case here. It must also be remembered that the coroner has no jurisdiction over the body of a deceased person until he issue his precept for an inquest; the property of a dead body rests with the family of the deceased or his executors. It is quite legal, therefore, for the relatives to give consent to a medical practitioner to make a *post-mortem* examination, and when this is done by a properly qualified man and death is confirmed as being due to disease no inquest should be held, especially when the death has occurred in a private house. Even where, under

special enactments, deaths have to be reported to the coroner, such as in the case of lunatics in asylums, it is not illegal for a *post-mortem* examination to be made before receiving the coroner's permission, and no action could be taken to prevent the authorities from making such an examination. It would be quite unreasonable to require the coroner's permission when the examination is made to confirm the diagnosis of death from a known natural cause, when there were no grounds for supposing that an inquest would be held.

It has been asserted by an eminent coroner that when a jury returns a verdict of death from natural causes that is in itself a proof that the inquest was unnecessary. Whilst not going so far as this authority, we cannot but feel that in the case to which we refer there was no occasion whatever for the coroner to have set in motion the machinery of the law, and still less for his animadversions upon the procedure adopted by the medical practitioners concerned. Their conduct was quite in accordance with the law and with the custom of the medical profession, and the attack made upon them by the coroner was entirely beyond the mark and unjustifiable.

ODONTOMES.

At the annual meeting of the British Dental Association held in London in 1906 the most complete collection of odontomes ever assembled was shown. It was sought to give permanence to the labour thus entailed by the appointment of a subcommittee, consisting of Messrs D. P. Gabell, W. W. James, and J. L. Payne, charged with the task of drawing up a report on the classification of odontomes.

In drawing up its report,¹ which has been issued recently, the committee took as a basis Bland-Sutton's classification, but after consideration of "several factors, among them the recognition of the wider function of the enamel organ, the discovery of the epithelial lining in certain cysts, and the investigation of a larger number of specimens," they have altered it in detail. As a classification they propose: (1) Epithelial odontomes, in which the abnormal development takes place in the dental epithelium alone. 2. Composite odontomes, in which the abnormal development takes place primarily in the dental epithelium, and secondarily in the dental papilla, and may occur in the follicle also. (3) Connective tissue odontomes, in which the abnormal development takes place in the dental tissues of mesoblastic origin alone.

The first class includes multilocular cysts, dentigerous cysts, and dental cysts. The difficulty of classification at once obtrudes itself. Of the three forms of tumour, only one, "dentigerous cyst," definitely conforms with the reporters' definition of "odontome" as a tumour derived from the special cells concerned in tooth development, and is of unknown etiology. As they admit, there is strong evidence that multilocular cysts may arise from ingrowth of the gum epithelium, as held by Eve; and in the case of dental cysts, J. G. Turner has shown clearly their dependence on chronic bacterial infection. It is permissible to believe, with the reporters, that the epithelial ingrowth demonstrated in the multilocular cysts arose from some portion of the tooth band, though demonstration appears impossible.

The second class includes (a) complex composite odontomes, compound composite odontomes; (b) geminated composite odontomes, gestant composite odontomes, enamel nodules; and (c) dilated composite odontomes. The report seeks to extend the use of the term "composite odontome" till it includes "all odontomes dependent on aberrations of the enamel organ with other dental tissues." It would thus include almost all calcified odontomes, and the three subdivisions are dependent on the general effect the irregular development of the dental epithelium has upon the dentine papilla.

The term "complex composite odontome" is used to include tooth tumours that are formless and whose tissues are irregularly mixed; "compound composite odontome" is the name given to Bland-Sutton's class "compound follicular odontome." These are tumours in which are found more or less numerous denticles or calcified masses together with cyst formations which may attain a large size. Bland-Sutton explains them as due to sporadic calcification of the cyst wall, but this explanation is obviously incomplete, and the report recognizes six different methods of origin. The first two, non-eruption of several supernumerary teeth and deformity of several of the ordinary tooth-germs, might well be classed as "compound follicular odontomes," and the sixth, sporadic calcification of a thickened capsule about a tooth germ or germs, is a restatement of Bland-Sutton's explanation (such calcification would give rise to bone and the tumour would be a cementoma). It may be questioned, however, whether the dental follicle is a distinct enough structure to be worth charging with tumour formation. Bland-Sutton falls back on it to account both for cystic tumours derived from the dental epithelium, where the follicle may be supposed to be the indefinite fibrous capsule lined with epithelium surrounding the crown of the tooth, and for cementomata which arise in parts (around the roots) where no follicle or capsule can possibly be found. We are glad the authors have tried to rectify this difficulty, but it may be doubted whether cystic tumours formed by the non-eruption of several teeth, supernumerary or normal, should be included in the same class as almost solid tooth tumours containing irregularly calcified tooth masses—they lie so far apart in the harmonic scale. We doubt, too, whether the terms "complex composite odontome" and "compound composite odontome" are sufficiently distinct and self-explanatory.

Of the further subdivisions of composite odontomes suggested, "geminated composite odontomes" may be found a useful class in connecting supernumerary teeth or geminated teeth with more obvious odontomes. "Gestant odontome" is the *dens in dente* of Continental writers; "enamel nodule" is self-explanatory and rightly included as odontomatous; "dilated composite odontome" does not seem to us a well-chosen term, since it is made to include both solid and hollow tumours, and refers only to form.

The third class made in the report includes fibrous odontomes and cementomes, and it is correctly stated that fibrous odontomes are probably a result of rickets. An important point is made when attention is drawn to the microscopic diagnosis of cementomes. They are rare tumours, composed mostly of non-laminated cementum with plentiful irregular vascular canals, while root-exostosis, with which they are liable to be confounded, is common, laminated, and little vascular.

The report denies the existence of malignant odontomes, with the exception of the composite embryoplastic odontome of Eve, and it seems to be

¹ *The Report on Odontomes.* By the Committee appointed by the British Dental Association. Members of the Committee—D. P. Gabell, L.R.C.P., M.R.C.S., L.D.S., W. W. James, L.R.C.P., F.R.C.S., L.D.S., J. L. Payne, L.R.C.P., M.R.C.S., L.D.S. London: The British Dental Association, 1914. (Demy 8vo, pp. 142, 45 plates, 91 figures. 7s. 6d. net.)

implied that a careful consideration of recorded cases of "burrowing epithelioma," etc., shows that these tumours are not malignant. This opinion will undoubtedly be disputed; burrowing epitheliomata are very malignant, and the origin of some of these growths from dental epithelium seems unquestionable.

The reporters appear to have felt that their effort is not final, but in publishing the results of eight years' patient labour, freely given, they have placed the whole dental profession under a debt of gratitude which can best be repaid by study and discussion of their work.

ORGANIZATION TO MEET THE WAR EMERGENCY.

The War Emergency Committee of the Metropolitan Counties Branch has formulated a proposal for dealing with the supply of medical men to the army upon very similar lines to those already adopted by the Scottish Medical Service Emergency Committee. It is argued that as the demands made upon the medical profession are certain to increase, it is wise to be prepared beforehand with some definite organized plan for satisfying the wants of the army with as little disturbance of civil practice as the grave nature of the circumstances permits. Therefore it is proposed that every medical man of military age—that is, 40 or under—should enrol himself as willing to take a commission within a few days after a certain date, if called upon to do so. The details of the arrangements for enrolment and calling up would be in the hands of a special committee of men well known in the medical profession, not necessarily members of the British Medical Association. The Committee would work through the organization of the British Medical Association, which has available the speediest means for approaching the medical profession. When any urgent demand arises for a fresh quota of medical officers, the Committee would select the necessary number of names from the roll, with due consideration for the position of individual men, and the needs of the community which they serve. The selected names would be forwarded to the War Office, where the authorities would accept such men as they approve. It is thought also that the Committee might render useful service in advising and assisting men in their preparation for leaving practice, in establishing classes for elementary instruction in military medical matters, and in endeavouring to provide against serious loss when the men called up return to civil practice.

CONGENITAL SYPHILIS IN THE EAST END.

DR. PAUL FILDES, assistant bacteriologist to the London Hospital, has made an extensive research into the prevalence of congenital syphilis among the newly born of the East End of London, and has set forth his results in an extremely interesting report.¹ The investigation was carried out on the assumption that an infant infected with syphilis, even if it shows no clinical signs of the disease, will give a positive Wassermann reaction either at birth or within two months, which according to observations on the adult is the longest possible incubation period for the reaction. The infants were chosen from the respectable labouring classes, and were all the offspring of married women who were on the books of the Maternity Charity of the London Hospital. In spite of the prevalent belief that a higher standard of morality prevails among Jews, who form so large a proportion of the population of the London Hospital district, the incidence of syphilis among them

did not differ appreciably from that of the Christians. This interesting ethnological point is, we understand, to be further considered in a subsequent publication; but it is held that the presence of the large alien element does not interfere with the application of deductions drawn from this population to groups of similar social status in different parts of London. Two series of examinations were made, the first at birth and the second two and a half to four months later, when the mother's blood was also examined. By this means it was held that all the subjects of congenital syphilis could be detected. In the first examination the blood was taken from the placental end of the cut umbilical cord, and at the subsequent examination from the thumb or great toe. The technique employed in testing the blood was that recently described by Fildes and McIntosh.² Of 1,015 infants examined at birth 14 (1.3 per cent.) gave a positive reaction, but were all apparently healthy, except one who presented obvious signs of congenital syphilis, and died in twelve days, in spite of treatment. Of the remaining 13, 7 examined two months later gave a negative reaction, though the reaction in their mothers was positive, and 6 did not return for examination. These results prove that a positive reaction at birth does not necessarily imply syphilis of the child, but merely the passage of the reacting substance from the blood of the syphilitic mother. At the second examination, when only 660 of the 1,015 infants were available, 3 (0.45 per cent.) gave a positive reaction. These three infants were healthy at birth, when the reaction was entirely negative, and two remained healthy, but one developed undoubted signs of congenital syphilis. Further inquiries made it unlikely that an undue proportion of syphilis existed among those infants who were not brought up for a second examination. Of 677 mothers examined, 27 (3.9 per cent.) gave positive reactions, but only 4 of these had syphilitic offspring. So far from every woman with a positive reaction having caused a positive reaction in the umbilical cord blood, in the majority (16) of the positive cases the umbilical cord blood had been negative. The placental blood is therefore no index of the prevalence of syphilis in women. The general conclusion arrived at by Dr. Fildes is that the ravages caused by congenital syphilis in infants are sometimes exaggerated. It is to be hoped that the example set will be followed by investigations of this kind, the importance of which from a medical and sociological standpoint it is difficult to overestimate.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.

The quarterly instalment of *A New English Dictionary on Historical Principles*,³ which appeared on July 1st, covers the portion of the alphabetic rubrics from *Trink* to *Turn-down*, and includes a large number of medical terms. Sir James Murray had hoped, by slightly enlarging this issue, to reach the end of *T*, but, in words which excite the sympathy of all his readers, he is forced to add to his prefatory note: "My long and serious illness, which lasted from May to November, robbed us of that satisfaction." All reviewers will unite in wishing the editor long life and strength to carry his monumental work to a successful end, and will congratulate him on the words with which he closes his preface: "The next issue will take us well into *U*." A great many medical terms, especially those in the department of chemistry, begin with *Tri-*, *Trio-* and *Trocho-*. Thus there is *triolein* (one of the glycerides of oleic acid), *trional* (the trade name of the synthetic drug diethylsulphonemethylmethane), *trioxide*, *trioxy*, *tripalmitin* (a crystalline substance occurring in palm oil and other fats and oils), *tripeptide* (a compound containing the residues of three

² Report to the Local Government Board upon the Prevalence of Congenital Syphilis among the Newly Born of the East End of London. By Paul Fildes, M.B., B.C. (Cantab.), Assistant Bacteriologist to the London Hospital. (From the Bacteriological Laboratory of the London Hospital—Professor William Balloch, F.R.S.) London: Wyman and Sons, Ltd., 29, Breams Buildings, Fetter Lane, E.C. (23.)

³ *A New English Dictionary on Historical Principles*. Edited by Sir James A. H. Murray. *Trink-Turn-down*. Volume 2. Oxford: At the Clarendon Press; London, Edinburgh, New York, Toronto, Melbourne, and Bombay: Oxford University Press, Humphrey Milford, July 1st, 1915. (6s.; 1.25 dol.)

amino-acids), *triphenin* (a synthetic drug with antipyretic and antineuralgic properties), *triphenylmethane*, *triphenylamine*, *trisaccharide*, *trisulfate*, *trisulphide*, *trisulphone*, *tristricin* (a carbohydrate), *trochoccephalic* (having a round form of skull due to premature union of the parietal and frontal bones, etc. More distinctly medical terms are *triplegia* (hemiplegia with a paraplegia of spinal origin added to it), *trismus* (a modern Latin word adapted from the Greek *τρισμός* *τρισμός*, a scream, also a grinding, rasping, and meaning tonic spasm of the muscles of the neck and lower jaw), *trochanter*, *trochlear*, *turbinal*, *turbidology*, etc. Under *trypanosoma*, which is derived from the Greek *τρύπανον*—a borer, and *σώμα*—a body, there is quite a family of words, including *trypanosomacide* (a substance having the property of destroying trypanosomes), *trypanosomiasis* (a disease produced by infection with trypanosomes), and *trypanosomal* (pertaining to or caused by trypanosomes). All these derived words are of modern origin, but *trypanosome* itself was introduced in 1843 by Gibby, who, in describing some living parasites in the blood of animals, wrote "je propose de nommer cet hématozoaire Trypanosome." In the near neighbourhood of trypanosoma is found *trypan*, which is a contraction for it, and is used in such a combination as *trypan red*, the drug which is employed in cases of trypanosomiasis; but the ordinary reader of the *Dictionary* will hardly thank the editor for transcribing the statement that the correct name for trypan red is sodium-ortho-benzidine-mono-sulphoacid-diazo-b-2-naphylamine-3-6-sulphoacid, which will seem as illuminating as the remark that the "snark was a boojum." To many even well-educated readers the derivation of *trypsin* will come as a surprise; it is from the Greek *τριψίς*—rubbing, because it was first obtained by rubbing down the pancreas with glycerin. Grouped round trypsin is the small family of derived words, *trypsinogen*, *trypso-gen*, *tryptic*, *tryptone*, and *tryptophan*. A large number of terms cluster round *tubercle*, and most of them took on a new shade of meaning when Koch in 1882 discovered the bacillus of that name; there are *tubercular*, *tuberculide*, *tuberculin*, *tuberculation*, the compound *tuberculo-*, *tuberculome*, and *tuberculosis*. All these are defined with Sir James Murray's usual exactitude, and illustrated by a profusion of quotations, most of which convey really useful information as well, so that after running them over the reader has an actual knowledge of the subject. No space remains to refer to the other medical terms dotted up and down in this section of the *Dictionary*; but it must be added to what has already been said, that the work is as complete and informative on the medical uses of such ordinary words as *trouble*, *truss*, and *turn*, whilst under *tupelo* the convenient *tent* is named.

SOLDIER'S HEART.

DURING the first months of the war the German medical press devoted itself mainly to wounds and their treatment, infectious diseases, and the hygienic measures necessary for their suppression. Early in 1915 many writers published their observations on the effects of the war on the soldier's heart, and it would appear that the constant strain of active service has provided an unexpectedly large number of cardiac casualties. Magnus-Levy¹ was struck by the frequency with which healthy-looking, well-built young men among the wounded complained of palpitation of the heart, a sense of pressure in the cardiac region, and slight dyspnoea on exertion. The pulse was 80 to 100, the apex beat was in the fifth space, in or to the left of the nipple line, and the cardiac dullness was increased. The cardiac sounds were muffled, and systolic or presystolic murmurs were audible, particularly after exertion. The second sound was loud, notably after exertion, which quickly increased the pulse-rate to as much as 120. Only in a few cases could it be proved that the patients had

already suffered from slight cardiac symptoms before the outbreak of the war, and in the majority of cases the strenuous life of the soldier was apparently alone responsible for the faulty action of the heart. Rheumatic endocarditis could be excluded in most cases in the absence of articular disease. In the overwhelming majority of cases the dilatation of the heart and the rapid pulse were traced to over-exertion and fatigue; and the slight rises of temperature sometimes observed among unwounded soldiers suffering from cardiac symptoms were regarded, not as a sign of infectious endocarditis, but as a result of instability of the body temperature due to fatigue. Fischer² was also struck by the frequency with which the wounded complained of cardiac symptoms. Among 131 wounded he found cardiac anomalies in 51, or nearly 39 per cent. In most cases there were adventitious sounds over the apex or base of the heart, which, in 13 cases, was dilated. Discussing the prognosis in these cases, Minter³ considered the outlook bright, provided over-exertion could be avoided in the future. He found treatment with digitalis of no use, and he admitted that rest in bed was unsatisfactory, as the patients became restless and were subject to attacks of palpitation at night. Mirtl's⁴ prognosis was more cautious, and he pointed out that, though the symptoms might disappear with rest, a complete recovery could not, as the x rays have proved, be anticipated. His experience of the Balkan wars of 1912 and 1913 had shown him that the soldier's heart was associated with persistent hypertrophy, which, though of a moderate degree, was often the cause of discomfort. When such cases were neglected, arterio-sclerosis was apt to supervene.

BUYO CHEEK CANCER.

CANCER of the cheek is exceedingly common in the Philippine Islands, in women as well as in men, and the cause is well known. In those islands "buyo" or betel leaf (*Piper betle*) is almost universally chewed by adults, and often by children of tender years; 90 per cent. of the elderly natives indulge in the habit, and Dr. George Davis, of the University of the Philippines, when received by the Sultan of Sulu, noticed that His Majesty frequently made use of a beautiful coloured glass spittoon, being himself an inveterate buyo chewer. It is important to remember that the buyo leaf is seldom chewed alone. Lime is carried in one of the compartments of the buyo box, and corrodes the brass in a very suggestive manner. The lime is spread over the buyo leaf, which is then folded and wrapped around a betel nut (*Areca catechu*). Since the American occupation, the buyo is flavoured with an accompanying "plug cut" of American or native tobacco. The lime is obtained from sea shells; it gives a pleasant sweet flavour to the betel nut and buyo leaf, and by a chemical action produces a red colour, dyeing the oral mucosa red and the teeth black. Old men and women, the latter the more inveterate chewers, use a paste when they have lost their teeth. Dr. Davis, who has written both on the etiology⁵ and on the surgery⁶ of buyo cheek cancer, considers that without doubt the lime is the essential cause of the malignant degeneration; but from clinical observations in a case in which, after resection of the left superior maxilla, lime was discarded, he feels certain that the essential oil of the buyo leaf, and the tannic and gallic acid in the betel nut, are predisposing factors. The ravages of buyo cheek cancer, as Dr. Davis's photographs show, are very extensive. This disease is evidently a definite lesion like Roentgen-ray epithelioma, chimney-sweepers', paraffin workers', and Indian kangri skin cancer, and the

malignant changes in the brands on cattle in the Western United States. For the extirpation of this formidable new growth Dr. Davis practises extensive plastic operations.

STATISTICS OF NOTIFIABLE DISEASES.

THE statistical return of the incidence of notifiable infectious disease upon the sanitary districts of England and Wales in 1914, which was recently issued by the Local Government Board,¹ is the fourth in this valuable series. The tables are prefaced by a useful summary of the principal facts. Perhaps the most interesting figures are those relating to scarlet fever, diphtheria, and enteric fever. The prevalence of the two former diseases has increased in the last few years. In the case of scarlet fever the total for 1914 was 165,045; for 1913, 130,707; for 1912, 107,508; and for 1911, 104,651. The corresponding figures in the case of diphtheria are 59,357, 50,903, 44,754, and 47,802. Enteric fever shows an increase as compared with 1913—8,778 cases in 1914, 8,263 in 1913—but has not regained the level of 1911—namely, 13,852; 315 cases of cerebro-spinal fever were notified in 1914, the figure for 1913 being 305. It is to be remarked that the duty of notifying infectious diseases to the medical officer of health does not apply in respect of persons living in any building belonging to H.M. the King, but that, owing to the unprecedented conditions prevailing in the later months of 1914, many notifications of military and naval cases were actually sent to medical officers of health. These have been included in the totals for England and Wales, but not in the returns for sanitary areas. The number of cases of pulmonary tuberculosis notified exhibits a marked decline—81,159 in 1914, 96,841 in 1913, 110,706 in 1912—but it is pointed out that a considerable number of duplications occur, so that the published figures do not admit of satisfactory comparison. It is hoped that this difficulty may be partially surmounted in the next annual report. Dr. R. Bruce Low contributes a preliminary statement as to the occurrence of small-pox abroad during 1914, and it is a matter of special interest to remark that small-pox appears to have been prevalent in Asiatic Turkey during 1914, and was epidemic in Smyrna. Beirut and Damascus also suffered greatly. More than 68,500 deaths from small-pox were recorded in India during the first nine months of the year. The whole report will, like its predecessors, be indispensable to epidemiologists.

SIR CHARLES TUPPER.

SIR CHARLES TUPPER, who lives in retirement at Bexley Heath in Kent, celebrated his 94th birthday on July 2nd. He was born in 1821, and educated partly in Canada and partly at the University of Edinburgh, where he took the degree of Doctor of Medicine. He is best known, however, as a statesman, and at one time or another he has held nearly every great office of State in the Canadian Government. How highly his services are appreciated by the people of Canada is well shown by a telegram sent to him on the occasion of his birthday by Mr. White, Acting Prime Minister of Canada, who said that "Canada, a united people in the crisis of this great war, faithful to the empire, and cherishing its great traditions, looks back to-day with pride, veneration, and affection to the Fathers of Confederation, whose dreams have been so amply fulfilled." We join heartily in Mr. White's wish that Sir Charles Tupper may long be spared to enjoy the esteem and regard of the Canadian people. The magnificent loyalty of Canada in the most critical time of our history and the splendid courage shown by her sons in the defence of the empire have drawn more close than ever the bonds which unite us to the great Dominion overseas.

¹ *Statistics of the Incidence of Notifiable Infectious Diseases in each Sanitary District in England and Wales and Preliminary Statement as to Small-pox Abroad during the Year 1914.* Reports to the Local Government Board on Public Health and Medical Subjects, New Series, No. 106.

and it is natural that we should be particularly proud at this time to recall the fact that one of Canada's greatest sons is a member of the medical profession.

Medical Notes in Parliament.

The Naval and Military War Pensions Bill.

THIS bill is described as a bill to "make better provision as to the pensions, grants, and allowances made in respect of the present war to officers and men in the naval and military service of His Majesty and their dependants and the care of officers and men disabled in consequence of the present war." It sets up a Statutory Committee of the Royal Patriotic Fund Corporation, but continues the existence of the corporation in accordance with the provisions of the Patriotic Fund (Reorganization) Act, 1903. The Statutory Committee is to consist of 29 members, but will have power to co-opt not more than 15 persons having special experience in work of the character to be performed by the corporation. Of the 29 members, 12 will be appointed by the Crown, among them a chairman and vice-chairman, who may both receive salaries; 1 member will be appointed by the Treasury, 1 each by the Admiralty and Army Council, 1 by the National Insurance Joint Committee, 1 each by the Local Government Boards in England, Scotland, and Ireland, 6 by the General Council of the Royal Patriotic Fund Corporation, 2 by the National Relief Fund, and 2 by the Soldiers' and Sailors' Families Association. To assist the Statutory Committee, local committees are to be established in every county and county borough, and the county council of any county may divide the county into districts and appoint a subcommittee for each. The chief duties of the Statutory Committee will be to decide any question of fact as to the amount of a pension or grant payable out of public funds to a dependant other than a widow or child; to make regulations for supplementary grants where in exceptional circumstances the pension or grant, or separation allowance payable out of public funds, is inadequate; to supplement pensions and grants and separation allowances payable out of public funds; to make grants or allowances out of funds at its disposal in cases in which no separation allowances or pensions are payable out of public funds; and to make provision for the care of disabled officers and men after they have left the service, including provision for their health, training, and employment. The Statutory Committee may refer questions to the local committee and request it to collect and supply information. The local committees may solicit and receive from the public contributions towards any of the purposes of the bill, which purposes are included among those for which the Royal Patriotic Fund Corporation may solicit and receive contributions from the public and donations of property. The Committee stage of the bill was completed in the House of Commons last week.

The report stage was taken on July 14th. Mr. Price (Edinburgh Central) complained that no notice had been taken of the recommendations of Sir George Murray's committee, which had recommended the setting up of technical schools to train disabled soldiers. How were the local committees going to train them? He suggested that a fresh bill should be introduced to deal specifically with disabled soldiers, and with finding employment for men not disabled on their return to civil life. Mr. Goldstone (Sunderland, Lab.) agreed that the Government seemed to have failed to recognize how great the problem of demobilization would be when the able-bodied soldier would return to civil life and be in competition with disabled men. Mr. Anderson (Attercliffe, Lab.) asked the House to declare that it was not satisfied with the bill. He maintained that the question of the training and employment of disabled soldiers was one for the nation and not for private charity. After Mr. Hogge had said that the Statutory Committee had the power to set up such a subcommittee as was desired, Mr. Hayes Fisher contended that the suggestions of Sir George Murray's committee had not been ignored in the bill. Though there were only three lines in the bill dealing with disabled officers and men they covered the ground, and there was nothing in the bill to prevent statutory bodies setting up special subcommittees. If the provision eventually

proved inadequate new legislation could be proposed. Mr. C. Ducean (Barrow-in-Furness, Lab.) objected that the scope of the bill was insufficient. The Chancellor of the Exchequer, in reply on the debate, said that under the bill the Government looked primarily for support from voluntary funds, but, so far as they proved insufficient, was prepared to supplement them out of public funds. More might be done if the funds expended were partly subscribed voluntarily, for the moment the charge was placed upon public funds private subscriptions dried up. The country was doing for its soldiers and sailors what no other nation had done, and he contended that the Government had acted on sound and reasonable lines in introducing the bill in its present form. The State did not intend to depart by one iota from its responsibility, and those who were anxious to benefit wounded soldiers and sailors should assist the Government to obtain as much by voluntary subscription as was possible. Mr. Hodge (Gorton, Lab.) contended that it was the duty of the State, and the State alone, to look after those who had been broken. There was not only the question of pensions, but the duty to men who came back from the front with nerves shattered; they ought not to be left to charity. It was the duty of the State to do everything possible to bring them back to their former condition. The report stage was concluded, and the third reading of the bill put down for next Monday.

Notification of Births Act.

A bill to extend the Notification of Births Act (1907) to areas in which it has not been adopted, and to make further provision in connexion therewith for the care of mothers and young children, was read a second time, on the motion of the President of the Local Government Board, on July 8th. Mr. Long said that the Act of 1907 had been adopted to so large an extent by local authorities that about 80 per cent. of the population came under its powers. The bill proposed to make the Act universal, and to deal also with the health of the children and mothers. The Act required the notification of births of children alive or stillborn after the expiration of twenty-eight weeks of pregnancy. All experience of the areas in which the Act had been in force went to show that where notification was followed by wise action on the part of local authorities or voluntary agencies most satisfactory consequences in regard to the health both of mothers and children ensued. He added that Clause 2 as originally drafted would be modified to meet the views of the Board of Education.

The bill was supported from all sides of the House. Mr. J. A. Pease, who was, until the reconstitution of the Government, President of the Board of Education, said that statistics showed how much could be done to prevent infantile mortality. During the last few years the rate had decreased from an average of 130 to 108. He asked for an assurance that the work of the Board of Education in connexion with the schools for mothers, nursery schools, crèches, and other arrangements for dealing with children under the age of 5 should not be handed over to the sanitary authorities. The Board of Education had been entrusted by Parliament with power to see that the children found on inspection to need medical treatment were so treated, and that grants should be made not merely for inspection but for treatment through the local education authorities. The substantial experience gained by the Board of Education in connexion with the feeding of infants between 3, 4, and 5 years of age had shown that to avoid waste of public money it was essential that they should be attended to before they went into the schools and not afterwards only. He would go further, and say that children, even at the age of 10, 11, or 12 months old, should be included in the scheme. If any attempt were made to poach upon the province of the Board of Education, which was developing to the advantage of the community, overlapping and extravagance would occur.

Mr. Percy Harris (Paddington) said that in some districts the adoption of the Act had not been followed by effective action owing to doubts as to the powers of local authorities, and as to the results which would flow from such action. The bill removed any doubt as to the powers, and what had already been done by public and private agencies made clear the extraordinarily fruitful field which was open.

Mr. King (Somerset, N.) advised members to read the recent reports of the chief medical officer of the Board of

Education. The whole outlook for education and the problem of the well-being of the people had been given a new meaning and a new promise, through what Sir George Newman had written and done. The argument was that the problem of the child's education depended upon its health, and more upon the state of health in which the child was when it entered school than any other point. Its health at that time depended upon the upbringing and teaching of the mother, and therefore the problem of education, in the first instance, was the teaching of the mother and the assistance given to her in the earliest years of the child's life, even the earliest months and weeks of its life, in regard to health and nutrition. In Fulham the mothers of 600 infants had received advice; in Leeds 2,000 children under 5 had been the subject of consultation during the year; in Manchester the number was 1,600, and in Bristol 1,200. It was quite clear that the Board of Education had been doing magnificent work.

Mr. Dickinon (St. Pancras) and Sir John Spear (Tavistock) expressed the hope that funds would be provided from the Imperial exchequer for carrying the bill into effect.

Mr. Currie (Leith) said that Scotland suffered because a grant had not been made as in England and Wales. Mr. Long, in his reply, said that under the bill the distribution of grants-in-aid would follow the invariable practice, and would be made in due proportion to the three countries. An additional grant from the Treasury had been procured, and it was proposed to make grants-in-aid to local authorities to carry out expenditure approved by the Local Government Board. Clause 2, in its amended form, had been discussed with the President of the Board of Education, and would meet the wishes of that Board.

The Committee stage of the bill was taken on July 13th, when Clause 1 was adopted without amendment. Mr. Walter Long brought up the new Clause 2, which was amended and adopted. Clause 3, applying the Act to Scotland and Ireland, was amended and adopted. The bill was then read a third time and passed. The bill was read a first time in the House of Lords on July 14th.

The text of the bill as amended is not available at the time we go to press, but it will be published at an early date.

Hospitals and Duty-free Alcohol.—Sir Philip Magnus asked the Chancellor of the Exchequer, on July 13th, if, having regard to the disappointment that would be caused if no relief from spirit duty was provided for hospitals in the course of this financial year, it was his intention to introduce a clause into this or the next Finance Bill to give such relief in the form of a grant which would be based on the duty paid on spirits by hospitals last year, subject to investigation of an advisory committee working in connexion with the Board of Customs and Excise? Mr. McKenna said that he agreed in principle to a grant from public funds of the kind referred to. He understood that this proposal met with general approval, and regretted that time would not allow him to deal with the matter now. He proposed, however, to do so on the first suitable opportunity.

Treatment of Wounded.—Mr. Walter Roch asked the Under Secretary for War, on July 7th, if he would obtain from the hospitals in this country returns showing (1) the number of cases of compound fractures and the number of such cases which had resulted in amputation being necessary; (2) what proportion of the patients treated had arrived there with septic wounds; and (3) the number of cases of abdominal wounds, and the number of cases of such abdominal wounds which had proved fatal. Mr. Tennant said that the information desired would lay upon the medical authorities a vast amount of work, and, inasmuch as they were now heavily taxed, he would be obliged if Mr. Roch would not press him to ask them to undertake the additional work involved. Mr. Roch asked if there was not a register in the hospitals of each individual case, and was it not merely a question of tabulating them in order to get the information asked for. Mr. Tennant replied that he had no doubt there was a register in each hospital, but what was asked for was a return from each hospital, and that would involve much labour. In reply to a subsequent question by Mr. King, Mr. Tennant said he could not say whether that was so or not, but he should

not think any register would contain the information as to how many of the patients treated arrived there with septic wounds.

Hospital Service in Egypt.—Sir A. Markham asked the Under Secretary for War, on July 8th, whether the Secretary of State for War refused to give his consent to private persons sending out to Egypt private hospitals at their own expense; and whether, as a consequence, when the wounded from the Dardanelles arrived at Alexandria they were sent to the German hospital to be nursed by German nurses. Mr. Tennant said that private hospitals were not, and were not now, required in Egypt. The arrangements for the reception of the wounded at Alexandria were adequate in all respects. The General Officer Commanding in Egypt exercised a wise judgement in making use of the German hospital. In fact, he would no doubt have been criticized adversely if he had failed to make use of all the suitable accommodation which was at his disposal.

Dentistry and the Army.—Mr. Tennant stated, on July 7th, in reply to Sir J. D. Rees, who inquired with regard to the arrangements made for dentistry for the troops, that in some places there were specially appointed dental surgeons, who devoted their whole time to the troops; in others the work was done by selected civilian dental surgeons on terms arranged between them and the local military authorities, subject to a limit laid down by the War Office. A number of whole-time dental surgeons had received commissions, but there was no Army Dental Corps, and no need for one. The Government had no laboratory for supplying dentures, but in certain places, including France, there were dental mechanics' shops for making and repairing dentures. At other places dentures were supplied by civilian dentists on terms arranged locally, subject to a maximum fixed on the advice of expert dentists. The Government was getting dentures at reasonable rates, and the taxpayer was carefully protected. In reply to a subsequent question by Mr. Raffan, Mr. Tennant said he was afraid the War Office must adhere to its decision not to recognize the work of unregistered dentists.

Army Medical Advisory Board.—Mr. Walter Roch asked the Under Secretary of State for War, on July 7th, if the Army Medical Council appointed by Lord Haldane still existed; if so, who were now the members of it, and how many times it had met since the commencement of the war? Mr. Tennant said the question probably referred to the Army Medical Advisory Board instituted by Lord Midleton, and referred Mr. Roch to the *Army List*, column 2494, where the names of the members were given. The Director-General of the Army Medical Services was in close touch with these gentlemen continually and they with him. The Board had no regular meetings, but the members were in constant touch one with the other.

Royal Army Medical Corps.—Sir J. D. Rees, on July 8th, asked the Under Secretary for War whether the pay of a junior temporary lieutenant in the Royal Army Medical Corps was £100 per year more than the pay of a captain in the Royal Army Medical Corps of the Territorial Forces, although the former might be and usually was absolutely new to military duties, and the latter might be and often was of ten years' standing as a commissioned officer in the Territorial Royal Army Medical Corps; and, if so, when would this inequality be rectified? Mr. H. Forster said the pay of a medical officer serving under special contract, with the temporary rank of lieutenant, was greater than the pay and allowances drawn by a captain in the Royal Army Medical Corps, whether Regular or Territorial, though not to the amount stated. Proposals were under consideration which might affect the comparison.

Compulsory Transfer of Men from the R.A.M.C.—Mr. Rendall asked the Under Secretary for War, on July 15th, whether Form 624, dealing with the compulsory transfer of men from one battalion to another, has been or will be withdrawn; and whether he will now take steps to remove the injustice which has been done to many men by the compulsory transfer from the Royal Army Medical Corps to fighting units, in view of the fact that many men joined the Royal Army Medical Corps for the sole purpose of helping sick and wounded men at the front. Mr. Tennant

said that instructions had been issued that it would be no longer necessary for members of the Territorial Force undertaking Imperial service obligation to also agree to liability to be transferred to another corps. The transfers referred to in the latter part of the question were apparently those of Regular soldiers. It was not proposed to reconsider them. In reply to Sir John Dewar, on July 11th, Mr. Tennant said that in the special case in which 82 Scotsmen had been transferred from the R.A.M.C. to an English corps, although they desired to be sent to a Scottish regiment, the men would have permission to transfer to Scottish regiments if they wished.

Astigmatic Recruits.—Mr. Tennant informed Colonel White, on July 11th, that astigmatic men had always been accepted as recruits provided they possessed a quarter of the normal vision without glasses.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

IRISH BRANCH OF THE BELGIAN MEDICAL RELIEF FUND. The committee appointed to collect funds for the distressed medical practitioners and pharmacists in Belgium met at the Royal College of Physicians of Ireland on July 8th. Mr. R. Dancer Parefoy, ex-President of the Royal College of Surgeons, was in the chair, and Dr. C. M. Benson (secretary to Council, Royal College of Surgeons in Ireland) and Dr. T. P. C. Kirkpatrick (registrar, Royal College of Physicians of Ireland), the honorary secretaries, reported that a sum of £999 had been collected from among the medical practitioners and pharmacists of Ireland, which, with £10 13s. 7d. interest allowed by the bank, brought the total of the fund to £1,009 13s. 7d. The expenses incurred in the collection amounted to £26 10s., leaving £983 3s. 7d. for distribution.

On the motion of Dr. J. M. Finny, seconded by Sir John W. Moore, the report was unanimously adopted, and it was decided to pay off the expenses and to hand over the balance to the Executive Committee in London, whose agents are distributing the funds in Belgium. A vote of thanks to the honorary secretaries having been adopted, the business concluded.

The following subscriptions have been recently received:

	£ s. d.		£ s. d.
The Belfast Drug Association	5 5 0	Dr. J. J. Gannon	1 1 0
The Dublin Retail Drug Association	10 10 0	Dr. E. F. Kough	1 1 0
Dr. C. Dundee	1 10 0	Dr. E. E. Lennan	5 5 0
Dr. J. H. Glenn	5 5 0	Dr. J. Marzan	1 1 0
		Dr. E. J. Watson	5 5 0
		Dr. R. W. Wilson	1 0 0

THE CENTRAL FUND.

The following subscriptions have been received by the Treasurer of the Central Fund during the week ending July 13th:

Thirty-third List.		£ s. d.
Dr. H. Gibbons	0 10 6	
Dr. F. de Havilland Hall (4th donation—total, £8 3s.)		1 0 0
Oldham Medical Society (per Dr. H. Pochin, hon. sec.) (4th donation—total £76 11s.)		2 2 0
Dr. Martin		2 2 0
Oldham Pharmaceutical Association (per Mr. H. Bagshaw)		5 0 0
Sunderland Pharmaceutical Association (per Mr. C. Hodson)		9 0 0
Somerset Pharmacists' Association (per Mr. S. G. Tyldeman)		2 2 0
North Devon Association of Pharmacists (collected by Mr. W. J. Shepperd, hon. sec.)		4 0 0
Miss A. M. Nicol (collected in weighing machine).		0 10 0

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vieux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

A NEW DISEASE.

We have discovered a good many things during this war, and one of them is a new disease. The last verb in that sentence is deliberately chosen and bids defiance to all literary snipers.

Possibly it may be thought to believe that in this tired old world anything can originate *de novo*, and doubtless some superior person will presently prove that this new disease is an old acquaintance in a disguise so thin that it should not have deceived for a moment either the youngest temporary lieutenant or the most aged dog-out. But there are certain things that must be taken into consideration.

If after three months' study, some of the best pathologists and sanitarians of the day fail to explain to their satisfaction a certain collection of morbid phenomena, and if that collection be one to which experienced clinicians hesitate to assign any of the existing morbidity labels, then it may be fairly regarded as a new disease in A.D. 1915, even though historical study reveal that the same phenomena habitually vexed the souls of the life insurance agents of ancient Nineveh. Moreover, it must be taken into account that never can the genesis of a new disease be more conceivable and its existence be less likely to pass unperceived than at a moment when thousands of men from all four quarters of the globe are massed together as never before in an environment foreign to all of them, and when their health is being studied in the light of more precise knowledge than ever previously existed.

As for the symptom-complex to which these remarks relate, it was first observed, I believe, about three months ago, and under the direction of the chief sanitary officer of the army in the field (Colonel Beveridge) it has been carefully studied from all points of view ever since. Its outstanding phenomena are those commonly resulting from subacute nephritis, including general dropsy, and the presence of albumin and renal casts in the urine. In most cases the onset of these phenomena seems to be rather sudden, but a history of a few days precedent sore throat or bronchial catarrh can commonly be obtained. A considerable proportion of the patients are men who have recently returned from periods of duty in the trenches, but it is to be noted that this is by no means always the case, and that it was when the weather began to get warm, not when trench life was at its worst, that the symptom-complex first began to be observed. After the condition has fully developed it persists unchanged for a fortnight or less and then subsides with some rapidity. In a few days the albuminuria disappears entirely. Hitherto there have been no deaths among the cases that have been observed, and so far as can be judged the recoveries are complete. In regard to the etiology and epidemiology no very illuminating feature has as yet been discovered. In a few cases there is room for believing that the patients may be old albuminurics, but this is quite exceptional. As many as possible of the more recent cases have been sent home to be kept under observation at St. Bartholomew's Hospital, and in a high proportion of these streptococcal infection of the tonsils has, it is said, been observed. But after all, streptococci are not rare inhabitants of the tonsillar crypts, and in the distribution of the cases there has been nothing, I understand, to support a belief that the condition is due to a virus passing from individual to individual.

The cases have been discrete, and no instance of the condition has been observed among the Indian troops. The latter point is noted because one of the first conceptions appears to have been that the condition might be of Oriental origin, and possibly a form of beri-beri. Other suggestions which I understand to have been considered are that the condition is a sequence of unrecognized scarlatina—cases of scarlatina among the troops have been fairly common; that it is a form of influenza; that it is due to an intestinal auto-toxaemia in men who become constipated owing to the conditions of life in the trenches, and at a time when they are taking large quantities of animal

food; and, finally, that it is due to some form of metallic poisoning.

Very great pains have been taken to test the foundation of the latter suggestion, but after examination of very numerous specimens of urine, no real support for it has been obtainable. On the whole one therefore seems thrown back upon the belief that the underlying cause of this curious but relatively innocuous symptom-complex must be some at present unrecognizable localized infection giving rise to a toxin which has a selective action on the renal epithelium.

ADDITIONAL WORK AND SPECIALIST PAY.

Additional pay of 2s. 6d. per diem has been granted from the beginning of the war to all officers classed as surgical specialists in the various hospitals, and by a retrospective order a like daily amount has recently become payable to those in charge of the clinical and other laboratories. The decision is just, for the pathologist is very distinctly a specialist; and though he does not share the tense moments of his surgical colleagues, his work is in some ways more trying. Constant in the calls it makes upon his energies, it is never quite at an end, and leaves him little time for recreation.

It is true, however, that the average pathologist does not seem to rue these facts; no man is more prone to talk shop whenever opportunity presents, and none exhibits a more infective enthusiasm. There is no doubt, of course, that his work on here is peculiarly interesting. Some of the problems with which he is dealing are new, and even though the majority must be described as old, the form in which they present themselves is novel, and the amount of material at his disposition is such as few pathologists have ever had opportunity to handle.

All these factors make for bacteriological happiness, and in addition questions of the diagnosis of typhoid fever and its congeners seem to offer constant opportunities for animated discussions. The most active of these recently, perhaps, has been as to whether by adhering too constantly to the MacConkey medium a good many typhoid carriers may not have been overlooked. Clinically, there would appear to be nothing to support this view, but bacteriologically there appears to be strong evidence that this medium is not sufficiently delicate for existing needs; in any case the use of Endo's fuchsin medium, as also of Conrad-Dragalski, is spreading. I am under the impression, too, that there is in progress a definite test of the truth of Dreyer's views as to the superior capacity of *B. typhosus* for withstanding ultra-violet rays as compared with *B. coli* and as to the diagnostic use to which this alleged power may be put.

Exactly how many pathologists there are at work I do not know. There seems to be a laboratory at nearly every hospital, and at some of these several workers are engaged. Among the latter are a considerable proportion of men whose reputes has spread outside bacteriological circles, so it may be safely assumed that the work as a whole is of a high order.

Not in all the laboratories is the work mainly clinical and bacteriological. In one at least a great deal of chemical analysis goes on (the hygiene laboratory, conducted by Major Tyndale, sanitary specialist at Boulogne), while at others there is a good deal of general, as distinct from bacteriological, pathology.

To most men, perhaps, the work being done at laboratories of the latter order—which includes the conduct of necropsies—is of more interest than that of the rest. I have myself seen so many highly instructive morbid anatomy specimens at one time and another in the course of the war that it is clear that the museums at home are likely to be immensely enriched by many practically unique specimens, if proper steps are being taken to preserve all *post-mortem* material of an unusually instructive character. As to this I have no information.

The natural course would seem to be to send them to the Army Medical School at Millbank, but possibly it would be better still to send them to some institution of wider scope, such as the museum of the Royal College of Surgeons in Lincoln's Inn Fields. In the strain of existing circumstances it must be difficult, if not impossible, for the army medical authorities to take upon themselves the laborious task of dealing with large numbers of specimens of morbid anatomy on really modern lines. It is also hardly fair to expect them to do so, for the interest

of the specimens themselves is rarely limited to the field of military surgery, and many of them call for correlated histological study.

It is not only on the British side that bacteriology is playing so large a part in the war. The French appear to be almost equally active, but are dealing with matters on somewhat different lines. They appear to prefer to centralize the work as far as possible by establishing a single large laboratory at each hospital base, instead of an independent laboratory at each individual hospital. The mobility of those which are established at no great distance from the fighting line they secure by providing each laboratory with wooden fittings, which serve as rests for the various appliances when work is in progress, but serve equally well as packing cases when the seat of the work has to be transferred. In this way it becomes comparatively easy to pack up a laboratory rapidly, place it on a lorry and send it wherever required. They also contrive to get rid of a considerable proportion of the general impediments of a laboratory by having all the media required by the workers prepared in Paris and sent out as demanded.

It is maintained, I understand, that this plan is advantageous not merely from the point of view of keeping the laboratories fairly mobile and of lessening the amount of labour of a more or less mechanical order that they must undertake. It is regarded also as being a more economical plan than that of leaving each laboratory to prepare its own media, and as being more likely to lead to comparable scientific results, since it eliminates the sources of error due to differences in the media employed by the individual workers.

These laboratories are provided with motor cars, which are sent out to bring in the fluids and other matter which require examination. In addition, most of the French field hospitals appear also to be provided with a small outfit suitable for the elementary kind of bacteriological work required to determine the presence or absence of organisms such as *B. tetani*, *B. perfringens*, and *B. tuberculosis* in various discharges.

GERMAN EXPERIENCES OF WAR SURGERY.

On April 7th the Deutsche Gesellschaft für Chirurgie held its annual meeting in Brussels, where over 1,000 German army surgeons met and discussed the surgery of the war. The opening address was given by Professor v. Schjerning, Generalstabsarzt and Feldsanitätschef.¹ After dilating with smug complacency on "the holy and great task" of the German army, which had resulted in a German congress, from which every stranger was excluded, being held for the first time in a foreign country, he came down to the more practical discussion of the surgical experiences of the war. He admitted that the present war had brought many surprises to the army surgeon, and that with regard to the nature of wounds, their course and treatment, many preconceived views had required readjustment. The results of operations and of after-treatment could not yet be satisfactorily judged, but enough experience had already been gleaned to supply material for an instructive discussion at the present time.

OPERATIVE TREATMENT OF WOUNDS.

Professor Garré dealt with the indications for operations at the front. He said the arrest of hæmorrhage was best effected by the use of tampons, or by seizing the blood vessel with forceps, which were included in the bandage. The permanent ligation of the vessel could then be effected in a field hospital. The use of elastic bandages should be avoided as much as possible, as their timely removal was often not feasible. Increasing the coagulability of the blood by the intravenous injection of a 7.5 per cent. solution of sodium chloride (put up in ampullæ of 3 to 5 cm. capacity) was to be recommended. Auto-transfusion, combined with stimulants, was the most effective procedure for combating loss of blood. After saline infusion, the blood pressure sank again too quickly as a rule, and the much exhausted patients not infrequently died. Tangential wounds of the skull always required operative treatment at the earliest possible date, but large trephine openings should be avoided. Intracranial hæmatomata should also be opened on as soon as possible, and a small trephine opening was usually sufficient for provisional relief of pressure. Ligation of the middle meningeal artery was

not always essential in this connexion. Tracheotomy was seldom necessary in wounds of the neck, lungs, and mediastinum, accompanied by severe emphysema. A large dose of morphia was usually sufficient to tide the patient over the critical stage, and when the emphysema could not be checked at its source, it could be relieved by the multiple incisions and aspiration. Of wounds of the chest, only those complicated by prolapse of the lung or an open pneumothorax called for operative treatment. Severe pulmonary hæmorrhage was best treated by absolute rest and morphia, alarming pressure symptoms being relieved by puncture. Bullet wounds of the abdomen fell into two categories: (1) Cases in which there was severe internal hæmorrhage, and (2) cases in which the stomach and intestine were wounded. Only in cases falling within one or other of these two groups was immediate operation indicated, and then only if there were proper facilities for operating and the wound had not been inflicted more than twelve hours earlier. When the intestine was wounded, a median laparotomy should be performed, the perforation of the intestine should be closed, or resection performed, and the whole intestinal tract should be carefully explored. The earlier the operation the better the prognosis. Injuries to the urinary tract and perineum required simple puncture of the bladder with a cannula 10 cm. long, of the circumference of a knitting needle, which could, if necessary, be left in place. By this contrivance, external urethrotomy and *sectio mediana*, which were difficult to perform, could be avoided. Free incisions were necessary for infiltration of urine.

SHELL WOUNDS.

Professor Garré proceeded to say that radical operative treatment was particularly necessary for wounds inflicted by shells, the fragments of which were usually contaminated with earth, and carried particles of clothing and leather into the wounds. In addition to the chemical injury thus inflicted on the tissues by the introduction of these foreign bodies, the wounds were further aggravated by the retraction of the severed muscles, which automatically aspirated dirt and other foreign bodies into the wound. In this manner cavities and pockets were formed, in which damaged tissues constituted a fertile culture medium for germs. The results were suppuration, phlegmon, sepsis, the much-dreaded gas phlegmon, gangrene, and tetanus. Every shell wound ought, therefore, at once to be exposed freely in the field hospital, all pockets ought to be opened, damaged tissues and foreign bodies removed, and the cavity of the wound lightly plugged or drained. To carry out this method properly, it was necessary carefully to explore every pocket with a gloved finger. Professor Garré admitted that his teaching was heretical, but he insisted that he had seen only beneficial results follow his heroic measures; on the other hand, he was opposed to early amputation of limbs which had been shattered by shells. However tempting it might be at first sight to amputate at a dressing station, to trim the wound, and to enable the patient to be transported further without pain, he was convinced that this course was unwise. At such an early stage the shock of an amputation was dangerous; it was impossible to decide on the most suitable site for operating, and when amputation was performed the stump usually became gangrenous. Summarizing his experiences, Professor Garré insisted that, at the front, only the most urgent operations should be performed. In the field hospitals the chief operations were the opening and cleansing of shell wounds. Operations on the skull and abdomen should be performed only by the fully trained surgeon.

FIRST AID AT THE TWO FRONTS.

Dr. Friedrich pointed out that the choice of treatment of wounds depended largely on the transport, and in this respect there were great differences between the west and east fronts. At the east front the transport was often very unsatisfactory, and at the dressing stations treatment had to be confined to the application of first dressings and of splints for fractures. The arrest of arterial hæmorrhage was satisfactorily effected by the use of artery forceps, and the examination of the dead showed that a considerable number of fatal casualties was due to hæmorrhage from large arteries. Every aid to the wounded was often rendered impossible by the enemy's fire. At the chief dressing station the most important work was the immobilization of the limbs by splints. Here, too, incisions for

¹ Berlin. Klin. Woch., May 24th, 1915.

phlegmon, including gas phlegmon, and infiltration of urine, should be undertaken. In the field hospitals the ligation of blood vessels, amputations, and excoriations should be performed. In the course of the war he had learnt to amputate more radically for shell wounds after seeing in the base hospitals how many of these cases, treated on conservative lines, terminated fatally from sepsis, or had to be treated later by amputation. At the west front there were greater facilities for conservative treatment. When amputation was performed for phlegmon, the simple, circular incision, without flaps, was the best. During the amputation digital compression was more satisfactory than ligation of the limb, which delayed the operation. Only a few grams of chloroform were necessary for each case. Dressings which had been applied at the front should be removed as soon as possible in order that gaseous infection might be detected at an early stage. As there was a free discharge from most of the wounds, the use of mastisol and other pastes was unsatisfactory. Small dressings, secured by sticking plaster, were apt to favour infection with the *Bacillus pyocyaneus*.

SEVERE HAEMORRHAGE FROM WOUNDS.

Herr L. Rehn had collected the experiences of 178 surgeons with regard to haemorrhage from wounds. Their reports left the general impression that severe haemorrhage was not common. Artillerymen and sappers were most exposed to this danger, and fragments of shell did more damage than shrapnel and rifle fire. Out of a total of 421 severe haemorrhages only 201 had been treated by ligation. The brachial artery had been wounded in 47 cases, and the wounded arteries next in order of frequency were the femoral and radial. In the field hospitals the arteries had been ligatured in 72 out of 188 cases of haemorrhage, the operation being performed at the site of election in 22 cases. Elastic bandages had been applied in 590 cases, but their use had been justified only in 260 cases. Much harm had been done, particularly in the beginning of the war, by the improvised use of straps, belts, etc., by soldiers for the arrest of haemorrhage. The indications for and the method of applying the elastic bandage were still insufficiently understood, and it was advisable for the wearer of such a bandage to be given a distinguishing mark, so that when he was transferred to a hospital in the rear, the readjustment of the bandage would not be neglected.

INFECTION OF WOUNDS: TETANUS.

Professor Küninell drew attention to the frequency of tetanus, which occurred in 0.6 to 0.65 per cent. of the wounded. The region of the Aisne appeared to be saturated with the germ of tetanus. The mortality among 350 cases was as high as 70 per cent., and this figure corresponded with v. Madelung's statistics. But in a hospital in Hamburg, where 125 cases of tetanus were treated, the mortality was only 25 per cent. This difference was due to the fact that the most severe cases, with a short incubation period, were treated at the front, while hospitals in the rear received the lighter cases. In August and September tetanus was frequent and severe, and its incubation period was short. In this period the mortality was at first 100 per cent., and later it fell to 75 per cent. Towards the end of October the disease suddenly disappeared, and from November to the beginning of January there were hardly any cases. After the battle of Soissons, the disease flared up again, a great number of cases occurring in a small section of the army. The incubation period was short and the mortality at first was 100 per cent.; after seven days it fell to 90 per cent., after fourteen days to 50 per cent., and after twenty days to 30 per cent. An important early symptom was difficulty in swallowing. The results of prophylactic treatment were good. It was advisable to give serum for every wound, and, when possible, the injection should be given in the trenches. A prophylactic injection of 20 units was sufficient. When, however, tetanus had developed, serum was of little use. Only with large doses—namely, 100 to 200 units—were beneficial results sometimes obtained. In Hamburg good results had been obtained with large doses of serum combined with old salvarsan. In the symptomatic treatment of the disease magnesium sulphate relieved the painful spasms. Hot baths, chloral, morphine, and scopolamine in large doses were also to be recommended.

(To be continued.)

AUSTRIAN EXPERIENCES.

In the *Wiener medizinische Wochenschrift*, Nos. 12, 13, 14, and 15, 1915, Dr. F. Demmer has given a long and graphic account of his experiences with the Austrian armies opposed to the Russians. He was sent as a surgeon from Professor Hochengog's hospital in Vienna, and, as he was constantly being shifted from one place to another, he had exceptional opportunities for observing the working of the medical service at the front and the base hospitals. At the front he soon came to the conclusion that operative interference should be reduced to a minimum, and every effort concentrated on preparing the wounded for transport.

Contrast between Wounds at the Front and in Vienna.

His first experience of the treatment of wounds was in Vienna, where, during the early days of the war, the majority of the wounds were slight, and the wounded were in excellent health, in spite of having taken, on an average, four to five days to reach Vienna from the front. In many cases the dressings had not been changed since they were first applied, yet serious complications were rare. After he had treated about 700 wounded in Vienna, he was sent to Tarnow, where there was a very different state of affairs. He found 284 wounded, the majority of the wounds being serious. Both the patients' general condition and the state of their wounds were deplorable. In many cases the wounds had been entirely neglected for over a week, and even the wounded who had secured dressings were in a pitiable state. On his arrival Demmer found two civil surgeons unable to make much headway for lack of material. For some days this state of affairs continued, fresh numbers of wounded pouring in, while great difficulty was experienced in evacuating the elder casualties. Between September 6th and October 12th 4,300 casualties were treated; they included 1,500 wounds, 1,200 cases of dysentery and haemorrhagic intestinal catarrh, and 1,600 casualties from other illnesses. Many of the wounds were quite recent, and it was observed that shrapnel wounds discharged freely and presented a dirty surface very soon after they were inflicted. Indeed, they looked no worse twelve hours after their infliction than they did six days later, and the author points out that the criticism of the treatment of such week-old wounds at the base hospitals was not justified. In other words, a dirty, suppurating shrapnel wound, a week old, does not necessarily imply mismanagement of the case. It was noticed that a free discharge was a more favourable sign than a dry wound, behind which there was often retention and inflammation. The wounded were spared much pain and the dressers much trouble by the surgeon, who was quick to distinguish between fever and simple exhaustion, and between starvation and mental depression. Prominent among the wounds were the very numerous fractures which had been absolutely neglected or imperfectly treated, and were usually associated with high fever. It was impossible to perform a "clean" operation, and Demmer never had the time or means to extract a bullet or perform a herniotomy or appendicectomy under ordinary aseptic conditions. On the other hand, free use had to be made of incisions for pus in febrile cases, and several amputations had to be performed for suppuration and gangrene.

Faults of First Dressings.

On October 12th Demmer proceeded to Sandomierz, where he hoped to treat wounds at an earlier stage. Here he was struck by the frequency with which the arms had been injured by bandages, which had been applied too tightly on account of haemorrhage, either by a comrade in the trenches or at a first dressing station. The hand was usually livid and numb, and the arm was very painful at the site of the bandage. When this was removed the wound bled a little again, but when slight compression was exerted, and the arm was secured to the body, the bleeding soon ceased. In this connexion he says that gunshot wounds seldom cause dangerous haemorrhage, even when arteries are involved. Though he worked at the front on three occasions, he never had to ligature a vessel for haemorrhage nor apply an Esmarch's bandage. Only once did he see a patient almost die of arterial haemorrhage. This was after a journey of five days in

a cart, the jolting of which kept on forcing a splinter of the tibia into the tibialis anterior artery.

Chloroform the only Anaesthetic.

The severely wounded patients were usually still suffering from shock when they came under Demmer's observation and they complained chiefly of thirst and cold. The patients suffering from fractures were the most restless; the fractures were set while the patients were still under the influence of shock. This lightened the work and often rendered the use of a general anaesthetic superfluous. Sometimes only 1 to 3 grams of chloroform were necessary, owing to the partial anaesthesia induced by shock. Had it even been advisable, there would often have been no time to defer an operation till the shock had passed off. Only chloroform was used for general anaesthesia, and no ill effects followed its use. Not more than 5 to 7 grams were used for each case, and the patients rapidly recovered from its effects without vomiting or other complications. In almost every case the patient was ravenously hungry two to three hours after the operation; he was allowed to eat and smoke, and this unconventional procedure was followed by no ill effects.

Failure of Plaster-of-Paris for Splints.

In the treatment of fractures and other wounds plaster-of-Paris was found to be very unsatisfactory material for splints. It was heavy to transport; it took long to dry, even when it was stored in tin boxes; and it had to be applied to the bandages at the last moment, as it escaped from the meshes of the bandages if applied earlier, owing to the jolting of transport. A further disadvantage was the frequency with which the plaster-of-Paris splints became softened by contact with the damp floors on which the patients lay, and by profuse discharge from the wounds, the result being that these splints often broke during the transport of the wounded. Although the author had previously thought highly of this kind of splint, these drawbacks convinced him of its unsuitability in warfare. He found wooden splints far more useful; they were light and easy to clean, and they could easily be altered to meet the needs of the individual case. His opinion of tin splints was less favourable.

Overcrowding of the Wounded near the Front.

In the middle of November Demmer was transferred to Olusz, where he was close to the fighting line, and where the wounded streamed in for first dressings. A stampede occurred at the railway station, and the trains were overfilled by the lightly wounded, while the severely wounded were left in the lurch. For nine days he worked with only half an hour's rest in the middle of the day, and there was such lack of accommodation and material that the severely wounded had to do without beds or even straw. In this period 3,300 wounded passed through his hands. Subsequently matters improved somewhat, and owing to the short distance the wounded had to travel they received early treatment. But the author's general impression was that, near the front, the surgeon's chief duty was to apply first dressings and prepare the wounded for further transport. Extensive operative treatment was out of place.

Conservative Treatment of Wounds of the Skull and Abdomen.

Injuries to the skull and brain were, he found, best treated on conservative lines, and he operated on only 7 out of 62 cases of shot wounds of the skull. As many of the patients passed out of his hands early he was unable to learn their ultimate fate. His treatment of abdominal wounds was also conservative. Among 73 such cases there were 18 deaths under conservative treatment and one death after an operation. In 59 cases he was able to discharge his patients much improved, after they had been treated four to five days near the front with absolute rest, starvation, and morphine. Iodine was found to have done much harm in cases of frost-bite; it often destroyed previously intact skin and provoked a weeping eczema, which was followed by an ascending thrombo-phlebitis and

phlegmon—the only indications for operative treatment of frost-bite in the field. In Demmer's opinion iodine should not be applied in frost-bite of more than the first degree.

THE WORK OF THE R.A.M.C. AT YPRES.

A DISPATCH from Sir John French, dated June 15th, covering the military operations between that date and April 5th, was made public this week. In that dispatch a high tribute of praise is again given by the Field Marshal commanding our Expeditionary Force to the efficiency and devotion of the R.A.M.C. Sir John French says:

I have much pleasure in again expressing my warm appreciation of the admirable manner in which all branches of the medical services now in the field, under the direction of Surgeon-General Sir Arthur Sloggett, have met and dealt with the many difficult situations resulting from the operations during the last two months.

The medical units at the front were frequently exposed to the enemy's fire, and many casualties occurred amongst the officers of the regimental medical service. At all times the officers, non-commissioned officers and men, and nurses carried out their duties with fearless bravery and great devotion to the welfare of the sick and wounded.

The evacuation of casualties from the front to the base and to England was expeditiously accomplished by the administrative medical staffs at the front and on the lines of communication. All ranks employed in units of evacuation and in base hospitals have shown the highest skill and untiring zeal and energy in alleviating the condition of those who passed through their hands. The whole organization of the medical services reflects the highest credit on all concerned.

Mr. John Buchan, in a long account on the second battle of Ypres, published in the *Times* of July 13th, in describing the third gas attack made on Sunday, May 2nd, by the Germans, wrote:

By this time our men had respirators—not yet of the best pattern—and they managed to let the gas blow past with little loss. Two battalions, however, had to give way a little. The 2nd Seaforths never moved. Their medical officer, Lieutenant James, a civilian doctor who had been with the regiment in South Africa, behaved with conspicuous courage, for, though badly affected by the gas, he continued for two days at his post. The 7th Argyll and Sutherland Highlanders actually charged through the gas under Colonel Garden, and took a German trench. The result was that the Northern Division, assisted by the 4th Hussars, succeeded in holding their ground. Many deeds of courage were reported for that day and for the following morning, when the 1st Rifle Brigade were attacked.

In speaking of the shortening of the line on May 3rd, he wrote:

The left did not move; it was the pivot of the operation. Battalions were withdrawn piecemeal, and picked riflemen from each company were left to cover the retirement. This withdrawal, in perfect order, in a very short time, and with no losses, was one of the most creditable achievements of the war. The work began as soon as the darkness fell. Every day of the fighting we had got in our wounded under cover of night, and in the cellars of Zonnebeke village operations had been performed by candlelight. This evening the wounded were evacuated, all but a small number of very bad cases whom it was impossible to move, and who were left behind in charge of two orteries. The Royal Army Medical Corps have never done more brilliant work in all their brilliant history. Under the guidance of Colonel Ferguson, assisted by Major Waggett (the well-known specialist on throat diseases), the cases were brought from the cellars and dug-outs and sent to and swiftly carried along the dark roads beyond the fire zone. The difficulty of such a withdrawal may be realized from the fact that at some places, like Gravenstafel and Broodseinde, the Germans were within ten yards of our line. Not less than 780 wounded were removed from our front, and the retirement of the battalions was equally skilful. Not a single man was lost. The brigade from the extreme north-easterly side of the salient had a difficult task. That from Fortuna had to move for nearly four miles down lines of parallel trenches. Most of the supplies and ammunition was removed, and what could not be carried was destroyed.

HONOURS.

The *London Gazette* issued on July 8th stated that the announcements published in the *London Gazette* of February 18th and March 24th with reference to Captain A. G. Wilson are cancelled, and the following substituted: Appointed a Companion of the Distinguished Service Order—Captain Harry Theodore Wilson, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN JOHN FITZGERALD GWYNNE, R.A.M.C. (Flanders).

Died of Wounds.

Lieutenant Colonel William Bridgett Pritchard, R.A.M.C. (T.F.), is reported as having died of wounds received in the fighting in the Dardanelles. He was educated at Owens College, Manchester, and took the M.R.C.S. and L.R.C.P. (Lond.) in 1890. After acting as assistant medical officer and house-surgeon at the Manchester Royal Infirmary, he went into practice at Manchester, where he was medical officer and public vaccinator of No. 4 District, Chorlton Union, and honorary anaesthetist to the Cancer Pavilion and to the Victoria Dental Hospital. He was in command of the 2nd East Lancashire Field Ambulance, his commission as lieutenant colonel being dated November 18th, 1911. Two of his brothers are serving in the same field ambulance—Major H. W. Pritchard and Quartermaster and Captain S. Pritchard.

Wounded.

Captain W. T. Harrison, R.A.M.C. (T.F.).

Lieutenant H. J. M. Cursetje, I.M.S. (Dardanelles).

Lieutenant D. Blair, L.D.S., 4th Battalion Black Watch (Flanders).

Lieutenant H. Pierce, R.A.M.C. (temporary) (Flanders).

(This name was last week erroneously given as Pearce.)

Lieutenant F. C. Bentz, R.A.M.C. (T.F.), (Dardanelles).

Lieutenant (temporary) C. P. V. McCormack, R.A.M.C. (Flanders).

DEATHS AMONG SONS OF MEDICAL MEN.

The following deaths at the front have been recorded among sons of the profession, all, except two, which date from the very beginning of the war and from April respectively, during the past ten days:

Major, Isaac Bayley, Lieutenant 14th Royal Scots, attached 1st King's Own Scottish Borderers, only son of Professor Isaac Bayley Balfour, F.R.S., Professor of Botany, Edinburgh University, killed in the Dardanelles on June 24th, aged 25. He was educated at Edinburgh Academy, Winchester, and Magdalen College, Oxford, and gazetted Lieutenant on January 14th, 1915.

Major, Percy D'Aguiar, Captain, the Guides, son of Colonel S. Banks, I.M.S. (retired), killed at Ypres on April 26th. He was born on May 9th, 1885, entered the Wilts Regiment on October 10th, 1903, joined the Indian army on June 25th, 1905, and became Captain on December 10th, 1912.

Bramwell, Charles Guy, Captain Cameronians (Scottish Rifles), only son of Dr. J. W. Bramwell, of the Old House, Kenton, Devonshire, late of Cheltenham, killed in the Dardanelles on June 28th, aged 35. He was educated at Cheltenham, and joined the army in December, 1899. He served in South Africa, 1899-1902, and took part in the relief of Ladysmith, the actions of Vaal Krantz and Tugela Heights, and in operations in Natal, Zululand, and the Transvaal, gaining the Queen's medal with three clasps and the King's medal with two clasps. He subsequently served in Northern Nigeria, and was Adjutant of the 5th Battalion, Scottish Rifles.

De Lantour, Edward Frederick, Sergeant 3rd Australian Light Horse, fourth son of Lieutenant Colonel H. A. De Lantour, New Zealand Medical Staff, of Wellington, N.Z., killed in action in the Dardanelles, early in June, aged 32.

Gibbons, Charles Barry, Second Lieutenant Royal Irish, elder son of Lieutenant Colonel J. B. Gibbons, I.M.S. (retired), killed in the Mesopotamian Campaign, India, in 1897-98, married Miss Govan, Douglas Moncrieff, Major 5th Gurkhas, younger son of the late Surgeon-Major G. M. Govan, I.M.S., killed in the Dardanelles. He was born on October 9th, 1896, joined the Royal Sussex Regiment on December 9th, 1896, joined the Indian army on February 22nd, 1899, became Captain in 1905, and Major on December 9th, 1914. He had served in the Tirah campaign in the North-West Frontier, India, in 1897-98, married with clasp and in Somaliland, East Africa, in 1902-3, including the action at Jiddah, medal with clasp.

Hamilton, Archibald Charteris, Captain 9th (attached 1st) King's Own Scottish Borderers, elder son of Dr. John R. Hamilton of Hawick, killed in the Dardanelles on June 28th, aged 35. He was in the employ of the Arakan Company, in Burma, where he served in the Arakan Campaign, in which he attained the rank of Captain, and came to Europe early in the year in command of the contingent of volunteers from Burma.

McCormick, Edward, son of the late Dr. J. J. McCormick of Liverpool, killed in the Dardanelles.

Russell, James Forthright, Lieutenant 210 Gurkhas, only son of Colonel A. E. Russell, C.M.G., R.A.M.C. (retired), A.D.M.S. Salisbury Plain, and nephew of Sir James Russell, Inspector of Anatomy for Scotland, killed at the Dardanelles on July 2nd,

aged 27. He was educated at Edinburgh Academy and Bedford School, and joined the Seaforth Highlanders in 1908, serving with that regiment in the Mohmand expedition on the North-West Frontier of India, and receiving the medal. In the following year he joined the Indian Army, and was posted to the 210 Gurkhas. When war broke out last year he was on furlough at home, and at once rejoined his regiment in India, and came with it, in charge of the machine gun section, to Egypt, where he took part in the repulse of the Turks on the Suez Canal, subsequently accompanying it to the Dardanelles.

Thomson, Alexander Guthrie, Sergeant-Major 2nd King Edward's Hospital of the Indian Army, and was posted to the Thomson, of Natal, killed in France, June 20th, aged 36.

Warde, G. B., Corporal Canadian Contingent, eldest son of Dr. W. B. Warde, of Tunbridge Wells.

NOTES.

CANADA.

THE Canadian Government has appointed a Hospital Commission under the presidency of Senator Longheed, Acting Minister of Militia. The Commission is authorized to incur all necessary expenses for the care of soldiers and for returning the sick and wounded.

SERBIA.

Dr. V. H. Rutherford, the prospective Liberal candidate for the Bishop Auckland Division, has left his country to inspect the Wounded Allies' Relief Committee's hospitals in Serbia and Montenegro. The Committee has lately received from its Serbian hospital, stationed at Kragujevatz, the information that the typhoid epidemic is practically at an end. The strictest measures are being enforced to prevent any outbreak of cholera.

FIRST AID FOR SOLDIERS.

As a highly practical contribution to the needs of our soldiers at the front the four-page leaflet of *Instructions for Rendering Immediate Aid*, prepared by Major Maclure (26, Dennington Park Road, London, N.W.), late president of the Volunteer Ambulance School of Instruction, is to be commended. Here in the simplest form, and in language which any soldier can comprehend, are given definite directions what to do in cases of bleeding, in cases of flesh wounds and broken bones, lacerations, fainting, and other emergencies, while a diagram on the front page illustrates the points where haemorrhage may be controlled. Over 120,000 copies of the leaflet have been supplied gratuitously to regiments on service, and Sir Frederick Treves has stated that 15 per cent. of casualties had been saved thereby from bleeding to death. These leaflets are now issued at 5s. per 1,000, and can also be had in Hindustani for the use of Indian troops. A simple coloured diagram has also been prepared for the use of those who may be instructing soldiers in first aid, and this is issued at 2s. 6d. Those who may wish to help in a useful work may communicate with Major Maclure.

THE WELLCOME BUREAU OF SCIENTIFIC RESEARCH.

At the beginning of the war the services of the Wellcome Bureau of Scientific Research were placed at the disposal of the Government. The Director-in-Chief, Dr. Andrew Balfour, C.M.O., has now received a commission as lieutenant-colonel R.A.M.C., and has been appointed to a consultant position abroad in connexion with questions relating to sanitation, epidemic diseases, and tropical diseases generally.

MEDICAL OFFICERS WANTED.

South-Eastern Mounted Brigade Field Ambulance.

Two young medical officers are required to complete this unit, which is connected purely with the cavalry. Applications to Major Treves, R.A.M.C. (T.F.), County Cricket Ground, Canterbury.

3rd East Anglian Field Ambulance.

Medical officers willing to undertake service abroad are required to complete establishment. Applications to the A.D.M.S., 21st East Anglian Division, Thetford.

21st Highland Mounted Brigade Field Ambulance.

Three medical officers are required—one to complete establishment of unit, and two for the Depot, Inverness. Particulars to be obtained on application to Captain Mowat, O.C. 21st M.B.F.A., Highland Mounted Brigade Camp, Thetford, Norfolk.

1st South Midland Mounted Brigade Field Ambulance.

Three medical officers are required for imperial service to complete 2nd line. Applications to Major D. M. Springs, 13, Albert Street, King's Lynn.

Hospital for French Soldiers.

A surgeon is wanted for a hospital of fifty beds for French soldiers, provided by Mrs. Doughty Wylie, with the approval of the French Government. The surgeon will be expected to stay until the end of September, and will receive 25 francs a day as pay. Until recently the hospital was at Arras, but is now moved to safer quarters. The matron and nurses are British, and the chief surgeon is French. Applications may be made to Dr. Henry Davy, Southernhay House, Exeter.

England and Wales.

CENTRAL COUNCIL FOR DISTRICT NURSING IN LONDON.

A MEETING of the Central Council for District Nursing in London will be held, by kind permission of the President of the Local Government Board, in the conference hall at the Local Government Board offices, Whitehall, London, at 11 a.m. on Tuesday next, July 20th, when it is hoped that the President of the Local Government Board, Mr. Walter Long, and the Parliamentary Secretary, Mr. Hayes Fisher, will be present.

The movement which has led to the formation of the council was initiated by representatives of the chief organizations for district nursing in London. Mr. Burns, then President of the Local Government Board, accorded a sympathetic consideration to the representations made to him on the subject, and on June 14th, 1913, convened a conference at the office of the Local Government Board. The Board, in pursuance of the policy approved by the Royal Commission on the Poor Laws, continued its support to a scheme having as its object the systematic co-ordination of voluntary and official agencies, and on June 12th, 1914, a further conference was assembled by Mr. Herbert Samuel, who had succeeded Mr. Burns as President. The constitution and functions of the Central Council were defined, a committee was empowered to invite representatives of the various interests concerned to serve on it, and the first meeting of the new council was opened by Mr. Samuel in the conference hall of the Local Government Board on December 1st, 1914. Sir William Collins, K.C.V.O., was elected chairman, and Dr. Christopher Addison, M.P., vice-chairman of the council.

The council seeks to bring into unison both voluntary and official effort, and to develop the efficiency of the district nursing services of London, according to need, and to meet modern requirements. It is not intended that there should be any interference with the separate existence or internal management of any of the associations; it is anticipated that, as in the case of the Houseless Poor Committee dealing with vagrancy, mutual co-operation and the settlement of overlapping areas of work, of standards of efficiency, of policy and the like, will be effectually arranged in council and committee. The inquiry already made indicates that the existing provision of trained district nurses is insufficient to meet the increased demand for the nursing of the sick poor in their own homes. The Central Council now affords a means for the reception and distribution of charitable and other funds intended for the home nursing of the sick. It is hoped also that the council may be enabled, by means of grants, to assist those poorer parishes which cannot afford the whole cost of a trained nurse. It will be a foremost object of the council to maintain the voluntary spirit by which the district nursing of London has been so well built up, and to preserve and develop the valuable machinery afforded by the existing associations. Care would also be taken to safeguard any requirements which may arise on account of creed.

A draft report on district nursing in relation to measles, German measles, and whooping-cough, and the need of nursing for cases of those diseases in poor homes will be presented to the meeting on Tuesday, and it will be proposed to instruct the Executive Committee to confer with other bodies or persons interested, with a view to preparing a scheme for the nursing of cases of those diseases and to promote conferences with representatives of local authorities, the medical profession, district nursing associations, and other bodies or persons interested, with a view to putting such a scheme into operation.

DUTIES OF MEDICAL OFFICERS UNDER THE MENTAL DEFICIENCY ACT.

Several matters relating to the duties of medical officers under the Mental Deficiency Act (1913) were touched upon in the quarterly report of the Asylums and Mental Deficiency Committee, which was presented to the London County Council on July 6th. The council have recently approved a number of their medical officers as medical practitioners for the purpose of signing certificates in connexion with any proceedings taken under Section 3 (1) of the Act by the parents or guardians of defectives. For

the purpose of this section, which enables the parent or guardian of a defective of certain classes to deal privately with him, two such certificates have to be given by two duly qualified medical practitioners, one of whom must have been approved for the purpose by the local authority or the Board of Control. The Asylums Committee have been considering the question of fee to be charged for these certificates, and have decided not to fix a uniform fee for the present, but to determine the fee to be charged on the merits of each particular case.

The duties of the medical officer under this Act are evidently capable of more than one interpretation. A case was cited in which a lad had been transferred from an industrial school to the guardianship of his parent by an order of the Secretary of State. The local authority had nothing to do with the making of this order, but its medical officer apparently has the duty of making a medical statement and also an initial entry in the medical journal which the guardian has to keep. The wording of the regulation is such as to imply the need for periodical visits by the medical officer of the local authority, although the committee have been of opinion that visits by the medical officer subsequent to the initial visit are only necessary when the defective is wholly or partially maintained by the council. The Board of Control, however, state that in this particular case the lad must be visited by the medical officer of the local authority at such times as are satisfactory to the board, and this although the local authority has no responsibility for the maintenance of the lad. The council's medical officer finds himself unable to certify that the lad is defective within the meaning of the Act, and in view of this circumstance, and also of the fact that the guardian has not provided a medical journal as he is well able to do, the committee have decided that the book shall not be furnished by the council, and, furthermore, that in view of the officer's inability to find that the case is actually one of defect, no further visits shall be paid.

Another matter under discussion affects the medical officers of prisons. It often happens that certificates are required by the managers of certified institutions to which it is proposed to send defectives, the purpose of these certificates being to enable the managers to decide as to the fitness of the case in view of the accommodation at their disposal. In cases where the defectives have been in prison, the necessary certificate has had to be given by the prison medical officer, and the Home Office has given its decision that fees for the certificates are not to be charged by the prison officers.

Between April 1st and June 30th of this year, information was received from various sources of 147 alleged cases of mental defect. During the same period 240 cases have been placed under supervision.

MEDICAL INSPECTION AND TREATMENT OF SCHOOL CHILDREN.

The Board of Education are to make their approval of the appointment of the school medical officer of the London County Council permanent instead of annual as hitherto. The arrangements for attending to the health and physical condition of the children are still, however, subject to annual approval. The Board has also approved the arrangements for the medical and dental treatment of the elementary school children provisionally for the current year; but they state that with regard to the experiment of employing an increased number of part-time assistant medical officers for the period of two years, the general expression of official satisfaction must not be regarded as approval of this partial reversion to a part-time system of medical inspection in London. In due course the working of this experiment is to be carefully inspected by the medical officers of the Board of Education. The Education Committee of the council reported the approval of appointments during the last three months of 56 doctors, 31 dentists, and 25 anaesthetists in connexion with the work carried on by the committees of various school treatment centres. Payment has been authorized to be made to the Woolwich School Treatment Centre for the treatment of aural cases at the rate of 880 a year during a recent eight-months' period.

MANCHESTER AND SALFORD SANITARY ASSOCIATION.

At a meeting of the Manchester and Salford Sanitary Association, held on July 6th at the Town Hall, Man-

chester, under the chairmanship of the Lord Mayor, an address was given by Sir James Barr on "The advantages, from a national standpoint, of compulsory physical training for the youth of the country." Sir James Barr said that the advantage of physical training in improving the physique and health of recruits must be apparent to every one, and he believed that if suitable physical training were made compulsory for the youth of both sexes there would soon be a great improvement in the British race, as there was plenty of good stock which only required development. The Boy Scouts were receiving the best primary education in discipline and high moral character, and the appointment of Baden Powell as Minister of Education would be a great forward movement. The present system of education was not conducive to the higher development of the race. He had great faith in the women of England who, except in the lowest strata, did not show so much deterioration as men. The mothers and children needed better looking after, so as to lessen the fearful mortality that occurred in early life. There should be systematic training in the laws of health. Boys should have drill and military training, so that, if needs be, every one should be able to take part in the defence of the country, and they should be encouraged to take part in games and sports, instead of merely watching professional players. Every individual should have opportunity for the education of latent faculties, but it was no use trying to draw out intelligence where there was none. At present the lower they went in the scale of intelligence the more money was wasted on so-called education, whereas a Government anxious to cultivate the best assets of the nation ought to devote more attention to the highest education of the best intellects than to the education of the mentally defective. The attempt to educate children above their mental capacity was an utter failure. On the other hand, if their health received proper attention, if their bodies were developed by physical drill and their senses properly cultivated by technical education, they would acquire a store of practical knowledge which would last a lifetime, while the drill and discipline would make them good citizens. The idea of many sickly sentimentalists that physical training would tend to Prussianize the country had nothing in it, because the British nation was in an advanced state of civilization, and was not a nation of cultured brutes. The Englishman, though often stupid and ignorant, was naturally honest, and could not be spoiled by physical and moral culture. This country might well take a lesson from Germany in organization. In the course of the same meeting Mr. William Thompson, by means of diagrams and lantern views, gave an interesting account of the smoke pollution of Manchester.)

MANCHESTER UNIVERSITY AND THE OFFICERS' TRAINING CORPS.

Since the war began, commissions have been taken by no fewer than 490 members of the Officers' Training Corps of Manchester, and of this number 307 were students of the Manchester University. The contingent is under the command of Sir Thomas Holland, Professor of Geology in the University, who has devoted all his time to the task, and there has never been any lack of recruits. Their work at the university was cancelled on Wednesdays and Saturdays, and these days were used chiefly for field operations, while, on other days during term time, classes were held at the university in signalling, with drills in the afternoons and lectures in the evenings. At different times several small camps were arranged, and from 80 to 100 men attended at each. Now that the vacation has come round, a course of lectures and instruction has been arranged that takes up practically the whole time every day. The number of men that can be in training is limited to 360 at any one time, and the applications for admission are so numerous that the contingent can be kept up to the full strength while carefully choosing the men; it is understood that only those men are accepted who give some assurance that they will take a commission at the end of the course.

THE annual meeting of the American Society of Tropical Medicine was held at San Francisco on June 15th. Dr. Milton J. Rosenau of Boston was elected president for the ensuing year.

Scotland.

MENTAL DEFICIENCY AND LUNACY (SCOTLAND) ACT.

ON July 2nd the first annual report of the General Board of Control for Scotland under the Mental Deficiency and Lunacy (Scotland) Act (1913) was issued. From its study it appears that the total number of mental defectives on the register of the board on January 1st, 1915, was 295. There were six institutions certified, with accommodation for 1,210 defectives. At the end of 1914 there were 19,557 insane persons in Scotland of whom the board had official cognizance, including the inmates of training schools for imbecile children. Of that number, 16,870 were maintained by the parochial rates, 2,621 from private sources, and 66 at the expense of the State. There was an increase in the total of 211 as compared with the previous year. During the year the voluntary patients numbered 181, and there were 98 each resident on January 1st, 1915. During the year 1,183 pauper patients were discharged as recovered, being 50 more than the five-year average; the number for the private patients was 222, or 9 above the five-year average. The number of escapes during the year was 141, of whom only 27 were still absent at the expiry of 28 days. The expenditure for the maintenance of lunatics in Scotland for the year ending May 15, 1914, was £445,967, and the total average cost per patient was £26 18s. 11d.

EDINBURGH HOSPITAL ACCOMMODATION FOR SOLDIERS SUFFERING FROM MENTAL SHOCK.

SOME time ago¹ it was announced that an arrangement had been come to between the Edinburgh Town Council and the Red Cross Society whereby the latter took over the whole of the Royal Victoria Hospital for the treatment of wounded soldiers. A further development in the facilities for treating these patients has to be recorded in the establishment first of one ward of twenty-five beds, and later of a second ward of twenty beds for soldiers suffering from mental shock and nervous exhaustion. These two wards are under the management of Drs. John Macpherson, Hamilton Marr, and John Carswell (Commissioners of the General Board of Control for Scotland), who have invited Drs. Ninian Bruce and Graham Brown to act with them as neurologists, and they have readily agreed; trained mental nurses have also been added to the staff; and now the beds are all occupied by soldiers sent from various parts of Scotland. The Red Cross Society has placed all patients admitted to this neurological hospital on the same basis as ordinary wounded soldiers for whom they make provision, and the Army Council has indicated that the cases will be treated at the usual rate paid by the War Office for wounded soldiers in established civil hospitals. A considerable number of cases have now been dealt with; most of the soldiers have been found after about six weeks' treatment to be fit for duty, and have returned to their units; others have recovered from their nervous troubles, but have been prevented by their wounds from undertaking further military service, whilst a few have developed permanent mental disturbance, and have been transferred to ordinary asylums. The need for this development of the care of the soldier in war time illustrates the extraordinary strain which modern military operations place upon those engaged in them, and also shows that the profession is not behindhand in dealing effectively with the need.

Ireland.

BELFAST MEDICAL MEN AND WAR WORK.

RECENTLY some thirty-five medical men from Belfast and adjoining districts offered their services to the War Office. Many of these medical men are connected with the chief hospitals and with the local university, as professor of surgery, clinical lecturers on surgery, medicine, and on other professional subjects. The offer was that groups of twelve to fifteen should work together for a period of about six months, and that this group would be kept constantly up to the full strength and changed about every six months, so that the services of a stipulated proportion of them should be available for the duration of the war. Many

¹ See BRITISH MEDICAL JOURNAL, May 8th, p. 825.

could not afford to sign for a year or for this uncertain period, but desired to help as far as was in their power. The idea was that they could staff a base hospital from the local medical school, and so relieve a number of R.A.M.C. men, and that this principle might be followed by the large medical schools of London, Edinburgh, Glasgow, Dublin, Liverpool, Manchester, and elsewhere. A certain unity would be maintained, full military regulations enforced, and some of the best professional skill—that of many men who have examined candidates for the R.A.M.C.—would be available, without undue or unbearable strain on any one volunteer. Much regret has been caused locally by the fact that the War Office has not so far seen its way to accept the offer, but has expressed its inability to make arrangements to deal with a body of surgeons in the way suggested by the scheme. It is hoped that this decision may be reconsidered; no one can see very far into the future at present, but it seems not improbable that the strain upon the base hospitals may increase, and with proper safeguards and regulations the scheme might be found workable. At the same time the proposal is novel, and it would probably not be easy to dovetail it into the existing arrangements without careful organization.

TYPHUS FEVER IN DONEGAL.

A serious outbreak of typhus fever has occurred in the Dungloe district of co. Donegal. Six patients have been admitted to the Glenties Fever Hospital. It was stated at the meeting of the Glenties guardians, held last week, that one house where there were four patients had been slunned by the neighbours, with the result that the patients were for a number of days without attendance. Dr. Gardner reported that, owing to the failure of a relieving officer to come and bury one of the patients who had succumbed, he, with the two nurses, was obliged to bury the body in a field near the house. This was not the first time he had had to bury a fever-infected corpse. The relatives and neighbours were asked to leave milk, turf, and water on the roadside. With great difficulty the nurses managed to buy only an insufficient quantity of milk, mostly sour; but how they managed for turf and water was a puzzle, for nobody would bring them either. The relatives were anxious about the cattle. It seemed not to matter that human beings should die and rot above ground as long as the cattle were all right. A brother of the patients came in a drunken state and assaulted the nurses. The whole affair, he said, was an almost incredible example of cruelty, selfishness, and cowardice, which it was humiliating to think could occur in Ireland in the twentieth century. It was stated that one doctor at first diagnosed the disease only as influenza, and that infection had spread owing to people coming into contact with those affected. The police were censured for not remaining to protect the nurses. The necessary steps are being taken to check the spread of the disease.

Canada.

GRADUATES IN MEDICINE.

At the annual convocation of McGill University on May 12th the degree of M.D., C.M. was conferred upon thirty-one graduates. The Medical Faculty of Queen's University recently conferred the degree of M.D., C.M. upon fifteen graduates, and the degree of M.B. upon twenty-seven. At Dalhousie University, Halifax, Nova Scotia, eleven graduates received the M.D., C.M. Seventy-one graduates were successful in obtaining the degree of M.B. from the University of Toronto. At Laval University, Quebec, the medical course has been lengthened from four to five years, and the five-year course has just been completed for the first time; last year there were no graduates, this year there are twelve. The medical course at Western University, London, Ontario, has also been lengthened from four to five years, and this is the last year that degrees will be given after only four years of study. The degree of M.D. was conferred upon twelve candidates, three of whom were at the time on active service. Licence to practise medicine in the province has been granted to 133 doctors by the Ontario Medical Council; thirty-nine of these are on active service, and thirty-six others have received commissions in the Army Medical

Corps, but could not leave for the front until they had received licence to practise. This means that almost 60 per cent. of those licensed this year to practise medicine in the province of Ontario are at the front or intend to leave very shortly. The figures for the other provinces are not available, but the proportion would probably be about the same.

THE HAMILTON HEALTH ASSOCIATION.

For the past seven years the Hamilton Health Association has been doing splendid work among those afflicted with tuberculosis. In November, 1908, a free dispensary was opened; at that time there were 36 patients on the visiting list of the association; there are now 527. Some of these patients only receive occasional calls, others are visited regularly, when advice is given concerning ventilation, taking of rest and exercise, care of sputum, etc. During the year ending September 30th, 1914, 2,070 visits were paid, 2,592 patients attended at the dispensary, and 687 persons were examined, 214 being children under 14 years of age. Tuberculin was given on certain days of the week; 46 patients received the treatment, and some are showing marked improvement. The association has provided a sanatorium with present accommodation for 75 patients and a preventorium for children under 15 years of age. The latter has recently been enlarged to double its original capacity. At the sanatorium there are at present 94 patients in residence, although the accommodation is really only sufficient for 75. The plans, however, have been prepared for a new building, which will be commenced very shortly.

CALGARY HOSPITALS.

Dr. Alexander Fisher, formerly superintendent of the hospital at Port Arthur, Ontario, has been appointed medical superintendent of the hospitals of Calgary, Alberta. As was stated in a former issue of the JOURNAL, the hospitals have been under the direction of Rev. A. D. McKillop, but at a meeting held a short time ago it was decided that a medical man should be appointed to the position. Dr. Fisher took up his new duties on June 1st.

Correspondence.

LEGAL RESPONSIBILITY FOR CRIME.

SIR,—We read with great interest the letters of Sir Bryan Donkin and Dr. Mercier in the BRITISH MEDICAL JOURNAL of June 5th and 12th respectively. As no other member of the Subcommittee on Crime and Punishment has commented upon them, we think that we ought to do so.

Sir Bryan Donkin may be pardoned for thinking that the subcommittee combined Sir James Fitzjames Stephen's and Dr. Mercier's proposals. The result is almost the same as if that course had been adopted. If it had, Dr. Mercier's name would have been given due prominence. All the subcommittee, we believe, were acquainted with his writings and services. The method actually adopted was to take Stephen's formula and to subject it to minute and prolonged examination, and the results of the discussions were submitted to the Subcommittee, who finally drew up and adopted the formula with modifications approved during the discussions. That the result has led to Sir Bryan Donkin's pardonable error, we think, adds—if possible—to Dr. Mercier's reputation.

Dr. Mercier is hypercritical. The definition is put forward as a tentative one for practical use, and, though it may, in logic, be an objection that its three heads overlap, it is the reverse of an objection to the definition in its practical application. An alternative formula may be of the greatest service in arriving at a just conclusion.

Dr. Mercier again lays too great stress on classification in his criticism of the second paragraph of the Supplemental Report. "Such" and "other" are quite intelligible if applied in each case grammatically with reference to the preceding sentence and not assumed to be a system of classification. May we suggest that "other" cases would include accused persons out on bail and prisoners awaiting trial, where the prison surgeon is doubtful, and also cases where alienists have been engaged to give evidence?

Our objections to the system of calling medical witnesses *en bloc* as witnesses for the court are not, as might

be inferred from Dr. Mercier's remarks, intended to be exhaustive. We would add that in no cases are expert witnesses expressing divergent opinions called one after another. There is always an interval—sometimes a considerable interval—between the experts supporting our view and those supporting the contrary.

Dr. Mercier concludes by reference to "reported cases." This is an ambiguous expression, but, if we rightly understand it, such cases are of a class where the least risk of injustice occurs. Would Dr. Mercier care to sustain the theory that no criticism could be passed, say, upon the trial and conviction of men charged before justices for summary offences of indecency under the Vagrancy Acts?

We desire to thank both Sir Bryan Donkin and Dr. Mercier for their kind references to ourselves.—We are, etc.,

JAMES SCOTT.
ROLAND BURROWS.

London, July 1st.

THE EMERGENCY BILL FOR MENTAL TREATMENT.

SIR,—I really must protest against the way in which Dr. G. M. Robertson and Lord Russell have treated Dr. S. E. White. This lady, without help or countenance from any one, entirely by her own unassisted efforts, had discovered two delightful and beautiful grievances, and paraded them with all the pride of a mother, and then these two unfeeling men, without a word of sympathy or apology, tore them from her maternal arms and dashed their heads against the stones. But is she downhearted? No! She comes up courageous and smiling, and does her best to find substitutes, and very fair substitutes they are. She still sees in Lord Russell's bill a furtive attempt to deprive the sane of their liberty, and to guard against this danger she advises him to insert a proviso making it obligatory to obtain the consent of the patient in writing and to give him a written notice that he cannot be detained against his will. As an enthusiast for the liberty of the subject, I rejoice to welcome this suggestion, but it does not go far enough. It should be applied not only to persons who seek entrance into hospitals and nursing homes, but to every case in which a person sleeps under a roof not his own. Such documents should be exchanged whenever a traveller puts up at an hotel, whenever a guest is invited to a week-end visit. Then, at last, we might have some hope that the liberty of the subject would be respected, but the hope would not become assurance until all visits exceeding the duration of a morning call are prohibited by law.

Dr. Robertson's 150,000 cases certified as insane, in only one of which was an action brought for wrongful detention, are well criticized by Dr. White and shown to be of no value as evidence that the detention was not wrongful; but it is clear that the criticism might have been far more damaging. No candid person can deny that, in order to bring an action at law, funds are necessary. Nor can any one deny that every one of Dr. Robertson's 150,000 cases was placed under control in order that they might be stripped of their possessions and reduced to penny. How is it possible for a pauper to bring an action for wrongful detention? This is the crowning villainy of the whole scheme. It is notorious that all medical practitioners, with the possible exception of Dr. White, are in league with the relatives of the so-called insane, and share in the division of the plunder. I see no remedy for this horrible abuse except in a law that shall make it penal (1) to allege that any person is a lunatic and (2) for any person to become insane. I shall be pleased to give Dr. White every assistance in my power in drafting a bill to this effect, and I have little doubt that Mr. Wedgwood or Mr. Outthwaite would introduce it into the House of Commons.—I am, etc.,

CHAS. A. MERCIER.

Parkstone, July 10th.

THE SUPPLY OF MEDICAL MEN.

SIR,—The question of organizing the services of the empire cannot leave untouched the important problem relating to medical men.

At present the burden is very unequally borne. A large number of men have given up their practices, which they will never recover. A large number are married men who

have passed their youth, so that when the war is over the work of beginning life over again will be very hard. On the other hand, a large number of men remain behind who are young and who are even in partnerships, so that their services could be dispensed with without great hardship.

In the one case men are daily losing by their patriotism, and in the other case they are gaining through the patriotism of others.

The first duty of organization should be to consider methods by which the gains of those remaining behind might be equalized against the losses of those volunteering for service.

It would be a further incentive to men to volunteer for service if steps were taken now to pass resolutions by all authorities who have in their hands the filling of medical posts, that in all future appointments priority will be given to doctors who have served in the great war.

It would be beneficial also if you would state in one short lucid article, in a tabulated form, complete particulars as to pay, allowances, length of service, rules as to pension and compensation on injury, and rules as to promotion—with regard to (1) R.A.M.C.(T.) temporary commission in a field ambulance; (2) R.A.M.C.(T.) commission as a regimental medical officer; (3) R.A.M.C. temporary commission.

The following problem, for example, has not to my knowledge been answered: What are the advantages and disadvantages of taking (1) an R.A.M.C.(T.) commission at 14s. a day and signing for general foreign service, or (2) taking an R.A.M.C. temporary commission at 24s. a day?—I am, etc.,

Temple, E.C., June 21st.

JOSIAH OLDFIELD.

SIR,—We are informed that the War Office proposes to employ about 6,000 medical officers to look after our armies. The taking away of so many men from civil practice entails a very considerable addition to the burdens of those who are left and a corresponding difficulty in maintaining efficiency. This will be more apparent when the winter months draw near. From the national point of view it is therefore very important that the War Office should be quite sure that this number is essential. What makes one a little doubtful are the following facts:

1. A large number of medical officers are doing purely administrative work which one would imagine could be left quite well to laymen.
2. An immense amount of time is spent in clerical work; for example, a wounded man will have at least three sets of notes made about his case—A, at a station close to the firing line; B, at Boulogne; C, at the base hospital in England. The first diagnosis, however erroneous it may prove to be, clings to the patient wherever he goes; his notes are left behind to be sent direct to the War Office. Apart from the wisdom of this arrangement such reduplications result in a demand for a large supply of medical officers, of whom many may never have an opportunity for the exercise of their medical capabilities.
3. A certain number are, or were until recently, employed in quite useless occupations from a medical point of view; for example, a rule was made that every convoy of wounded must be accompanied by a medical officer. This applied even to short distances of a few miles, where the time taken in unloading the ambulance would be almost equal to that required for completing the journey to a point where something effective might be possible. Apparently the sole reason for this officer's presence was to close the mouth of criticism in the event of a patient dying on the road.

I do not know if the War Office has obtained already the full number of men asked for, but I do urge most strongly that the authorities, by the elimination of unnecessary clerical work, by modifications in administration, and by judicious redistribution, should use to the fullest possible advantage the trained minds which have been placed so unreservedly and often at so great a sacrifice at the country's service.—I am, etc.,

July 13th.

G. P.

TEMPORARY RANK IN THE R.A.M.C.

SIR,—All other temporary branches of the army and navy get rank in proportion to their ability and experience (engineers, navigators, paymasters, etc.). The medical department is the exception. A medical man must start at the bottom and remain there till the end. Unless he is a consultant his ability and experience have no value. There are many like myself who are in general practice and have surgical appointments who have done

far more surgery than many "assistant surgeons" who have suddenly acquired the rank of major, and who have had no previous experience in military surgery. What the R.A.M.C. man must know is military routine; professional knowledge is superfluous, perhaps objectionable. Deputy Surgeon-General Gough tells us we are lieutenants because we do not know the treatment of military wounds. Where did the young captains (R.A.M.C. Regulars) little more than twelve months qualified in many cases) get their special knowledge of military surgery? All grievances of the profession arise from the one cause—want of unity. For my part I will either be a private or major (R.A.M.C.). I do not mind which, but certainly not a lieutenant. Let us be loyal to our country and to our profession at the same time.—I am, etc.,

July 6th.

A FORTY-YEAR-OLD LAGGER.

SIR,—I greatly regret that so little protest has been made on the question of temporary rank in the R.A.M.C.

I trust this very important question will be vigorously taken up, especially by the British Medical Association at the next annual meeting, and then not allowed to drop. Many think this body ought to have considered this matter months ago and insisted on adequate rank being given.

I particularly refer to medical men over 40 years of age. Almost all of such have joined out of simple patriotism, and at great inconvenience and financial loss, to quickly realize what the greatly inferior rank accorded to them means in having to "give place" to majors and captains mostly their juniors in age and experience; to most this is galling and totally uncalled for.

The lowest rank that should be offered men of such age is that of captain, and ought in simple fairness to be that of major.

For obvious reasons this is a matter of great importance, and higher rank than that of a subaltern should be insisted on and obtained; if not, I am afraid after the first year's covenanted service many men over 40 years of age, and a large number of those younger also, will refuse further service.—I am, etc.,

July 10th.

TEMPORARY SUBALTERN AGED 49.

THE MORTALITY OF APPENDICITIS.

SIR,—I observe that Mr. Grey Turner finds fault with my estimate of the general mortality in cases of appendicitis when I place it as high as 25 per cent. in certain types of the disease. But according to his own figures, as given in Table III, Groups 4 and 8, I find a mortality of 33 per cent.

Mr. Hugh Lett, of the London Hospital, has made two most valuable—indeed, I might say classical—contributions to the literature of this subject. In his former paper, published in 1905, the mortality of appendicitis with general peritonitis stood at the appalling figure of 76.5 per cent. Ten years later, over a like number of similar cases, the mortality had been reduced to 20 per cent.

But both these figures and Mr. Grey Turner's underestimate the general mortality which attends this particular type of the disease, in that they leave out of account altogether the not inconsiderable number of cases which are moribund when first seen by the practitioner, or become so before operative treatment is proposed. Surgeons in large consulting practices tell me that they are constantly being brought to see such cases. It may of course be urged that if these cases are allowed to become moribund it is for want of treatment. This is so, but they must none the less be allowed for in reckoning up the total death-rate due to appendix disease. I do not think, therefore, that I overestimated the case when I wrote that in certain types under modern conditions we still had a mortality running up to 25 per cent. This ought not so to be. And the main object of my paper was to bring under the notice of practitioners a type of the disease which, while most grave from the point of view of prognosis, had not yet received the attention it deserved. It is a type, moreover, with a very definite symptom-complex and with a margin of safety extending usually to twenty-four hours. The cases may show no elevation either of pulse or temperature, and yet delay in operating means the deluging of an abdominal cavity free from protective

adhesions with a large quantity of foul infective material. Let us warn the practitioner of this type of case and the explanation of it and we shall have fewer cases of general peritonitis of appendicular origin to deal with.

If I differ from Mr. Grey Turner on one small point I admire the excellence of his results, and cordially agree with him in his general conclusion, namely, that accidents aside, with early operation mortality from this disease might nearly vanish.—I am, etc.,

Belfast, June 21st.

S. T. IRWIN.

THE PREVENTION OF GAS POISONING.

SIR,—A note by Mr. Rushton Parker which appeared in the JOURNAL, on the question of using alcohol as an antidote to chlorine gas in warfare, induced me to try a few experiments.

I find that an inhaler composed of a double fold of lint, or three or four folds of thick muslin, saturated in dilute alcohol, placed over the mouth and nose, enables one to breathe chlorine gas in air without any discomfort from the chlorine, which seems to become effectively absorbed by the alcohol.

A certain amount of the alcohol is, however, volatilized and inhaled, and after a time becomes somewhat irritating. In course of time there appears to be a synthesis of chloroform, and the vapour of the new compound has a soporific effect.

The ordinary solution of sodium bicarbonate—about 10 per cent.—tried under similar conditions, appears to be cooler and pleasanter to use.

The physical difficulty of dragging air through a respirator sufficiently closely webbed to cause the filtering out of the chlorine and its absorption by some fluid appears to be the chief drawback with most respirators.—I am, etc.,

Dublin July 9th. J. C. McWALTER, M.D., LL.D., D.F.II.

THE TREATMENT OF DIABETES MELLITUS.

SIR,—Dr. Cammidge throws light on some very dark places, and my letter has fully served its purpose in calling forth so able and lucid a reply.

The fact that the potential acidity of oatmeal is 12 per cent., a percentage considerably higher than that of other foods Dr. Cammidge mentions, will, I think, partly explain its injurious effects in many cases I have observed.

Such careful study of food constituents as that set forth by Dr. Cammidge would, of course, have a far wider application than in the mere treatment of diabetes, as the following cases will show.

A lady who had acquired an uncontrollable passion for claret and potatoes, both of which she took freely at every meal four times a day, began to suffer from rheumatoid arthritis, and ultimately had to take to her bed, as almost all her joints were steadily approaching ankylosis. It appeared that her regular medical attendant was of opinion that two such articles of diet could prove of no harm, even in excess, I suppose on the ground that rheumatoid arthritis is alone due to bacterial infection. However, on being advised as to a rational diet she partially recovered, and has remained comparatively well ever since.

A gentleman whom I saw some time ago, whose joints with few exceptions were hopelessly ankylosed, related a similar story, having had a similar liking for the same articles of diet.

A lady of 82 who had lived a most careful and abstemious life, and had known scarcely a day's illness, was induced to add chipped potatoes to her diet; of these she became very fond, and partook of them freely every day. After a few weeks in which her health steadily declined, she was struck down by an attack of herpes zoster, the pain of which and the restlessness brought on extreme exhaustion, so that her life was despaired of. She eventually recovered, and is now as well and active as ever, and adhering rigidly to her former diet. It is, however, unpleasant to think what might have been the termination of this malady, so fatal in old age, had her medical adviser been of opinion that potatoes in her case were harmless, or have thought it of no consequence to inquire into any sudden change of diet, which in one so old, and who had enjoyed such uninterrupted good health, seems certain to have been the cause of her trouble.

Though far from going the whole length with Dr. Haddon, one cannot help but admire the persistency of his teaching, and feel the truth of his assertion that the study of the physiological or pathological activity of foods has too long been neglected in the regular curriculum, and such welcome up-to-date knowledge as that set forth in Dr. Cannidge's letter very clearly shows the lines on which such study should be pursued.—I am, etc.,
Liverpool, June 21st. WM. BRAMWELL, M.D.

ON THE CURVE OF THE EPIDEMIC.

SIR,—As the address that Mr. Trachtenberg gave was insufficient my letter to him was returned to-day by the G.P.O.

Incidentally I may point out that the phrase "in my letter of June 12th" was placed by the printer at the end of the first paragraph instead of in the second paragraph, which should begin:

As stated in my letter of June 12th, my expression . . .

I had expected Mr. Trachtenberg to send a correction of his error when he stated that I gave $y = a \cos^2(mt - a)$ as the solution of Dr. Brownlee's equation. With an amazing simplicity he seems to regard a perfectly legitimate transformation, made in order to facilitate the work of integration, as my solution!—I am, etc.,

Newcastle-on-Tyne, July 10th. A. S. PERCIVAL.

Mr. Percival's letter was printed in accordance with the typewritten "copy."

INDEMNITY DEFENCE POLICIES.

SIR,—In the annual report of the London and Counties Medical Protection Society, which has just been brought before my notice, appears a statement to the effect that the indemnity policy which that society has entered into is superior to that of other similar societies in that the costs and damages are paid when an action is lost by the member either as a plaintiff or defendant. This condition of insurance is exactly similar to that which obtains in the Medical Defence Union indemnity policy, as a defensive action covered by the policy entered into by their members with the Yorkshire Insurance Company is interpreted to refer to the member either as plaintiff or defendant. It often happens that a member, being libelled or slandered, a duty involves upon the Medical Defence Union to defend his professional repute by raising an action on his behalf, and if the member is insured in the Yorkshire Insurance Company the policy covers costs of the other side should a verdict adverse to him result. Frequently the best method of defence is the institution of proceedings, and it is well recognized both by the Union and the Yorkshire Insurance Company that such proceedings constitute "defensive actions."

I ask you to allow me to communicate with the profession through your columns, as being the quickest and best means of correcting any misunderstanding which may have arisen from the misleading statement in the annual report referred to above.—I am, etc.,

London, W.C., July 12th. A. G. BATEMAN.

Public Health
AND
POOR LAW MEDICAL SERVICES.

POOR LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

COUNCIL MEETING.
A COUNCIL meeting was held in the Council Chamber of the British Medical Association, 429, Strand, on July 6th, Dr. D. B. Balding being in the chair.

Burley Union.

The council agreed to a proposition made by Dr. Agnew of Burley, in a letter dealing with the dispute in that union, that Dr. Bird should be consulted as to whether any further assistance could be given by the association.

Poor Law Medical Officers and Military Duties.

The Honorary Secretary read the following letter which he had forwarded to the Local Government Board:

Right Hon. Herbert L. Samuel, M.P.

Sir,—Owing to complaints that have reached us from various quarters, the subject of the treatment of Poor Law medical officers undertaking military duties was considered at the meeting of our

council on April 27th, when the following resolutions were unanimously carried, and I was directed to send copies to your Honourable Board:

1. That in all cases where military duties are discharged by Poor Law medical officers, the salaries paid to such officers should be on a scale not less than paid by the War Office to members of the R.A.M.C. discharging similar duties.
2. That where the duties are part-time only, an addition should be made to the medical officer's salary in proportion to the extra labour involved.

My council especially desire to protest against the inequity of granting an inferior commission, carrying with it a lower scale of pay, to a medical officer put in charge of a military hospital with a number of beds, than according to Army Regulations would be supervised by a member of the R.A.M.C. with a higher commission.—I am, yours obediently,

MAJOR GREENWOOD, Honorary Secretary.

On May 22nd he received the following reply:

Sir,—I am instructed by the Local Government Board to refer to your letter of the 12th inst., relative to the remuneration of medical officers of Poor Law institutions used for military purposes, and to enclose for the information of the Poor Law Medical Officers' Association a copy of a memorandum, dated April 28th, 1915, which was prepared by the Board after consultation with the military authorities.—I am, Sir, your obedient servant,

L. A. BRODIE, Assistant Secretary.

A memorandum was enclosed which indicated the conditions concerning the employment of Poor Law medical officers by the military authorities as agreed to by the War Office and the Local Government Board. The terms, as recent practice had shown, were misleading. Thus it was promised that suitable commissions should be given to Poor Law medical officers employed for the whole of their time, yet a member of their council in charge of a military hospital of over 500 beds had received a major's commission, while the medical superintendent of a smaller hospital at Edmonton had been given the commission of Lieutenant-colonel.

The resolutions had been communicated to the British Medical Association, and considered by a special committee appointed to review the relations of the profession to the War Office. The question was raised there as to whether there was any regulation that a medical officer in charge of a military hospital of 500 beds and upwards should hold the rank of lieutenant-colonel.

Surgeon-General Evatt, to whom the Honorary Secretary had referred the matter, said there could be no doubt as to this being a military regulation, which would be found under *War Establishment Expeditionary Force, 1911-12*: "General Hospital with 520 beds to have a Medical Officer of the R.A.M.C. with the rank of Lieutenant-Colonel." The Honorary Secretary directed to communicate again with the Medical Secretary and transmit to him the information imparted by Surgeon-General Evatt. It was certainly worth an explanation why the procedure adopted at Edmonton had not been carried out in the case of Dr. Thackray Parsons at Fulham.

The Honorary Secretary read a letter from Dr. Poeh, resident medical officer to the Tuxteith Park Poor Law Institution Infirmary, Liverpool, who had charge of the male side of the infirmary, which was now entirely occupied by wounded soldiers. As he had no commission and only received his usual salary, he considered that he was entitled to some recognition of his military services. According to the recent Memorandum the Army Council was prepared to grant temporary commissions to the members of the medical staff of a Poor Law institution employed for military purposes, "if it did not seem quite clear to the council that Dr. Poeh's duties were entirely confined to military work, and after some discussion it was decided to write to Dr. Poeh and point out the terms of the Local Government Board memorandum. At the same time the council was unanimously of opinion that Dr. Poeh ought to receive some recognition of the important services he was rendering.

Letter from Dr. Denning of Epping.

A letter was read from Dr. Denning of Epping, who had recently been treated by his guardians with gross injustice. There had been severe friction between the workhouse master and the medical officer, the master had issued complaints, and in consequence the guardians had suspended Dr. Denning and called for a Local Government Board inquiry, which had not as yet made any adjudication. The Honorary Secretary was instructed to watch any further developments of the case.

ANNUAL GENERAL MEETING.

The annual general meeting was held on July 6th in the Council Chamber of the British Medical Association, 429, Strand. Surgeon-General Evatt was in the chair.

Vote of Sympathy.

On the report from the Honorary Secretary that Dr. Holder of Hill was seriously ill, a vote of sympathy was unanimously carried, and the hope was expressed that a better report of his condition would be forthcoming in the future. The resolution further included an acknowledgment of the services he had rendered to the association for so long a period, and of his labours to promote the interests of the Poor Law Medical Service generally.

Report of Council.

The report of the council was then put before the meeting. The Honorary Secretary said that it had already been published in the *Poor Law Officers' Journal* and in their *Poor Law Supplement*, and a copy sent to every member of the association. Their work had been a good deal hampered by the war, which

had developed other questions considerably affecting the interests of Poor Law medical officers. He specially drew attention to the urgent necessity of all Poor Law medical officers giving their utmost assistance to the work of the association.

The balance sheet was next submitted to the meeting, and, after some discussion, was unanimously approved.

Election of Officers.

Surgeon-General Evtatt was unanimously re-elected President, and Dr. B. Balding Chairman of Council, for the ensuing year.

The Honorary Secretary drew attention to the long service of Dr. Balding, and Dr. Balding thanked the members for their recognition of his efforts to promote their welfare, and hoped that he might still be able to attend their council for a time. Dr. Major Greenwood was unanimously re-elected Honorary Secretary.

Dr. Napper stated that it was not his intention to accept re-election to his office of Treasurer. He thought, under the business arrangements, the duties of Treasurer would be better performed by the Honorary Secretary, or by Mr. Frank Greenwood, their solicitor, as most of their business was done in his office. After some discussion, Mr. Frank Greenwood, the senior member of the firm Messrs. Beckings and Co., was elected to succeed Dr. Napper, to whom a hearty vote of thanks was unanimously passed for his great services in the past. Dr. Withers Green was unanimously re-elected auditor.

The following were elected members of the Council for 1915-16: Dr. W. Holder (Hall), Dr. Gidley-Moore (Fyfield), Dr. Lloyd Brown (Eastbourne), Dr. A. Drury (Halifax), Dr. C. Biddle (Merthyr Tydfil), Dr. Withers Green (London), Dr. Napper (Cranleigh), Dr. Thackray Parsons (London), Dr. A. P. Agnew (Barnley), Dr. Geo. Jackson (Plymouth).

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

GRADUATION CEREMONIAL.

The ordinary July graduation in Medicine in Edinburgh University was this year combined with that in Arts, and the joint ceremonial took place on Thursday, July 8th. The only medical man to receive the honorary degree of Doctor of Laws on this occasion was Professor Arthur Thomson, M.B., who has recently been in charge of the Department of Anatomy in Oxford University. The smallness of the list of doctors of medicine, which only contained the names of eleven men and two women, was no doubt due to the war, which cannot be regarded as favourable to the acquirement of additional degrees or to the prosecution of scientific research. No gold medals were awarded. Eighty-five students, including seven women, obtained the degrees of Bachelor of Medicine and Bachelor of Surgery, four in first class and the same number with second class honours. The lists of the M.D.'s and M.B. Ch.B.'s, along with the details of Fellowships, scholarships, and prizes which were gained, is appended. Sir William Turner, the Vice-Chancellor, in his address to the graduates, spoke of the Roll of Honour of the university, which contained 3,550 persons' names, of whom 2,513 had received commissions. He pointed out that the Chancellor, who headed the list, was First Lord of the Admiralty, and that the Lord-rector was Secretary of State for War. That sixty-five members of the staff engaged in teaching and administration were serving with the forces, and that 2,200 graduates, of whom 1,252 were medical, had joined the navy and army. There were also 457 of the present students training in the Officers' Training Corps, so that the total of the Roll was 4,000. The Vice-Chancellor brought his remarks to a close by quoting from a letter from a graduate of the university and a doctor of medicine 'Sir Arthur Conan Doyle, in which he said "it was good to hear that the name from Edinburgh University had, both in the firing line and behind it, showed that the old iron was in their blood."

- M.D.—E. Aitken, S. Rolton, C. H. Corbett (Lieutenant R.A.M.C.), J. Graham, Annie Jackson, W. H. Johnston, D. C. Macalessil, Elizabeth Macleod, J. Maxwell, E. C. Peake, A. A. Rutherford (Lieutenant R.A.M.C.), G. W. Thaxley (Surgeon R.N.), G. A. Wilson (Lieutenant R.A.M.C.).
M.B., Ch.B.—J. C. Anderson, J. M. Anderson, J. S. Armstrong, J. W. W. Baillie, T. Y. Barkley, H. J. P. Briwer, J. E. M. Campbell, W. M. Christie, A. G. Clark, T. L. Clark, A. R. F. Clarke (Lieutenant R.A.M.C.), S. R. B. Laurie, G. Clark, W. A. Cochrane, C. H. B. Coetzee, M. K. Cooper, M. D. Danie, M. W. Dazdig, P. C. Davie, C. W. S. Davies-Jones, D. Dunlop, Mary O. Ferrisone, E. L. Galant, A. M. Gibson, A. W. Gunn, W. M. Hillyer, A. Henderson, G. Hepburn, M. Helen C. Howard, V. H. Hoashoo, R. M. Hume, E. B. Israel, T. Janakiramiah, O. D. Jarvis (Lieutenant R.A.M.C.), S. B. G. S. Johnston, D. H. Jones, Miriam H. Kerr, S. A. Kunny, P. W. Lam, Jean Blanche Larnie, N. B. Shanklin, J. W. Simpson, G. H. Law, B. Lawson, A. J. Lim, H. L. H. Lim, P. MacD. Little, G. L. Louden, J. E. M. McCartney, Helen M'Donnell, J. M'Dowall, W. E. M'Intyre, Marjorie McNaughton, J. W. Macleod (Lieutenant R.A.M.C.), S. H. D. Mallory, Mary Martin, M. McCallum, M. F. McInnes, A. R. Menon, T. C. S. C. Morton, F. H. Nixon, W. P. Patterson, J. W. Potter, O. D. Price, W. J. Purdy, N. I. Reiss (Lieutenant R.A.M.C., R.N.), J. W. G. Riddell, J. W. Riddoch, J. Rodger, C. Russell, W. Shanklin, J. W. Simpson, G. H. Sinclair, E. T. Solomon, H. M. Stewart, C. M. Stewart, H. A. Steen, J. D. Walker, J. W. Wattles, L. H. Warden, W. G. Weston, J. J. Whitehead, M. E. Willcock, J. M. Wishart, F. G. Wright, A. Young.

* Highly commended for thesis. † Commended. ‡ First-class honours. § Second-class honours.

Fellowships, Scholarships, and Prizes. Cameron Prize in Practical Therapeutics: Sir Lauder Brunton, Bt., M.D., Edin., LL.D., for his valuable researches in pharmacology and their applications to therapeutics, initiated in his M.D. thesis on digitalis, which was awarded a gold medal by the Senatus of this University in 1868, and continued and extended in the second edition of his work on the Therapeutics of the Circulation, published in 1904.

Goodsir Memorial Fellowship: Stuart Bolton, M.D. Straits Settlements Gold Medal: Donald Cameron Macaskill, M.A., M.D. Ettles Scholarship (to the most distinguished student during the five years' curriculum): James Elvins M'Cartney, M.B., Ch.B. Freeland Harbour Fellowship: John William Riddoch, M.B., Ch.B. Murchison Memorial Scholarship in Clinical Medicine: Charles George Lambie, M.B., Ch.B. Beany Prize in Anatomy and Surgery: James Whiteford Potter, M.B., Ch.B. Moulal Scholarship in the Practice of Physic: James Elvins M'Cartney, M.B., Ch.B. Conan Doyle Prize (to the most distinguished student from South Africa): Michael Ferreira Mering, M.B., Ch.B. Buchanan Scholarship in Gynaecology: William Alexander Cochrane, M.B., Ch.B. James Scott Scholarship in Midwifery: James Wilfrid George Hewat Killick, M.B., Ch.B. Dorothy Gilliland Memorial Prize (to the most distinguished woman student): Elizabeth Marjory Macnaughton, B.Sc., M.B., Ch.B. Wellcome Medals in the History of Medicine: Gold Medal—Robert Edward Burns; Silver Medal—Charles Simpson. Cunningham Memorial Medal in Anatomy: Henry James Parish, Whiteside Bruce Bursary: Duncan Ferguson Yuille.

The following candidates have been approved at the examinations indicated:

- FIRST M.B. (Physic)—J. J. Binnie, H. Dittmar, G. B. Falcon, M. Vera Cruz, E. G. Ryan, A. G. Lornie, J. C. Timothy, F. C. Veitch (Chemistry)—Jessie R. Bruce, Elizabeth E. Critchley, H. Dittmar, Millicent Fox, R. L. Galloway, Marjorie H. King, Catherine A. J. Mitchell, D. Rankin, Janet C. Rugg, Apollina A. Wright (Zoology)—Elizabeth J. Alexander, S. M. Alexander, C. S. Appleyard, A. Arnitt, C. W. Badger, C. W. Baillie, W. L. Ballour, Jean F. Bertholomew, F. D. M. Benton, H. Berelowitz, A. E. Blackley, Alice Bloomfield, L. R. Bonford, J. M. Bonnar, W. H. S. Boyd, Jessie B. Bruce, E. M. Byres, D. A. Cadman, Margaret S. Caskie, G. G. Campbell, C. E. Clarke, C. H. Cook, Elizabeth E. Critchley, Dorothy G. Davidson, A. W. P. De Helin, R. A. W. Davison, Margaret L. Dobbie, H. R. Dodson, N. M. Dott, Evelyn W. A. Dunderdale, J. C. Durrard, B. G. Falconer, B. A. G. A. Edelman, E. E. Evans, C. B. Falconer, J. M. Falconer, O. Fitzpatrick, M. V. Foley, B. Tyrrell, A. C. du Val, R. Walker, W. A. Weatherhead, J. Wolfson, A. T. Woodward.

UNIVERSITY OF ABERDEEN.

The following degrees have been conferred:
M.D. A. M. Brown, A. F. A. Fairweather.
M.B. (1st B). R. S. Cumming, C. Allison, M. Ballie, A. H. Brown, F. W. C. Brown, G. C. Bruce, H. F. Copland, D. C. Cruickshank, J. K. Dastoor, G. Dewar, H. G. Donald, I. G. M. Firth, Elizabeth Gray, J. W. M'Keggie, A. L. C. Mackenzie, A. S. Mackie, J. Melvin, J. E. S. Menzies, T. Menzies, F. G. Milne, B. Mitchell, H. Mitchell, P. W. Noble, J. A. Scroggie, J. A. Seiler, J. Smith, Elizabeth Stephen, Esther Stephen, H. F. Stephen, J. R. Tibbles, W. C. D. Wilson.

The John Murray Medal and Scholarship, awarded to the most distinguished graduate (M.B.) of 1915, has been bestowed upon R. S. Cumming.
The following candidates have been approved at the examinations indicated:

First Professional.—Annie Anderson, R. M. Anderson, E. G. W. Bisset, N. C. Bodenstein, Euid Calder, Margaret M. Chapman, H. B. Cook, H. C. Cunningham, J. A. Dawson, Marjory J. Duffton, Dorothy M. J. Emalie, W. A. Falconer, V. L. Ferguson, J. C. O. Gordon, P. G. Grant, J. Grant, G. G. W. Hay, J. B. Jessiman, W. Lawie, Mary V. Littlejohn, M. M. MacLennan, H. McRobert, J. I. Miller, F. H. Mollere, A. G. Morrison, Margaret Porteous, G. A. Sheehy, J. G. Smith, H. R. Spink, Sophia M. G. Stuart, H. Thurd, A. Thomson, Louise Tomory, T. W. Turner, V. M. W. Watson, E. Tule.
Second Professional.—M. Dugan, G. S. Escoffery, A. C. Fowler, V. Y. Garden, R. D. Lockhart, A. M. Manuathach, A. C. Paterson, C. Reid, Margaret A. Reid, A. Ritchie, Agnes L. Sempie, Annie Simpson, F. Wilson, W. L. Yell.

The following have been approved in the subjects indicated:
Systematic Chemistry: W. J. Adam, H. D. Low, *Physics only*: C. A. Allan, Lyla C. Forbes, *Botany only*: C. A. Aymer, G. M. C. C. Joyce, W. J. Middleton, D. M. Thomson, *Zoology*: S. M. W. Bodie, Maud G. Mackintosh, *Practical Chemistry*: G. Brown, A. B. Wood, *Botany and Physics*: Isabel C. Brown, W. S. Cochran, A. V. R. Don, D. R. Dugan, J. Findlay, M. M. Gunn, K. A. Hay, G. B. Morgan, F. R. Mutch, C. L. Noble, E. N. D. Repper, D. G. M. Vatt, Hiap, T. Wee, *Physics and Systematic Chemistry*: J. Hutchison, *Zoology and Physics*: F. Maclean, *Botany and Practical Chemistry*: Bethia M. Newlands, Ethel V. G. Smith.
THIRD PROFESSIONAL. *New Regulations*: G. S. Davidson, J. S. B. Forbes, W. C. Mackinnon, A. H. Mitchell, A. K. Robb, T. O. Rolston, *Old Regulations*: C. W. Bennett, G. S. Benga, G. S. Lawrence, J. W. M'Keggie, C. Light, W. D. Whamond.
* Commendation for thesis.
* Second-class honours.
* Passed fourth professional examination with distinction.
* Passed with distinction.

UNIVERSITY OF ST. ANDREWS.

Graduation Ceremony.

A GRADUATION ceremony took place at St. Andrews University on July 8th. Owing to so many students having enlisted, there were only a few men students in the back benches, and the proceedings were unusually quiet. The following is a list of graduates:

M.B., Ch.B.—Margaret A. Alexander, Agnes W. Andrew, M. L. Bery, A. C. Cassels, D. Dempster, Margaret Fairlie, G. M. Grant, C. B. Macdonald, W. J. Macdonald, M. C. Macleod, D. H. Murray.
Lecturer in Bacteriology.
Dr. W. J. Tilloch has been appointed Lecturer in Bacteriology and Assistant to the Professor of Pathology in the Medical School, Dundee, for the next academic year.

UNIVERSITY OF MANCHESTER.

The following candidates have been approved at the examination indicated:
D.P.H.—H. F. Hutchinson, E. M. de Jong, O. M. de Jong.

UNIVERSITY OF LONDON.
KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.

Burney Test Scholarships.

The first election of scholars under the Burney Test bequest has been made as follows: Mr. Meredith Blake Robson Swann, B.A., of Gonville and Caius College, Cambridge; Mr. Edward Balfour Creed, B.A., of Trinity College, Oxford.

UNIVERSITY OF BRISTOL.

The following candidate has been approved at the examination indicated:
Second M.B., Ch.B. D. G. Cosham.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE SCHOOL OF PHYSIC.

The following candidates have been approved at the examinations indicated:

PRELIMINARY SCIENTIFIC (*Physics*).—F. W. Harris, M. F. Meade, C. de L. Shortt, Jessie Gilbert, V. G. Walker, S. J. Laverty, J. D. Watson, *Chemistry*.—T. R. Warren, C. E. McQuade, J. C. Gillespie, F. W. Robertson, Gertrude Rice, F. Medall, J. S. O'Brien, E. W. Shaw, J. T. Myrland, J. H. O'Donnell, H. P. Stack, J. H. Coillaco, G. F. Keatinge, J. F. Sheppard, J. D. Watson, P. J. Duggan, N. Long, A. R. Aldin, R. D. Murphy, C. W. Parr, V. G. Walker, A. H. Thomson, J. H. Crosbie, Jessie Gilbert, J. J. Quinlan, E. F. Hawthornthwaite, H. Birsey, R. Coulman, R. W. Power.

INTERMEDIATE MEDICAL. Part I (*Anatomy and Physiology*).—H. L. Parker, V. M. Keatinge, V. G. Walker, E. Gill, W. Sweetnam, H. Albertson, J. C. Fouché, E. W. Deale, J. A. Acheson, R. M. Devereux, P. C. Part, E. S. Mack, W. A. Shannon, Margaret Wolfe, L. T. Nugent, P. Caser, C. G. Ambrose, E. R. Fry, F. J. Swanepool, E. E. Kollins, Mary C. Sheppard, Ethel M. Luce.
Part II (*Applied Anatomy and Applied Physiology*).—S. A. Clark, A. I. Stern, T. E. Hill, W. F. Wicht, H. J. Wright, H. Banks, D. S. Preulker, F. W. Sullivan, R. W. Pritchard, W. Gardle-Brown, G. Marshall, Millicent Hamilton-Johnston, C. Weir, H. H. Molloy.

FISAL MEDICAL. Part I (*Materia Medica, Pathology, Medical Jurisprudence and Hygiene*).—A. Ferriss, T. Lane, G. W. Shaw, T. P. Curnham, C. R. B. Ramsay, H. J. Rice, L. Blumberg, C. L. McDonough, Marie A. Hadden, E. O. Marks, A. G. Wright, F. J. Smith, Ellen C. Gwynn, F. A. McHugh, *Medical Jurisprudence and Hygiene and Materia Medica*: P. W. O'Connor, H. S. Caupion, *Pathology* completing examination: A. H. Price (*Materia Medica and Pathology* completing examination), E. Frier, T. W. Sweetnam, *Medical Jurisprudence and Hygiene* completing examination.

Part II (*Surgery, B.Ch.*).—C. C. Abertyn, I. W. Corkey, E. D. Hayes, S. W. Fisher, G. Joughin, Evelyn Ross, N. McC. Boyce, M. Ryan, J. V. Cope, C. F. Brady, D. C. Finn, E. W. Craig, R. W. O'Connell, W. Dowling, J. Shaw, R. W. Sheehan, A. J. Horce, C. D. Pile, G. O. Alley, E. Boyers, M. R. King, A. H. Watson, (*Medical Jurisprudence and Hygiene and Materia Medica*).—E. J. McGinley, H. McW. Daniel, G. Joughin, F. R. Shaw, Evelyn Ross, E. D. T. Hayes, G. Brennan, C. D. Pile, E. W. Craig, W. J. Dowling, A. W. Todd, D. C. Finn, A. H. Watson, R. W. Sheehan, E. G. Fishie, G. O. Alley, A. J. Horce, C. McL. West, G. Stanton, C. F. Brady, R. W. Acheson, S. W. Fisher, (*Misurgery, E.S.O.*).—G. D. Pile, G. B. Gable, J. Adie, C. H. Comerford, E. Lipman, A. H. Watson, T. W. Sweetnam, M. McC. Russell, C. G. Sherowitz, H. H. Graham.
* High marks.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examination indicated:

FISAL COLLEGE.—A. P. Adams, S. Barron, C. H. Brennan, S. Brown, T. A. Buchanan, S. E. J. Cairns, G. A. Campbell, T. M. Cronin, B. J. Cusack, W. J. R. Dimond, J. C. Ferguson, C. E. H. Galer, E. N. H. Gray, J. J. Gray, F. J. McLean, W. G. D. M'Call, F. R. H. Mollay, M. Moran, J. A. Muegan, C. J. O'Carroll, P. J. D. O'Malley, L. M. Rowlette, R. A. Ryan, T. H. Sarsfield, J. A. Watson, P. I. Wigoder, H. J. Villiers.

The Services.

TERRITORIAL FORCE.

EXCHANGE DESIRED.

LIEUTENANT ARTHUR E. TAIT '58, Beaconsfield Road, St. Albans, 12nd East Anglian Field Ambulance T.I., desires to be transferred to home service work in or near London, and could undertake either hospital work or the training of a field ambulance. The unit is ordered to the Dardanelles. The pay is 14s. a day, together with 3s. field allowance, and is 9d. a day in lieu of rations.

The annual report of the Convalescent Homes Association states that the association now consists of three hospitals and twenty convalescent homes. During the year 1914 three more homes—namely, the Children's Convalescent Home, Beaconsfield; the Convalescent Home for Children, Hawkesbury, Tunbridge Wells; and the Suffolk Convalescent Home, Felixstowe—joined the association, while the Beau Side Home, Home Hastings, resigned its membership. A list of convalescent homes and sanatoriums receiving London patients, which was prepared by the late Mr. Hayes and issued under the auspices of the association, gives particulars of some 200 institutions, and also contains a general index with nearly 350 references.

Obituary.

BRUCE GOFF, M.D., F.R.F.P.S. GLASGOW.

By the death of Dr. Bruce Goff of Bothwell the profession in the West of Scotland has lost one of its most distinguished members and the British Medical Association one of its most loyal and devoted adherents.

He was born at Hammernessmith in 1832, when it was a country district surrounded by green fields. His father died two or three years later. He was educated privately and became a medical student of Glasgow University in 1849, where he graduated M.D. in 1853, having in the interval passed part of his studentship at the University of Edinburgh. After graduation he became house-surgeon in the Glasgow Royal Infirmary to Professor Lawrie, and later was for some time his private assistant. Next he proceeded to Paris, where he worked under such distinguished masters as Nélaton and Dubois. At this time Dr. Goff was elected a member of the Paris Medical Society. On his return to this country he settled in private practice at Bothwell, then a pleasant village on the Clyde with something of a reputation as a health resort. Here his sterling qualities were readily recognized and he speedily built up a very extensive connexion, which increased considerably with the development of the Lanarkshire coalfield and became probably one of the largest mining practices in Scotland. This practice he conducted with great acceptance for over forty-five years.

When he was able to allow himself a little leisure from his purely professional duties he took an active part in medico-political work. He was the champion of the general practitioner—particularly of the country practitioner—whose status and position it was his constant endeavour to improve. Early in his career he became a member of the British Medical Association. About 1880 he was elected president of the Glasgow and West of Scotland Branch in succession to the late Sir William Gairdner, and from that time onwards he took a large share in its work. He was a regular attender at the meetings, where his opinions and advice were always highly valued. In 1884 a wider sphere of usefulness was opened up to him by his appointment as representative of the Branch on the Central Council in succession to Dr.—now Sir David C.—McVail. Dr. Goff applied himself to his new duties with characteristic energy, and from that time his commanding figure and his agreeable personality were well known at all the important meetings. He continued to represent the Branch on the Central Council till 1908, when the by-law limiting the period of service came into operation. On his retirement in that year he was invited to be the guest of the evening at a largely attended dinner at St. Enoch Hotel, Glasgow, when he was presented with a handsome service of plate as a mark of the esteem in which he was personally held and as a slight acknowledgement of his long and valuable services. Practically every medical man in the area of the Branch subscribed to the fund for the presentation.

Dr. Goff's activities on behalf of the Association did not cease at this period. Till two years ago he remained chairman of his Division and was its Representative at Representative Meetings. He was a member of the Central Ethical Committee and of the State Sickness Insurance Committee—the first committee set up to deal with the National Health Insurance Act.

In local medical circles Dr. Bruce Goff was held in the highest respect. He became a Fellow of the Faculty of Physicians and Surgeons of Glasgow by examination in 1855. Rising through the various grades of office, he was elected President in 1895 for three years, he being one of the very few country practitioners to hold that important position. For a long period he was one of the managers of the Glasgow Royal Infirmary, and later, for a considerable number of years, he was on the Board of Management of the Western Infirmary, Glasgow, a position which he continued to hold till the end of his life. In politics Dr. Goff was an enthusiastic Conservative. At the time of his death he was the oldest member of the Scottish Episcopal Church of St. Mary, Hamilton.

He was a strong supporter of the Volunteer movement, which he joined in 1859; he retired a few years ago, having received the V.D., and having been given the rank of honorary colonel R.A.M.C. (T.F.)

He gave up active general practice sixteen years ago, thereafter devoting himself to consulting work and to his various public duties.

He was always a courteous, cultured gentleman. He formed his opinions with care and deliberation, and was always prepared to uphold them. At the same time he was tolerant of the views of others.

During the last twelve months his strength had been gradually failing, although his mental faculties remained clear and vigorous to the last. He passed peacefully away at Bishopton, near Glasgow—the residence of one of his sons—on Sunday, July 4th, and was laid to rest in Hamilton Cemetery on the following Wednesday, deeply mourned by all who knew him. He is survived by four sons, two of whom are in the profession—Dr. John Goff of Bothwell, who succeeded him in practice, and Dr. Bruce Goff of London.

Professor SAUNDY (formerly President of the Council and of the Association) writes: I should like to be allowed to contribute a few words of appreciation of the late Dr. Bruce Goff, of his character as a man, and a valuable member of the Council of the Association. I cannot trust my memory to be accurate, but it seems to me that Dr. Goff was a member of the Council when I first joined it somewhere about 1885, and he certainly was still a member when I left it twenty years later, and again when I rejoined it as President-elect five years ago. The West of Scotland Branch could not have had a better representative than he proved himself to be for so many years. Few members of the Council exercised greater personal influence, for his calm and judicial speech made his colleagues recognize that there was much to be said for the side taken by him in any discussion. He was a graceful speaker, and was constantly called upon and readily performed the ceremonial duty of proposing or seconding votes of thanks to those who had been officially more prominent, though perhaps less generally useful. I do not know why he was never elected to serve either as Chairman of Council or Treasurer of the Association, but I think it must have been because he lived so far from London that he was unable to make the sacrifice of time which would have been involved had he accepted either of these offices. There are few past or present members of Council who do not remember with pleasure his genial presence, or recall him with other feelings than those of affection and respect. It has sometimes been said that the Council was formerly dominated by consultants; but Bruce Goff was a general practitioner, and shared with many others of the best type, of whom I need only name Husband, Clayton, Carpenter, Wheelhouse, Holman, Parsons, and Bridgewater, the influence exerted by general practitioners in the days when the Council was an unreformed body.

THE LATE LIEUTENANT T. S. LUKIS.—A correspondent in India sends us a note on the social work carried on in London by the late Lieutenant T. S. Lukis, M.D., of the 13th Battalion, London Regiment, who died of wounds on March 15th. A short memoir has already appeared, dealing chiefly with his medical career, in the JOURNAL of March 27th. He was one of the pioneers of the Boy Scout movement in East London. Starting his operations in Whitechapel, with Toynbee Hall as his head quarters, he founded the first Hoxton troop on May 27th, 1908. At first fortnightly excursions were made to Epping Forest, but his object was to show that scout work could be successfully carried out in the heart of London. With that object in view he spent Saturday afternoons, week after week, in playing scout games in an area of which Finsbury Circus was the centre. At first the movement excited a good deal of ridicule, being new to the neighbourhood, but perseverance won success in the end, and his work found imitators, several other troops being founded in that part of London, and meeting with equal success. Dr. Lukis was in camp with his scouts near Chelmsford last August when war was declared. He took the lead in forming a scouts company in the 13th London Regiment, and, following his example, over eighty of his scouts joined the army.

WE regret to announce the death of Dr. HENRY ALGERNON HOBSON, a well-known and highly-esteemed practitioner of Hove. The sudden end of a valuable life was the

result of an accident due to the darkening of the front at Brighton. Dr. Hodson, who was 63 years of age, received his professional education at University College, London, and became M.R.C.S. Eng. in 1875 and L.R.C.P. and L.M. Edin. in 1876. After qualifying he held the offices of senior house-surgeon at the Royal Free Hospital in London and clinical assistant at the Hospital for Women, Soho Square, and at the Central London Ear and Throat Hospital. He had been in practice for many years at Brighton and was surgeon to the Hove Hospital and Dispensary and to the Brighton and Hove Surgical Homes. He was surgeon to the 1st Battalion Sussex Volunteer Training Corps (Brighton). He was a member of the British Medical Association, and took an active part in its work. Dr. Hodson leaves a widow, a daughter, and three sons all of whom have been engaged in the fighting in British East Africa since the beginning of the war.

DR. JAMES McARTHUR of London, Ontario, died of heart failure on May 23rd, in his sixty-first year. He was born at Ailsa Craig, near London (Ontario), and after receiving his early education entered Queen's University, Kingston, where he obtained the degrees of B.A. and M.D. He had practised in London for the past thirty-five years with a rare devotion to duty. Dr. McArthur was one of the founders of the London Medical Association, and for fifteen years a member of the Ontario Medical Council. Last year he was elected President of the Council, and it was due largely to his efforts that reciprocal relations were established between the province of Ontario and Great Britain. He leaves two sons and three daughters.

COLONEL JOHN GASSON HARWOOD, Army Medical Staff (ret.), died at Southsea on July 8th, aged 58. He was born on August 27th, 1856, educated at Bart's, and took the diplomas of M.R.C.S. and L.S.A. in 1879, as well as the F.R.C.S. Edin. in 1888. He entered the army as surgeon on March 6th, 1880, became surgeon-major on March 6th, 1892, lieutenant-colonel on March 6th, 1900, and colonel on June 29th, 1906, retiring on March 15th, 1909. The Army List assigns him no war service.

LIEUTENANT-COLONEL THOMAS CANEBELL McCULLOCH, R.A.M.C., died suddenly of heart disease at the Alexandra Hospital, Coshua, Haiti, on June 25th. He was born on May 4th, 1861, educated at Glasgow, where he took the M.B. and C.M. with commendation in 1884, and entered the army as surgeon on February 5th, 1887, becoming major on February 5th, 1899, and lieutenant-colonel on July 29th, 1911. He served in the third China war in 1900, when he was mentioned in despatches in the *London Gazette* of September 13th, 1901, and received the medal. From May 1st, 1902, to April 25th, 1906, he was Deputy Assistant Director-General of the Army Medical Service, and in 1906 he served as a member of the committee for the investigation of Mediterranean fever.

CHARLES EDWARD WOODRUFF, lieutenant-colonel in the Medical Corps of the United States Army, who died on June 13th, was born in Philadelphia in 1860. After graduating in arts in the University of Pennsylvania, he spent three years at the Naval Academy, Annapolis. Abandoning his intention of becoming a naval officer, however, he turned to the study of medicine and graduated M.D. at Jefferson Medical College in 1886. After serving as an assistant surgeon in the United States Navy for a year, he was transferred to the Army Medical Corps, from which he was compelled to retire owing to ill health in 1913. Two periods of service in the Philippines convinced him that the tropics were unsuitable for white men. His views on this subject, which were strongly held, were set forth in books entitled respectively *The Effect of Tropical Light on White Men*, *Expansion of Races*, and *Medical Ethnology*. Even those who do not agree with his conclusions must admit the wealth of practical experience on which they are founded and the ingenious argumentation by which they are supported. After his retirement from the army Colonel Woodruff travelled extensively and embodied his observations in a number of pamphlets. At the time of his death he was associate editor of *American Medicine*.

WE regret to announce the death of Professor KOBERLÉ, the distinguished surgeon, of Strassburg. Born on January 4th, 1828, he was in his 88th year. He had a great influence on the progress of surgery in France. He was in a special manner the pioneer of ovariotomy in that country, and his early efforts to gain a recognized footing for the operation were encouraged by the award of a prize of £80 by the Academy of Medicine. In 1868 he had already performed the operation in 69 cases with a successful result in two-thirds of the number; at the end of the following year he was able to report to the Paris Société de Chirurgie that he had done 123 ovariotomies. In 1870 he published a treatise, entitled *Manuel opératoire de l'ovariotomie*. His name was also well known in connexion with hysterectomy, the morcellément of tumours, and other surgical procedures. There was a great controversy as to priority between him and Péan in regard to the invention and use of hæmostatic forceps. Koberlé remained at Strassburg after 1870, but he held himself aloof from the Germans, and refused the honours which they pressed upon him.

Medical News.

MR. EDMUND OWEN, Surgeon-in-Chief to the St. John Ambulance Association, and Consulting Surgeon to St. Mary's Hospital, was, we regret to learn, taken suddenly ill on July 13th, and is unable to attend to the business of the Joint Committee of the British Red Cross Society and the St. John Ambulance Association, in which he has taken so large a part.

DR. FREDERICK WILLIAM PRICE has been elected a Fellow of the Royal Society of Edinburgh.

At a meeting of the Royal Society of Edinburgh, held on July 1st, the Makdougall-Brisbane prize was awarded to Professor C. R. Marshall for his studies "on the pharmacological action of tetra-alkyl ammonium compounds."

MRS. SCHARLIEB, M.D., M.S., will give an address to pupils and parents at the distribution of scholarships and exhibitions won by pupils of the Manchester High School for Girls at the Free Trade Hall, Manchester, on Thursday next at 3 p.m.

THE Secretary of the Chelsea Hospital for Women has received a further sum of £1,000 from the executors of the T. S. Whitaker Estate towards its rebuilding fund. The hospital is giving special facilities for the admission of the wives and near relatives of soldiers at the front and also to Belgian refugees.

DR. J. W. AND MRS. MULLIGAN recently left Abersychan, Monmouthshire, where they have lived for nearly half a century, to take up their abode in Ireland. Dr. Mulligan has been a Justice of the Peace, an alderman of the county council, and a member of Abersychan Urban District Council for many years, whilst Mrs. Mulligan was an active member of the Pontypool Board of Guardians for twelve years. In recognition of their public services they were presented with a handsome set of candelabra, silver candlesticks, salvers, hot-water jug, flower vases, and an illuminated address.

DR. SHIPLEY, Master of Christ's College, whose papers on insects and war in the BRITISH MEDICAL JOURNAL have been read with so much interest, has prepared for the National Health Society a leaflet on mosquitoes, in which he describes the places in which they breed, the way in which the larvae and pupae can be destroyed, giving preference to crude mineral oil, 10 c.c.m. to the square metre (a tablespoonful to the square yard), or, failing that, heavy mineral oil. He discusses, also, methods of destroying the adult mosquito. He mentions experiments made by himself and Professor Nuttall, in which they found that the mosquitoes avoided a box lined with khaki cloth, and collected in that lined with dark navy blue. After stating that many essential oils, cedar wood, lemon grass, eucalyptus, or citronella, applied to the neck, wrists, and ankles are said to keep mosquitos away, he adds that the wearing of two pair of socks often protects the ankles, as the proboscis of the mosquito is too short to penetrate through the double thickness. We may add that probably it is not so much the thickness, for they will sting through thick woollen stockings, as the doubling of the close material, which makes it difficult for the insect to pass its proboscis through two thicknesses.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notices to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ATTENTIONS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atlong, Westrand, London*; telephone, 2531, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medusera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

H. R. would like to be recommended a good carbon snow apparatus. He has used several, but finds the condensing apparatus is not satisfactory.

DR. R. R. RESTOUL (78, Hartington Road, Liverpool) will be much obliged to any one who will kindly send him his results of the treatment of urethral stricture by fibrolysis.

INCOME TAX.

TAXPAYER has been in the habit of calculating his firm's income tax return on the basis of gross receipts. For the current year the surveyor of taxes refuses to accept this, and claims that the book debts at the beginning and end of the year must be taken into account.

Theoretically the surveyor is no doubt right, but the notoriously difficult existing with regard to "bad debts" in all general medical practices has given rise to a long-standing arrangement by which the practitioner's return is based on cash receipts only. This avoids the "bad debts" difficulty altogether, and, inasmuch as in the great majority of cases the book debts at the beginning and end of the year are of approximately the same value no loss would appear to be incurred by the Revenue. Unless there are very exceptional circumstances in the case our correspondent might point out to the surveyor that his action is a distinct departure from a long-standing practice, and if he persists might communicate with the Board of Inland Revenue on the subject.

LETTERS, NOTES, ETC.

DR. JAMES HAMILTON (Chelsea) writes: During the past month I have had a series of cases all presenting exactly similar symptoms. I wonder whether other practitioners have had the same experience and whether they will agree with me as to the cause. Each case was taken suddenly ill with "cold," followed by acute pain in region of liver and umbilicus, and then diarrhoea with dark-greenish yellow offensive motions and temperature ranging from 101° to 104° and persisting for about a fortnight. The only other signs which were common were congestion of fauces, tenderness over the liver and spinal neuralgia. In two cases vomiting of a greenish matter was present, and in all nausea. The ages ranged from a schoolgirl of 14 whose temperature was still—after ten days—over 100, to an old lady of 78. The ages of the others are 48, 35, 64, 62, and 19. Some minor cases I do not record. My impression is that the hot weather with cold east or north-east winds set up changes in the liver and duodenum which interfered with metabolism. In no case was there any questionable food. Very old writers speak of bilious fever. I treated all cases with calomel in repeated doses and an alkaline and bismuth mixture, and some with resorcin and naphthalin, but medication did not seem to cut short the attack—although it might have been more serious if not treated.

THE DEARTH OF DOCTORS.

MR. ARTHUR DAVENPORT (Teignmouth) writes: In view of the frequent complaints of the "dearth of doctors," may I suggest, as a remedy, the prompt recall of our missionaries from Asia, leaving the current work of their stations in the capable hands of their devoted native assistants? The services of the surgeons of both sexes would be simply invaluable, while the junior clerical members might render good service at the front, the ladies aiding as nurses where their help was most required. The seniors might make themselves very useful in many ways—for example, in converting selfish well-to-do people who outwardly display unpatriotic self-indulgence and

the like, and in persuading those who are the victims of alcoholic thirst to amend their ways. The enthusiastic salutations of the natives in the Far East to the French priests hastening home last August to fight for their country would seem to indicate that our missionaries, by their indifferent quasi-neutral attitude, will lose much influence and respect if they coldly and apathetically remain in the mission field instead of coming to the aid of their country in its present time of trouble.

"THE POISON WAR."

MR. A. A. ROBERTS writes: By your review of the above book, contained in the BRITISH MEDICAL JOURNAL of July 3rd, I am pleased to see that there are some points of interest to the profession published in the series of articles under the title of "The Poison War." It is stated in the preface that this book is only intended as an appeal to the lay mind. Complicated or lengthy details are, in consequence, deleted as far as possible, and in any criticism, the rigidity of censorship must be taken into account, also the alterations in the text, to meet its requirements. I take it that your critic thinks there must be an error in either the description or drawing of the naval poison gas machine (p. 35). Will you allow me to say that both of these are correct. It is represented in the description that the "floats" are weighted, and the weight figures in the illustration, one of the connexions to the first air box is also weighted, to counterbalance.

The description might have been clearer if I had said that the object of the buoy is to keep the floats in position, but that is surely apparent. Your critic has misread the passages if he reads, as suggested, that I referred to sulphur dioxide as less soluble in water than chlorine. Such a remark attributed to me would be an absurdity, in view of my practical experience with these gases. Moreover, I distinctly say that, in the event of generation of sulphur dioxide, the nozzle would of necessity have to be "at or in close proximity to the surface," and I am of opinion that the solubility of the gas would to some extent be impaired by the particular method of its generation.

INSECT POWDER FOR LIFE.

WE were consulted recently by an army medical officer as to a particular powder recommended to keep lice out of the clothes. Microscopic examination showed that it consisted principally of powdered insect flowers (*Chrysanthemum cinerifolium*); the powder, however, contained an undue quantity of woolly tissue, probably derived from the presence of a rather high proportion of stalk. A careful examination for other ingredients resulted in the detection of a small quantity of lead chromate, which is, no doubt, present as an impurity, since this chemical is a common adulterant of insect powder. No other substance could be found, and the powder therefore appears to be a low grade of insect powder, coloured with lead chromate. Readers might do well to consult the articles by Dr. A. E. Shipley, F.R.S., regarding lice, published in the BRITISH MEDICAL JOURNAL of September 19th, 1914, p. 497, and February 27th, 1915, p. 395.

BADGE FOR DOCTORS' CHAUFFEURS.

DISTRICT MEDICAL OFFICER writes: "A.W.'s" suggestion for the marking by a badge of doctors' chauffeurs may be useful; but the distinguishing badge for doctors, although long advocated, would be much more to the point, if now established and enforced. For obvious reasons it would identify doctors, whether for civil or military purposes.

EPSOM COLLEGE ELECTION.

MRS. JAMES WELSH, 44, Worthing Road, Southsea, widow of Fleet Surgeon Walsh, H.M.S. *Good Hope*, wishes to express her most grateful thanks to all who so kindly gave their votes, support, and sympathy to her son Raymond Neville in the June election, 1915, for foundation scholarships for Epsom College, in which he was third among the successful candidates.

THE MEDICAL DIRECTORY.

MESSES. J. AND A. CURETTE write: The annual edition for the *Medical Directory* will be posted to the profession on July 19th. We sincerely hope that all practitioners will make their returns to us as quickly as possible, so that the issue for 1916 may be accurate and full of the latest information. The list of practitioners resident abroad will be reinstated.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, no later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

Notwithstanding the rules of the Post Office to receive post-restants letters addressed either in initials or numbers.

THE SCIENCE COMMITTEE

OF THE

British Medical Association.

REPORT TO THE THERAPEUTIC SUBCOMMITTEE.

I.—THE COMPOSITION AND PHARMACOLOGICAL ACTION OF SPIRITUS AETHERIS NITROSI.

BY
C. R. MARSHALL, M.D.,
PROFESSOR OF MATERIA MEDICA;

AND
ELIZABETH GILCHRIST, M.A., B.Sc.,
ASSISTANT TO THE PROFESSOR OF MATERIA MEDICA;
UNIVERSITY OF ST. ANDREWS.

Sweet spirit of nitro is defined by the *British Pharmacopoeia* (1914) as "an alcoholic solution containing not less than 1.52 or more than 2.66 per cent. by weight of ethyl nitrite, together with aldehyde and other allied substances." In the 1898 edition it is more simply defined as "an alcoholic solution containing ethyl nitrite, aldehyde, and other substances," but, as shown by the quantitative test given, it must contain not less than 1.75 nor more than 2.5 per cent. of ethyl nitrite. The definition and quantitative test of the 1885 *Pharmacopoeia* are similar. In the previous (1867) *British Pharmacopoeia* the definition given is "a spirituous solution containing nitrous ether," and the quantitative test—the separation of 2 per cent. of its volume on the addition of twice its volume of saturated solution of calcium chloride—indicates that it was intended to contain at least 2 per cent. of ethyl nitrite. The mode of preparation has not been materially changed during these years. In the short-lived *Pharmacopoeia* of 1864 the spirit was prepared by distilling sodium nitrite, sulphuric acid, and rectified spirit. The sweet spirit of nitre of the London, Edinburgh, and Dublin *Pharmacopoeias* was obtained by distilling certain proportions of alcohol and nitric acid.

It is evident from the mode of preparation and the tests given that ethyl nitrite has been regarded as the active ingredient of sweet spirit of nitre since the establishment of the *British Pharmacopoeia*, although, as far as we know, this view did not receive experimental support until the investigations of Professor Leech. It does not appear, however, to have found universal acceptance, and the British Pharmaceutical Conference asked the co-operation of the Therapeutic Subcommittee of the Association in further work on the nature of the active ingredient or ingredients. The following statement was submitted to the Subcommittee by the secretaries of the Conference:

It is desirable that we should know if the important constituent in spirit of nitrous ether be the acetaldehyde, the ethyl nitrite, or the alcohol. If the first, then a pharmacopoeial test could be devised which would insist on its presence. If the ethyl nitrite be the only constituent of importance then suitable processes of preparation and testing could be defined. Since the liquor ethyl nitritis *B.P.* 1898, which is a solution of ethyl nitrite, has practically not come into use, whereas the old sweet spirit of nitre of the London *Pharmacopoeia*, containing aldehyde but little or no nitrite, is still in use, the question is of practical importance.

The matter was referred to one of us for report. For the purposes of the investigation Mr. Finemore, one of the secretaries of the British Pharmaceutical Conference, kindly prepared and sent to us samples made according to the old London *Pharmacopoeia* and the *British Pharmacopoeia* (1898) and a solution of ethyl nitrite in alcohol. We have also prepared sweet spirit of nitre according to the *British Pharmacopoeias* 1898 and 1914, and the German *Pharmacopoeia* 1900; and a solution of ethyl nitrite. These and specimens bought from a retail pharmacist have been used in the investigation.

METHODS OF PREPARATION.

The methods of making the preparations other than those of the *British Pharmacopoeia* were as follows:

London Pharmacopoeia.

Nitric acid 34 fluid ounces, alcohol 40 fluid ounces; distil 28 fluid ounces. (Prepared by Mr. Finemore.)

Mr. Finemore noticed that this product contained practically no ethyl nitrite, and he therefore decided to prepare a spirit by continuing the distillation as long as practicable. The distillate was then diluted with alcohol to the *B.P.* (1898) standard for ethyl nitrite. This preparation is labelled in Table I—L.P., mod. I (London *Pharmacopoeia*, modified I).

A third spirit was made in the same way, except that the nitric acid and alcohol were allowed to stand twenty hours before distilling, and the distillation was continued until red fumes were evolved from the liquid in the distilling flask. This preparation is labelled in Table I—L.P., mod. II.

German Pharmacopoeia.

Nitric acid (25 per cent.) 3 parts, alcohol 5 parts; allow to stand two days; distil on a water bath into 5 parts alcohol until yellow fumes commence to be evolved from the mixture in the flask; neutralize the distillate with magnesia; after twenty-four hours redistil on a water bath into 2 parts of alcohol until 8 parts of product are obtained.

Ethyl Nitrite.

Ethyl nitrite was prepared by the interaction of sodium nitrite, sulphuric acid, and alcohol in a flask surrounded by ice. The ethyl nitrite formed was distilled by gently heating the flask with warm water, and after neutralization with sodium bicarbonate was dissolved in absolute alcohol. The strength was subsequently adjusted to meet the requirements of the *Pharmacopoeia* for spiritus aetheris nitrosi.

CHEMICAL COMPOSITION.

Our analyses of the various sweet spirits of nitre showed that they contained not only ethyl nitrite and aldehyde but also ethyl nitrate and paraldehyde. If not acid or if neutralized they relatively quickly become acid on keeping owing to the formation of small quantities of nitrous, nitric, and acetic acids. The amounts of nitrite, aldehyde, and paraldehyde and the total acidity were determined for each specimen. The nitrite was estimated by the official method with potassium iodide and dilute sulphuric acid, using a mercury-charged nitrometer in place of the brine-charged one recommended. The aldehyde was determined colorimetrically by means of Schiff's reagent, a known concentration of pure aldehyde with sodium nitrite added being used as a control. The paraldehyde was converted into aldehyde by distilling the preparation with dilute acid, collecting the distillate in an ice-cooled receiver, determining the aldehyde by means of Schiff's reagent, and estimating by difference. The acidity was determined in the usual way, using phenolphthalein as indicator. As there seemed little doubt from the mode of making some of these preparations that ethyl nitrate must be formed and must be present in the final product, it was decided to endeavour to determine the quantity, if any, present. Evidence was obtained of its presence in some of the preparations, but although we tried several methods we were unable to devise one for the quantitative estimation of this substance in an alcoholic solution containing also ethyl nitrite and aldehyde. As it seems improbable that the combined nitrogen in the preparations can be present in any other form than as nitrates or nitrites, it was resolved to determine the total nitrogen by Dumas's method and calculate the nitrate by difference. This method of estimation, however, provided some unforeseen difficulties, and the various preparations, with the exception of one specimen of spiritus aetheris nitrosi *B.P.*, were not examined until some time after they were made. One of the chief difficulties was the high figure for nitrogen. A preliminary combustion of ethyl nitrate yielded the theoretical quantity of nitrogen gas, but with ethyl nitrite in alcoholic solution the yield of gas was consistently high, although a longer furnace and a longer copper spiral than usual were employed. This high yield was probably due to the formation of some nitric oxide; it was proved not to be due to undecomposed ethyl nitrite. An allowance has been made for this abnormal yield in

Table I, and the figures for ethyl nitrate must therefore be regarded as only approximately accurate. The figures refer to grams in 100 grams of spirit.

PHARMACOLOGICAL EXPERIMENTS.

The pharmacological action of these preparations was investigated soon after their composition had been determined. Considering the well known action of paraldehyde and the small concentration present in any of these preparations—the amount in a full pharmacopoeial dose of 1 drachm being not more than 3 minims—it does not seem probable that any portion of the activity of sweet spirit of nitre can be due to this substance; and, although the alcohol present will account for the carminative action of the preparation, it will not explain its whole action, and particularly its vaso-dilating action. This, as many observers have recorded, is a well marked effect of spiritus aetheris nitrosi. The acidity commonly associated with this preparation is also of no importance, except from the point of view of incompatibility. Consequently, any peculiar activity of sweet spirit of nitre must be due to the ethyl nitrite, ethyl nitrate, or acetaldehyde, which are the only other ingredients found to be present.

Ethyl nitrite is a fairly powerful vaso-dilator, and its pharmacological effects, except after excessive doses, are solely due to this action. Ethyl nitrate is also a vaso-dilator, but its action is relatively slight when compared with that of ethyl nitrite. Professor Leech showed that in man doses of 5 minims produce a mild and prolonged dilatation of the blood vessels, and no other obvious effect. In animals large doses induce an alcoholic intoxication. Acetaldehyde was shown by Professor Coppola to be a more powerful narcotic to frogs than paraldehyde; but as far as we know its action has not been investigated on higher animals.

The presence of ethyl nitrate in sweet spirit of nitre and its occurrence in larger quantity in preparations made by the older methods, for which some physicians are reported to have a preference, suggested that it might play an active part in the action of this preparation. Its effect, however, is relatively slight. It increases slightly the intensity and duration of action of the ethyl nitrite and appears to have no other effect. In comparing the action of the three preparations made by Mr. Finnemore and labelled *London Pharmacopoeia*, on the blood pressure of a dog, the preparation containing no nitrite but about 10 per cent. of ethyl nitrate caused, in doses of 0.5 c.c.m., a fall of blood pressure reaching its maximum of 7 per cent. in 115 seconds. The same dose of L.P., mod. I, containing 2.04 per cent. of ethyl nitrite and about 5 per cent. of ethyl nitrate, produced a fall of 43 per cent. in 40 seconds; and the same dose of L.P., mod. II, containing 1.84 per cent. of ethyl nitrite and about 12 per cent. of ethyl nitrate, caused a fall of blood pressure of 40 per cent. in the same time, and only differed in a slightly slower and less complete return towards the normal. Similarly, when equal doses of the spirits of the British and German Pharmacopoeias, adjusted to contain the same percentage of ethyl nitrite, were compared, the fall of blood pressure was found to be almost exactly the same in each case, although the German pharmacopoeial preparation contains much more ethyl nitrate than that of the *British Pharmacopoeia*. The average fall with different doses of the preparation of the German Pharmacopoeia was 36.1 per cent.; with the same doses of the preparation of the *British Pharmacopoeia* it was 35.5 per cent.

The injections were made into the external jugular vein in each case, and the various preparations were measured

in the injection syringe and diluted within it, in order to avoid loss of ethyl nitrite.

The intravenous injection of aldehyde in relatively small quantities also causes a fall of blood pressure. The fall is later in appearing, and is more transient than that produced by ethyl nitrite, and is usually followed by a rise extending slightly above the normal. The fall of blood pressure from injections of 0.01 gram acetaldehyde was 20 per cent.

That the aldehyde and ethyl nitrate play relatively little part in the activity of spiritus aetheris nitrosi was shown by experiments on one of ourselves (M.); 4 c.c.m. of aldehyde (more than one hundred times the amount present in a maximal dose of any of the spirits examined) was taken in 50 c.c.m. of water. It produced slight cerebral depression, slight diuresis, and a fall of blood pressure, but no other obvious effect. The influence on the blood pressure during the first hour is shown by the dotted line in the graph (Fig. 1). In a second experiment 20 c.c.m. of spiritus aetheris nitrosi, B.P.—that is, five times the maximal dose—was taken after all but traces of ethyl nitrite had been removed. It was dissolved in 100 c.c.m. of water, and contained all the ingredients of sweet spirit of nitre except the ethyl nitrite. This quantity produced no decided subjective or objective symptoms beyond some fall of blood pressure, the course of which is shown by the interrupted line in the graph (Fig. 1). For comparison, the effect

Fig. 1.—Graph showing blood pressure (Martin's instrument) after 20 c.c.m. spiritus aetheris nitrosi, B.P., deprived of ethyl nitrite (uppermost broken line, A); 4 c.c.m. acetaldehyde (dotted line, B); 4 c.c.m. liquor ethyl nitritis (dot-dash line, C); 4 c.c.m. spiritus aetheris nitrosi (continuous line, D).

of an ordinary dose (4 c.c.m.) of the same spirit of nitrous ether added to 50 c.c.m. of water and drunk immediately is shown (continuous line in graph); and for comparison with this the effect of the same amount of ethyl nitrite in the same quantity of alcohol and water (dot-dash line in graph).

In view of these and other experiments it seems to us that the activity of sweet spirit of nitre is due to the ethyl nitrite present. The ethyl nitrate, which was found in unexpectedly large amounts in some of the preparations, probably aids the vaso-dilating action of the ethyl nitrite, but its effect is relatively slight and of little practical importance. It possesses an agreeable ethereal smell and sweetish taste and, although ethyl nitrite is also somewhat sweetish, to it must be attributed most of the sweetness which spirit of nitre possesses. The aldehyde and paraldehyde merely give their characteristic odour and taste to the preparation and have no other action. The amount of alcohol in a full pharmacopoeial dose can have little action other than a local and carminative one, and in this it is probably aided by the other substances present. The diaphoretic and diuretic actions of sweet spirit of nitre which are obtained under favourable conditions, we believe, are mainly due to its vessel-dilating effects.

CONDITIONS AFFECTING ADMINISTRATION.

As we believe ethyl nitrite to be the active ingredient of sweet spirit of nitre, we have made some experiments on

the changes in concentration of this substance when the spirit is subjected to certain conditions commonly occurring in practice.

Changes on Addition of Water.

When spiritus aetheris nitrosi is added to water, bubbles of gas immediately commence to be given off. These are bubbles of ethyl nitrite, which boils at 17 C., and is insoluble in water. All the other ingredients, in the amounts present, are soluble in the diluted alcohol produced by the addition of sufficient water for the purposes of administration. Of these ingredients ethyl nitrate is the least soluble in water (1 in 64 at 18 C.) and by the cautious addition of water to certain preparations a small quantity of this substance can be thrown out.

The quantity of ethyl nitrite further decreases when the mixture is left standing, and in about an hour, if left in an open vessel, the ethyl nitrite has practically disappeared. If the mixture is constantly stirred the loss is more rapid. Equal volumes of sweet spirit of nitre and water stirred to ensure thorough mixing and left to stand for five minutes contained 71 per cent. of the ethyl nitrite previously present. A similar mixture constantly stirred for five minutes contained only 34 per cent. of the nitrite present in the spirit before mixing.

The following tables and graphs of experiments made show the loss of ethyl nitrite under varying conditions. The spiritus aetheris nitrosi used was made according to the directions of the *Pharmacopoeia* (1898), and 5 c.cm. gave 35 c.cm. NO, indicating 2.6 per cent. of ethyl nitrite.

The loss of nitrite when the spirit is mixed with an equal volume of water and exposed to the air is shown in Table II. The mixture was made in the cup of the nitrometer, and after the lapse of definite intervals of time was run into the nitrometer and the amount of nitrite estimated.

TABLE II.

5 c.cm. sp. aether. nit.	Time Mixture allowed to stand.	C.cm. of NO.
5 c.cm. sp. aether. nit.	...	35 c.cm.
5 c.cm. sp. aether. nit., 5 c.cm. H ₂ O.	2 mins.	28 c.cm.
"	5 mins.	25 c.cm.
"	10 mins.	19 c.cm.
"	20 mins.	12 c.cm.
"	30 mins.	5.6 c.cm.
"	60 mins.	0.6 c.cm.

The loss of ethyl nitrite during this time is shown in the graph (Fig. 2), where the ordinate represents percentage of ethyl nitrite and the abscissa the time the mixture was allowed to stand. A similar curve was obtained when brine was used in place of water. As will be shown subsequently, the spirit itself, when exposed, does not lose nitrite anything like so rapidly. That the loss is due to

Fig. 2.—Graph showing loss of ethyl nitrite when spiritus aetheris nitrosi, B.P., is mixed with an equal volume of water and allowed to stand in an open vessel.

dissipation of the ethyl nitrite by exposure is shown by the fact that a similar mixture of equal parts of spiritus aetheris nitrosi and water immediately corked and left overnight lost only 50 per cent. of ethyl nitrite.

The following table shows the loss of ethyl nitrite when a 10 per cent. solution of sweet spirit of nitre in water is

allowed to stand in a corked medicine bottle at ordinary temperatures in a dull light; and the accompanying figure (Fig. 3) illustrates graphically the loss of ethyl nitrite under these conditions.

TABLE III.

Time after Mixing.	C.cm. of NO.
0	3.5
2 minutes	2.6
1 hour	2.2
21 hours	1.8
45 "	1.5
69 "	0.8
95 "	0.4

Fig. 3.—Graph showing loss of ethyl nitrite when a 10 per cent. solution of spiritus aetheris nitrosi, B.P., in water is dispensed and allowed to stand in a corked medicine bottle.

That the degree of dilution of spiritus aetheris nitrosi with water affects to a certain extent the immediate loss of ethyl nitrite was shown among other methods by running 5 c.cm. of the spirit into the nitrometer and adding successive quantities of 5 c.cm. of water and measuring the gas given off. After the first addition of water, 2.4 c.cm. of ethyl nitrite gas was liberated. With each further addition of 5 c.cm. of water 0.2 c.cm. of gas was discharged.

Dilution with water does not appear to affect the other ingredients of spiritus aetheris nitrosi to any material extent.

Changes on Keeping.

The effect of keeping spiritus aetheris nitrosi under the usual conditions of retail trade has led to some difference of opinion. Our own experience on this point may therefore

Fig. 4.—Graph showing the loss of ethyl nitrite in sweet spirit of nitre of (i) the *British Pharmacopoeia* (top line, P); (ii) the *German Pharmacopoeia* (middle line, F); and (iii) in *liquor ethyl nitriti*, B.P. (bottom line, G), during the time the bottles were frequently opened (continuous line), and during the time they were rarely opened (broken line).

be of value. When kept in a stoppered bottle in an upright position ethyl nitrite is lost owing mainly to its evaporation. If a full bottle is kept unopened in the dark the loss is gradual; it is much more rapid when the bottle is only

partially full. Thus a bottle nearly full lost 8 per cent. of its ethyl nitrite in little more than a month when kept unopened in the dark; the same bottle nearly empty kept under the same conditions lost 30 per cent. of its nitrite in nine days. When a bottle is occasionally opened the loss of nitrite is also much more rapid. A specimen kept in an amber-coloured bottle which was being frequently opened lost 25 per cent. of its nitrite in five weeks. When somewhat more than half full it was left unopened for four months, and only lost 27 per cent. of its nitrite. The loss of ethyl nitrite in preparations kept in colourless bottles, and used at intervals, is illustrated in Fig. 4. This graph suggests that the ethyl nitrate present in sweet spirit of nitre tends to diminish the loss of ethyl nitrite.

These observations led to some experiments on the effect of free exposure of spiritus aetheris nitrosi. When exposed in an open vessel, ethyl nitrite is lost rapidly. The spirit naturally evaporates, and the volume decreases, but to a much less extent. The effect on the volume of the spirit and the amount of nitrite produced by exposure of 50 c.c. in a measuring cylinder for three days is shown in the accompanying graph (Fig. 5). The aldehyde present

Fig. 5.—Graph showing decrease in volume of spirit (broken line) and diminution in concentration of ethyl nitrite (continuous line) when sweet spirit of nitre is exposed in a narrow measuring cylinder.

in the spirit also diminishes, but to a relatively slight extent. In four days it fell 23 per cent.—from 0.52 to 0.4 per cent.

The acetaldehyde may be a factor in causing loss of ethyl nitrite, but as we found no aldehyde in freshly prepared sweet spirit of nitre we are inclined to regard the presence of this substance as due to subsequent secondary reactions, and some of our experiments seem to indicate that an equilibrium is eventually established between the amounts of ethyl nitrite and of aldehyde present. The addition of 0.6 per cent. of pure aldehyde to a 1.85 per cent. solution of ethyl nitrite in absolute alcohol caused an initial and relatively rapid diminution in the quantity of ethyl nitrite as compared with the original solution, but eventually the loss in the two solutions became uniform.

The changes which the spirit undergoes on keeping are difficult to follow, but they are probably due in the first instance to hydrolysis of some of the ethyl nitrite and the formation of a small amount of nitrous acid. The increase of acidity was followed by conductivity experiments carried over seven days. They showed that the change during this period was practically uniform, a graph of the change in electrical conductivity forming practically a straight line.

Our examination of this preparation seems to show that the commonly accepted view that ethyl nitrite is the active ingredient is correct. Although the other ingredients play a part in its action this is a subordinate one, and is of little practical importance. The rapid loss of ethyl nitrite which follows the addition of water strongly suggests that to obtain the best effects it is necessary to prescribe sweet spirit of nitre as such and dilute it just before administration.

II.—FLUID EXTRACTS OF SENNA.

BY

RALPH STOCKMAN, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, UNIVERSITY OF GLASGOW.

I RECEIVED from Mr. C. A. Hill three specimens of liquid extracts made from Alexandrian senna. He informed me that all three were prepared in the same way—by maceration in water, concentration, and the addition of 25 per cent. of 90 per cent. alcohol to preserve them. Sixteen fluid ounces of the liquid extract represent 1 lb. of the crude drug. The preparations were made respectively (1) from the whole fruits (the preparation commonly known as ext. sennæ leguminum liquidum, liquid extract of senna pods, or merely liquid extract of senna), (2) from the pericarp freed from the seeds, (3) from the uncrushed seeds.

I used these preparations as ordinary aperients in my infirmary wards for some months, the usual dose being 1 fluid drachm.

(2) I have no doubt that (2) is the best preparation. It usually acted as a satisfactory purgative, and caused less pain and griping than the others. Sometimes, however, there was a good deal of griping and pain.

(1) With this preparation the purging was more violent; there was often complaint of severe griping, sometimes with sickness and faintness.

(3) With this there were frequent complaints of pain and griping, and it was decidedly less effective as a purgative than (1) and 2. Possibly this might be due to the purgative principles not being fully extracted.

III.—COPAIBA OIL AND RESIN.

BY

RALPH STOCKMAN, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, UNIVERSITY OF GLASGOW.

I RECEIVED from Mr. J. C. Umney specimens of pure oil of copaiba and of the resin of copaiba. He informed me that they were obtained from one sample of copaiba.

The object of the investigation was to ascertain whether the oil or resin, or both, constitute the active constituents in the oleo-resin of copaiba.

I gave the oil of copaiba in doses of 15 minims three daily and 15 minims six times daily and the resin of copaiba in doses of 15 grains and 30 grains three daily as an emulsion with macilage only. Their action was first tested on three cases of gonorrhoea. In each case the resin was given first—in 15 to 30 grain doses three daily. The patients were in hospital and subjected to careful daily observation. The resin was quite well tolerated by the stomach, but had apparently no effect on the urethral discharge. It caused no urethral irritation. Subsequent treatment in each case with oil of copaiba was followed by distinct improvement, especially when the dose was raised to 15 minims six times daily.

I made a large number of observations to test whether the oil and resin increased the antiseptic powers of the urine. Both substances are excreted in the urine. It is unnecessary to detail the experiments, but the result obtained was that the resin of copaiba is either inert or nearly so, while the oil of copaiba exerted a distinct effect in delaying putrefaction and in hindering the growth of certain organisms artificially added to the sterilized urine.

My conclusion is that the resin of copaiba is practically inert as a genito-urinary antiseptic.

THE Cancer Committee of the Danish Medical Association has, it is announced, decided to postpone till further notice the fourth international conference on cancer, which was to have been held at Copenhagen in 1916.

ACCORDING to the *New York Medical Journal*, scopolamine-morphine anaesthesia in childbirth has been discontinued in the St. Louis City Hospital. The treatment has been employed since last February, and the reason given for its discontinuance is that the method has not proved to be entirely satisfactory.

Experimental Observations

ON THE

ANTISEPTIC ACTION OF HYPOCHLOROUS ACID AND ITS APPLICATION TO WOUND TREATMENT.

BY

J. LORRAIN SMITH, M.D., F.R.S.,
PROFESSOR OF PATHOLOGY;

A. MURRAY DRENNAN, M.B., F.R.C.P.E.,
FELLOW OF CLINICAL PATHOLOGY, UNIVERSITY OF OTAGO, N.Z.;

THEODORE RETTIE, D.Sc.,

RESEARCH ASSISTANT UNDER MEDICAL RESEARCH COMMITTEE;

WILLIAM CAMPBELL, M.B., B.Sc., LIUT. R.A.M.C.,
DEMONSTRATOR OF PATHOLOGY.

(From the Department of Pathology, University of Edinburgh.)

The primary object of the following investigation was to find an antiseptic which could be applied as a first dressing in the field to prevent sepsis.

The ideal antiseptic for the type of infection which occurs in wounds received in the field must possess the power of rapidly destroying spores as well as ordinary bacterial forms. There are two chief laboratory methods of investigating the action of antiseptics:

1. By testing their action in killing or preventing the growth of organisms on artificial culture media.
2. By testing their action in sterilizing infected organic matter.

In our investigation we employed both methods, but especially the latter, as the conditions here resemble more closely those occurring in infected wounds containing much necrotic tissue or other organic matter.

The result of preliminary observations was to direct attention to the hypochlorites. It has been accepted, especially by those working at disinfectants for public health purposes, that the hypochlorites are among the most potent germicides. Ridal,¹ using carbolic acid as a standard, expresses the germicidal power of hypochlorites as follows: Carbolic acid, 100; hypochlorites, 14,600 to 22,000.

The hypochlorites, used mainly in the form of bleaching powder, have been largely employed for sterilizing water supplies, but their use in general surgery as antiseptics has been very limited. It is an interesting fact that as far back as 1846 Semmelweis stamped out an epidemic of puerperal fever in Vienna by the use of bleaching powder.

Solutions of alkali hypochlorites, for example "Eau de Javelle," have been used with success in surgical practice. The fundamental practical difficulty in the use of hypochlorites is that in solution they rapidly lose their strength by decomposition. In the case of Eau de Javelle this difficulty has been overcome by making a strongly alkaline solution; but this constitutes a new difficulty, in that such a highly alkaline solution cannot be applied to the tissues unless greatly diluted.

In our observations on the hypochlorites we found that hypochlorous acid is a more potent germicide than its salts, and we have accordingly devised a method in which the free acid is employed as the antiseptic agent. The acid may be used as a gas or as a solution in water.

HYPOCHLOROUS ACID.

For use as an antiseptic the gas is most conveniently prepared by the action of boric acid on bleaching powder in the presence of a small quantity of water. The solution is obtained when the same action occurs in the presence of a large quantity of water.

For convenience we have given the name "Eusol" to a powder consisting of equal weights of finely ground bleaching powder and powdered boric acid intimately mixed; while the solution of free hypochlorous acid prepared in this way we have named "Eusol."

METHODS OF PREPARATION AND CHEMICAL NOTES.

To prepare Eusol, ordinary commercial bleaching powder or chloride of lime is ground in a mortar to a fine powder, and then intimately mixed with an equal weight of boric acid powder. The mixture should be kept in closely stoppered bottles, and not exposed to light more than necessary.

Eusol may be prepared by two methods:

1. Twenty-five grams of Eusol are shaken up with 1 litre of water, allowed to stand for a few hours, then filtered through cloth or filter paper.

2. To 1 litre of water add 12.5 grams bleaching powder, shake vigorously, then add 12.5 grams boric acid powder and shake again. Allow to stand for some hours, preferably overnight, then filter off, and the clear solution is ready for use.

This solution contains:

Hypochlorous acid	0.54 per cent.
Calcium bichlorate	1.28 "
Calcium chloric	0.17 "
Total	1.99

The hypochlorous acid is estimated by titration with N/10 arsenious acid solution; this method is best, as the presence of chlorates does not affect the result.

The chemical reaction involved in the preparation of hypochlorous acid by the method described may be represented by the following equation:

If the reaction takes place in the presence of a large quantity of water, a solution of hypochlorous acid is formed; if little water is used, gaseous hypochlorous acid is given off.

The hypochlorous acid in the form of a gas is more mobile, and will be absorbed by the tissue more rapidly and in larger quantity than from the solution; this will explain its greater efficiency as an antiseptic.

As the ultimate decomposition product in the tissue is hydrochloric acid or sodium chloride, there is no reason to fear toxic absorption from this antiseptic.

A concentration of 0.5 per cent. hypochlorous acid has been found the most satisfactory. Stronger solutions may be prepared by this method, but no advantage is gained, as they rapidly lose strength, coming down to about 0.5 per cent. free acid, after which they decompose more slowly; for practical purposes a solution of 0.5 per cent. remains effective for from three weeks to a month. The rate of decomposition may be seen from the following experiments:

Solutions made up—

(1) March 25th, 1915	0.83 per cent.
" 26th, "	0.76 "
" April 15th, "	0.33 "
(2) March 25th, 1915	0.42 per cent.
" 26th, "	0.4 "
" April 15th, "	0.3 "
(3) March 11th, 1915	2.02 per cent.
" 12th, "	1.5 "
" 16th, "	0.78 "

From these results it appears that a solution originally 0.83 per cent. decomposes to 0.3 per cent. in the same period as a 0.4 per cent. solution. A solution of even 0.25 per cent. HClO has been found effective as an antiseptic both by experiment and in surgical practice.

Andrews and Orton² carried out an important elaborate investigation on the value of hypochlorous acid as a disinfectant. They found that very dilute solutions of hypochlorous acid have intense antiseptic properties. They showed that a suspension of *Staphylococcus pyogenes aureus* in pure distilled water was sterilized in one minute by the presence of 1 part of HClO in 100,000. In a suspension in broth I in 5,000 did not, but I in 3,000 did, kill the staphylococcus in 30 minutes. From this they concluded that the potency of the pure acid was so much diminished by the presence of organic matter that it was unsuited to ordinary use.

We carried out various tests on the decomposition of much stronger solutions in the presence of organic matter.

Decomposition in the Presence of Organic Matter.

1. To 100 c.cm. of 0.4 per cent. HClO there was added 1 gram of intestine; this was kept at room temperature and the solution tested at intervals:

Original solution	= 0.4 per cent.
After 30 minutes	= 0.34 "
After 105 minutes	= 0.33 "

2. A similar experiment:

Original solution	= 1.6 per cent.
After 35 minutes	= 1.5 "

3. To 5 c.cm. of broth were added 1.5 c.cm. 0.5 per cent. HClO:

Solution, giving	0.25 per cent.
After 30 minutes	0.18 "

4. Experiment similar to (5):

Original solution	= 0.8 per cent.
After 5 minutes	= 0.8 "
After 30 minutes	= 0.7 "

As a solution of 0.5 per cent. HClO may be safely applied to open wounds, the objection which Andrewes and Orton have based on experiments with very dilute solutions does not apply.

EXPERIMENTAL TESTS.

1. Preliminary.

In the first series of observations relatively small amounts—15 to 30 c.cm.—of the antiseptic to be tested were used. Equal portions of large intestine, or other infected tissue obtained in the *post-mortem* room, were exposed for definite times at room temperature to the action of the antiseptic. The tissue was then washed in several changes of sterile water and incubated in peptone broth. The results were read in twenty-four and forty-eight hours. It is unnecessary to detail these. The following antiseptics were tested:

Phenol	Salicylic acid (1 per cent. alcoholic solution)
Acrosyl	Sod. salicylate (10 per cent. aqueous)
Kymol	Methyl salicylate (10 per cent. in spirit)
Chinosol (1 in 3,000)	Glycerine
Hydrogen peroxide	Bleaching powder (10 per cent.)
Mercury binoiodide (1 in 1,000 aqueous)	Bleaching powder and hydrogen peroxide
Tinct. iod. mit.	Boric acid (saturated aqueous solution).
Potassium permanganate (4 per cent.)	
Methylated spirit	
Turpentine	

In the above experiments the infected tissue was sterilized on one occasion only—namely, where 1 in 20 phenol had acted for thirty minutes. In all the others growth occurred within twenty-four hours.

These results were probably due in part to the fact that so small an amount of antiseptic was used. The amount of antiseptic used has been shown to have a very important influence on the result (Chick and Martin²).

In the second series of experiments larger amounts of antiseptic were used; as a rule 200 c.cm. The details of these are shown in the following table.

(D).—The tissue used in this series was child's intestine. Consequently there was less thickness of tissue to penetrate.

Amount.	Antiseptic and Strength.	Time.	Growth.	
			24 hrs.	48 hrs.
200 c.cm....	Phenol, 1 in 20	30 min.	—	?
200 c.cm....	Salicylic acid, 1% in alcohol	30 min.	?	+
200 c.cm....	Sod. salicylate, 10%	30 min.	++	++
200 c.cm....	Bleaching powder, 10%	30 min.	—	—
200 c.cm....	Chinosol, 1 in 500	30 min.	+	+++
200 c.cm....	Eau de Javelle	30 min.	—	—
200 c.cm....	HaO ₂ (10 vols.)	30 min.	++	+++
300 c.cm....	HaO ₂ (3 vols.), 100 c.cm.; Bleaching powder, 10%, 200 c.cm.	40 min.	-?	++
80 c.cm....	Iodine	30 min.	+	++
200 c.cm....	Boric acid, saturated at 37° C.	50 min.	—	+

From this table it is seen that only bleaching powder solution and 1 in 20 phenol were effective. The boric acid solution tested at 37° C. for fifty minutes could not be exactly compared.

E.—A similar series on large intestine gave no sterilization with any antiseptic.

F and G.—Tissue used was large intestine; 1.2 grams were taken, and parallel tests were made at room temperature and at 37° C.

In this series bleaching powder, 10 per cent. and 5 per cent. was the most effective in preventing or inhibiting growth; iodine and 1 in 20 phenol caused some inhibition.

2. Experiments with the Powder "Eupad"

K.—This was the first experiment in which free hypochlorous acid was employed as a gas. The amount of

intestine used was 1 gram. Each portion was subjected to the action of the antiseptic for thirty minutes. In the first observation a 10 per cent. solution of bleaching powder was used, but in the others 1 gram of dry powder was spread around the piece of intestine and moistened with a few drops of water. The pungent odour of hypochlorous acid given off when the proportion of bleaching powder to boric acid was 1 in 1 was much more noticeable than in the other proportions.

	24 hrs.	60 hrs.
10% bleaching powder	—	+
1 bleaching powder to 3 boric acid	—	++
1 bleaching powder to 2 boric acid	—	—
1 bleaching powder to 1 boric acid	—	—
Bleaching powder alone	—	—
Boric acid powder alone	++	+++
Tissue alone	+++	++++

The conclusion from the above was that hypochlorous acid was more effective than hypochlorite.

C.C.—Effect of Gaseous Hypochlorous Acid.

In Nos. (1) and (2) the intestine was separated from the moistened powder by a layer of corrugated and damped filter paper. In No. (3), 1 gram of the moistened powder in a watch-glass was placed in a Petri dish alongside of, but not in contact with, a piece of intestine; thus only the gas was allowed to act, and that at a distance.

Antiseptic.	Tissue.	Time.	Result.
(1) The gas set free from 1 gram moistened Eupad	1 gram child's intestine	24 hrs. at 37° C.	Sterile
(2) The gas set free from 1 gram moistened Eupad	1 gram child's intestine	2 hrs. at 37° C.	Sterile
(3) The gas acting at a distance...	1 gram child's intestine	24 hrs. at 37° C.	Sterile

NOTE. In each case the hypochlorous acid was neutralized, at the end of the specified time, by a solution of sodium thiosulphate. Control experiments on tissue untreated with antiseptic, but similarly washed, gave copious growth in culture.

E.E.—1 Similar Experiment with Adult Intestine from a Case of Generalized Peritonitis.

Antiseptic.	Time.	Result. Growth in	
		24 hrs.	48 hrs. and later.
(1) 2 grams Eupad moistened and covered with filter paper (same as in C.C. (1))	24 hrs. at 37° C.	—	—
(2) 2 grams Eupad moistened and covered with filter paper (same as in C.C. (1))	1 hr. at 37° C.	?	+
(3) 1 gram used as in C.C. (3)	24 hrs. at 37° C.	—	—
(4) 1 gram used as in C.C. (3)	1 hr. at 37° C.	+	+

F.F.

Antiseptic.	Tissue.	Time.	Result. Growth in	
			24 hrs.	48 hrs. and later.
(1) 2 grams moistened Eupad applied over all surfaces of tissue	1 gram adult intestine much swollen	24 hrs. at 37° C.	—	—
(2) 2 grams moistened Eupad applied over all surfaces of tissue	1 gram adult intestine much swollen	1 hr. at 37° C.	—	—
(3) 1 gram moistened Eupad applied over all surfaces of tissue	1 gram adult intestine much swollen	20 hrs. at room temp.	—	—

The conclusion from these series of experiments was that where the gaseous acid alone was acting a marked sterilizing result followed. Where the exposure was for only one hour sterilization was produced in one case out of the three.

In all these experiments the large intestine was used; the pieces selected were of the same weight, and relatively of the same thickness. In some cases the intestine was incubated overnight. In all cases there was a strong fetor. The bacteriology was not investigated in each case, but in several instances an examination revealed the presence of innumerable organisms, both spore bearers and ordinary forms.

Immediately on the application of the gas the odour disappeared. After the action had proceeded for some time a distinct bleaching effect was produced.

3. Experiments with the Solution Ensil.

In the following experiments the strength of the hypochlorous acid is given in each case; in several instances stronger solutions than the standard 0.5 per cent. were employed. These experiments were similar to those already described for the other antiseptics. Phenol 1 in 20 was used as a control in most instances.

Antiseptic.	Tissue: Pneumonic Laug.	Time.	Result. Growth in		
			24 hrs.	48 hrs.	72 hrs.
(1) 50 c.cm. unfiltered emulsion, approximately 2% HClO	1.0 gram 2.5 "	30 min.	?	-	++
(2) 50 c.cm. filtrate, approximately 2% HClO	1.0 gram 2.5 "	30 min.	-	-	++
(3) 50 c.cm. bleaching powder, 10% solution	1.0 gram 2.5 "	30 min.	?	-	++
(4) 50 c.cm. phenol 1 in 20	1.0 gram 2.5 "	30 min.	?	+	++
Control: Tissue alone			++	++	+++
(Comparison with Espad—(1) Moistened powder	1.0 gram 2.5 "	30 min.	-	-	-
(2) Moistened powder	1.0 gram 2.5 "	10 min.	-	-	+

NOTE.—The different weights of lung used were of different thickness, the 2.5 gram being approximately twice as thick as the 1.0 gram. In all these experiments growth occurred after 48 hours, showing that penetration had not been sufficient. Experiments with dry powder on the same tissue have been added for comparison, and here it will be noticed that even after only ten minutes' exposure almost complete sterilization has been effected. This tissue contained living spore-bearing bacilli.

Further Observations on the Sterilizing Effect on Intestine of Hypochlorous Acid in Different Strengths, and comparison with Bleaching Powder and Phenol.

In all the above experiments the tissue after exposure to the hypochlorous acid was washed in sterile water and sterile thiosulphate until no trace of hypochlorous acid could be detected.

The thickness and state of decomposition of the portions of intestine determine the result to a large extent.

Hypochlorous acid 0.5 per cent. never completely sterilized the tissue when applied for thirty minutes; in that time, however, 3.2 per cent. HClO gave complete sterilization with adult colon. In twenty-four hours, at room temperature 0.5 per cent. hypochlorous acid did produce complete sterilization, though not invariably; and even 0.25 per cent. gave this result.

If the result of the application of the powder to intestine be referred to, it will be seen that much more uniform sterilization occurred; the antiseptic in this case being in the gaseous form.

In the control experiments with phenol, occasional sterilization occurred with 1 in 20, but failed with 1 in 40. Great variation in the action of 1 in 20 phenol was noticed in all the experiments; it is possible this may be due to

the presence or absence of spore-bearing organisms. As will be seen below, phenol has little action on spores.

4. Experiments with Cultures of Organisms on Artificial Media.

O. The organisms used were *B. coli*, *Staphylococcus pyogenes aureus*, *B. anthracis* (spores in culture). Hypochlorous acid 0.5 per cent. was applied, and control experiments were done with 1 in 20 phenol; 10 c.c.m. of antiseptic were added to 10 c.c.m. of a broth culture, or to an agar slope culture. Most of the experiments were carried out at 37° C. The results are shown in tabular form:

Antiseptic.	Medium.	Organism.	Time of Application and Result.		
			2 min.	15 min.	30 min.
HClO 0.5 %	Broth	<i>B. coli</i>	-	-	-
HClO 0.5 %	Broth	<i>Staphylococcus</i>	-	-	-
HClO 0.5 %	Broth	<i>B. anthracis</i>	-	-	-
HClO 1.0 %	Agar	<i>B. coli</i>	-	-	-
HClO 1.0 %	Agar	<i>Staphylococcus</i>	-	-	-
HClO 1.0 %	Agar	<i>B. anthracis</i>	-	-	-
Phenol 1 in 20	Agar	<i>B. coli</i>	-	-	-
Phenol 1 in 20	Agar	<i>Staphylococcus</i>	-	-	-
Phenol 1 in 20	Agar	<i>B. anthracis</i>	+	-	+

P.

Antiseptic.	Medium.	Organism.	Time of Application (5 min.) and Result.		
			-	-	-
HClO 0.67 %	Agar	<i>B. anthracis</i>	-	-	-
HClO 0.9 %	Agar	<i>B. anthracis</i>	- washed as usual.	-	-
HClO 0.9 %	Agar	<i>B. anthracis</i>	- unwashed.	-	-
Phenol 1 in 20	Agar	<i>B. anthracis</i>	+	-	-

R.

Antiseptic.	Medium.	Organism.	Time of Application and Result. (Room Temperature.)		
			1 min.	2 min.	3 min.
HClO 0.25 %	Agar	<i>B. anthracis</i>	+	+	not washed.
HClO 0.36 %	Agar	<i>B. anthracis</i>	+	+	not washed.

NOTE.—In the case of the broth cultures, after treatment with the antiseptic a small quantity was taken and added to a fresh culture tube. The agar cultures were first washed with sterile water and then subcultures made.

From the above tables it will be seen that 0.5 per cent. hypochlorous acid in every case killed the organisms even with only two minutes' exposure. Anthrax spores were killed as readily as the non-sporing organisms. While phenol 1 in 20 killed staphylococci and coli, it failed to affect the anthrax, even after thirty minutes' exposure.

Weaker strengths of hypochlorous acid than 0.5 per cent. failed to kill anthrax spores in three minutes at room temperature.

V.—Experiments on Subtilis Spores with Eusol, Eau de Javelle, and Phenol.

An emulsion of *subtilis* spores was filtered through glass wool, and one drop of emulsion was added to 1 c.c.m. of the antiseptic; after five minutes the antiseptic was neutralized by sodium thiosulphate solution, and the whole was then mixed with 10 to 15 c.c.m. of broth and incubated. The experiments were carried out at room temperature.

A.

Antiseptic.	Result: 24 hrs.	Growth in 1 week.
(1) HClO 0.5 % (= 0.5 % Cl)	-	-
(2) Bleaching powder solution (= 0.75 % Cl)	?	+
(3) Eau de Javelle (= 0.32 % Cl)	?	+
(4) Phenol 1 in 20	-	-

* As the phenol could not be neutralized as in the case of the other antiseptics a relatively large amount remained in the culture, and thus the negative result is not a true value.

B.—The same series of experiments was done, but the thiosulphate was added to the antiseptic before the emulsion was put in, the antiseptic being thereby neutralized before the bacteria were added. The phenol, as before, remained in the culture unaltered. The order, therefore, of the two series was as follows:

- A. Antiseptic, emulsion, thiosulphate, broth.
B. Antiseptic, thiosulphate, broth, emulsion.

The result of B. was as follows:

- (1) + (2) + (3) + (4) (phenol) -.

W.—Experiments with Anthrax, Sporing Culture.

The method was similar to that used in V. (A.). One drop of filtered anthrax emulsion was added to 1 c.c.m. of the antiseptic solution, and at intervals of one, two, and five minutes one loopful of this was taken out and inoculated into a tube of broth and incubated.

Antiseptic.	Time of Exposure.	Growth after	
		24 hrs.	48 hrs.
(1) Eau de Javelle, HClO (= 0.32 % Cl)	1 min.	-	-
	2 "	-	-
	5 "	-	-
(2) Eau de Javelle (= 0.32 % Cl)	1 min.	+	+
	2 "	+	+
	5 "	+	+
(3) Phenol (1 in 20)	1 min.	+	+
	2 "	+	+
	5 "	+	+

A further experiment was done on the same lines, but using five loopfuls instead of one to inoculate the broth tube. This gave the same result.

A.A.—This is a similar experiment with weaker solutions of hypochlorous acid on anthrax spores.

Antiseptic.	Time of Application.	Result.
HClO 0.25 % ...	1 min.	4 tubes inoculated; only one remained sterile.
HClO 0.25 % ...	1 min.	4 tubes inoculated, and all gave a growth of anthrax.

It will be noticed from the above that while 0.5 per cent. hypochlorous acid was effective in killing anthrax spores in one minute, 0.25 per cent. was too weak, and only succeeded in 1 out of 8 experiments.

L.L.—Experiments on the Effect of the Gaseous Hypochlorous Acid on Anthrax Spores.

A sporing culture was spread upon pieces of filter paper, which were then dried. The gas was prepared by the action of a few drops of water on 1 gram of Eupad; this was placed in a watch-glass in a Petri dish. The piece of filter paper to be tested was placed in the Petri dish alongside, but not in contact with, the watch-glass. Two series were done—one in which the paper was moistened; the other in which it was kept dry. The results were as follows:

A.—Series with Dry Filter Paper.

Time of Exposure.	Result. Growth in Broth after:		
	24 hrs.	48 hrs.	72 hrs.
Three similar experiments, 5 min. each	+	+	+
Three similar experiments, 10 min. each	+	+	+
Two similar experiments, 30 min. each	+	+	+
One experiment, 70 min.	—	—	—
One experiment, 2 hours	—	—	—

B.—Series with Moistened Filter Paper.

Time of Exposure.	Result. Growth in Broth after:		
	24 hrs.	48 hrs.	72 hrs.
Two similar experiments, 5 min. each	—	—	—
One experiment, 15 min.	—	—	—
One experiment, 30 min.	—	—	—
One experiment, 60 min.	—	—	—
Control with filter paper alone, in broth	++	+	+++

This series is especially interesting. The potency of the gas is manifest, and in conjunction with the experiments on intestine this series demonstrates the efficiency of the gas acting at a distance and its penetrating effect. No microscopical change was observed in anthrax spores when treated with solutions of hypochlorous acid of different strengths.

ANIMAL EXPERIMENTS.

In the first series hypochlorous acid alone, in different strengths, was injected into rabbits in order to test its toxic or other effects.

Hypochlorous Acid Alone.

Expt.	Where Injected.	Strength.	Amount.	Result.	Remarks.
1	Subcutaneous	0.37%	5 c.cm.	Lived	No pain, animal not disturbed.
2	Subcutaneous	1.7%	"	Lived	Slight pain, then at ease.
3	Intramuscular	0.37%	"	Lived	When killed muscle was pale from necrosis around injection.
4	Intramuscular	1.7%	"	Lived	Pain for a few seconds, lethargic.
5	Intraperitoneal	0.37%	"	Lived	Haemorrhages in stomach post mortem.
6	Intraperitoneal	1.7%	"	Died in 24 hrs.	No pain animal not disturbed.
7	Intravenous	0.37%	"	Lived	Death took place suddenly after 2.5 c.cm. had been injected. No thrombosis.
8	Intravenous	1.7%	"	Died	Necrosis of muscle, as in (5).
9	Intramuscular	1.2%	"	Lived	No disturbance whatever.
10	Intraperitoneal	1.2%	"	Lived	
11	Intravenous	0.48%	"	Lived	

It was noted in the above experiments that little or no pain resulted from the injections. In the case of the fatal result in (6) it was doubtful whether the injection was responsible, and a similar experiment with a 1.2 per cent. solution caused no disturbance. The most interesting result was seen in (7), where an intravenous injection of a 0.37 per cent. solution caused no disturbance whatever; this is a result which needs further study, and we intend to pursue the point later. The experiment was repeated with 0.48 per cent. solution, and the animal was in no way disturbed. The stronger solution (1.7 per cent.) was fatal to the animal almost immediately; it became suddenly comatose, and after a few sighing respirations it ceased to breathe, the heart beat irregularly for some seconds, and there was no clotting in the heart or vessels. The animals which survived were killed later, and at the site

of inoculation there was oedema of the tissues, and, in the case of the intramuscular injections, distinct necrosis of the muscle along the path of injection occurred, with considerable oedema of the fibres.

The next series of experiments were done with anthrax cultures containing spores. An agar culture was emulsified with 5 c.cm. of normal saline, and equal amounts of Eusol of different strengths were added; 2.5 to 3 c.cm. of this mixture were injected subcutaneously, either at once or after periods of one to five minutes. Emulsions were also made with the Eusol alone, 5 c.cm. being used to wash off one agar culture, and 2 to 3 c.cm. of this injected subcutaneously. Controls were done with equal amounts of anthrax emulsion alone in saline, and with emulsions of anthrax in 1 in 20 phenol.

"Eusol" and Anthrax Spores.

Expt.	Animal and Weight.	Material Injected and Amount.	Time of Contact.	Result.
1	R. 11 D. 2350 g.	2.5 c.cm. anthrax in saline	—	Died in 48 hrs.; anthrax recovered.
2	R. 12 D. 1820 g.	2.5 c.cm. anthrax in saline + 2.5 c.cm., 1.2% Eusol	Immediate injection	Died in 3 days; no anthrax found, but Gram-negative coccus.
3	R. 13 D. 2050 g.	2.5 c.cm. anthrax in saline + 2.5 c.cm. phenol, 1 in 20	Immediate injection	Died in 48 hrs.; anthrax recovered.
4	R. 14 D. 2050 g.	2.5 c.cm. anthrax in 1.2% Eusol	Immediate Injection	Died in 4 days; anthrax recovered.
5	R. 15 D. 1950 g.	3 c.cm. anthrax in phenol, 1 in 20	15 min.	Died in 48 hrs.; anthrax recovered.
6	R. 16 D. 1670 g.	3 c.cm. anthrax in 1.25% Eusol	5 min.	Died in 3 days; anthrax recovered.
7	R. 5 C. 2250 g.	3 c.cm. anthrax in phenol, 1 in 20	15 min.	Died in 3 days; anthrax recovered.
8	R. 6 C. 2040 g.	3 c.cm. anthrax in 1% Eusol	5 min.	Lived.
9	R. 7 C. 2300 g.	3 c.cm. anthrax in 0.5% Eusol	5 min.	Died in 3 days; anthrax recovered.
10	R. 17 D. 2090 g.	Emulsion of anthrax in saline and filtered through glass wool; 2 c.cm. of this mixed with 2 c.cm. 1% Eusol, 1 c.cm. of mixture injected (strength of Eusol = 0.5%)	1 min.	Lived.
11	R. 18 D. 2000 g.	Do. do.	2 min.	Lived.

Cultures were made from the anthrax culture before emulsification, and all were positive. After treatment with phenol, cultures were made in Experiments 5 and 7, and these were positive. Cultures made from the emulsions containing Eusol in Experiments 6, 8, 9, 10, and 11 were negative.

It was found impossible to avoid the formation of lumps of culture in the emulsions, especially those made with Eusol direct; consequently in the last two experiments the lumps were removed by filtration through glass wool, leaving a uniform opalescent emulsion. The difference between the cultural and the animal results is to be explained by the fact that, in making the culture from the injection fluid, only a loopful of the fluid was taken, while both fluid and lumps were injected into the animals.

It will be noticed that even where the unfiltered emulsion was injected death was delayed as compared with the phenol experiments; death was due to the survival of organisms in the lumps. The experiments with filtered emulsion bear this out. Where phenol was used the animals died in every case, even although the phenol was allowed to remain in contact with the anthrax for fifteen minutes before injection.

These results are quite in keeping with the previous results of the action of Eusol on anthrax cultures, and they show that the organisms are killed, and have not merely their power of growth inhibited. Further, the spores are killed as well as the bacteria.

A microscopical examination of a drop of fresh blood mixed with an equal amount of 0.5 per cent. Eusol showed

no obvious change in either red corpuscles, leucocytes, or platelets; at the end of a quarter of an hour a finely granular precipitate appeared in the film, which became slightly opaque; the colour of the haemoglobin was not discharged.

CLINICAL OBSERVATIONS.

Through the kindness of our surgical colleagues we have had the opportunity of observing the results of treatment with hypochlorous acid in a number of cases.

The following statement gives the conclusions which have been justified by the application of the method in practice. As will be seen, this part of the investigation is still in an early stage, and further clinical observations will show how far the promise of the laboratory results can be realized in practice. It is only necessary here to deal with the cases in groups, reference to individual cases will be made where some special point is illustrated.

Considerably over 100 cases of all kinds have been treated with the antiseptic in one form or another.

The first group of cases is that from the surgical out-patient department of the Royal Infirmary, Edinburgh. It comprises the usual list of injuries, wounds chiefly of the head and hands, lacerated, contused, or incised, many septic.

Eusol (0.5 per cent. hypochlorous acid) was employed in this series as a lotion, a soak covered with waterproof, or a dry dressing—that is, gauze wrung out of the solution and then applied with the usual covering of wool and bandage. For comparison, similar injuries were treated with tincture of iodine or with boric soaks.

Over 50 cases have been treated, and it was noted that the majority of septic cases were clean in one to three days and healed in seven to fourteen days. In control septic cases treated with boric soaks four to six days were usually required to clean the wound.

In clean injuries little difference was to be observed between the Eusol-treated cases and the iodine-treated cases, but much less smarting was produced by the Eusol; this was especially noticed in the case of children.

In several cases where the wound appeared to be clean sepsis appeared where only Eusol dry dressings had been applied; this sepsis was removed by one application of a Eusol soak, and its appearance is to be ascribed to a too weak application having been put on in the first instance. In some cases treated with tincture of iodine sepsis also appeared, and this was easily removed by a Eusol soak, one application for twenty-four hours usually being sufficient.

The second series consisted of fourteen cases, mostly in children, occurring in the out-patient department of the Deaconess Hospital, Edinburgh. It comprised cut heads, whitlows, septic ulcers, and boils.

Both Eusol and Eupad were used in this series. The Eusol was used as in the first series. The Eupad was employed dusted on moistened gauze, and applied as a soak for five to thirty minutes; if pain occurred the soak was removed; in two cases—a cut head and a whitlow—the soak remained on for twenty-four hours with no bad results. After the Eupad dressing was removed, a Eusol soak or dry dressing was applied as the circumstances indicated. In these cases with Eupad the gas was the chief agent.

No pain was caused by the Eupad on the cut heads, and in twenty-four hours when the dressing was removed, the cuts were clean and dry, and healing occurred uneventfully in three to six days.

The whitlows also rapidly cleaned under the Eupad dressings followed by Eusol soaks, and no pain was complained of. A large boil on the leg was opened, and a drain of gauze powdered with Eupad was inserted; on the second day the wound was dry, and no pus could be expressed; the drain was repeated for another day, and afterwards only dry sterile gauze put on; it had completely healed by the ninth day.

In one case of septic sores on the arm of a child a Eupad dressing caused pain and slight vesication. This was one of the early cases where the amount of Eupad used was in excess of what was required. Also the wound was on the flexor aspect of the arm where the skin is much more easily irritated than that of the scap.

A series similar to the last, except that the patients were adults, was obtained from the Victoria Hospital, Edinburgh, at present used as an auxiliary Red Cross hospital.

The cases were mostly superficial wounds due to shrapnel. Eupad was chiefly used and it was applied either dusted on directly as a powder, or dusted on gauze and moistened; some cases had it applied as a fomentation. The Eusol was used at first chiefly as a lotion to wash the wounds, and later fomentations of it were applied. The results were very satisfactory in whatever way used; septic wounds rapidly cleaned and only in a few cases was pain complained of. It was noticed that where pain occurred it was the skin around the wound that showed signs of slight irritation and not the wound itself; by smearing vaseline on the skin around this effect was obviated. In one case only was actual vesication produced and only of very slight degree; this was a case in which the moist gauze containing Eupad had been too long and had been folded double at one end—this caused a too great concentration of the gas from the powder and consequent irritation. One case of a discharging sinus due to a bullet wound was drained by a wick of wool dusted with Eupad; within two days the discharge became serous.

In order to see if the powder could be applied in a practical form as a first field dressing, another series of cases was done at the Royal Infirmary surgical out-patient department. Sterile gauze pads, of the same size and folded in the same way as the regular first field dressing supplied to soldiers, were made, and in the centre was placed a definite amount of Eupad; at first 1 gram was inserted, but as that was found to be completely exhausted in use, 2 grams were used later. These pads were applied to injuries such as cut heads and hands when the cases were admitted to the out-patient department; if the wound were bleeding, the blood was allowed to damp the gauze; if bleeding had ceased, the pad was moistened with a little water. The pads were allowed to remain on the wound for twenty-four hours, and then further treatment was employed as indicated. Seven cases were treated with pads, and the wounds were clean on the patients' return; no pain or discomfort was complained of.

Where only 1 gram of powder was placed in the pad, no trace of hypochlorous acid could be smelt after twenty-four hours' application, but with 2 grams a slight odour was still present in the damp powder.

Recently in the same department a number of cases of chronic ulcers of the leg have been treated with Eupad, either dusted on directly or applied on damp gauze. The results have been very striking; several ulcers which had been treated with the usual methods for weeks with no apparent improvement cleaned up in a few days under Eupad.

The antiseptic has also been applied in large wounds. In the Dalmeny House Hospital (Red Cross) a number of severe shrapnel wounds have been treated with Eusol; it will be sufficient for the present purpose to refer to two of the worst cases.

CASE I.

The first was that of a soldier who had a compound comminuted fracture of the left femur. He was admitted to Dalmeny House Hospital about one month after the wound was received. There was much pain and copious foul-smelling discharge from two sinuses on the front and back of the thigh, and there was pus around the fragments of bone seen by the X rays; the temperature was raised. The wound was treated for some weeks with hydrogen peroxide syringed through; then weak tincture of iodine was similarly employed. Progress was very slow. Eusol (0.5 HClO) was then used in the same manner, and within three days the odour had disappeared and the discharge and pain were much less; within ten days the temperature had fallen to normal and the patient felt much easier. The discharge gradually became less and serous in character and the fetor did not return. The Eusol treatment was kept up, and improvement was steady and marked. X-ray photographs showed callus forming around the splintered ends, and now the bone has united and the sinuses are practically closed. From the pus a Gram-negative bacillus of the coli group was isolated. In this case there seems no reason to doubt that definite improvement followed the application of Eusol.

CASE II.

The second case was that of a soldier who had a severe shrapnel wound of the right arm, received on May 5th at Hill 60. He had been treated with boric soaks until admitted to Dalmeny House Hospital on May 15th. On admission there was extensive laceration of the extensor muscles and the radius was shattered; a gaping defect

wound was present, bathed in foul-smelling pus; there was great pain and the temperature was swinging. A soak of Eusol (0.5 per cent. HClO) diluted 1 in 4 with sterile water was applied, but had to be removed as so much pain was complained of. A dressing of hyperisotonic saline was then applied; this was also painful. Eusol was then made up in normal saline in 1 in 10 strength, and this was borne without undue pain as an arm-bath for one hour. This was repeated daily. The odour disappeared after one or two applications, the wound rapidly cleaned up, and pain disappeared. The temperature dropped in a few days to normal. By May 31st there was marked improvement and the wound was clean and granulating in spite of the fact that there were fragments of bone and shrapnel still to come away. On June 7th healing was well advanced, and only a little serous discharge was present. Skin grafting was performed on the 19th and took, and the wound was practically completely healed on June 30th.

In the ear and throat department of the Royal Infirmary cases of cerebellar abscess have been washed out with Eusol with good results; immediate removal of the marked fetor present occurred. It has also been employed in mastoid operations with similar encouraging results.

In the maternity hospital Eusol has been used, full strength, as a douche, and caused rapid diminution of discharge.

Both Eusol and Eupad have been used in several of the wards of the infirmary and by some of our surgical colleagues in their private practice; cases such as the following have been treated: Periappendicular abscess, perineal abscess, cystitis, gangrene of feet, pyorrhoea alveolaris, follicular tonsillitis.

The general conclusion from the clinical observations is that hypochlorous acid, both in solution and as a gas, has a high antiseptic value in surgical practice.

Since there is no danger of absorption of the antiseptic or its decomposition products the rule may be safely followed of applying the antiseptic in the strongest form consistent with the comfort of the patient.

Any bad effects that might arise are purely local in incidence, and therefore easily controlled.

Eusol (0.5 per cent. HClO) has so far given no indication of deleterious action even on devitalized tissues, and may be used, therefore, with impunity in full strength. Eupad, which acts in virtue of the gas given off, is much more powerful in its antiseptic action and causes more irritation. The irritation, however, chiefly affects the surrounding skin and can easily be obviated. Pain is a useful warning that the application should be diluted.

The strongest effect observed in a wound was a superficial bleaching of the tissue and slight blistering of the surrounding skin; this was only produced by a thick layer of moistened powder. We have never seen any sign of necrosis in the form of slough formation. When the powder amounts to one or two grams enclosed in a gauze pad no harmful effect is to be anticipated.

Further investigation is required to define the nature of the reaction which hypochlorous acid causes in the tissues. Although it kills organisms so rapidly, no disintegration occurs; and there is no apparent breaking down of tissue cells.

It causes congestion and oedema, and there is a flow of lymph from the surface of the wound. Two factors are at work here: a direct action by the acid on the blood vessels, and the hyperisotonic effect of the salts in solution; when the solution is diluted the hyperisotonic effect is correspondingly reduced, and the antiseptic action alone remains. It is unquestionably of the greatest value that this solution combines the hyperisotonic effect with intense antiseptic power, small risk of damage to the tissues, and entire absence of toxic absorption.

It is a matter for further investigation to inquire how far benefit may be derived from the addition of sodium chloride to the solution to increase its hyperisotonicity.

When the antiseptic is applied to a wound the discharge in the first place loses any fetor which may have been present, and from being purulent rapidly becomes serous.

The antiseptic is easily exhausted, and therefore requires frequent renewal. It should be clearly understood that the function of this antiseptic is the elimination of sepsis; once sepsis is removed from the wound it may be discontinued and replaced by any bland dressing. It is in the treatment of septic wounds that the special power of this antiseptic is made manifest.

It is to be noted that hypochlorous acid tarnishes metals, and therefore instruments should be kept in a separate cupboard, and not left in the solution longer than necessary. It bleaches and destroys cloth fabrics if left in contact with them for a prolonged period.

An important point in connexion with this antiseptic is that the ingredients are easily obtained, and at a very small outlay. The cost of making one gallon of Eusol is approximately one penny.

METHODS OF USE.

It is convenient to group these under an independent heading. While we indicate those methods we have observed in use, there are no doubt others which further experience will suggest.

(a) *Eusol*.—Standard strength, approximately 0.5 per cent. hypochlorous acid.

1. As a lotion; diluted, if necessary, with water or normal saline.
2. As a fomentation; covered with waterproof.
3. On gauze wrung out of the solution and applied without a waterproof covering.
4. As a bath; full strength, or diluted as indicated.

(b) *Eupad*.—Where it is desired to apply a more concentrated antiseptic Eupad may be employed as follows:

1. Eupad enclosed between layers of gauze or lint charged with water sufficient to moisten the powder; this is applied to the wound and covered with wool and a bandage.
2. Applied as above, but covered with waterproof. This should be applied only for a short period—ten to twenty minutes as a rule. Occasionally this strong application causes pain, and should this occur, a weaker application is indicated.
3. On strands of gauze or wool impregnated with the powder and used for drainage.
4. As a dusting powder—for example, on open septic sores.

The general principle of the antiseptic application is that it should secure the maximum antiseptic effect with the minimum of local irritation.

Where it is found desirable to increase the antiseptic effect of the solution, a little of the powder may be added to it just before it is applied, or a small amount of powder may be dusted on to the wet gauze. In these ways the action of the solution may be reinforced.

In conclusion we have to express our indebtedness to members of the surgical staffs of the hospitals to which we have referred for their kind co-operation and help in this investigation.

CONCLUSIONS.

1. Comparative tests confirm the conclusion already arrived at by various investigators that hypochlorous acid is the most powerful antiseptic known.
2. Practical methods of using this antiseptic have been devised.
3. It can be used either as a gas or as a solution. The advantage of using the gas is that it will penetrate and will act at a distance.
4. Both the gas and the solution, while extremely potent against organisms and their spores, cause little or no harm to the tissues.
5. The effect of this antiseptic is purely local; its decomposition products are devoid of toxicity, and there is therefore no danger to be apprehended from absorption.
6. A flow of lymph is induced from the wound as part of the reaction of the tissues.
7. Fetor is rapidly eliminated.
8. If pain and irritation occur they can be easily controlled by reducing the concentration of the antiseptic.
9. The practical advantages of this antiseptic for *field use* are:

- (a) It can be used as a dry powder and therefore obviates the difficulty of procuring water.
- (b) It can be introduced into the gauze pad of the first field dressing.
- (c) Where water is available the same powder can be made up as a lotion for general use.

10. The constituents of the powder are inexpensive and easily procured; and the preparation of the antiseptic is extremely simple.

11. For convenience the powder has been called "Eupad" and the solution of hypochlorous acid "Eusol."

This investigation was undertaken at the request of the Medical Research Committee.

HINTS ON WAR SURGERY.

BY

COLONEL A. W. MAYO-ROBSON, C.V.O., F.R.C.S.,

CONSULTING SURGEON EASTERN MEDITERRANEAN.

THIS unpretentious paper, made up of hints derived from practical experience, has been written at the suggestion of some of my young friends who have been called to serve almost immediately after receiving their qualification to practise, and of others who have been engaged in general practice for years but have felt it their duty to offer their services to the State in this time of great national need.

Practically all the injuries requiring attention are gunshot wounds due to rifle bullets, pieces of shell or shrapnel bullets—the first being pointed, the second irregular in shape and size, and the third round.

The wounds from rifle bullets are frequently small and aseptic, but if the missile has turned on its axis, has been diverted in its course, or has first struck the ground, it may make a very large wound, and in the last case may be septic.

The velocity of a rifle bullet in the first thousand yards being very great, a hard bone if it be struck will be shattered, and the separate fragments of bone may have so much force transmitted to them that each becomes a mischievous projectile.

Tincture of iodine seems to be the best antiseptic for use in the fighting line. Every soldier should therefore have a small quantity with him, so that he can apply a little to the wounds and to the skin for half an inch around them before applying the protective gauze pads.

The first dressing should not, as a rule, be disturbed until a hospital is reached unless there be haemorrhage, in which case it will be advisable to change it at the first dressing station in order to arrest the bleeding; if the haemorrhage is only slight, compression over the first dressing may suffice until a hospital is reached.

If, on reaching a hospital, the first dressing is dry and sticking to the wound, and there is neither pain nor bleeding, the dressing need not be disturbed.

Unless absolutely necessary, as for haemorrhage or other emergency, it is undesirable to perform set operations on the field or in transit, whether on a hospital ship or train.

Although bullet wounds are frequently aseptic and do not require a change of dressing, yet, if the wound be extensive or septic, they should be treated like shell wounds.

Shell and shrapnel wounds are, as a rule, septic, and should be freely irrigated and drained, the irrigation being subsequently repeated twice or thrice daily if possible. The best fluid for irrigation is normal saline solution, but sea water drawn from the hot-water service taps on board the hospital ships or taken up from the sea two miles from shore, or plain boiled water, or weak iodine water, or a light pink solution of potassium permanganate may be equally well used. After irrigation and free drainage the wound may be filled with a 10 per cent. saline solution or with hydrogen peroxide solution 5 to 10 per cent., but it is senseless waste to use an expensive antiseptic solution to irrigate wounds.

If the drainage is not free the wound must be enlarged or a counter opening made. The dressings must be applied in such a way as not to occlude the drainage tubes.

The removal of bullets and pieces of shell is not necessary unless the foreign bodies are causing pain, keeping up suppuration, or lying in positions dangerous to vessels, nerves, or joints.

The greater number of nerve injuries recover spontaneously, therefore early operations on nerves are to be deprecated.

In primary or recurrent haemorrhage on the field pressure should, as a rule, be adopted, and only in exceptional cases is it necessary or desirable to ligature vessels, but if the pressure has not effected its purpose the bleeding vessel or vessels must be ligatured at the first dressing station.

In secondary haemorrhage it is not well to wait for repeated bleedings but to ligature the bleeding vessel without delay, as the next haemorrhage may be fatal or may so far reduce the strength of the patient that amputation may be necessary, or possibly further treatment may even be impossible.

If, owing to unavoidable delay or to deficient drainage, gas gangrene threatens or has actually developed, a 10 per cent. solution of hydrogen peroxide should be injected deeply into the tissues at various points beyond the infected area and free incision made into the gangrenous tissues and thorough irrigation and drainage carried out.

In gas gangrene of the extremities subsequent to the treatment just mentioned the arm or leg bath can be advantageously employed, but where that is impracticable boric or iodized water poultices can be used and changed every four hours.

The application of sutures to lacerated or infected wounds should be avoided.

In abdominal injuries a morphine injection should be given or a tabloid of morphine administered by the mouth immediately the patient is discovered. It is desirable to avoid giving food, and, as far as possible, even fluid, by the mouth. Thirst may be quenched by rectal injections of normal saline fluid. These cases nearly always die if transported far in an early stage, therefore let them remain as long as possible near the front.

If peritonitis supervenes, the patient should be propped up in the Fowler position, and drained above the pubes. The operation can be carried out under local anaesthesia in a few minutes. The abdomen should not be washed, and any long operation should be avoided until the base hospital is reached, when, should anything be called for, it can be done under the most favourable conditions.

Serious head injuries bear transport badly, and must be operated on as soon as possible for the removal of blood clot and depressed bone causing pressure on the brain.

Fracture of the long bones and injuries to joints should be immobilized by splints or some temporary apparatus, obtained on the spot before removal from the field.

Conservatism is the rule of treatment for fractures, and amputation should be avoided or rarely adopted as the only possible alternative. Immediate amputation is only called for in case of complete smashing or almost total tearing off of a limb.

Later, amputation may be required for traumatic gangrene or for rapid extension of gas gangrene, and, rarely, for extensive diffused aneurysm, or for serious wound complications attended with osteomyelitis and extensive suppuration.

In all shell wounds or septic bullet wounds a dose of antitetanic serum should be administered as a prophylactic as early as possible after the injury.

In erysipelas or any streptococcal infection the use of antistreptococcal serum should not be omitted.

THE late Surgeon-General Arthur James Payne left unsettled property to the value of £49,983.

THE governors of the Tower Hamlets Dispensary, an institution founded in 1732, and carried on until recently in Stepney, resolved a few months ago to close it. This resolve was due partly to the difficulty of collecting funds, and partly to the diminution in the number of patients attributed to the Insurance Act, and to the establishment of tuberculosis dispensaries, and of medical treatment centres for school children. At a meeting on July 12th the governors received a deputation from the Stepney Board of Guardians, who desired that the dispensary should be continued, and promised an increased subscription from the board. Dr. Corner said that medical practitioners in the district regretted the closing of the dispensary, but the chairman held that that matter could not be reopened, the only question to be determined being the best method of disposing of the sum of £450, the net cash balance in the hands of the governors, who, however, also own the building, valued at £550. The meeting appears to have separated without coming to any definite decision.

THE DIAGNOSIS OF TYPHOID FEVER IN INOCULATED SUBJECTS.

By GEORGE D. DAWSON, M.D., D.P.H. MANCH.,
UNIVERSITY OF MANCHESTER.

(A preliminary account of a research carried out, under the direction of Professor Delépine, at the Public Health Laboratory, Manchester University. The expenses in connexion with this research were defrayed by a grant made by the Medical Research Committee.)

Some observations made whilst working with a certain strain of the *Bacillus enteritidis* (7160)* suggested that this bacillus might be of use in the diagnosis of typhoid fever in inoculated persons. In such cases the usual Widal test affords little or no help to a rapid diagnosis.

During the period January to June, 1915, quantitative agglutination tests, more than 1,000 in all, were made with the *B. enteritidis* 7160 and with the *B. typhosus* with blood obtained from the following classes of persons:

CLASS 1.—Persons who had been inoculated with typhoid "vaccine," and who, as far as could be ascertained, were not suffering and had not suffered from any illness resembling typhoid fever—50 cases. In none did the blood give a positive reaction with the *B. enteritidis* 7160. The blood of nearly all these cases caused agglutination of a typical *B. typhosus*; the reaction was very marked in most cases. In a small percentage the result of the test was negative.

CLASS 2.—Persons who had not been inoculated with a typhoid "vaccine," and who were suffering from typhoid fever—50 cases. The blood of all these persons caused agglutination of a typical *B. typhosus*. In 44 a positive result with the *B. enteritidis* 7160 was obtained at the first test. In 6 a negative reaction with this bacillus was found on a first examination, but on testing a second sample of blood in 5 of these 6 cases, each gave a positive reaction. From the sixth case a second specimen of blood has not yet been obtained.

These results showed beyond doubt that active typhoid infection confers on the blood a power of clumping the *B. enteritidis* 7160, which is not produced by injection of dead typhoid bacilli. They afforded strong presumptive evidence that an inoculated patient whose blood gives a positive reaction with the *B. enteritidis* 7160 is infected with the *B. typhosus* or a near ally.

CLASS 3.—To test these conclusions, 14 cases of suspected typhoid fever in inoculated men were investigated. Each case gave a positive Widal reaction. In 7 the clinical evidence decidedly favoured a diagnosis of typhoid fever, and in each case the blood was found to give a positive reaction with the *B. enteritidis* 7160. From 4 of these cases the *B. typhosus* was isolated, in 3 from the stools, and in 1 from the blood. From none of these cases was the *B. enteritidis* or a *B. paratyphosus* isolated. The other 7 cases, clinically, were much more doubtful. In none was a positive reaction with the *B. enteritidis* obtained. Careful bacteriological examinations of the blood and excreta failed to discover the *B. typhosus*, the *B. paratyphosus*, or the *B. enteritidis*.

CONCLUSIONS.

1. A positive reaction with the *B. enteritidis* 7160 is due to something more than previous antityphoid inoculation, and hesitation in diagnosing typhoid (or paratyphoid) infection should be occasioned only by the necessity of excluding infection with the *B. enteritidis* itself. The symptoms associated with *B. enteritidis* infection are, however, generally clear enough to make the distinction easy.

2. A single negative test with the *B. enteritidis* 7160 does not exclude a diagnosis of typhoid fever, though, if obtained late in the course of an illness, it would constitute good evidence against typhoid infection. Repeated negative tests are much more conclusive, and should be of value in deciding the nature of doubtful cases. The time required, however, is a hindrance to rapid diagnosis, which is absent in the case of a positive reaction.

A full account of this research is in course of preparation, and will be published later.

* A bacillus recently isolated by Professor Delépine from the spleen in a fatal case of food poisoning.

CHEAP ABSORBENT DRESSINGS FOR THE WOUNDED.

By CHARLES W. CATHCART, F.R.C.S.,
SENIOR SURGEON, ROYAL INFIRMARY, EDINBURGH.

1. Pinewood Sawdust.

IN THE BRITISH MEDICAL JOURNAL for October 17th, 1914, I published a short note on the value of pinewood sawdust as a cheap material from which very efficient absorbent dressings for surgical work can be easily made. In the following number of the JOURNAL favourable opinions of this material were expressed by Professor Rushton Parker and by Mr. F. D. Bennett, and on May 26th of this year an instructive paper on "Pinewood Sawdust as a Surgical Dressing," by Professor Rushton Parker, was published in the *Clinical Journal*. To these recent papers and letters your readers may be referred for information as to the value of pinewood sawdust.

My present reference to the subject will be limited to an indication of some recent improvements in the method of preparation.

Instead of a fairly open muslin we now use one with a close mesh, which has 70 by 50 threads to the square inch. This retains the finer particles of wood in the bags and renders the use of a No. 40 sieve unnecessary. It costs 2½d. a yard of 40 in. wide. A No. 8 riddle or sieve is used as before to exclude the larger fragments of wood, and all that passes through it is employed for the dressings.

The bags are now made of three sizes—namely, 12 by 8 in., 10 by 6 in., and 7 by 5 in. The same sizes are used for the other two materials recommended in this paper. The method of tearing the muslin and sewing the bags is described in one of the leaflets to be afterwards referred to.

Besides sawdust, however, there are two other substances—both also home products—which are better absorbents than cotton-wool, and are available under present circumstances at a very low cost. These are *fresh sphagnum moss*, and moss becoming peat, which for short we may call *peat moss* or *moss peat*.

2. Sphagnum Moss.

The following particulars are taken from an article contributed to the *Scotsman* on November 17th, 1914, by Professor I. Bayley Dalfour and the present writer:

Bog moss or sphagnum is the only moss which in nature has a far-reaching influence upon the surface of the earth as a soil-forming agent, and it is the only moss which has proved itself as yet to be of economic value to civilized nations. Its formative influence and its economic value respectively depend upon the peculiar construction of the plant. Its smooth stem is densely beset with leaves, and emits a branch at every fourth leaf; often these branches are turned downwards, and apply themselves more or less closely to the stem. At the periphery of the stem are one or more layers of fine colourless chambers, known as capillary cells, whose thin walls have big perforations, and are strengthened against collapse by a thickening band running spirally or in rings around the inside. The leaf is formed of a single layer of chambers or cells. Some of them, narrow and green, form a network of feeding cells, in the meshes of which are larger, broader, colourless cells, perforated and thickened after the fashion of those of the peripheral layers of the stem. The whole construction results in a system of delicate capillary tubes, having the effect of a very fine sponge. The perforated cells readily take in water and hold it firmly. The water can be squeezed out of them but they do not collapse, and are ready to take in water again.

In life the plant takes all its water from the atmosphere. It is not dependent on soil water, and from top to bottom is laden with the water retained in its delicate chambers. By its mode of branching the plant forms compact cushions. These have a bulging centre, and as the older parts die off below and pass into the condition of peat, the tops constantly and vigorously elongate and branch so long as the precipitation of moisture from the atmosphere suffices. While the older cushions are thus growing new cushions are being formed by lateral extension, and thus there is formed what is known as "High Moor." By gradual extension at the periphery the

plant may in time cover miles of country, spreading over, and in the end exterminating, adjacent vegetation, even forest. On all our mountains and moors sphagnum is found in patches of varying extent, small or large.

The presence of these capillary cells makes sphagnum economically useful. Horticulturists have long made use of it as an agent for holding moisture around such plants as orchids; moreover, by chopping it and mixing it with soil in pots, they secure that moisture does not pass too quickly through the soil. In recent years the upper layers of the sphagnum deposit have come largely into use for stable litter instead of straw on account of its great power of absorbing and retaining fluids. There is, however, a further economic use which has been found for it—the importance of which at this critical time cannot be over-estimated—that of a substitute for cotton-wool in the dressing of wounds. For this purpose its resilient perforated cells fit it admirably, and, indeed, suggest its superiority to cotton-wool in absorptive capacity. We owe the introduction of sphagnum moss as a surgical dressing to Germany, where it has been established for this purpose for many years. *Las est et ab hoste doceri.* In the early eighties of last century a workman at one of the outlying peat moors in North Germany accidentally sustained a severe lacerated wound of the forearm. In the absence of anything better to apply to the wound, his fellow-workmen wrapped it up with fragments of peat which were lying near, and after an interval of ten days he arrived at the surgical clinic at Kiel with the original dressing undisturbed. It was feared that the wound when exposed to view would be found in a very unsatisfactory state, but, on the contrary, when the peat dressing was removed the wound was found to have healed in a most satisfactory manner. The unexpectedly good result obtained with a dressing material which at first sight seemed so unpromising led to a careful inquiry into its nature and properties. An investigation was made from the physical, chemical, and bacteriological points of view of the growing plant on the surface of the moor, downwards through its various stages of decay to the brown amorphous deposits of fully-fermented peat at a varying distance below. The practical outcome of this inquiry was that the value of sphagnum moss as a surgical dressing was found to be due to its marvellous power of absorbing fluids. The growing plant, collected and dried, has this power at its maximum, but the light brown layers of semi-decayed moss which lie above the peat proper retain great absorptive powers, and constitute the valuable material known as "moss litter." It was probably from this layer that the extemporized dressing already referred to was taken. After its value had been discovered, many papers dealing with sphagnum moss as a surgical dressing were published in German surgical journals, by Neuber and others. Before long "moos" (that is, sphagnum moss) came to be accepted as the standard material for surgical dressings and other similar requirements in medical practice in some of the largest German hospitals and in private practice. Thirty years' experience has not lessened the favourable opinion at first formed of it in Germany, but we have been slow in this country to recognize its value. British surgeons use mostly the prepared product known as "absorbent cotton-wool." It is much less efficient than sphagnum moss, and is considerably dearer than moss would be if we used the moss which grows plentifully in our own country instead of importing it prepared from abroad. The methods of preparation employed are not designed to improve the absorbent powers of sphagnum moss; they could not do that. They only furnish the surgeon with the moss in more compact and more conveniently handled forms. For practical purposes, however, sphagnum moss, which can be gathered on our moors and damp places, can be utilized without any preparation worthy of the name in a technical sense. The growing plant and its underlying layers of withered stems and leaves should be collected, picked free of other plants, and dried. It has afterwards only to be lightly packed in bags of "butter muslin," which are then sewn up and handed to the surgeon, to sterilize and place on the wound. Such pads are soft, elastic, and very comfortable for the patient. They are easily packed, convenient to handle, and extraordinarily absorbent.

No doubt many proprietors in districts where moss grows plentifully would allow school children, Boy Scouts, and others to collect the moss, and members of the Red Cross Society with time to spare might be found willing to carry out the simple preparation which

the surgeon requires. An organization for the purpose would have to be formed, but this should present no great difficulty.

It would be well if moss destined to be sent by train to any centre or centres were dried in the district in which it was collected, as by far the greater part of the weight of the fresh plant is due to the water it contains. This will be evident from the following simple experiment recently performed in the Royal Infirmary: 5 lb. of the fresh moss were weighed out, then pressed, and slowly dried by heat. It was found that the dried plant, which had retained 4 lb. 6 oz. weight of water, itself only weighed 10 oz.

Until the British firms can put on the market the moss from our own moors at a moderate price, much may be done by voluntary workers to make use of this at present neglected but most valuable surgical dressing for our wounded men.

Since this article was written several letters on the subject, from the Marquess of Breadalbane and others, have appeared in the *Scotsman* and other Scottish newspapers, and the moss is being collected and sent into the War Dressings Supply, Edinburgh, by voluntary workers from all parts of the country. The same might, no doubt, be done in many parts of England, Wales, and Ireland.

As an inducement—if such be required—to proprietors to allow this moss to be collected and removed from the moors it may be mentioned that sphagnum moss harbours the beetle which is responsible for grouse disease. This was pointed out recently in the *Scotsman* (June 19th):

For this well-known plant an unusual demand has recently sprung up in hospitals, as it is believed to be an excellent substitute for cotton-wool for dressing purposes. In numerous parts of the Highlands it is being gathered by many willing hands and forwarded to the receiving depôts. . . . Proprietors and shooting tenants would hail with pleasure the total extermination of this pest. It is within its narrow, simple leaves that the destructive leather beetle lays its clutch of eggs. A widely acknowledged authority on the economy of moors—Mr. Percy H. Grimshaw—has given it as his definite opinion that practically all cases of diseased heather are due to the ravages of this insect. A somewhat similar statement was made in the report of the Grouse Committee issued seven or eight years ago. Owing to its perennial dampness, it is difficult or impossible to destroy sphagnum by burning, and the picking of it by hand will operate potentially to the benefit of game preserving.

Peat Moss.

This name has been given to the semi-decayed sphagnum moss which forms the upper layers of certain deposits of peat. Other deposits have been formed from heather. As a material for surgical dressings the less decayed and therefore more fibrous upper layers are preferable. These are selected at Messrs. Richardson's "moss litter" works by the instructions of Mr. Richardson, who has kindly interested himself in this matter. The selected "bricks" after being torn up by machinery are compressed into bales and sent out like those of ordinary moss litter. After the removal of the binding wires the bales are easily broken down into a loose material which can be further reduced by rubbing between the hands. In this process a good deal of fine dust is produced, but, like the fine wool dust, it is retained by the close mesh of the muslin employed for the bags and is a valuable absorbent. These peat moss dressings are extremely absorbent and very light.

As absorbents all three of the above-mentioned materials—sawdust, dried sphagnum moss, and peat moss—are superior to cotton-wool in one important particular: they diffuse the discharges in the bags and retain them much better. While a mass of absorbent cotton-wool laid over a freely discharging wound will allow the discharge to pass through to the bedclothes before the greater part of the cotton-wool has been used, bags of these materials suck up the discharges and become filled with them. They are all very valuable also where there is an outflow of urine.

As regards price, the chief expense is the muslin for the bags. Sawdust and peat cost a fraction of a penny per pound. Voluntary workers in the country collect and dry the moss, and in most cases send it to the War Dressings Supply Organization in Edinburgh carriage paid. What the price would be were all the workers paid is another matter, but in present circumstances the cost is very little.

The following appreciation of the value of pinewood

sawdust as a dressing for septic wounds is very valuable. It is the translation of a letter from Dr. Stauffer, Médecin en Chef, Hôpital Dumerloque, Dinard, to Mrs. Bronley-Davenport, of the War Hospital Supply Depot at Hove. She has kindly given me permission to publish it:

Madame, Miss du C gave me, from you, a few days ago, some bags of pine sawdust to try as a wound dressing. I have used the bags in my treatment for ten days. I found them very satisfactory, and it is with pleasure I communicate to you the result.

1. From the point of view of absorption the bags are more advantageous than the best cotton, one bag alone of 45 grains takes the place of 250 of cotton. The absorption takes place equally slowly, and, thanks to the large pores of the sawdust, the infiltration is much more general in the case of the bags than it is in that of the cotton-wool. The bag never gets wetted right through in one place alone before the whole of the sawdust has become absorbed. The opposite takes place in a wound dressing of cotton. One spot is wetted through quickly, and spoils the bandages, the body linen, and the sheets, whilst the surrounding dressing remains dry.

2. Its power of deodorization is very strong. The smell of the pine is so penetrating that it covers nearly always that of the wounds; and the bandages become impregnated with this smell, and can therefore be used again, which, for a military hospital, means a considerable economy in bandages.

3. From the two preceding considerations there necessarily follows a very appreciable economy in bed linen.

I shall be pleased and infinitely grateful if, Madame, you would send me a considerable quantity.

Conclusions.

To sum up, there are several advantages in using absorbent dressings made of the materials mentioned: they are thoroughly satisfactory as dressings, are very cheap, and can be prepared by voluntary workers without technical training. None of them is injured by sterilizing.

The War Dressings Supply Organization in Edinburgh prepares all three forms of dressing, and sends them out to hospitals for the wounded, where necessary, free of charge, in other cases at a minimum cost to cover working expenses.

As some of the leaflets drawn up to help workers to collect sphagnum moss and to prepare the dressings from it as well as from sawdust and peat may be useful to others wishing to organize similar work, I shall be glad to see that they are supplied if requests are addressed to me at the Royal Infirmary, Edinburgh.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

WOUND DRESSING.

I HAVE found the following method useful in the treatment of many of the wounded arriving from the front:

Take an ordinary patty tin and punch a hole about the size of a shilling through the middle. These tins may be bought, of various sizes, at a cost of 2d. or 3d. a dozen. They are saucer-shaped, with rolled-over edges. Place the patty tin over the wound, resting by its rounded border on the healthy skin beyond the wound; fix it to the skin by one or two narrow pieces of rubber strapping, and cover it with sufficient antiseptic gauze and wool (or oakum) to absorb any escaping discharges, and apply a bandage over all in the usual way. The patty tin should be bent, if the part be rounded, to fit comfortably. This is easily effected by hand.

The advantages of this method of treatment are many:

1. There is no pressure on the wound, as the dome of the tin stands half an inch above it. Any drainage tube projecting from the wound is likewise shielded from pressure.

2. If there be much discharge, it can easily escape into the hollow of the tin, instead of being blocked in the wound by the dressings.

3. When a dressing is changed there is nothing adhering to the wound, since nothing touches it. There is consequently no bleeding or pain and no damage to granulation tissue or young skin when the dressing is removed.

4. The patty tins may be boiled and used over and over again, thus making for economy.

5. The state of the wound can be judged by looking through the hole in the tin, which may often be left an extra day in position.

6. Should a wet dressing be desired, an unpurported tin may be used to cover it, instead of oilskin.

ECLAMPSIA OF PREGNANCY.

I was recently called in by a colleague to see a woman suffering from acute eclampsia in the seventh month of her eighth pregnancy. She was unconscious, and fits were occurring every few minutes; the tongue protruded for about 4 inches from the mouth; the urine was loaded with albumin, and there was no sign of commencing labour.

Injections of morphia had proved unavailing. Hyoscine and morphia were injected, and the patient was put under chloroform and a lumbar puncture made till the canal was drained; it was under pressure (120 drops to the minute). She was next bled to 1 pint, and was then given 2 pints of Rogers's hypertonic solution intravenously. Two phials of pituitary extract were afterwards injected. The tongue was well slit from tip to base at each side.

After six hours I found her sitting up in bed, quite sensible. There had been no further fits, and large quantities of urine had been excreted. I then gave 40 grains of calcium chloride, and injected two more phials of pituitary extract, and twelve hours later spontaneous delivery occurred without any one being present. The child was dead. There have been no unpleasant symptoms since, but her urine still contains some albumin.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

DORSET AND WEST HANTS BRANCH.

At a meeting held at Sherborne on July 7th, Dr. C. D. MCBRAT, President, in the chair, Dr. CUNWY of Yeovil read a paper on *The thyroid gland*, which dealt with the development, anatomy, physiology of and pathological changes in, the gland. Under the latter heading was given a description of Graves's disease, which was looked upon as a disease arising from a derangement of the perfect balance normally existing between the actions of all the internal secretory organs, more especially the thyroid, suprarenals, and pituitary gland, the cause of the derangement being, more often than not, a sexual one. An allied condition, though not true Graves's disease, occurred in young married women after the birth of the first child, and the underlying cause here was certainly a sexual one. This condition was characterized by a loss of flesh and colour, and a placid nature became an easily worried one. These women always felt better when pregnant. Cases coming under the heading of thyroid inadequacy were next dealt with, and lastly the treatment of the various conditions was described and illustrated by the treatment of actual cases. The paper was discussed by the PRESIDENT, Dr. EDWARDS, Dr. MIDELTON, Dr. HAYLOCK, and Dr. SIMMONS. Dr. WHITTINGDALE showed a case of *Complete ophthalmoplegia* in a woman, aged 68. She was married, and had one child; there had been no miscarriages; no history of syphilis. She first noticed drooping of the left eyelid about Easter, 1915, and at the same time had pains behind the left ear running up to the vertex, sickness and slight vertigo occasionally. Later complete ptosis supervened, with a fixed pupil and loss of all power of movement in the eye. The other eye and both discs were normal. The knee-jerks were not very active. She had been taking antiseptic remedies, but without any benefit except to the headaches. Dr. MCCARTHY showed a case of *Dermatitis* of six months' standing in a healthy domestic servant, 22 years old, immediately following a severe scald of the foot. The affection was symmetrical in character, covering the face and neck, and in the former situation having the distribution of lupus erythematosus. The general opinion expressed was that it was an artificial eruption, the agent employed being probably lysole.

Rebickos.

MOYNIHAN'S "ABDOMINAL OPERATIONS."

THE commanding position held by Sir BERKELEY MOYNIHAN in the surgical world is sufficient to ensure a warm welcome for the published records of his experiences in any branch of surgery, and with the surgery of the abdomen his name has been long associated as a daring pioneer and brilliant exponent of the highest achievements. We are accordingly more than gratified at the issue of a third edition of his work on *Abdominal Operations*.¹ In the preparation of this edition extensive revision has been necessary, and considering the rapidity of progress in abdominal surgery, it is not surprising that much has had to be rewritten. The work is essentially practical and personal, only operations and methods practised by the author himself being described, and it is only his own opinions which are freely given. The book, therefore, appeals directly to the operating surgeon of any grade of experience.

The general arrangement of the material follows ordinary lines. The first section, on general considerations as to abdominal work, includes technique, subphrenic abscess, incisions, wounds; the second is concerned with the stomach; the third with the intestine, and so forth. The individual sections contain far more than bare descriptions of operations; complications; post-operative treatment; results of operations in other hands; conditions of success, warnings to avoid failure—all are discussed in the frankest informal way. On most of the abdominal states found in surgery the author has opinions fairly well fixed.

The problem of the surgical treatment of gastric ulcer is still unsolved. Sir Berkeley Moynihan's experience is that routine performance of gastro-entostomy is insufficient. If the ulcer be in the pyloric region, and if there be obstruction from contraction of the scar of former ulcers, gastro-entostomy will cure. Ulcers lying in parts of the stomach other than the pyloric antrum are best treated by excision. An ulcer on the lesser curvature, if of large size, should be excised and gastro-entostomy performed. An ulcer on the posterior wall may be reached by the trans-gastric route. Large ulcers involving liver or pancreas cannot be excised, and the treatment is gastro-entostomy combined with jejunostomy. The discussion on the operative treatment of gastric cancer is appropriately most elaborate, and forms a treatise in itself. The diagnosis of cancer of the stomach in the early stage can be assured only in one way—by thorough examination of the viscus as it lies in the surgeon's hand. Searching inquiry into the history, chemical examination of stomach contents, Roentgen-ray inspection of the behaviour of a bismuth meal, may all go towards the diagnosis; they will not certify it. There are three main indications for operation in chronic gastric diseases: In all cases of chronic gastric ulcer; when gastric stasis is present; when a tumour is present. In all these three conditions medical treatment may relieve, but it cannot cure. Early operation may discover an early cancer. The author is emphatically of opinion that in all cases of cancer wherever possible a radical operation should be attempted. He is in agreement with Mayo in the opinion that gastrectomy may with great benefit be performed not only as a possibly curative operation, but also deliberately as a palliative operation when growths are present in inaccessible glands or in the liver.

We have endeavoured to indicate in an imperfect way some of the wealth of surgical experience contained in this book, but readers will only know its value by exploring for themselves. The work is a classic written with freedom and informality of style. The author's scientific keenness vies with his human "desire to rob surgery of its terrors." The main terror of surgery is its death-rate, and thanks are due in great measure to Sir Berkeley Moynihan that the mortality of extensive abdominal operations is gradually diminishing. This consummation is being attained on the one hand by earlier diagnosis, and on the other by more perfect technical skill—gentle manipulation, careful protection of delicate structures, absolute asepsis,

¹ *Abdominal Operations*. Vols. I and II. By Sir Berkeley Moynihan, M.S. Lond., F.R.C.S. Eng. Third edition, revised. Philadelphia and London: W. B. Saunders Company, 1914. Roy. 8vo. pp. 492; 371 figures. 42s. (the two volumes.)

and operating with that "speed which should be the achievement not the aim of the operator."

We cannot praise this work more highly than to say that it is well worthy the reputation of its author, and that it should be the cherished possession of every active-minded surgeon.

OSTEOLOGY AND ARTHROLOGY.

IN the first part of the fourth volume of *Quain's Anatomy* Professor BRUCE deals with the bones and joints, subjects which, in our opinion, had not in earlier editions been treated with the attention to detail which characterized, for example, the descriptions of the muscular and nervous systems, an attention which we felt we had a right to expect in a book that for a good many years past has been regarded as a work of reference. The defect was all the more glaring in that it occurred in so characteristically English a textbook, for English teachers have always set great store on a knowledge of osteology as the basis for a knowledge of anatomy generally.

In the present edition the defect is more than made good; in fact the subjects are more fully treated than in any other textbook in our language, and only the absence of the outline markings on the bones for muscular attachments remains to remind us of the former shortcoming. The editor has incorporated in the volume all the recent work which has been done on the subjects in Britain, on the Continent, and in America, and he rightly takes the opportunity presented by the preface to acknowledge particularly his debt to Le Double and Pick. We are, further, glad to find Piltner's work on the accessory elements in the carpus and tarsus so well represented, but regret that greater prominence has not been given to Schwabbe's description of the markings on the endocranial surfaces of the temporal bone. The attention paid to the morphological side of the subjects is an old feature, and is well maintained in the present edition, while the fullness with which the embryological side is considered is an innovation rendered necessary by the great advance in embryology.

The form and arrangement of the book are the same as those to which we have become accustomed from past editions, while the changes in nomenclature are so few and are made with such judgement and discretion as to disarm all criticism.

A large number of new illustrations have been added, and are in every way worthy of the place they occupy.

We have no hesitation in stating that the volume furnishes us with the most interesting and readable account of the parts of anatomy of which it treats with which we are acquainted.

GUIDES TO DIAGNOSIS.

WE are pleased to see that Dr. LEFFWICH'S *Index of Symptoms* has reached a fifth edition. It is a distinctly healthy sign that a work of this character should be in constant and steady demand. For a young man just starting practice no sounder investment could easily be named than a copy of this excellent work; and no surer way of progress in diagnostic method and acumen than the establishment of a habit of referring to it in every case of doubt or perplexity. It is not, of course, a book that can be read in the ordinary way, but, as the title suggests, an index and purely a work of reference. As such its completeness is admirable, and its compilation must have entailed a vast amount of thought and research. In his preface to the first edition the author points out that in doubtful cases a diagnosis is commonly reached by process of exclusion. The physician, having seized upon a few prominent features, is at once able to say that the disease is one of perhaps a dozen. Further investigation may narrow down the possibilities to one ailment. But if, on the contrary, he find himself at fault and proceeds to a hunt through his library, he is met by the difficulty that in most medical works diseases, not symptoms, form the headings. In the present work he can, however, follow the same order as that which is taking place in his own brain. By turning

² *Quain's Elements of Anatomy*. Edited by Sir E. A. Schäfer, LL.D., Sc.D., M.D., F.R.S., J. Symington, M.D., F.R.S., and T. H. Bryce, M.A., M.D. Vol. IV, Part I, *Osteology and Arthrology*. By T. H. Bryce, Eleventh edition. London: Longmans, Green, and Co. 1915. (Roy. 8vo, pp. 337, 28 plates; 247 figures. 12s. 6d. net.)
³ *An Index of Symptoms with Diagnostic Methods*. By R. Winnington Leffwich, M.D. Fifth edition. London: Smith, Elder and Co. 1915. (Post 8vo, pp. 528, 85 figures. 10s. 6d. net.)

up one after the other the symptoms of which he seeks the source, he is guided to the diseases in which they occur, and, as the author truly remarks, "a mere glance will often furnish the missing clue." In the present edition a large number of new symptoms and many new clinical tests have been added, and the interlineary notes have been considerably amplified. This increase in matter will doubtless enhance the value of the book, which, although of handy size, is no longer adapted for carrying in the pocket. In a work of so comprehensive an aim perfection is not reasonably to be expected, but the author comes as near it as may be. We are surprised to miss phthisis from the list of diseases causing reflex or irritative vomiting, although enlarged bronchial glands and fibroid lung are included.

The book now published by Dr. R. C. CABOT, on *Differential Diagnosis*,⁴ is the third edition so far as regards the first volume of a work we noticed some four years ago (August 26th, 1911, p. 447); but the second volume is entirely new, being an extension of the original plan on the same lines, but including a number of other headings. The plan of the book is to take a subject, such as pain, distinguished as to its situation, or fever, cough, or hæmaturia, and after somewhat brief general remarks on the bearing of these "presenting symptoms," the subject is illustrated and amplified by descriptions of cases, which are discussed, and a diagnosis arrived at on the facts so far as they are available. The first volume dealt with pain in various situations and with eleven common symptoms. In the second volume nineteen other symptoms are discussed, including abdominal and other tumours, ascites and abdominal enlargement, vertigo, hæmaturia, hæmoptysis, dyspepsia, melæna, pallor, and polyuria. The major part of the book is taken up by the reports of cases; there are 383 in the first, and 317 in the second volume. In noticing the first edition we ventured to express a doubt as to the utility of these discussions, as in the majority of cases the correctness of the diagnosis is, after all, left in doubt. In very few of the cases was there either a necropsy or such a biopsy as places the condition beyond dispute. For example, there are 12 cases of hæmoptysis, with two deaths, but only one *post-mortem* examination. In one other the existence of tuberculosis is affirmed on the basis of the inoculation of a guinea-pig. In all the other cases the diagnosis is doubtful; the author comes to a conclusion in many cases, and gives his reasons for doing so; but such disquisitions are scarcely convincing, and, although the reader is in no position to dispute the conclusions, he may feel himself unable to derive much benefit from the exercise. Leaving aside the cases and passing to the general introductory remarks, we find these are marked by extreme dogmatism; it is surprising to be told that it is questionable whether vertigo bears any relation to stomach derangement, or that diarrhoea is rarely caused by errors of diet, or that the "truly gastric causes of indigestion may be reduced almost entirely to two—cancer and ulcer." It is quite true that vertigo is rarely seen in grave cases of stomach disorder, but it is none the less very frequent in cases of slight stomach derangement, the greater number of which are too transient to call for medical assistance. Similar considerations apply to those most numerous cases of diarrhoea which are caused by indiscretion of diet; further, we are unable to follow the ruling that excludes from among the common causes of dyspepsia gastritis, either acute or chronic, and atonic dilatation of the stomach. The time devoted to the study of such a book as this might be better given to the observation and recording of cases in the wards.

NOTES ON BOOKS.

*General Surgery*⁵ is part of an annual series, and is adorned with forty-five excellent half-tone plates representing advances in operative surgery and technique.

⁴ *Differential Diagnosis*. Vols. I and II. By R. C. Cabot, M.D. Philadelphia and London: W. B. Saunders Company, 1915. (Roy. 8vo, Vol. I, pp. 754; 155 figures; 2s. net. Vol. II, pp. 708; 254 figures; 2s. net.)

⁵ *The Practical Medicine Series*. Under the general editorial charge of C. L. Mix, A.M., M.D., and R. P. Vaughan, Ph.D., M.D. Vol. II: *General Surgery*. Edited by John B. Murphy, A.M., M.D., LL.D., F.R.C.S. (Eng.), F.A.C.S. Series 1915. Chicago: The Year Book Publishers, 1915. (Cr. 8vo, pp. 602; 97 plates, 180 figures.)

Dr. MURPHY has evidently spared no pains in order to keep the work up to date. The summaries on anaesthesia and analgesia are of special importance, because in the introduction the editor lays stress on the fact that the number of deaths from anaesthetics reported in the public press of Great Britain from 1910 to 1915 was 700. In the text he analyses a review, by A. L. Flemming, of inquests in England on cases of death during anaesthesia, which was the subject of an editorial in an American contemporary. Chloroform comes out very badly, but the percentage of fatalities with other less frequently used anaesthetics cannot be accurately compared with the percentage of chloroform deaths. In Flemming's opinion a large number of these fatalities would not have occurred if ether had been used during the induction, or at any rate during the struggling stage. The volume contains abstracts of recent work on the gall bladder; infections of that reservoir independent of calculus are not so rare as is generally believed. Bacteriological examination of the fluid contents of the gall bladder gives trustworthy results only in the acute stage. The editor himself insists that a diagnosis of the presence or absence of infection in the gall bladder can only be made with certainty by excising portions of its wall for cultural and microscopic purposes.

The ninth volume of the American Society of Tropical Medicine⁶ contains the papers read before the society and published under its auspices in 1914. The papers show that a considerable amount of work has been devoted to amoebic dysentery, a branch of tropical medicine to which Americans have paid special attention. The volume also contains papers on plague, beri-beri, leprosy, malaria, and other tropical diseases, and is well worth careful study by those interested in tropical medicine.

⁶ *The American Society of Tropical Medicine*. Vol. ix, 1914. New Orleans: Tulane University Press, 1915. (Roy. 8vo, pp. 248; illustrated.)

IMPERIAL CANCER RESEARCH FUND.

The annual meeting of the Imperial Cancer Research Fund was held on July 20th; Sir William Church, in the unavoidable absence of the President, the Duke of Bedford, occupied the chair. The Committee re-elected Professor G. Sims Woodhead and Dr. Bulloch, F.R.S., as their representatives on the Executive Committee, whilst Sir Thomas Barlow, Bt., K.C.V.O., was nominated for election by the Royal Colleges as an additional member of the Executive Committee. Sir Rickman Godlee, Bt., K.C.V.O., was elected a member of the General Committee.

REPORT OF EXECUTIVE COMMITTEE.

The report of the Executive Committee stated that owing to the serious depletion of the staff caused by the fact that most of its members had obeyed the call of the War Office for trained investigators and were on active service, the work of investigation had been greatly interfered with. Fortunately Dr. Tsurumi, formerly assistant to Professor Kitasato and Dr. Takahashi, recommended by Professor Honda, Director of the Imperial Naval Medical College, Tokio, came to this country from Germany on the outbreak of the war, and had offered their services. They had been selected as suitable workers, and had carried out valuable researches and materially assisted the Director in the routine work. Of the seven laboratory attendants of serviceable age, four joined the army with the result that the work had been further limited for want of trained assistants. In December Dr. Bashford, owing to failure of health, resigned his appointment of General Superintendent of the Fund and Director of the Laboratories. The Committee, in accepting his resignation, fully recognized that to him the successful organization of the Imperial Cancer Research Fund was mainly due. He ably represented the Fund both at home and abroad at various congresses and other meetings, and his acknowledged position as the head of cancer research in this country was largely due to the judicious manner in which he assisted and encouraged investigators in other laboratories, whilst always taking care to emphasize the value of the support he received from the Executive Committee and from the Royal Colleges of Physicians and Surgeons. It was to his foresight that the Fund was indebted for the firm opposition taken in regard to the German Cancer Committee, which, with its head quarters at Berlin, endeavoured to gather all cancer research under its control. Great

Britain alone, through the action of the Executive Committee, remained outside the German net, and it was gratifying to know that this attitude was endorsed by the subsequent withdrawal of France and the United States of America. Dr. James Alexander Murray was appointed to succeed Dr. Bashford as General Superintendent of the Fund and Director of the Laboratories.

REPORT OF GENERAL SUPERINTENDENT OF RESEARCH.

The investigations of the past year which called for notice dealt with the factors determining metastasis formation and immunity.

Metastasis Formation.

The process of metastasis formation consisted of two phases. The initial phase was comprised in the passage of the tumour cells through the endothelial layer of the lymphatic or blood vessels in the primary focus, whether this was a spontaneous or a transplanted tumour. This might take place early or only after a long delay, this feature being characteristic of the new growths of many organs and determining largely the prognosis and surgical treatment of the disease in man. The second phase was separated from the first by the mechanical transport and arrest of the intravascular emboli in sites remote from the primary focus. It comprised the processes which ensued at the place of arrest, ending with the new vascularization and establishment of the secondary or metastatic growth. By intravenous inoculation of tumour emulsions the factors concerned in the first phase were eliminated, and success or failure of growth were determined entirely by the processes at the site of arrest. This was carried out with a number of carcinoma and sarcoma strains by Dr. Takahashi, and on comparing the frequency of growths resulting in the lungs with the other characters of the tumours, it was found that the results corresponded closely with the occurrence of metastasis when the strains used were transplanted subcutaneously. Those which naturally metastasized grew in the lungs with ease, while those which had never done so were uniformly negative on intravenous implantation. On the other hand, the percentage of success on subcutaneous transplantation furnished no indication of the probable fate of intravascular emboli. The investigation had shown that, in the transplanted tumour strains examined, the occurrence of pulmonary metastases depended on the ability of the tumour cells to survive and proliferate after arrest in the lungs. The property of the cells which especially favoured metastasis was a capacity for rapid growth leading to organic union with the vessel wall before destructive vacuolation occurred.

Immunity.

As had frequently been pointed out in communications from the laboratory, immunity to cancer had only been demonstrated against cancer grafts and the tumours arising from them. The procedures which were effective under these conditions were without effect on spontaneous tumours or autologous grafts of spontaneous tumours. So long as a passive transference of the resistant condition from actively immunized animals to fresh individuals, and particularly to spontaneously affected animals, remained an unattained ideal, no application could be made of the knowledge acquired of cancer immunity to the treatment of cancer. While in the past resistance to grafted carcinoma had been clearly demonstrated, technical difficulties had militated against an equally satisfactory study of sarcoma immunity. The frequency of spontaneous absorption of transplanted sarcomata and the high resistance to a subsequent inoculation of carcinoma and sarcoma of such cured animals seemed to contrast strongly with the apparent indifference of most sarcoma strains to immunity induced by preliminary treatment with normal tissues. Dr. Tsurumi had succeeded, by using a suitable sarcoma strain and careful attention to dosage, in demonstrating a complete parallel between carcinoma and sarcoma immunity. The time of development after the preliminary treatment, the acme of resistance, and the subsequent decline had been shown to be the same as those already established for carcinoma. In addition, Dr. Tsurumi had carried out an elaborate serological study of the properties of cancer cells by using them as antigens to immunize animals of strange species. The haemolytic, cytolytic, precipitating, and agglutinating

characters of the immune serums obtained in this way had been tested in a variety of combinations. The results were unsuited for a short summary, and a full account was in preparation and would be published as soon as possible.

Statistics.

It had frequently been noted that in the progressive recorded increase of cancer mortality the death-rate from uterine cancer had remained stationary. Cancer of the breast, on the other hand, participated in the general recorded increase. In past years relative ease of diagnosis and success of operative treatment had been put forward tentatively to account for this difference. In the Registrar-General's Report for 1913 the deaths from cancer of the female generative system had been distributed according to the marital condition of the victims, and from the proportions of single and married (including widowed and divorced) in the population, the death-rates in the two classes had been calculated. The results confirmed the generally accepted view that cancer of the uterus was more common in the married than in the single. The excessive mortality of the married commenced at once, and was well marked throughout the child-bearing period. Towards the end of life the mortality of the single rose steadily till it equalled that of the married. It was usual to attribute this increased mortality to the greater exposure of the uterus in those who had borne children to damage and infection with the accompanying chronic irritation. Cancer of the ovary showed the opposite condition. The mortality was greater in the single throughout life, and it was only in the highest age-periods, where a slight terminal decline could be seen, that the curves approached each other. In cancer of the breast the curves ran closely together for the greater part of the active sexual period. As the menopause was approached, the mortality of the single began to exceed that of the married, and continued in excess to the end of life. Dr. Stevenson correlated the contrasted behaviour of uterus and mamma with the decline in fertility, which was so marked a feature of recent vital statistics, and the results might be summarized by saying that while child-bearing increased the liability to cancer of the uterus, normal activity of the mamma acted as an insurance against cancer of that organ. The protection was even greater in the case of cancer of the ovary. These data were practically incompatible with the parasitic hypothesis of the etiology of cancer, for the argument which might be supported by the figures for cancer of the uterus was refuted by the data relating to the breast and ovary. Again, the excess of mortality in the unmarried from cancer of the breast would appear to be at variance with the generally observed association of chronic irritation with the induction of cancer. The hypertrophy and liability to inflammatory and other injury associated with pregnancy and lactation would seem to be of subsidiary etiological significance. The extent to which the recorded mortality from cancer coincided with the absolute incidence of the disease had a topical interest from the effect which the present abnormal conditions might have on the registration of the causes of death. The profound dislocation of the civil medical service might be expected to enhance the discrepancy, due to errors of diagnosis, between the absolute incidence and the recorded frequency of cancer. The point would have to be borne in mind when the data for these years came under review, and the results should supply a valuable indication of the magnitude and distribution of the errors of diagnosis of cancer in the country generally.

The report was adopted.

REPORT OF HONORARY TREASURER.

Sir W. Watson Cheyne stated that during the past year the list of subscriptions and donations, as compared with the year 1913-14, showed a reduction of £600, which was to some extent compensated for by a slight increase of legacies, amounting to £378. The expenses of the Research had exceeded the fixed income of the Fund from investments by the sum of £1,444 16s. 7d. It had in hand at the present time on deposit and on current account a sum of £2,877; in view of possible loss of income, it was thought advisable to retain a substantial balance on current account, but it was intended to invest at once the sum of £2,000 in the War Loan.

British Medical Journal.

SATURDAY, JULY 24TH, 1915.

THE RISK OF MALARIA IN THE SUMMER AND AUTUMN CAMPAIGN.

It has been suggested, and not without good reason, that there is a danger of malaria becoming prevalent in Flanders this autumn. Though this disease has practically completely disappeared from England, it still occurs in Holland, and there is no reason, given the proper conditions, why it should not appear now in Flanders.

To appreciate the extent of the danger, certain conditions must be kept in mind. In the first place a malaria-carrying mosquito must be present; in the second, human beings carrying gametocytes (that is, the sexual forms of the malarial parasite) in their blood must be there to infect the mosquito; and in the third place, a suitable temperature must exist in order that the development of the parasite may take place in the insect host.

As regards the first of these conditions, a suitable mosquito, the *Anopheles maculipennis*, which is the chief malaria carrier of Italy, Greece, and the southern parts of Europe, is present, not only in Flanders and France, but, as a matter of fact, in England itself. Malaria carriers—namely, people harbouring gametocytes in their blood—are probably present, because Indian troops are employed in Flanders at the present moment. Such being the case, the question arises whether malaria may be expected to break out. Practically the answer will entirely depend on the weather. If the season is sufficiently hot malaria may be expected.

To those not conversant with the somewhat intricate epidemiology of malaria the truth of this may be explained by turning for a moment to the conditions which prevail in Italy. The malarial season there commences about the middle of June, and the incidence goes on increasing through July, August, and September; it then falls as the weather becomes cooler, and disappears entirely during the winter and spring months. Throughout the year people who have suffered from malaria and who have not been properly treated are subject to relapses from time to time, and in the agricultural areas, where the disease chiefly prevails, there must be many such persons. They are not specially dangerous in the cold months, but when the temperature becomes sufficiently high the mosquitos begin to bite, and if they bite such individuals they will take up the parasites, which will undergo development in them, and thereby render them infectious. It is on this account that fresh attacks of malaria in climates with a cold season are limited to certain months of the year—namely, those months with a high temperature. Experimental work on filariasis and malaria has demonstrated how important a suitable temperature is to the life-history of parasites. The development of the embryo, *Filaria bancrofti*, and of the gametocytes of malaria, in the mosquito is dependent upon the temperature of the air being high, 80° F. or over; if the temperature falls below this the development is at once checked, or does not take place at all.

In the tropics, where high temperatures are practically always present, there is no definite malarial season, and people may acquire malaria at any time. Such conditions are very rarely present in England, and that is one of the chief reasons why indigenous malaria is so rare in this country. It must be remembered, however, that it may occur, because in certain summers spells of suitable weather are met with (in the Coronation year, 1911, for example). Lately there have been three or perhaps four cases in which people have contracted malaria in England; all have occurred during the late summer—that is, during the warmest time of the year. As a rule, however, the English summer is so variable and cold that the *Anopheles maculipennis* does not condescend to bite, and so never runs the chance of becoming infected.

The temperature of Flanders and the North of France may be a little hotter than that of England, but does not differ very much; a cold summer in one usually means the same condition in the other. So far the weather in England has been this year quite unsuitable for the development of the malarial parasite in the mosquito, and unless a very much warmer spell occurs in August and September, there will be little or no chance of a malarial epidemic or outbreak in the North of France. Another point of interest about the indigenous malarial cases in temperate climates, such as those mentioned, is that they are generally of the benign tertian type, a form of malaria that is not specially dangerous or associated with a high death-rate. The North of France and Flanders, like England, are too cold for the development of the malignant types of the disease.

Apart, however, from the danger of malaria, mosquitos are likely to be very troublesome in Flanders this summer owing to the large amount of flooded country that now exists. In some places where the sea-water gains an entrance, it may be too salt to suit the larva of the mosquito, but further inland where the influence of the sea is not felt there will be vast breeding grounds. Varieties such as *Culex pipiens*, *Grabbania dorsalis*, *Theobaldia annulata*, *Anopheles maculipennis*, and *A. bifurcatus* may be expected; but here again the amount of annoyance these will cause will depend largely upon the temperature. If the weather becomes hot they may quite easily become an intolerable nuisance, whereas if it keeps cold and wet they will not bite much. *Grabbania dorsalis* is very common in the marshy ground north of the Royal Albert Docks in London and bites persistently in hot weather. This is the real explanation of stories of the yearly invasion of the East End of London by hordes of mosquitos imported in steamers coming from the East. It can hardly be necessary to say that any mosquitos taken on board such steamers die before they reach England, probably long before.

In certain favourable localities oiling the pools and collections of water where the mosquitos breed will help to keep down their numbers, and this method would seem to be the only one to adopt in Flanders and France, because mosquito nets for the troops are impossible, although those out of the firing line living in houses may find that a portable mosquito net will save annoyance and trouble.

In the Dardanelles the conditions as regards climate and temperature are similar to those found in Italy, Greece, and Cyprus. In all these places the weather is now getting very hot and the malarial season beginning. What will happen in the Gallipoli peninsula will depend on whether or not there are suitable collections of water—streams and swamps—for the *Anopheles* to breed in. The scarcity of water

is, however, one of the difficulties with which the French and British forces have to contend, and the accounts which have hitherto reached this country seem to show that there is little or no malaria there and few mosquitos. Flies, however, are present in enormous numbers and are causing much trouble, and the part they may play in the spread of disease deserves further consideration.

HOSPITALS AND DUTY-FREE ALCOHOL.

As some misapprehension appears to exist with reference to the action of the British Medical Association with regard to the matter of the exemption of hospitals from duty on alcohol used for medicinal purposes, it may be well to give a brief statement of the facts. In the first place, it should be said that in the action it has taken the Association has been in co-operation with the Pharmaceutical Society. When the Finance (No. 2) Bill came up for second reading it was found that the Government had introduced into it a new clause extending the provisions of 2 Edw. VII, c. 7 (authorizing the use of duty-free alcohol) to hospitals, and in a special section a definition of hospitals was given. No warning had been given that such a clause would appear in the bill, and when its terms became known the representative organizations of medicine and pharmacy, which were both concerned in the matter, called the attention of the Chancellor of the Exchequer to certain objections to the clauses as drafted. The clauses after some debate were withdrawn, and thereupon Mr. Bridgeman, one of the junior Lords of the Treasury, asked representatives of the two associations to meet him with a view to devising some form of words which would obviate the difficulties anticipated. Mr. Bridgeman fully understood that the opposition of the British Medical Association and the Pharmaceutical Society was not to the principle of making a concession to hospitals, but to the method by which this concession was proposed to be made. At the interview the defects in the official clause were pointed out, and an alternative method of procedure suggested. This alternative commended itself to Mr. Bridgeman, and he has since written stating that the suggestions have been accepted by the Government, but that seeing that the new clause desired would necessitate a recommitment of the bill, the Government had decided to incorporate the suggestions in the next Finance Bill.

Stated briefly, the criticisms of the British Medical Association and of the Pharmaceutical Society were directed to two points: The first was that the clause as originally drafted, and now withdrawn, would have based the amount of the grant to a hospital on the amount of alcohol which it had contrived to consume; the second was that the whole question of duty-free alcohol was one which had exercised both medical and pharmaceutical opinion for a long time, and could not properly be dealt with in the summary fashion proposed. It was pointed out that the official definition of a hospital opened the door to widespread abuse in the formation of one-man "hospitals," and that a later addition to the official clause limiting the benefit to institutions not run for gain was insufficient to shut out the possibility of abuse.

The constructive suggestions put forward by the British Medical Association and the Pharmaceutical Society were, first, that a full and proper inquiry should be held into the best way of dealing with the subject of duty-free alcohol in medicine; secondly, that in the meantime there should be made to duty

recognized hospitals a fixed grant equal to the tax on all the alcohol used for medicinal purposes in the year 1914; and, thirdly, that an advisory committee should be appointed to assist the Commissioners of Customs and Excise in determining whether applications from hospitals claiming the benefit of the Act should be approved.

The whole profession, hospitals included, have to thank the British Medical Association, acting in co-operation with the Pharmaceutical Society, for ensuring that medicine shall be exempt from the new eighteenpenny tax on raw alcohol. It cannot be doubted that the action of the Association on the further and larger matter will be as fruitful of good.

INCOME TAX.

WE have on more than one occasion called attention to the unfairness which arises in cases in which the Income Tax authorities insist on a strict application of the rules under which expenses are deductible from assessments made under Schedule E on fees or other emoluments of "offices." In the issue of July 2nd, 1910, we dealt with the question at some length, and the Board of Inland Revenue not very long afterwards apparently waived the technical right—which still exists—of separately assessing such fees under Schedule E, and, so far as can be ascertained, the method of assessment now usually adopted is to create one assessment under Schedule D, into which is gathered the professional receipts from all sources, whether private or "public." Generally speaking, this tacit concession fairly meets the case, although from time to time correspondents have informed us that in particular cases surveyors of taxes appear to be reluctant to recognize that this method of assessment is really in operation. Moreover, this concession seems to be subject to certain limitations. For instance, at present a considerable number of doctors hold commissions in the R.A.M.C.(T.) as medical officers attached to local military hospitals, and carry on their civil practice and appointments concurrently. In these cases the army pay is taxed by the Paymaster-General through the pay agents, with apparently no deduction for the expenses incurred for the use of the telephone, private instruments, motor car, etc., of the practitioner. In the case of an appointment to a civil hospital the difficulty would be avoided by returning the remuneration as part of the general profits, and deducting therefrom the whole of the expenses of the practice. In equity there is no reason why a similar course should not be adopted where a military hospital is concerned, but in law there appears to be this difficulty, that the department of the Paymaster-General is a separately constituted assessing authority, and therefore the whole income of the practitioner does not fall within the purview of the local officials. In the result he is in some cases deprived of an adequate allowance for the expenses incurred by him in carrying out his military work. The whole matter shows the impossibility of applying equitably the venerable rules of assessment contained in the Income Tax Act of 1842 to an income earned in modern conditions. In these days of high rates of duty the taxpayer is entitled to expect careful consideration and strictly just treatment, not by a tacit or avowed concession but by right of statutory provisions open to judicial interpretation. The income tax machine which was set up by the Act of 1842 has certainly been subjected to many additions and improvements, but, if we may judge from the public statements of leading politicians, all parties are agreed that it is now high time that the old machine was laid aside and replaced by one embodying all the improvements made in the old, but fully adapted to deal with the more complicated professional and industrial conditions of the twentieth century. We trust that when that work has been done the medical practitioner will find

it easier to obtain those allowances to which he is entitled, but which the archaic redivision of his income into "schedules" too often denies him.

THE HISTORY OF SPECTACLES.

So many myths surround the history of the invention of spectacles that the task of sifting truth from fiction is almost heroic. We are indebted to Dr. K. K. K. Lundsgaard,¹ of Copenhagen, for a critical view of the numerous and conflicting accounts of this invention, which, though about six centuries old, has been of general value for the past century only. The popular notion that spectacles were used by the Chinese has been dismissed as erroneous by Professor F. Hirth, of Columbia University. Some historians have attempted to credit the Romans with the use of spectacles on the rather flimsy assumption that Nero was in the habit of holding an emerald to one eye to see the better. It is highly improbable that he was short-sighted, for this would have disqualified him as a charioteer, in which capacity he seems to have given, to himself at least, perfect satisfaction. His eyes, it is true, were weak, and it is conceivable that the emerald was used to relieve photophobia. Emerald-gazing has from time to time been regarded as a valuable remedy for weak eyes, and it is, therefore, also possible that Nero followed the dictates of his oculist while enjoying the pleasures of the arena. Again, he may have flouted his emerald to point his political sympathies with the so-called Green Party. It is not even stated that the emerald was polished; and the view that it was used as an aid to vision seems to depend for its correctness solely on Pliny's words: *Nero principis gladiatorum pugnas spectabat in smaragdo*. Coming to a much later date, Dr. Lundsgaard does not give Roger Bacon much credit for the actual invention of spectacles; he thinks it is even doubtful whether Bacon's speculations on vision and his optical theories were original. The magnifying properties of glass spheres were, at any rate, recognized before this time. Yet, the invention of spectacles was made in his lifetime, and it is impossible altogether to dissociate him therefrom. It is very probable that the invention was made independently by different workers towards the close of the thirteenth century, for the use of spectacles was apparently introduced simultaneously in widely separate localities. Important among these is Florence. Here the church of St. Maria Maggiore contained the grave of one Salvino Armati, with an inscription to the effect: "Here rests Salvino Armato Armati of Florence who invented spectacles. May God forgive him his sin. In the year of Our Lord 1317." Francesco Redi of Pisa discovered a manuscript of the year 1299 in which the writer referred to the benefit he had derived from the use of the newly invented spectacles. In a sermon preached in Florence in 1305 Giordano da Rivalto said: "It is not twenty years since the invention was made of eyeglasses, which improve vision, and are one of the most useful inventions known to the world." For some centuries only convex glasses were used, and it was not till the middle of the sixteenth century that the value of concave glasses was appreciated. The earliest evidence we have of their use is probably the painting of Pope Leo X by Rafael, who represents the Pope as holding what is evidently a concave glass in his hand. In a painting of the same period by Lucas Müller, of Christ and His companions, a man is portrayed with concave glasses—an anachronism of which the painter was doubtless blissfully unconscious. In 1760 Benjamin Franklin, who was short-sighted, had spectacles made with the upper halves concave and the lower convex; but it was not till 1823 that McAllister of Philadelphia succeeded in grinding glasses so as to correct astigmatism. Spectacles were usually made of glass, the best specimens of which came from Murano, where the secrets of its

manufacture were successfully preserved from the thirteenth to the sixteenth century. Towards the close of the seventeenth century Christian Porschmann of Königsberg made spectacles of amber, which he boiled in oil to get rid of the yellow colour. The Scandinavian and German name for spectacles is *brille*, which is probably derived from the word "beryl," although Stilling has traced it to the word *parilla*, a pair.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.

The annual meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held on July 15th at 20, Hanover Square, London. In reviewing the year's work, Lord Balfour of Burleigh, who was in the chair, said that new ground had been broken by the association in connexion with the National Insurance Act; it had got into touch with a number of the approved societies. Unfortunately, much of this work had been arrested, only temporarily it was hoped, by the war. The war, itself, however, had furnished practical evidence of the value of the principles which the association inculcated, for the advantage of open-air life and physical drill to those members of the new armies who had been accustomed to sedentary occupations was very quickly made manifest. It was also gratifying to know that in Leeds alone forty-seven men who had been successfully treated in the sanatorium were serving with the colours. The annual report was adopted on the motion of the chairman, seconded formally by Sir William Osler, and to the vacancies on the Council caused by the death of Lord Justice Kennedy and the resignation of Sir James Kingston Fowler, the meeting elected the Right Hon. Charles Hobhouse, M.P., and Dr. F. N. K. Menzies. Professor Joseph Denys, the director of the Bacteriological Institute of Louvain, who was greeted with special warmth on account of the misfortunes which have befallen his university, then delivered an address on the eradication and prevention of tuberculosis. So far as the human sources of tuberculosis were concerned, the mediums through which the disease was spread might be restricted for practical purposes to the sputum and to supporting discharges. In the latter the germs were comparatively few, and to destroy them it was only necessary to take the ordinary precautions of disinfection. With the sputum it was a different matter; in the first place, because of its more easy dispersal, and in the second, because of its enormous germ-content: 1 c.cm. of sputum might contain a million million germs, and taking the moderate estimate of 20 c.cm. as representing one day's expectoration of a single patient, and supposing only 1 per cent. of the germs to be living, this would mean the setting free of germs to the number of two hundred thousand millions a day. The sputum was the real enemy against which unceasing war must be waged. It should never be allowed to adhere to linen or any surface, for, once dried, it would scatter into the air as dust, a certain proportion of which would find a lodgement in the respiratory or digestive tracts. It was necessary that the patient should use a spitting vessel or flask, and that the contents be destroyed several times a day. The value of the spitting flask was proved beyond doubt by experiments which had been carried out under his direction, when a large number of samples of dust were collected from hospital walls and elsewhere, and injected into some hundreds of guinea-pigs. The results proved (1) that it was easy to find germs in the immediate surroundings of a consumptive who did not use a spitting flask; (2) that outside the immediate surroundings of a consumptive such germs were not to be found, owing to the effect of light, desiccation, etc.; and (3) that germs were not found in the surroundings of consumptives using spitting flasks. The careful consumptive,

¹ *Medicinsk-Historiske Smaaskrifter*. Edited by Vilhelm Maar, pp. 79. Vilhelms Trydes Forlag, Copenhagen.

therefore, was not a danger to the community. The perspiration of consumptives, he thought, could hardly be an infective agent, nor could the breath during normal quiet breathing, though it was otherwise during the paroxysms of a cough. Infection from cattle might come through meat or through milk. Infection through meat was less likely, because the bacilli were not usually in those parts of the animals used for food; animals known to be diseased were segregated and destroyed, and, moreover, cooking was a sterilizing process. In the case of milk, however, bacilli were very liable to be absorbed alive by the mucous membrane of the digestive tissues, and the obvious preventive was sterilization by boiling. He thought that something might be done in the human subject while the tuberculosis was still in the closed stage, before the bacillus had communication with the exterior. The object was to prevent the foci of the disease from becoming open, and he was among those who considered that by means of tuberculin treatment it was possible to destroy the germs in the persons in whom they were interned. Every measure of diagnosis and early identification should be taken, and it would be useful if some information were printed on the rules of all dispensaries as to the symptoms of early tuberculosis. The medical man should also bear in mind the fact that consumption generally existed in nests, and the most stringent inquiry should be made into the family history. Another desirable thing would be to send to a sanatorium for a brief period cases with regard to which there was even the slightest amount of suspicion, so that the patients would have a discipline in personal hygiene which would stand them in good stead on returning to ordinary life. No extreme measures were required; it was a matter of goodwill, knowledge, and understanding. The first of these could generally be depended upon, but if it were not forthcoming, then recourse must be had to the public opinion of the culprit's neighbours, who were the first to suffer for his refractoriness. The thanks of the meeting to Professor Denys were expressed by Lord Balfour.

PITUITARY EXTRACT AS A GALACTAGOGUE.

As is well known, the administration of extract of the posterior lobe of the pituitary gland to a lactating animal is followed by an increased secretion of milk from the mammary gland. It is indifferent whether the extract is given by subcutaneous, intramuscular, or intravenous injection; the effect appears within half a minute or less. Two explanations of this occurrence have been offered. One view is that pituitrin is a powerful stimulant for non-striated muscle generally, and that its action as a galactagogue is confined to expulsion of the milk already secreted in the gland, by causing contraction of the involuntary muscle with which the gland tissue and its ducts are freely supplied. The other view asserts that the pituitary extract stimulates the secretory mechanism of the gland. Evidence in favour of each of these views has been brought forward by different physiological experimenters. Quite recently Simpson and Hill¹ have shown experimentally that the injection of barium salts has no such galactagogue action. Now it is generally recognized that involuntary muscle fibre, like that of the mammary glands, is very sensitive to the influence of barium salts, which immediately throw them into a state of tonic contraction. It is argued that if the galactagogue action of pituitrin is by way of these muscle fibres, barium salts would necessarily be effective galactagogues. Simpson and Hill, therefore, conclude that pituitary extract acts on the secretory mechanism of the mammary gland when it produces a quickened flow of milk. Physiologists, however, will perhaps be slow to accept so positive an

assertion as this while it is based on what may be called merely negative evidence. There is nothing to show that barium salts actually do cause contraction of the involuntary muscle fibre in the mammary glands, as they do in other parts of the body. Again, pituitrin, though generally a powerful tonic stimulant of non-striated muscle, acts inhibitorily on it in some organs—in the arteries of the kidney, for example. To Sir Edward Schäfer² it appears impossible to accept the view that pituitrin stimulates the secretory mechanism of the mammary gland. If it did, the extract would be able to produce a flow of milk from the gland after it had been emptied of milk; experiment shows that it cannot do this. He offers two alternative explanations. One, already mentioned, is that the extract causes the involuntary muscle of the lactating gland to contract and squeeze out the milk it already contains. The other, suggested by Milroy, is that injection of the extract causes relaxation of the tonically contracted muscle fibres round the ducts, allowing the milk retained in the gland to escape; this hypothesis would fit in with the result of the experiment with barium salts described by Simpson and Hill. Sir Edward reasserts the presence of unstriated muscle fibres in the reticulum supporting the mammary alveoli, and pins his faith to the first of the alternative explanations mentioned above. He points out that the *vis a tergo* of the secreting cells in forwarding their secretion could hardly empty the mammary alveoli to the extent to which pituitary extract empties them.

SPANISH "INTELLECTUALS" ON THE WAR.

The manifesto of the ninety-three German "intellectuals," which was so startling a revelation to the world of the true nature of Teutonic "Kultur," called forth vigorous replies from leaders of thought in this country, in France, Russia, Portugal, Roumania, the United States, and Brazil. Quite recently the "intellectuals" of Spain have joined in the denunciation of the German manifesto. In a declaration signed by the foremost representatives of science, medicine, philosophy, literature, and art, they warmly profess their sympathy with the cause of the Allies as representing the ideals of justice. "Our conscience," they go on to say, "condemns, wherever they occur, these deeds which degrade human dignity, and the respect which men owe each other even in the fiercest excitement of war." They hope that the triumph of the cause which they hold to be just will "establish the essential qualities by means of which each people, great or small, weak or strong, has brought human culture into being, will destroy the ferments of egoism, domination, and shameless violence which are the causes of catastrophe, and will firmly cement a new international fraternity in which force will fulfil its object, which is to safeguard right, reason, and justice." The signatories state that they have been moved to break silence because, owing to the pusillanimity of her politicians, Spain has been made to appear as if she held herself aloof and feared to express any opinion on the great issues now being decided in this supreme moment of the world's history. This declaration will be welcomed by the countries which are fighting for the cause of civilization and the liberation of the world from an attempt to crush it under the heel of Prussian militarism. Hitherto Spain has, owing to a particularly active German propaganda, political and commercial, and to other causes which need not be discussed here, appeared to be pro-German in her sympathies. The manifesto from which we have quoted will serve to redeem her from the reproach of being on the side of barbarism. To us it is a matter of special satisfaction to see the names of many distinguished representatives of Spanish medicine in the list of signatories.

MODERN ARMOUR.

The war has had many surprises in the way of the re-introduction of appliances which were supposed to be entirely out of date, such as hand grenades, but perhaps the most curious is the revival of armour for the person. The French War Office has issued a number of metal skull caps to be worn under the kepi, and Le Dentu and Devraigne have recently presented a report to the Paris Academy of Medicine which affords evidence that this metallic cap may be of considerable value. Owing, apparently, to the nature of trench warfare, the number of wounds of the head seems to be unusually large; thus, among 105 soldiers killed or wounded during a single week the wounds were of the head in 14 cases—that is to say, in nearly one-eighth. Devraigne has collected some further statistics, from which it appears that of 55 cases of wounds or blows of the head from projectiles 42 occurred in men who had not worn the metal cap, and of them 23 suffered fracture of the cranium, while 19 had scalp wounds only. On the other hand, of 13 who were wearing the metal cap, 8 suffered from concussion only, and 5 escaped without abrasions. Le Dentu concludes that the metal skull cap is a real protection, but states that it is not popular with the men, owing, probably, chiefly to defects in its construction; it is too hemispherical to fit the cranium well, and it keeps in the perspiration, and for this reason and on account of its weight is apt to produce headache. The main reason why the use of metal armour has been abandoned in modern warfare is the belief that the thin sheet of metal would not turn a bullet and that fragments from the armour might make the wounds worse. There can be no doubt as to the possibility expressed in the second objection, but as to the first the facts are not conclusive. Le Dentu quotes two cases in which a bullet perforated a metal skull cap in the temporal region, circled round between it and the scalp, and escaped through the cap on the other side in the same region. One of these men suffered no wound, the other had an abrasion of the scalp. From the metal cap to armour for the chest is so small a transition that it is not surprising to find that the use of such a protection for the chest has been suggested. So far as we are aware, however, there is no evidence at present forthcoming as to its efficacy.

THE LONDON SCHOOL OF MEDICINE FOR WOMEN.

A LETTER signed by the Prime Minister, Lord Curzon of Kedleston, and Mr. Arthur Balfour, dated July 15th, has been published in the following terms: "The war has constituted a turning-point in the position of medical women, and there are new openings and new opportunities for them in many directions. Increasing numbers of women are desirous of entering the profession, and to provide for their adequate educational needs the London (Royal Free Hospital) School of Medicine for Women is now practically doubling its laboratory accommodation. The council of the school has already received £15,000 of the £30,000 required for the additional buildings and their equipment. We would direct your attention to the effort started by a number of representative men and women to help to raise the balance of £15,000 by means of subscriptions of £1 each." The school was founded in 1874 by Dr. Sophia Jex-Blake in a small private house in Hunter Street, Brunswick Square; larger premises were built on the original site in 1900, but the school has now outgrown these buildings also. In 1874 there were 14 students, to-day 220, and a further entry of over 60 is expected next term. The Royal Free Hospital has not only thrown open its wards to women students, but has made qualified women eligible for resident and visiting appointments. The school is a school of the University of London in the Faculty of Medicine, and of the thousand women on the *Medical Register*, over 600, it is stated, have received their

training at it. They are doing good work in public health departments, in sanatoriums, in Poor Law institutions, in medical missions, and in hospitals both in Great Britain and India, as well as in private practice. Many of them are working among the sick and wounded both in this country and in France and Serbia, and a military hospital in Endell Street for 550 wounded soldiers is in charge of former students of the school. The Queen recently allotted £250 from a fund placed at her disposal by the wives of Freemasons to pay for the training and expenses of a woman student. The council of the school has secured from the Foundling Hospital a piece of land adjoining the present premises, and the building of an extension, comprising enlargements of the present laboratories, new research rooms and new lecture rooms, from the designs of Mr. H. V. Ashley, F.R.I.B.A., has already been begun. Subscriptions may be sent to Her Grace the Duchess of Marlborough, the Honorary Treasurer of the Extension Fund, London (Royal Free Hospital) School of Medicine for Women, 8, Hunter Street, Brunswick Square, W.C.

THE WAR REGISTER.

It is hoped that those members of the profession who have not yet returned the War Register form, sent to them by the British Medical Association, will do so without delay, in order that the Register may be completed as soon as possible. The forms have been issued by the British Medical Association in order to find out if there are any members of the profession still available for whole-time service with the Royal Army Medical Corps.

THE Marine Department of the Board of Trade has issued a notice with regard to sight tests in the mercantile marine and fishing service announcing that the Board has decided to discontinue the use of wool tests in the examination of candidates in the sight tests after January 1st, 1916.

Medical Notes in Parliament.

R.A.M.C. and Territorial Force: Promotion of Lieutenants.—Viscount Middleton asked the Government in the House of Lords, on July 21st, whether it was intended to make any increase in the pay of medical officers of the Territorial Force, who had been obliged to give up their home practice on volunteering for foreign service. Lord Newton stated in his reply that, in view of the admitted grievance of the junior officers, it had been decided to promote to the rank of captain all lieutenants in the R.A.M.C. and the Territorial Force who had given six months' mobilized service. This would be done immediately, and would date as from April 1st last. The further consideration of this question was not entirely precluded.

Promotions in the R.A.M.C.—Sir Joseph Walton asked, on July 19th, whether, in consequence of the war, a large number of R.A.M.C. lieutenant-colonels had been promoted to colonels, and similarly a large number of majors had been made lieutenant-colonels; whether all lieutenants had been made captains, and why no captains had also received accelerated promotion. Mr. Tennant said that a number of captains had received accelerated promotion, and further promotions would be made when the necessity arose. The names of several had been recently submitted for gazette.

Medical Officers and War Office Services.—Mr. Charles Duncan asked the Financial Secretary to the War Office, on July 15th, whether the medical officers of Rochester, Chatham, and Gillingham were performing any services for the War Office, and, if so, would he state the amount of remuneration being paid to them. Mr. Forster said that

the answer to the first part of the question was in the affirmative. In the case of Chatham the remuneration was 24s. a day and in the others 15s.

Asylum Medical Officers.—Sir Philip Magnus asked the Under Secretary of State for War, on July 20th, whether a retired medical officer of the asylum service who accepted medical duties under the military authorities was deprived of his pension under Clause 7 of the Asylum Officers' Superannuation Act to the extent that no such officer might receive more of the superannuation allowance than, together with the pay from the military authorities, was equal to the remuneration of the office or employment in respect of which the superannuation allowance was awarded; that, consequently, in some cases the officer employed worked for less than half the salary paid to other men; and that no such disability applied to military and naval pensioners; and whether, in view of the scarcity of medical men at the present time both for the army and for civil practice, he would take steps to ensure the restrictions under Clause 7 of the Asylum Officers' Superannuation Act being waived. Mr. Tennant said that the provision in question was not peculiar to asylum officers, but was applicable generally to persons drawing civil superannuation allowances. It was not proposed to alter the law, so far as he was aware, but the matter was one for the Treasury rather than the War Office.

Retransfer to Royal Army Medical Corps.—Mr. Tennant stated, on July 15th, in reply to Mr. Jowett, that under instructions already issued men might be retransferred to the Royal Army Medical Corps provided it was clearly established that they had conscientious scruples as regards taking life. In replying to Mr. Suowden, on July 19th, Mr. Tennant repeated his previous statement that men in the R.A.M.C. who had conscientious objections to taking life would be specially dealt with, and added that he hoped that the great bulk of those members of the R.A.M.C. who had been transferred to other regiments would be reinstated in their original corps.

Treatment of Nerve Strain.—Dr. Macnamara, in reply to Mr. Rendall, who asked a question on July 14th regarding the treatment of sailors in the Royal Navy disabled by nerve strain, said that suitable accommodation and treatment were provided in the base naval hospitals for all cases of nerve strain and neurasthenia. All such cases were naturally most carefully diagnosed before any decision was come to as to whether they were certifiable or not. Certification of all naval cases was carried out by naval medical officers and not by an asylum doctor. No man so certified could, however, be sent to any asylum until his discharge had been approved by two Lords of the Admiralty. All cases of insanity attributable to the service, and all men who had length of service to their credit, were treated in the naval asylum, and not in a general asylum. Mr. Tennant, in replying to Mr. Ginnell on July 20th, referred to the answers already given in the House of Commons, stating that every endeavour was being made to treat soldiers suffering from traumatic neurasthenia and mental strain in such a manner as to avoid sending those not certifiable into asylums, and for this purpose arrangements had been made to treat such cases in certain private and civil hospitals in the United Kingdom; a Red Cross military hospital had been opened in Lauchshire for their reception. The question of the boarding-out of such persons had been considered, but the practical difficulties in the way were considered insuperable.

Naval and Military War Pensions Bill.—On the motion for the third reading of this bill, on July 20th, the Chancellor of the Exchequer moved to recommit the bill in order to omit from the statutory committee the representatives of the National Relief Fund and the Soldiers' and Sailors' Families Association. He did this on the ground that members of the National Relief Fund did not think that they would be justified in handing over the funds entrusted to them by the public to be administered by any other body. The omission of the representatives of those bodies from the statutory committee would not preclude

representatives from sitting on the local committees. After some discussion the amendment was accepted, and the bill read a third time.

Dardanelles Operations: Casualties to End of June.—In reply to Mr. Joynton-Hicks the Prime Minister stated that the total casualties sustained by both naval and military forces in the Dardanelles up to June 30th are as follows:

Officers:	Killed	541
	Wounded	1,257
	Missing	135
			1,933
Men:	Killed	7,543
	Wounded	25,557
	Missing	7,401
			40,501
Total casualties	42,434

Sir Ian Hamilton's further dispatch, containing his recommendations promised in his dispatch of May 20th, would be published as soon as the names had been checked; it was also stated that Admiral de Robeck's dispatch dealing with the landing operations would be published shortly.

Inoculation for Enteric Fever.—Mr. Yeo asked the Under Secretary of State for War, on July 14th, whether some of the British soldiers in Europe who were inoculated against typhoid fever a few months ago were being re-inoculated; whether these men were being told that in order to be properly protected against typhoid they must be inoculated every six months; and whether periodical re-inoculation for the troops was being generally recommended. Mr. Tennant said that the answer to the first two parts of the question was in the negative. Re-inoculation was recommended after two years for men protected by two doses, and after six months for men who had been only partially protected by single doses of vaccine. On July 15th Mr. Chancellor asked the Under Secretary of State for War if he was aware that on June 28th the H Battery, Royal Horse Artillery, mobile section, 2nd Cavalry Brigade, who had been serving at the front for eleven months, were paraded and addressed by Colonel Budworth, who called the men who had exercised their legal right to refuse inoculation cowards, said he would like to hand them over to the Germans, threatened refusal of leave, and in some cases sent them to the tranches as punishment; whether the War Office sanctioned the calling men cowards and refusing leave after eleven months' fighting without a complaint; and whether he would reprimand this officer and protect from such treatment soldiers who had acted on the faith of his word. Mr. Tennant said that he had no information about this case, but if the information was correct he felt sure that the Field-Marshal Commanding-in-Chief, in whose hands the discipline of the Expeditionary Force rested, would have taken proper notice of the matter. Mr. Chancellor asked, on July 19th, by what means the cases of typhoid, which on May 4th numbered 963, had been reduced on May 22nd to 827, although deaths from typhoid had increased from 100 to 128, and whether the reduction was due to mistakes in diagnosis, or to the transfer of typhoid cases to other classifications so as to make the failure of inoculation as a preventive less apparent. Mr. Tennant said it would be well if Mr. Chancellor refrained from suggesting that the medical authorities were guilty of manipulating the statistics in an untruthful, unscientific, and *ex parte* manner. The reduction in the number of cases was due to the original (that is, clinical) diagnosis not having been confirmed in some cases by the subsequent bacteriological examination, which disclosed that those cases, though originally returned as enteric fever, were not that disease at all. The House generally and the public at large would hear with satisfaction that inoculation was abundantly proving its efficacy in preventing enteric fever and in lowering the incidence of death amongst those who were unfortunate enough to contract the disease.

Vaccination of Territorial Troops.—Mr. Tennant informed Mr. Yeo that as the result of inquiries he was informed that the statement that men of the Queen's Royal West Surrey Regiment (T.) had been threatened with compulsory vaccination on board ship was absolutely unfounded.

Convalescent Accommodation for Scottish Soldiers.—Mr. Tennant stated, on July 15th, in reply to Sir A. Williamson, that endeavours were being made to find a suitable place in the north of Scotland for the establishment of a hospital for convalescent soldiers belonging to that part of the country.

Hospital Ship "Oxfordshire."—Mr. Tennant stated in reply to Mr. Watt, on July 19th, that there was no truth in the allegation that on the hospital ship *Oxfordshire*, from Havre to Southampton, on March 19th, sixty wounded British soldiers were taken out of their cots to make room for sixty Germans. He was glad to have the opportunity of correcting a rumour as unpleasant as it was ill founded.

Asphyxiating Gas.—Mr. Tennant informed Sir Henry Dalziel, on July 15th, that the communiqué issued by the War Office to the press on July 11th, stating that the allies had not resorted to the use of gas, referred to the operations in the Gallipoli Peninsula, and was a denial of statements made by the Turks that gas had been used by the British forces. There was no change of the policy announced by the Secretary of State for War in the House of Lords.

Civilian Dispensers.—Mr. Glyn-Jones on July 14th asked whether the War Office had during the past few weeks engaged as civilian dispensers in military hospitals qualified pharmacists on the condition that they receive 40s. a week with free rations and free accommodation; and whether the War Office would permit the pharmacists so engaged to enlist for the purpose of performing the same duties and receiving therefor the same emoluments as they now received from the War Office as civilians. Mr. Tennant said that if the men in question were of military age and were otherwise fit to enlist, they could do so, but they would be required to come on the ordinary Royal Army Medical Corps rates of pay. Mr. Glyn-Jones: Then the War Office is not prepared to pay them the same rate of pay inside the army as they are prepared to pay for exactly the same skilled work to civilians. Mr. Tennant said that he did not know whether that was an accurate statement of the comparison between the two rates. Local commanders, he understood, had encouraged the service of these men on a temporary basis, and they were paid as were all people engaged temporarily—at a higher rate than if they came on the permanent rate. In answer to a further question Mr. Tennant added that he would be very glad to make use of the assistance of the Pharmaceutical Society with a view to meeting any further need for the use of pharmacists in the army or navy.

The Milk and Dairies (Consolidation) Bill passed through Committee of the House of Commons on July 19th without any amendment, and was read a third time. The bill, which was introduced in fulfilment of a promise made during the discussion of the bill of last session, consolidates without any amendment the main provisions of the law relating to milk and dairies. It does not profess to be a complete code of the law relating to these matters, but in the fifth schedule an attempt has been made to collect, for the information of dairymen, the chief provisions affecting them outside the scope of the present bill. This schedule enumerates the provisions of the Public Health Acts, and the Public Health (London) Act, 1891, with respect to nuisances and the sale of food so far as they relate to milk and dairies, the Sale of Food and Drugs Acts, 1875 to 1907, the Public Health (London) Acts, sections 69 and 71, the Public Health Acts Amendment Act, 1907, sections 53 and 54, and the Infectious Disease Prevention Act, 1890, section 4.

Payment of Vaccination Officials.—Mr. Hayes Fisher, in replying to a question by Mr. Peto on July 14th regarding arrears of pay of vaccination officials, said that the President of the Local Government Board agreed that a case had been made out for the change of payment from a system of fees to a system of salaries, but felt that the present was not an opportune time for a general change in the method of remuneration of vaccination officials.

Supply.

Treatment of Tuberculosis.—In Supply on June 15th a vote of £235,000 for the year ending March 31st, 1916, for the payment of grants towards the cost of sanatorium benefit to the dependants of insured persons under the

Insurance Act, 1911, and of the treatment of tuberculosis generally, was agreed to. In reply to questions Mr. Montagu said that it did not necessarily follow that the money voted would be spent; as a matter of fact, there was a decrease this year as compared with last year of 195,000. Mr. Charles Roberts, Chairman of the Joint Committee of Insurance Commissioners, repeated the statement that an arrangement had been made whereby soldiers suffering from tuberculosis discharged from military hospitals should immediately be transferred to sanatoriums or other residential institutions, and said that the grant was being applied with great economy, and the scheme for the benefit of tuberculous soldiers was for the moment holding the field. The existing sanatoriums were taking over the soldiers as beds became available.

Pathological Laboratories.—On the vote for £25,000 to assist in the provision of laboratory facilities with a view to the prevention, diagnosis, and treatment of disease, Mr. Pringle asked for explanations. Not only the staff of ordinary practitioners, he said, but also the staff of specialists had been largely depleted and many pathologists had been drafted into the ranks of the Royal Army Medical Corps, so that there was practically nobody left in this country to run the laboratories. Mr. Montagu said that the scheme had been started last year, but the money voted had not been spent, because it was not found possible to set the machinery going. Local pathological investigations would be of the utmost value in arresting the spread of disease, and it was desirable that they should be started with the least possible delay. The sum originally granted was £50,000, but it was felt that for the reason suggested so large a sum could not be utilized. At the same it was desirable to make a start, and the need had been increased in consequence of diseases resulting from the war. If the necessary medical and expert knowledge for carrying on the scheme could not be obtained the money would not be spent. After some further discussion the vote was withdrawn.

Highlands and Islands Medical Service.—On the vote for the expenses of the Highlands and Islands Medical Service Board and for a grant-in-aid of the Highlands and Islands Medical Service (£42,015), Mr. Macpherson (Ross and Cromarty) said that a great many doctors and nurses in the highlands and islands of Scotland had left for the front, and he asked for an assurance that the wild parishes in those districts would not be deprived both of doctors and nurses. He hoped that a certain amount of money would be used to provide a comfortable house, well situated in the midst of the parish, for a doctor in each of the districts. Referring to the prevalence of consumption in the island of Lewis he expressed the hope that the Medical Service Board would formulate and bring into operation a scheme for dealing with the disease. After some further discussion, the Secretary for Scotland (Mr. McKinnon Wood), who replied, said that the provisions of the Insurance Act, and now the war, had made it very difficult to obtain doctors for places where the practice was not very lucrative and where the work was often very arduous. The country owed a great debt of gratitude to the Highlands and Islands Board, the members of which were unpaid. Mr. Morton (Sutherland) criticized the Board on the ground that certain schemes it had prepared had not been approved by the Treasury and the Secretary for Scotland. Mr. Montagu said that the schemes were now in course of being approved, and there was no desire to block them. The vote was agreed to.

Friendly Societies' Deficiency.—A sum of £14,712 was voted for the year ending March 31st, 1916, to make good the deficiency on the income account of the fund for friendly societies.

Universities and Colleges.—On the votes for universities and colleges, including special grants, the whole amounting together to £356,200, Mr. Montagu said that among the first institutions to feel the brunt of the war were certain universities, colleges, and medical schools which were depleted to a very large extent of their students, and which had suffered a serious diminution in their income from sources other than fees. Special grants would be paid only to those universities, colleges, and medical schools which were already in receipt of parliamentary grants. The special grants were to assist them over a period of difficulty, and no new expenditure was contemplated. The votes were passed, as was also a vote of £64,000 for universities and colleges in Ireland. In reply

to Mr. King, Mr. Birrell said that Ireland would not benefit by the special grants.

Scientific Investigation.—A vote of £48,582 and a supplementary grant of £25,000 for scientific investigations, etc., were passed.

Navy and Army.—Token grants for the navy and army expenditure for the year 1915-1916, including the medical establishments and services, were passed under the 10 o'clock rule.

The National Registration Act, 1915, which received the Royal Assent on July 15th, directs a register to be formed of all persons, male and female, between the ages of 15 and 55, not being members of the Naval Forces, or of the Regular or Territorial Forces. It applies to all other persons except prisoners in a prison, certified lunatics or defectives or the inmates of any Poor Law institution, hospital, or any other prescribed institution, prisoners of war, or persons interned. The central registration authority is the Registrar-General, acting under the directions of the Local Government Board, and the local registration authorities are the Common Council of the City of London, and the councils of metropolitan and municipal boroughs, and of urban and rural districts. It is the duty of the local registration authority to compile and maintain a register, to tabulate the contents thereof, and to make them available for any purpose that may be prescribed in accordance with the instructions issued by the Local Government Board. The central registration authority will prepare and issue forms to local registration authorities which will cause them to be distributed to every dwelling house. It will be the duty of every person to fill in the forms and to give the following particulars:

(a) Name; place of residence; age; whether single, married, or widowed; number of dependants (if any), distinguishing wife, children, and other dependants; profession or occupation (if any), name and business address of employer (if any), and nature of employer's business; and (in the case of a person born abroad) nationality, if not British; and

(b) Whether the work on which he is employed is work for or under any Government Department.

(c) Whether he is skilled in and able and willing to perform any work other than the work (if any) at which he is at the time employed, and, if so, the nature thereof.

Any person refusing or neglecting to fill up the form, or making any false return, will be liable, on conviction under the Summary Jurisdiction Acts, to a fine not exceeding £5, and, in the case of a continuing offence, to a further fine of £1 for each day during which the offence continues. When the form has been filled up, completed, and corrected, the person to whom it refers is to be supplied with a certificate of registration, which must be signed and preserved by him. No person is to be registered in more than one area, and employers are required to furnish information and to render such assistance as may be prescribed in respect of all persons in their employment required to be registered. The Act applies, with necessary modifications in administration, to Scotland and Ireland, and will continue in force during the continuance of the present war, and no longer. The expenses, both of the central and local registration authorities, are to be met out of moneys voted by Parliament, but if a local registration authority exceeds the amount sanctioned by the Treasury the excess must be paid out of the rates.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE CENTRAL COMMITTEE.

A MEETING of the Central Committee was held on July 15th, when the following brief statement of the receipts was submitted by Dr. Des Voeux, the honorary treasurer:

Total Contributions Received.

£ s. d.		£ s. d.	
From November 24th	921 15 0	April	2,308 19 5
to end of month	1,516 10 0	May	3,368 0 5
December	2,106 15 0	June	1,212 11 8
January	2,436 10 0	July (to date)	447 5 6
February	1,137 16 8		
March			£15,456 4 2

Detailed Source of Contributions.

£ s. d.		£ s. d.	
From Australia	1,859 0 0	From Scotland	1,161 9 3
Canada	1,450 4 5	Ireland	129 17 10
New Zealand	1,095 19 0	England	9,735 15 8
Colonial total	£4,405 3 5		

The statement does not include the money which has been collected by the Irish Branch Fund, the receipt of which is acknowledged in the list of the week's subscriptions below. The greater portion of the money received is still on deposit at the bank and bearing interest, but, as already announced, arrangements are now in force for sending regularly large sums to the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés, sitting at Brussels.

THE WEEK'S SUBSCRIPTIONS.

The week's subscriptions include £983 received from Dr. C. M. Benson, Secretary to the Council of the Royal College of Surgeons in Ireland, and Dr. T. C. P. Kirkpatrick, Registrar of the Royal College of Physicians in Ireland, the joint secretaries and treasurers of the Irish Branch Fund. A previous sum, amounting to nearly £130, received from Ireland was largely made up by subscriptions received through Dr. Macnaughton-Jones and mainly from Cork.

The subscriptions received from a group of medical men in Cheltenham represent the balance of a fund raised among themselves to provide a furnished house for two Belgian doctors, who resided in it for nearly three months before returning to Belgium.

Thirty-Dial List.

£ s. d.		£ s. d.	
Sir George Savage	5 0 0	Lieut.-Col. G. T. Birdwood, I.M.S.	5 0 0

Liverpool Belgian Doctors' Relief Fund (subscribed entirely by doctors) (2nd donation—total, £422 2s.)	22 2 0		

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

THE WAR.

THE WORK OF A HOSPITAL SHIP.

In the July number of the *Journal of the Royal Naval Medical Service*, Fleet Surgeon Trevor Collingwood, M.V.O., Senior Medical Officer of H.M. Hospital Ship *Soudan*, gives an account of her work in the Dardanelles. The *Soudan* is a converted transport of 6,696 tonnage, with bed accommodation for 202 cases and arrangements for 100 more beds in an emergency. From the first operations, which consisted of the destruction of the forts at the entrance, 137 naval casualties were received between February 25th and March 19th. After this there was a lull for a time, only 4 wounded being sent on board. The next operations consisted in a landing of the army, supported by the navy, under a very heavy fire from both sides of the Straits. From April 25th to May 1st, 429 wounded were received, 352 military and 30 naval ratings being admitted on the same day.

On February 25th, about noon, the *Soudan* arrived at Tenedos: in the evening 7 cases of shell wounds were received from the *Ayamemnon*. Four of these were very severe: in one, a case of extensive deep wound of the right thigh with splintering of the femur and wounds of both legs, signs of tetanus showed themselves on the sixth day; antitetanic serum was used, but death occurred two days later. No definite cause was discovered; but Fleet Surgeon Collingwood says, "It is of interest to note that the guns on board were protected by bags of sand, which I believe were not obtained locally, but brought from England, and that some of the bags were struck by the shell fire near this boy." There were no cases of gangrene. Two cases of compound comminuted fracture of the leg were treated with pure carbolic applied under an anaesthetic, and antiseptic serum was administered at the time. In one of these, in which both legs were injured, the wounds of the right limb, when the man was taken on board six days after, were foul and septic, and were again treated with pure carbolic under an anaesthetic. The wounds of the left leg were fairly healthy, and were not again treated with carbolic, yet after a few days both wounds seemed to be going on satisfactorily. "This," says Fleet Surgeon Collingwood, "may be of some interest in connexion with the present discussion about early treatment of wounds with pure carbolic. The second application, though not quite orthodox, was apparently beneficial."

In addition to the wounded 83 cases of disease and injury were treated on board the *Soudan*. Special mention is made of two cases of paraplegia, one the result of an injury to the spine by a coal hoist, the other due to caisson paralysis from diving.

On March 22nd the *Soudan* left for Malta, where 113 cases, including 76 wounded, were landed at the Royal Naval Hospital. On April 25th the *Soudan* was again at the entrance to the Dardanelles then the scene of great naval and military activity. By the evening 10 military officers and 342 soldiers had been received. In 230 of the more serious cases the following regions were injured: Shell wounds—head, 8; chest and back, 3; upper limbs, 13; lower limbs, 22. "In many cases it was difficult to say whether the wounds had been inflicted by shell fragments or bullets, for many of the latter were very severe; one bullet extracted was about 1 in. in diameter, of cast iron with ring of casting marked; another was about $\frac{3}{8}$ in., and made of lead; from one wounded officer were extracted seven fragments of an electric flash lamp, four pieces of metal, a small piece of glass, two pieces of the composition, and a small piece of the splintered femur." By 8 p.m. 382 had been received, making, with 48 already on board, a total of 430 cases. Permission was therefore given by the Vice-Admiral Commanding for the *Soudan* to draw off in order that the staff might be able to attend more carefully to their patients. During the period from February 25th to May 2nd the number of cases treated on board the *Soudan* was 733, of whom 570 were wounded and 163 ordinary medical and surgical cases. By midnight most of the men were asleep and as comfortable as could be expected in the circumstances, except about a hundred who required special attention. The profound shock in several of the abdominal cases made operation

impossible. Five amputations were performed, with two deaths.

On May 2nd, the army having established a footing ashore, the *Soudan* was ordered to withdraw to a safer anchorage a little way off. On May 17th, at noon, she was again placed at the disposal of the military, and proceeded to Gaba Tepe to receive wounded from the Australian and New Zealand contingents. On that day 34, on May 18th 90, and on May 19th 190 were admitted, but later in the day 104 of the less severely wounded and sick were transferred to the *Gateka*, an army hospital carrier, as it had been arranged that as far as possible the *Soudan* was to receive only seriously wounded that required prompt and expert surgical treatment. On May 20th 67 were received, and on May 21st 30, making in all 411 cases in the five days, only a few being medical; included amongst the wounded were 9 Indian soldiers. Nine wounded prisoners were also received, including an Albanian lieutenant and Turkish warrant officer. There were three deaths, but no cases of tetanus. During this period some sixty anaesthetics were given for major operations (six laparotomies with five deaths, and six amputations with one death), and for examination and dressing of some severely wounded. The *Soudan* left the Dardanelles on May 21st, and arrived at Malta on May 24th, when all the army wounded were transferred to the old military hospital at Valetta, and were accommodated in the large ward, over 500 ft. in length, used in the past by the Knights of Malta.

FLIES IN FRANCE.

From many letters—some published in the newspapers and some private—it is clear that flies are causing a good deal of annoyance to the British forces in the field, especially to men in certain parts of the actual front in Northern France, and in the Dardanelles. In France the extent of the nuisance does not seem to be nearly so great as might have been expected. The weather conditions this summer have not so far been highly favourable to non-parasitic insect life, and the medical authorities of the army, we learn, have paid great attention to the extermination of flies in camps and billets and hospitals.

The general character of the steps that have been and are being taken is indicated by the following paragraphs which we derive from a memorandum on the subject addressed by the Director-General of Medical Services, Sir Arthur Sloggett, early in the spring, to the principal medical officers of all army corps, divisions, and areas, as also to the commanding officers of all medical units and the medical officers in charge of regiments.

In a preliminary note the Director-General pointed out the reasons why great numbers of flies might be expected in default of the adoption of adequate measures for their prevention, and then directed that the carrying out of those recommended by him should be ensured by constant expert supervision. Continual search was enjoined for breeding places; the appearance of house flies in excessive numbers was at once reported through the usual channels, and attention be paid to the whole subject by all officers responsible for the sanitary supervision of troops and areas.

Fly Development.

The memorandum itself, after the allusion to the evidence that flies, especially house-flies, are capable of transmitting disease, stated that the eggs of house-flies, when deposited in suitable media in the presence of heat and moisture, hatched into larvae in from six to twenty-four hours.

The larvae become pupae or chrysalids in from four to six days, and the adult flies emerge about five days later. Complete development thus takes from ten to twelve days, but in very hot weather may be accomplished in seven days.

Their usual breeding place was horse manure, but house-flies would also breed in human excreta, garbage, and other organic refuse.

Ninety per cent. of all house-flies lay their eggs in stable manure. Uncovered accumulations of all such substances constitute a risk of infection, and should, therefore, be sought out and put in a state of defence against deposition and development of eggs, or burnt, buried, or removed at least once in every seven days.

Destruction of Breeding Places.

The treatment of manure was considered under three headings: (1) Existing manure heaps in farmyards; (2) fresh accumulations of manure belonging to inhabitants; (3) manure and scrapings from military horse-lines.

(1) Flies, it was pointed out, do not breed readily in stale or fermented manure, so old manure is less dangerous than fresh; nevertheless old manure heaps in farmyards should always receive special treatment.

Fresh additions should be prohibited; the heap should be concentrated as much as possible, and should then be lined and covered over (top and sides) with one foot of earth, well beaten down with spades. Fly maggots congregate chiefly at the outer edges of manure heaps, but they also tend to migrate and may even be found some distance away in wall crevices, under rubbish, or several inches beneath the soil. Attention should therefore be paid to the sides of the manure pit, where exposed by concentrating the manure, and these should be well sprayed with cresol, and the spraying repeated after a few days. If it is necessary to open the heap after it has been covered, in order to withdraw manure, the exposed surfaces must, as soon as possible, again be protected as described above.

(2) Fresh accumulations of stable manure belonging to civilian inhabitants should if possible be carted to a general dumping ground, several hundred yards from the nearest farm or village; and should there be either concentrated and sprayed with cresol once a week, or be spread out to dry.

Although somewhat resistant to drying and sunlight, fly larvae usually seek cover and moisture. On the other hand, the eggs are susceptible to desiccation, which prevents hatching, and thus in dry weather the spreading of manure on suitable dumping grounds may give good results.

(3) Manure from military horse-lines should, together with horse-line scrapings, be incinerated whenever possible. If this be impracticable it should be either—

(a) Removed in carts or by means of a tram-line, where one exists or can be made, to a dumping ground as far from the camp or billeting area as possible, and preferably in a valley. Here it should be lined and earthed over (one foot of earth on top and sides of the heap) as it is deposited, or spread out and burned when dry. To avoid nuisance from heaps awaiting removal, the manure may be temporarily stored in the cart, which should be tightly rammed. When sold to farmers, precautions and supervision are necessary pending and after removal.

(b) Made into heaps, which may be dealt with by either of the following methods:

- (i) Lined over and covered with an even layer of earth 12 inches deep.
- (ii) Sprayed with kerosene or cresol, or with borax solution $\frac{1}{2}$ lb. to the gallon.
- (iii) Sprayed with kerosene and the top layer burned.

The treatment should be applied particularly round the margin of the heap, and to the walls enclosing it if such exist, and each fresh addition of manure must be treated immediately it is thrown on. Crude borax, in the proportion of 1 lb. to 15 cubic ft. of manure, is said to have been tried with considerable success. Though destructive to the ova and larvae of flies, it is non-poisonous, and does not lessen the value of the manure.

The memorandum also pointed out that horse-luts should not be stabled or picketed close to billets or dwelling huts, or near to kitchens or dining-rooms of standing camps.

Cleanliness of stables and horse-lines, and the daily removal of horse droppings and manure must be ensured. When possible fresh straw-stuff should be used instead of litter. A single neglected stable or horse-line may cause a plague of flies in an entire camp. Picket lines should be burned over once a week.

In regard to other possible breeding places than manure, it was pointed out that all human excreta should either be incinerated or covered with earth. Trench latrines should be shallow whenever possible, and constantly supervised to ensure that the excreta were kept covered with earth. Less than 1 ft. of dry earth over excreta would not infallibly prevent flies from emerging if eggs had been deposited before the faeces were covered. When latrine buckets were used, sufficient cresol solution should be added to cover the excreta completely. If the contents were to be incinerated, kerosene or crude tar oil might be used instead.

All garbage, kitchen, and other refuse, including empty meat and jam tins, should be placed in covered water-tight receptacles, and burnt as soon as possible. The

receptacles should be regularly cleaned with cresol solution, or, after washing, smeared with crude tar oil. Liquid kitchen garbage should be kept separate from dry. All camp refuse should be burnt where practicable; otherwise it should be buried at a sufficient depth. Fresh additions to refuse pits should be covered over at once with a layer of earth, not less than 1 foot in depth. Chloride of lime, if used, should be renewed periodically.

Old collections of garbage, if their incineration or removal or burial is not practicable, should be treated in the same fashion as manure and scrapings from horse-lines.

General Precautions.

The keeping of pigs in close proximity to standing camps should be prohibited, and the carcasses of animals should be efficiently buried.

The floors of dining-rooms and kitchens should be kept free from grease and organic matter, and tables, meat blocks, and kitchen utensils cleaned immediately after use.

The men should be warned of the necessity of cleanliness in the handling of food of all kinds, and all available precautions should be taken to prevent the access of flies thereto. Whenever possible all kitchens, meat stores, and dining-rooms should be fly-proofed by wire meshing. Food in hospitals should be kept covered with gauze.

When any pollution of the ground had occurred, especially around kitchens and latrines, chloride of lime should be freely used. Living larvae present in the soil were likely to be destroyed if the earth were impregnated with lime or chloride of lime.

Fly Destruction.

Various fashions of destroying fly eggs and living flies were mentioned. In stables a trap for fly eggs could be made by putting some fresh manure on a tray. Flies would lay their eggs therein, and each evening the tray could be removed and incinerated. In hospitals, kitchens, and billets, "fly balloons" made of wire gauze and baited with jam or sugar were useful as traps, as also were "bangle foot" tapes, and other like contrivances, coated with a sticky gum. A fashion was also described and illustrated of adapting a galvanized iron refuse bin to form a fly trap while still serving as a receptacle for refuse. Two fly poisons were also recommended for use.

A fly poison, which is harmless to man, can be made by mixing one teaspoonful of formalin with eight teaspoonfuls of milk (or condensed milk diluted 1 to 1 with water). This mixture should be placed in open saucers and exposed in living rooms and other places, care being taken that no other liquid is accessible. The flies which drink of it die in from fifteen to twenty minutes.

Under strict supervision, and with due precautions to ensure the safety of man and animals, sodium arsenite, as employed in South Africa, may be used in base camps. An effective formula is 1 lb. of the poison and 12 lb. of coarse black sugar or treacle dissolved in 20 gallons of water, but the exact proportions are not material. The arsenite, which is not readily soluble in cold water, should be dissolved first in a little boiling water, and can then be added to the sweet solution. This poisoned bait is distributed where flies congregate, by being sprayed with a syringe or spray-pump over such places as manure heaps and the surrounding vegetation; or leafy branches are dipped in the solution and hung up, out of harm's way, over latrines, etc. Where the poison is sprayed on and about manure heaps, or elsewhere in the open, it need only be applied very lightly, and must, of course, be renewed after rain. When thoroughly carried out and combined with the measures detailed above for the covering over or destruction of breeding places, this method has given excellent results.

Since the date of the issue of this memorandum the importance of attention being paid to the subject has, we hear, been further emphasized by the Director-General in sundry other ways. In particular, the principal medical officers of all divisions have been directed to draw up periodical reports on the measures adopted in their areas for the destruction of flies, manure, and food refuse, and to submit them through the usual channels to the Director-General in order that the most effective system may be brought into general use.

There has also been included in orders a statement to the effect that in the opinion of an advisory committee of entomological experts established some time ago, sodium arsenite is to be regarded as the most effective of all possible fly poisons.

GERMAN EXPERIENCES OF WAR SURGERY.

(Continued from p. 111.)

The following notes on the proceedings of the Deutsche Gesellschaft für Chirurgie which met in Brussels on April 7th are published in continuation of those which appeared last week:

GAS GANGRENE.

Fränkel's bacillus was the cause of the gas gangrene, which occurred chiefly among the wounded who had been neglected in the field for a long time. It was of the greatest importance to detect the disease in its first stage, for only by early treatment could the patient's life be saved. The condition was not difficult to diagnose, for the skin acquired the colour of copper, was puffy, and gave a hollow note on percussion or stroking, and emphysematous crackling on palpation. The discharge also contained bubbles of gas. By energetic operative treatment it was possible, not only to save the patient's life, but also the limb involved. Professor Kümmell was surprised to find the results of this treatment in war time better than in times of peace, when the mortality was 80 to 85 per cent. It was necessary to decide whether gangrene was already present or not. In the latter case extensive incisions were often sufficient to arrest the further spread of the disease, particularly when hydrogen peroxide was applied to the widely opened wound. When, however, gangrene had supervened, it was necessary to amputate at once, to cut no flaps and use no sutures. It was not essential to amputate much above the level of the healthy skin, but deep incisions had to be made as far as the emphysema extended. It was improbable that tetanus and gas gangrene could be completely avoided, even if it were possible to excise the wounded tissues early in every case. Early radical treatment was, indeed, apt to interfere with the uncomplicated recovery of many wounds, and the speaker had learnt to open and excise the channel of the wound, and remove the bullet, only when fever developed.

Herr Franz had not observed a single case of tetanus among 2,000 wounded soldiers who had received prophylactic injections of serum. Gaseous infection was observed in 2 per cent., and the mortality from this complication was 55.4 per cent. The disease usually developed within four days of the infliction of the wound. The discoloration of the skin was not pathognomonic, for the same discoloration might be observed over an infected hæmatoma. When the gaseous infection was deep-seated, crackling of the skin, drying up of the wound, and the characteristic odour might not be present. In these cases the development of severe, inexplicable pain, of œdema, of a boxy note on stroking the skin with a razor, the increase of the pulse-rate to 140 or 150, and striking pallor of the face, were of diagnostic importance. The moist tongue distinguished the case from one of sepsis, and there was neither enlargement of the spleen nor albuminuria. Gaseous infection was five times more common in the lower than in the upper limbs, probably because the former were more exposed to contamination with the soil. Bacteriological examination showed the blood to be infected with toxins, but not with bacteria. It was, however, pointed out by Professor Kümmell that, in cases terminating fatally from gas gangrene, Simmonds had invariably found Fränkel's bacillus in the blood of the heart.

WOUNDS OF THE CHEST.

Professor Sauerbruch said the proportion of wounds of the chest to other wounds was as 836 to 22,145. In this estimate the wounds terminating fatally on the field, and representing about 30 per cent. of all the chest wounds, were not included. Pressure symptoms caused by hæmorrhage into the pleural cavity were seldom so great as to necessitate puncture of the chest. On the other hand, secondary hæmorrhage occurring two to three weeks after the infliction of a wound, often at first slight trivial, frequently proved fatal. A closed pneumothorax, produced by a bullet leaving small wounds of entry and exit, was not of itself a serious condition. Extra-pleural bullet wounds of the chest usually did well without active treatment, whereas shell wounds of the chest, even when the pleura was intact, invariably required immediate radical treatment, consisting of removal of the shell, free opening of the wound and application of tampons. The results of this treatment were

satisfactory. Still more active measures were required when shell wounds extended to the lungs; and Professor Sauerbruch said that he had recently succeeded in saving several cases by operating under a negative atmospheric pressure. He had operated on only two cases of wounds of the heart and mediastinum, and both patients had died.

Professor Borst considered the prognosis of bullet wounds of the chest was good, provided complete rest were ensured, and the patients were kept under morphine. The mortality was 24 per cent., but when those cases were excluded in which fragments of rib or foreign bodies had been carried into the wound, the mortality was only 12 per cent. The temperature in these cases was often raised at first, then it fell to normal, and rose again on the sixth or seventh day, and remained high for some time. This fever was due to acute inflammation of the lung, and not simply to absorption of exudate, as many surgeons believed. The treatment of such cases of infected hæmatothorax should be limited to frequent aspiration, which had a beneficial effect on the temperature. Resection of ribs was superfluous. In shell wounds, on the other hand, recovery could be ensured only by radical treatment; among 83 such casualties he had seen, 74 terminated fatally in a field hospital, and others probably proved fatal at a later date. When the chest was penetrated in the axilla, at the level of the seventh to the ninth ribs, the abdominal cavity was usually involved. Of 82 such cases 71 terminated fatally. He made a rule of operating on all such cases, whether the wound were inflicted by a bullet or a shell, and he had lost only four out of fourteen such cases.

Professor Forchard insisted that effused blood should be withdrawn from the chest as soon as compression of the lung was no longer necessary for the arrest of hæmorrhage. He had never caused a hæmorrhage by the early aspiration of effused blood from the chest, and he was convinced that such a secondary hæmorrhage could not be provoked by the changes in the intrathoracic pressure caused by aspiration. Only 5 per cent. of the deaths from wounds of the chest were due to hæmorrhage, whereas more than 60 per cent. were due to infection. A wound of the lung might become septic more than a fortnight after it was inflicted, and he was, therefore, in favour of deferring the transport of such cases till the third or fourth week.

(To be continued.)

ROCKEFELLER WAR RELIEF COMMISSION.

THE report of the Rockefeller Foundation, dated June 27th, which is published in the July number of the *Military Surgeon*, the organ of the Association of Military Surgeons of the United States, gives an account of the work of the Foundation's War Relief Commission. It was decided in October, 1914, to send a War Relief Commission to Europe for the purpose of obtaining expert advice based upon a first hand study of conditions as to the time, place, and means of rendering aid most effectively. The Chairman of the Commission was Mr. Wickliffe Rose, Director-General of the International Health Commission, the other two original members being Mr. Ernest P. Bicknell, Secretary of the American Red Cross Society, and Mr. Henry James, jun., Manager of the Rockefeller Institute. The Commission, which sailed for Europe early in November, soon came to the conclusion that the most urgent problem of the moment was to provide relief for starving and, in some cases, disease-swept nations. The following is a summary of the work done in various countries:

Belgium.

As immediate action was called for, the Foundation, without waiting for the report of the Commission, devoted itself to the relief of the Belgians, co-operating for this purpose with the Belgian Relief Committee of New York and the Commission for Relief in Belgium. The expenditure in providing the greater part of five full cargoes of supplies amounted to a little more than a million dollars (£200,000). The War Relief Commission went to Belgium in November and made a thorough inspection of the agencies for relief in that country. It then organized an office in Rotterdam for receiving, storing, and shipping the large quantities of clothing sent to the Commission for Relief in Belgium from different parts of the world. Later, the Foundation organized several thousand Belgian women—refugees in Holland—into sewing camps, for which raw materials and sewing machines were provided, in order that useful employment for the idle, and the need of refugees for underclothing, might be supplied. In this relief work in

Holland the Foundation has expended about 90,000 dollars (£18,000). The Foundation has also appropriated funds at the rate of 20,000 dollars (£4,000) a year for the payment of stipends to scientific professors of Belgian universities, for whom laboratory facilities have been provided in England.

France.

As a result of a tour of inspection through Northern France made by three members of the Commission in December, immediate relief was supplied to certain communities where distress was great and no other source of food supply was available. This led to the organization of a comprehensive plan for the relief of the whole of that portion of France occupied by the German army. At the outbreak of the war Dr. Alexis Carrel, of the Rockefeller Institute for Medical Research, was spending his vacation in France, his native country. He was detailed by the Government to the military hospital at Lyons, but later was placed in charge of a hospital, with about 100 beds, established in a hotel at Compiègne. The French Government provided administrative officers as well as competent surgeons, and the Foundation funds with which, under the direction of the Rockefeller Institute for Medical Research, Dr. Carrel's hospital was equipped with complete apparatus and supplied with technicians to assist him in research in such bacteriological, pathological, chemical, and surgical conditions as might arise.

Serbia.

About 125,000 dollars (£25,000) has been expended for the equipment and maintenance of this Commission, of which the Rockefeller Foundation has furnished about 85,000 dollars (£17,000), the rest having been supplied by other contributors to the Red Cross.

Poland.

As the result of an inspection of that part of Russian Poland controlled by the Austrian and German armies, the Foundation authorized the War Relief Commission to assist in the establishment of a neutral Commission for Relief in Poland, and guaranteed its administrative expenses up to £2,000 a month.

Turkey.

The War Relief Commission has now completed a careful survey of conditions as they affect non-combatants in all the belligerent countries except Italy and Turkey. It has been arranged that a member of the Commission shall visit Turkey at an early date.

Future Work of the Commission.

The War Relief Commission has established head quarters in Switzerland, and its members will continuously keep track of conditions which may develop in the various war areas, and advise the Foundation of such needs as may be found to exist. It will also study the work of existing relief organizations, including the sanitary work in Serbia, with a view to rendering immediate advice or aid when and where it may be required.

OUTFITS, R.A.M.C.

"MOBILE" asks for advice as to the outfit which a lieutenant R.A.M.C. should take with him when ordered overseas, whether to France or to the Dardanelles, and whether employed at a base or sent on more active service; he asks also whether swords and revolvers are now taken by medical men.

The official information on this subject is contained in the official publication (79.6167) *Field Service Manual, 1914, Army Medical Service (Expeditionary Force)*, issued with Army Orders, November 1st, 1914. Price 3d. The pamphlet is published by Wyman and Sons and the Government publishers in Edinburgh and Dublin, and for abroad by Mr. T. Fisher Unwin, Adelphi Terrace, W.C. It can be obtained through any bookseller. The following short list, which is official, may be of service:

LIST OF ARTICLES OF OUTFIT REQUIRED BY OFFICERS OF ROYAL ARMY MEDICAL CORPS.

British warm great-coat (optional).	Service dress cap.
Service dress great-coat.	Service dogskin gloves.
Service dress jacket.	'Sword (R.A.M.C. pattern) with sword knot.
Service dress trousers.	'Pistol (any pattern, but must take Government ammunition).
Bedford cord breeches.	Haversack.
Leggings, brown leather.	Waterbottle (aluminium), with stop.
Spurs, brown straps.	Mess tin.
Brown leather marching boots.	Sam Brown belt.
Khaki shirts.	
Khaki collars.	
Khaki ties.	

* Not required on home service.

Camp Kit.

The actual cost of which, up to a maximum of £7 10s., on production of the receipted bill, will be refunded by the Accountant for Regimental Services at Aldershot:

1 camp bedstead and bag.	1 chair.
1 pillow.	1 blanket.
1 waterproof sheet 7 ft. by 4 ft. 5 in.	1 valise or bag to hold above, with name painted on it.
1 wash-stand with basin, bath, and bag.	

In addition to the above articles, three general service blankets will be issued on application to the officer commanding the unit to which posted.

Field Kit.

The following additional articles are required for active service in the field. (The articles may be varied, but a total weight of 35 lb. must not be exceeded:

- Brassard (issued on joining).
- Identity disc (issued on joining).
- Books (Army Book 153 and Field Service Pocket Book). (Issued on joining.)
- Cap-comforter in pocket of great coat.
- Compass, magnetic, pocket (or prismatic, in case).
- Dressing, field (issued on joining).
- Glasses (binoculars or telescope, or both, in one case).
- Grease or vaseline.
- Holland containing knife, fork, and spoon; hair-brush and comb; tooth-brush, shaving-brush and razor.
- Instruments, pocket case of.
- Knife, clasp, with ring and swivel.

N.B.—Candidates for commissions should not provide themselves with uniform or equipment until they receive from War Office instructions so to do.

It will be seen that the sword and pistol are not required on home service, and we understand that many officers do not go to the expense of purchasing a sword, which is not worn in the field. We believe also that R.A.M.C. officers are advised that it is unnecessary to carry a pistol. We understand that the latter can best be obtained through a Government source, and that both are issued by the various units, on repayment, when the officers join the forces overseas, if considered necessary. It is not, we understand, necessary to provide both a service dress great-coat and British warm great-coat; apparently most officers prefer the latter. For the Dardanelles a jacket and trousers of thin serge or drill will probably be preferable to cloth, but these are matters upon which it would be well for the inexperienced officer to take the advice of reputable army outfitters. The outfit required is the same whether at the base or otherwise.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN JOHN FITZGERALD GWYNNE, R.A.M.C., was killed in action in Flanders on July 8th. He was born in August, 1889, the eldest son of the late Charles Nelson Gwynne, M.D., of Sheffield, and was educated at Sheffield University, where he took the degrees of M.B. and Ch.B. in 1911. After filling the posts of resident medical officer to the Sheffield Royal Infirmary and assistant medical officer to Southwalk Union Infirmary, East Dulwich, he entered the R.A.M.C. as lieutenant on January 30th, 1914, and was promoted to captain in the general promotion of all the lieutenants in the corps on March 30th, 1915. He had been serving with the Expeditionary Force in Belgium and France since August last. While holding the post at the Sheffield Royal Infirmary his charm of manner and high character endeared him to all with whom he came in contact, and the same qualities earned him many friends since the war began. A brother officer R.A.M.C. in a private letter writes: "It was awfully sad about Jack Gwynne. He was shot through the head. He had the D.C.M., had been mentioned three times in dispatches, and recommended for D.S.O. or V.C. He made a tremendous reputation for cool bravery and courage out here, not only in his own division but all along the line where he has been. We all hope the V.C. will be awarded."

Captain James Johnstone Dykes, of the 15th Battalion King's Own Scottish Borderers, is reported in the casualty list published on July 20th as killed in the Dardanelles. He took the L.D.S. of the Royal College of Surgeons, Edinburgh, in 1907, and the Scottish triple qualification in 1911. He was honorary dental surgeon to the Dumfries and Galloway Royal Infirmary and to the Dumfries and Maxwelltown industrial schools and girls' home. He was also a member of the British Medical Association. He joined the Territorial Forces as a combatant officer in 1906, and became Captain on June 2nd, 1913.

Wounded.

Lieutenant O. H. Blacklay, R.A.M.C.(T.F.), Dardanelles,

Invalided.

Lieutenant-Colonel Peter Murray Kerr, commanding the 15th Battalion of the King's Own Scottish Borderers, now in the Dardanelles, has been invalided home for dysentery. Colonel Kerr, who took the M.B. and C.M. at Edinburgh in 1867, is, in civil life, surgeon to the Dumfries and Galloway Infirmary at Dumfries.

DEATHS AMONG SONS OF MEDICAL MEN.

Only three cases of the sons of doctors having been killed in action appear to have been reported during the past week. Two others from the earlier months of the war are added.

Ingram-Johnson, Reginald James Theodore, Second Lieutenant 3rd Durham Light Infantry, elder son of Dr. A. E. Ingram-Johnson, of South Moor, Stanley, County Durham, killed in action in France, aged 20. He joined the special reserve of his regiment on November 7th, 1914.

Martin, Cecil Taylor, R.N., Assistant Clerk, H.M.S. *Month-mouth*, elder son of Dr. George Martin, of 4, Park Terrace, Nilloth, Cumberland, killed in action off the coast of Chile, on November 1st, 1914, aged 17.

Prairie, Thomas, Lieutenant Leicestershire Regiment, only son of Lieutenant-Colonel Sir David Prairie, C.I.E., I.M.S. (ret.), Director, Royal Botanic Gardens, Kew, killed in action in Flanders, October 21st, 1914. Lieutenant Prairie got his commission on October 9th, 1912, and qualified as interpreter in French in 1913.

Ranking, James Gabriel Lancaster, Captain Indian army, eldest surviving son of Lieutenant Colonel G. S. A. Ranking, I.M.S. (ret.), killed in action in the Persian Gulf on July 12th. Captain Ranking was born on October 14th, 1883, entered the army on January 21st, 1903, joined the Indian army on April 23rd, 1904, and became Captain on January 21st, 1912. He entered the Political Department on December 8th, 1907, and at the time of his death was British Vice-Consul at Akwaz, and Assistant to the British Consul at Basra. Ranking's father, Stanley, William Alexander, Second Lieutenant 2nd Lancashire Fusiliers, only son of Dr. Stauwell, of Rochdale, killed in Flanders. He was educated at Blundell's School and at Guy's.

*NOTES.**BRASSARD FOR CIVILIAN DOCTORS.*

A WAR OFFICE notification, No. B.M. 2306 1915 (T.F.3), dated June 30th, states: "Medical practitioners specifically engaged for continuous duty in military hospitals (voluntary or otherwise), or in medical charge of troops, or in recruiting duties, may be allowed to wear the Red Cross brassard."

WOUNDED ALLIES RELIEF COMMITTEE.

The Wounded Allies Relief Committee (Sardinia House, Kingsway, W.C.), has issued a report on the work done since it was established with the approval of the War Office and Admiralty and of representatives of the Allied Powers shortly after the outbreak of war. Its earliest act was the escorting to England of the first batch of Belgian wounded, for 1,600 of whom it found hospital accommodation. A register of the men's names, addresses, and regimental details was compiled; an inquiry bureau established to assist the reunion of scattered families; and a military post office, working in connexion with the Bureau de Correspondance Belge at Havre, was set up. The register, which records over 100,000 names, has been continued at the request of the British Registrar-General, is partly subsidized by the Local Government Board, and is consulted by the Belgian Government for all military purposes, such as the tracing of soldiers destined to return to the front, the granting of pensions, etc. For those Belgian soldiers who are permanently disabled, the Committee has provided financial homes, which, being rent free, are run with a minimum of expense. To numerous crippled soldiers it has supplied artificial limbs and surgical appliances. It has in process of equipment a home for men who, through exposure in the trenches, have contracted tuberculosis. In Belgium itself the Committee supports a fleet of motor ambulances and a number of caravans, equipped with hot baths, scrub kitchens, and disinfectors. In France it maintains and manages two hospitals—at Dieppe and Lianozes—which have a total accommodation of between 200 and 300 beds. At a time when the Serbian Red Cross organization was in great straits the Committee dispatched £500 by telegraph, and later, at the request of the Serbian Government, equipped and sent out a typhoid hospital, with the result that at the end of March doctors, nurses, and hundred beds, and 100 patients, left for Kragevitz, the headquarters of the Serbian army. Owing to the disappearance of the epidemic, the unit is now adapted for the reception of the wounded. The Committee dispatched a Sanitary Commission to Montenegro, and, on its advice, two units of 100 beds each were sent on June 2nd to combat typhus in Podgoritz and Nikshich. These units, which, owing to the state of Montenegro, had to be accompanied by over £2,500 worth of stores and food.

The Committee has received from Dr. Isobel Ormiston, head of its Sanitary Commission to Montenegro, a letter in which she states that owing to the decrease of the epidemic these units will probably shortly be adapted for the reception of wounded. The epidemic appeared during the later part of March in the new provinces on the Serbian side. It was

brought from Serbia by soldiers who were brought in for artillery purposes. Very few civilians have been attacked up to the present, and general opinion inclines to the view that typhus fever or any infectious disease will not, owing to the configuration of the country, tend to spread from the new provinces and Serbia into Montenegro proper save by the passage of infected individuals. A mild type of enteric fever with a low mortality is endemic in various parts of Montenegro. Dr. Druetti, who was sent to Montenegro in April by the Italian Government, has been responsible for all the isolation and disinfection arrangements, and has also prepared an isolation hospital for imported cases of typhus discovered in Cetinje. He has likewise inaugurated a scheme for the massaging of travellers coming from the high range of mountains which separates the old from the new provinces. There is great distress among the refugees and the civil population owing to the impossibility of getting food into the country. The useful and patriotic work done by the Wounded Allies Relief Committee is constantly expanding. The honorary treasurer is Mr. T. O. Roberts (Manager), London County and Westminster Bank, 217, Strand, W.C.

SERBIA.

The Special Correspondent of the *Times*, writing from Salonika, says that there are now some 420 British doctors and nurses in Serbia. They have comparatively little to do, for there have been no new cases of wounded men for some five months; typhus, practically extinct, and typhoid has ceased to be a serious public danger. Besides their regular staff of 100 and thirty officers of the R.A.M.C. who are at Belgrade, there are the following British hospital units in Serbia: At Skopje, Lady Paget's and Lady Wimburne's Hospitals, each with a staff of 45; and the British Field Hospital with a staff of 25; at Kragevitz, the Scottish Women's Hospital with a staff of 40; Mrs. Sinclair Stobart's Hospital with 47; the Wounded Allies' Aid (second unit) with 16, and the Allies' Field Ambulance (B.R.C.) with 16; at Vrnjetka Banja, the British Red Cross (second unit) with 50, and Mr. James Berry's Hospital with 24; at Belgrade, the Scottish Women (second unit) with 50; the British Farmers' Unit with 45; and the British Eastern Auxiliary with 16. There is said to be a want of nurses in the Serbian hospitals, there being no trained women in Serbia itself. The British Red Cross is in some straits for ready money, and for a long time to come funds will be badly needed.

An International Sanitary Commission, of which Sir Ralph Paget is Chairman, has been established, with head quarters in Nish. Under it the general medical and sanitary work of the country has been roughly apportioned between the different co-operating nations. France has the charge of the northern half of the country, and the United States of America the south and its immediate neighbourhood is under the Russians. The British have had the care of the army and most of the hospital work, except that done by the Serbians themselves. The share of the burden which the United States is bearing continually increases, and will increase. Dr. Strong is a man of wide experience, and he has behind him the practically unlimited financial resources of the Rockefeller Foundation.

FRENCH HONOR FOR BRITISH MEDICAL OFFICER.

Lieutenant Oswald Robert Kelly, son of the late Dr. Bernard Kelly, of Rotherhithe and St. John's, S.E., who has been serving at the front since last September as a medical officer of the Red Cross, has been awarded the Cross of the Legion of Honour, and the Military Cross, by the French Government. Dr. Kelly, who received his medical education at Westminster Hospital, graduated with honours at the London University.

AN AMBULANCE TRAIN.

The London and North-Western Railway Company has completed for the War Office two additional ambulance trains for use in France, and some of the most interesting vehicles were open for inspection at Euston station on Wednesday. According to the plan exhibited, the complete train will measure 925.6 ft., and will consist of sixteen coaches; of these, nine are ward coaches, five are stater length coaches, and two are accommodation. Each coach will carry thirty-six cot cases in three tiers on either side; the two upper cots fold back, when the lower can be used for sitting-up cases. There is in addition at the rear of the train a coach providing eighteen cots for infectious cases; accommodation for a guard is also provided in this coach, which is 57 ft. long. In the front of the train there is a second brake of the stater length, providing accommodation for a guard and room for stores. Two kitchen cars were shown, both fitted with cooking ranges, a room for the cooks, steward's store, and pack store. The staff car provides accommodation for three medical officers and four nurses, and the personnel car has sleeping accommodation for 28. There is a well-appointed pharmacy car, which provides also stores for linen and medical comforts, an office, and a treatment room. Movable buckets are used throughout for the disposal of excreta. The train is very well appointed, and the cots of good design and easily adjusted; it seems, however, that it will not be easy to get a helpless man into the topmost tier of cots.

*MEDICAL OFFICERS WANTED.**2nd London Sanitary Company.*

Qualified medical practitioners engaged in public health work, preferably those holding the D.P.H., are required at once for commissions in the 2nd London Sanitary Company (R.A.M.C.T.).

There is every probability of successful candidates being sent to the front at an early date. Apply personally or by letter to Captain Coley, R.A.M.C.T., 2nd London Sanitary Company, Duke of York's Head Quarters, Chelsea, S.W.

23rd North Midland Field Ambulance.

Two medical officers are required to replace establishment, which is expected to go abroad shortly; also two medical officers for the third line of the unit. Applications to Lieutenant-Colonel Pockett, O.C. 23rd North Midland Field Ambulance, St. Albans.

22nd East Lancashire Field Ambulance.

Three medical officers are required to replace three officers proceeding overseas. Must be under 40 years of age and willing for foreign service. Pay and allowances as in regular army. Applications to Lieutenant-Colonel A. Callum, O.C., Heathfield, Sussex.

England and Wales.

DISTRICT NURSING OF MEASLES AND WHOOPING-COUGH IN LONDON.

The meeting of the Central Council for District Nursing in London at the offices of the Local Government Board on July 20th was well attended. Sir William Collins was in the chair, and the principal business was to consider a report of the Executive Committee on the subject of district nursing in relation to measles, German measles, and whooping-cough.

Mr. Walter Long, the President of the Local Government Board, welcomed the members, and referred to the fact that it was under the aegis of the department that the work of the Council was started two years ago, when his predecessor (Mr. John Burns) opened a conference in that same hall on the subject of district nursing in London. Mr. Long said that it had been suggested to him recently that there were more reasons than one, by no means all of them military, why the word "German" should not be introduced as a description of one of the affections they had to consider. He was assured that German measles might with advantage be regarded as a form of measles proper, and both diseases considered as one. Measles had proved itself a serious affection, and its prevalence, its treatment, and its prevention were matters for the most serious consideration. As to the general question of the position of nursing organizations, he said that one of the practical difficulties the Council had to contend with was an almost inevitable tendency towards jealousy (for want of a better word) as between different bodies which were formed for similar purposes. It should be remembered that they all had a common object, and in their special concern at the moment—that of saving the lives of the children—there was no room for antagonisms. That work always important, was probably more important to-day than it had ever been before. He was able from his own experience as a patient to compare the nurses of his childhood with those of the present day, and the change within the space of fifty years was, indeed, marvellous. Without the nurse the efforts and skill of the greatest of doctors would be thrown away.

Mr. Hayes Fisher, Parliamentary Secretary to the Local Government Board, who paid a tribute, as Mr. Long had also done, to the public work of Sir William Collins, said that a danger in front of a body such as the Central Council was that, being fed with money from official sources, the local sources would tend to dry up. He trusted that the Council would do something to stimulate local rivalries and arouse local interest.

The report of the Executive Committee on the subject of measles and whooping-cough, which was presented to the meeting by Sir William Collins, stated that, while conducting a larger inquiry, the Committee had found its attention arrested by the special need for the more effective care of children suffering from these diseases. The information collected showed that in the five years 1905-9 measles alone caused 9,301 deaths in London, almost entirely among little children. The mortality increased in proportion to overcrowding and poverty, and diminished with every improvement in the social status. Much of the mortality was due to the common impression that the disease might safely be treated by the mother

alone. It was estimated in the evidence taken by the Committee that in 50 or 60 per cent. of the cases no medical man was called in. This, indeed, was one cause of the failure of compulsory notification in the towns which had tried it. A system of notification through the school teachers and attendance officers was in process of organization by the London County Council authorities, and there was reason to believe that the machinery already at work might be linked up with arrangements whereby the early services of a trained nurse might generally be made available.

After quoting the advice of Dr. Foord Caiger, of the South-Western Fever Hospital, Dr. Rindell, of the Liverpool Hospital at Fazakerley, and Dr. Biernacki, of the Plaistow Hospital, as to the desirability of district nurses dealing with cases of measles or whooping-cough in the course of their duties, the Committee advised that, given suitable training and special instruction, district nurses, acting as they did under rule and supervision, might safely be trusted to undertake the nursing of these diseases in the course of their ordinary work. The question of the nursing of infectious and obstetric cases by the same persons was also considered, and the Committee was of opinion that, provided due care was taken to comply strictly with the rules laid down, a district nurse need not be debarred from attending to simple cases of measles or whooping-cough and also to maternity cases; but in the event of any complication she should seek medical aid. With regard to the relation of the district nurse to the medical practitioner in the nursing of measles or whooping-cough, the Committee suggested that possibly the special circumstances might be met if an arrangement could be made, following the precedent of the Midwives Act, for the payment of a medical man called in to attend a child of poor parents on the recommendation of a recognized district nurse. If this could be done, under suitable safeguards, it would provide a systematic means of bringing medical assistance to bear on the cases most in need of it, and at an early stage instead of too late. Possibly the public authorities and district nursing organizations concerned could confer with representatives of the medical profession in each borough, with a view to settling the methods of procedure which should be reciprocally acceptable.

Sir Arthur Downes formally moved the recommendation of the Committee that the report be approved, printed, and placed on sale, and further—

That the Executive Committee be instructed to confer with the Associations for District Nursing in London and other bodies or persons interested, with a view to preparing a scheme for the nursing of cases of measles, German measles, and whooping-cough; and

That the Executive Committee be authorized to promote conferences with representatives of local authorities, the medical profession, district nursing associations, and other bodies or persons interested, with a view to putting in operation a scheme for the nursing of measles, German measles, and whooping-cough.

There was no discussion, and the recommendations were carried *unanimé et contradictoire*. The remaining business before the meeting, which included a grateful acknowledgement to the trustees of the London Parochial Charities and to the Worshipful Company of Salters for grants, the appointment of a Finance Committee, and the approval of draft standing orders, was carried through with equal expedition, and the gathering broke up after a vote of thanks, moved by the Bishop of Southwark, and seconded by Sir William Church, had been accorded to the President and Parliamentary Secretary of the Local Government Board, and acknowledged by Mr. Hayes Fisher.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN MANCHESTER.

The number of children in the public schools in Manchester in 1914 was about 123,000, and the report of the school medical officer states that in the year the total number of examinations at medical inspections on school premises was 34,836. The average time occupied by the examination of each case—excluding the special cases of epilepsy, mental defect, etc., which attended at the offices for more extended examination—was about 7½ minutes, but, partly owing to interference by the war, the speed of examination had to be considerably accelerated. Parents had been notified that treatment was required in about 12,600 cases, and the report gives full details of the facts

disclosed by the inspection. In the reports of the last three years it was noted that there had been a small but definite increase in the average height and weight of the children, but in 1914 it appears that there was a small decrease all round. All the figures for both boys and girls being below the anthropometric standard of 1885. The standard of cleanliness in the schools, it is stated, has undoubtedly risen, and though vermin and nits are still very common, gross cases are now comparatively rare. During the year 293 cases were cleansed at the cleansing station, and in 57 cases parents were prosecuted for carelessness. In order to deal more effectively with verminous and dirty children four nurses were added to the staff, and raids are made from time to time, without notice, on the schools for the purpose of detection. Something like 800 children have been attending at the office of the school medical officer for medical supervision, the cases being mainly of phthisis, rickets, debility, anaemia, ringworm, chronic skin or eye disease, epileptics, mental defectives, and miscellaneous cases which have been referred by the assistant medical officers. Of this number no fewer than 406 were cases of phthisis or suspected phthisis. There were 2,585 children excluded from school under the official authority of the school medical officer, 1,720 of these being on account of ringworm. Arrangements have now been made for the treatment of chosen cases of ringworm by x rays, and the total cases treated in this way were 185. It is also noted that the x rays have been used in the diagnosis of certain diseases, especially diseases of the chest. Special attention has been paid to physical children; 64 have been admitted to the Summerset Home, 125 sent to sanatoriums, and 409 sent into the country for a holiday in 1914. Altogether 951 children were reported as physically or mentally defective, including mental defectives, epileptics, cripples, pre-tuberculous children, blind, deaf, and dumb. Of this number, 440 were mental defectives, and during the year 124 mental defectives were admitted to special schools. But it is noted that there are now a large number of mentally defective children attending the ordinary elementary schools, for whom there is no suitable provision, while the policy is continued of excluding from the special schools that grade of child which is uneducable. At the Soss Moss School for Epileptics there are now 100 children in residence, 26 having been admitted during the year, and 21 discharged. Of 122 cases treated at this school, 12 are said to be probably cured, 66 improved, 36 stationary, and 8 worse. At the Residential Schools for Cripples 44 cases were admitted during the year, the total number under treatment at the schools being 157, of whom 96 were suffering from tuberculous disease of bones or joints, and 53 from rickets. Operations, mostly for deformities due to rickets, were done in 34 cases sent to the Royal Infirmary from the schools.

Towards the end of 1913 the school medical officer, in a report on the question of the provision of school clinics, stated that for a full provision six centres would be needed, each centre having a doctor, a half-time dentist and one nurse, and that treatment should be provided for skin disease (including ringworm), defective eyesight, dental caries, and diseases of eyes and ears, with provision later for the operative treatment of tonsils and adenoids. During 1914 the committee endeavoured to secure premises for three centres. One of these was ready in January, 1915, and a smaller but useful clinic was later acquired in a second district.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN SALFORD.

It is evident from the annual report of the Education Committee for Salford that treatment is becoming an increasingly large part of the work of the school medical staff. The staff consists of the M.O.H. of Salford, two whole-time medical officers, a whole-time dentist, and five nurses. During the year 1914 treatment was advised in the cases of 1,019 children. The parents were notified that treatment was necessary, but they are said never to be advised to take their children to the hospital unless they state definitely that they cannot afford private treatment. Inquiries by school attendance officers later showed that 443 had actually received treatment, 322 other parents promised to obtain it, but in 254 cases the parents refused to obtain treatment. The conditions for which treatment is provided by the authority at the school clinic are as follows:

1. Visual defects: In addition to the routine eyesight examination, 548 children were specially examined by retinoscopy, and spectacles were prescribed for 212.

2. Ringworm: Out of 497 cases of scalp ringworm, 117 were treated by the x rays, the parents paying a nominal charge of 2s. 6d. per child treated. With 15 exceptions, it was found necessary to depilate the whole scalp according to the live exposure method of Kienbeck, and the children were allowed to return to school wearing a cap as soon as epilation was complete and no stumps remained.

3. Ailments such as chronic ear discharge, chronic nasal discharge with obstructive deafness, eczema, impetigo, and septic conditions of the skin: During the year 565 new cases were treated under this head, requiring 7,354 attendances. Treatment is carried out by the school nurses under the direction of the M.O., who devotes one half-day per week to the supervision of these cases.

4. Tuberculosis: The routine inspection revealed the fact that 1 per cent. of the children were suffering from actual and 2.9 per cent. from suspected pulmonary tuberculosis, 1.4 per cent. from glandular tuberculosis, and 0.1 per cent. from other forms of the disease.

5. Dental disease: The actual treatment of dental disease was only commenced last August, but from then to the end of the year 472 children received treatment.

In addition to the treatment given at the school clinic, 17 new cases have been sent to special institutions for the blind, deaf, and dumb, and a total of 69 children are now being maintained in institutions at the part cost of the town council.

Ireland.

LUNACY IN IRELAND: ANNUAL REPORT OF INSPECTORS OF LUNACY.

INSANITY, as far as it comes officially under the notice of the Inspectors of Lunacy in Ireland, is still on the increase. The annual report of the inspectors states that the total of insane persons in establishments in Ireland at the end of last year was 25,180—an increase of 171 on the previous year. This increase, however, was 50 less than the average increase for the preceding ten years—a fact from which some little comfort may be derived. The opinion has often been expressed that the increase of lunacy in Ireland is more apparent than real. Constant improvements in the treatment of lunatics in public asylums has led a great many persons to place their insane or mentally afflicted relatives in these institutions. Thus, in the years from 1880 to 1914 the number of inmates of district and auxiliary asylums increased by 12,860; the criminal lunatics in Dundrum Central Asylum decreased by 9; the patients in private institutions increased by 283; while the pauper lunatics in workhouses decreased by 1,073. In the same period the proportion of insane under care to the total population was more than doubled, but the rate of increase appears to be lessening. Another reason why the number of lunatics in Ireland appears to be increasing is that the immigration authorities in foreign countries are becoming stricter, and none but persons of perfectly sound mind are now allowed to enter the United States or other countries. Thus, the insane, as well as the aged and infirm, are left with us, while only the sane and healthy are able to emigrate.

The report discusses the question of the effect of the war on persons of unstable brain, and finds that there is no evidence, so far, that the horrors of war had any influence in increasing insanity in Ireland, but it is noticed that there was an increase last year in the number of cases admitted in which alcohol is assigned as the principal cause, and this is considered an indirect effect of war conditions.

COLLECTION FOR THE IRISH HOSPITAL IN FRANCE.

In Dublin, as in London and many other towns, July 14th was celebrated as "France's Day." In Dublin the collection in the streets was for the benefit of the Irish Hospital in France, a hospital which is one of the nearest, if not the nearest, to the fighting line in Flanders. In addition to the large number of voluntary lady collectors, valuable aid was given by the City of Dublin Voluntary Aid Detachments and the Boys' Brigade, the total number of collectors being about 1,500. The day's programme was carried out under the auspices of "La Croix Rongou Française." The directress of the Irish Hospital in France travelled specially to Dublin to help in carrying

out the day's programme, and was one of the busiest workers throughout the day. The Honorary Secretary and Committee were well pleased with the reports of the workers, and anticipate a very substantial measure of assistance for the Irish Hospital.

VACCINATION IN IRELAND.

Last week, in the King's Bench Division, before Mr. Justice Ross, in the case of the Local Government Board *v.* Letterkenny Board of Guardians, an application was made on behalf of the Local Government Board for a conditional order of *mandamus* to compel the Letterkenny Board of Guardians to put the provisions of the Vaccination Acts into force in their Union. An affidavit of the Secretary of the Local Government Board stated that the attention of the guardians had been called to the necessity of putting these Acts into operation, as the Board were of opinion that there was a real and imminent danger of an outbreak of small-pox should this disease be conveyed to Ireland after the war. It was stated that after the Franco-Prussian war of 1870 there was a world-wide diffusion of the disease. Various proposals were made by the guardians, and correspondence followed, but in the result no action was taken, and the guardians were then notified that legal proceedings would be taken to compel them to enforce the Acts. Under these circumstances the present application was brought. Mr. Justice Ross granted the conditional order.

At the last meeting of the North Dublin Union a letter was read from the Local Government Board relative to a notice of motion authorizing that in future no prosecution be brought under the Vaccination Act by a relieving officer without the consent of the Board being first obtained. The Local Government Board, in its letter, stated that such a resolution, if passed, would impede the due administration of the Acts, and pointed out that the guardians should not entertain the proposal contained in the notice of motion. The opinion of the legal adviser to the guardians was read, and was to the effect that the magistrates were the authority to decide whether there was valid reason for exemption in any case, and that if the resolution were passed it would be a direct breach with the Local Government Board, and would, if adopted, be illegal. The Chairman said, in view of the Local Government Board's letter and their adviser's opinion, it was his duty to refuse the motion.

PUBLIC HEALTH OF BELFAST.

At the meeting of the City Council on July 1st the medical officers of health reported the notification of 177 cases of scarlatina during the last month. The Public Health Committee has now had five years to study and deal with this outbreak, and the public fail to see any advance; in fact, as the Irishman said, we seem to be "progressing backwards." Measles is also rife, and will raise the infant mortality.

The tuberculosis scheme does not appear to prosper. A sum of £13,000 was to have been obtained from the Government for the enlargement of the Whiteabbey Sanatorium when it was taken over by the City Council from the Poor Law guardians; this has been held up, and now it may be taken for granted that no Government will expedite the giving of such a sum. Again, £10,000 a year has been for the time lost, apparently owing to failure to come to an agreement with the Insurance Committee. The Whiteabbey Sanatorium costs over £14,000 a year; a large number of medical appointments had been made, representing payments of over £2,000 a year. The Chairman of the Committee of Management of Hospitals and Dispensaries (Alderman Dr. King-Kerr) said the matter had been hanging over for more than a year; they had admitted over 100 insured persons into the sanatorium for whose treatment they had not received a penny; they had notified the Insurance Committee that they would refuse insured cases. The Insurance Committee were paying their tuberculosis officer £500 a year; the Corporation were paying their officer the same sum; amalgamation would save £600 a year. The dispute between the Local Government Board, the Insurance Commissioners, the Insurance Committee, and the Hospitals and Dispensaries Committee of the City Council had been going on ever since; there were fewer patients in the sanatorium now than when the Council took it over. A new responsible head of the sanatorium (Dr. Gilliland) had

been appointed, but the Council could not get rid of their obligation to the guardians' officers, Dr. Hall and Dr. Rankin. Dr. Hall was now appointed a visiting physician at a salary of £175 a year, although his relations with Dr. Gilliland are not set forth.

The ratepayers sincerely hope that the recent exhortation of the Chancellor of the Exchequer as to economy will be taken to heart by all these bodies.

Correspondence.

LEGAL RESPONSIBILITY FOR CRIME.

SIR,—Kindly allow me to thank my friend Dr. James Scott, and Mr. Roland Burrows, for their very courteous reference to me in their letter to the JOURNAL last week; and also to add a few explanatory words to what I said in my letter which was published in the JOURNAL of June 5th.

What I said, or at least intended to say, was that the subcommittee's proposal was in effect a combination of Sir James Stephen's and Dr. Mercier's. I certainly did not insinuate that the subcommittee had not thought the whole question out for themselves, both individually and collectively. I recognized explicitly that the omission of Dr. Mercier's name was unintentional, but deemed it fitting to call attention to this omission in view both of what I hope will be the signal and enduring importance of the subcommittee's recommendation, and also of Dr. Mercier's undoubtedly original publication of the new proposal embodied therein.—I am, etc.,

London, W., July 18th.

H. BRYAN DOKKIN.

SIR,—I am grieved that Drs. Scott and Burrows should think me hypercritical. I had no intention of pointing out any errors except those that seemed to me material. I think no cases would come under A (c) that would not already have been covered by A (a) or A (b). Drs. Scott and Burrows virtually admit that this is so, but they say it may be of the greatest service to have an alternative formula. It may be so, but I do not think it is hypercritical to doubt it. I should fear that an alternative formula, which is not an alternative formula, but, as Drs. Scott and Burrows admit, an additional formula, may confuse the issue.

When I express my difficulty in discovering what cases are included under "such" and what are included under "other," I am told that I lay too great stress upon classification. It is true that I used the word "class," but I am not wedded to it, and it is not necessary to my argument. When the report speaks of "such cases," it refers, I suppose, to some kind, sort, variety, aggregate, group, batch, lot, or bunch of cases; and when it speaks of "other cases" I assume that it refers to a different kind, sort, variety, aggregate, group, batch, lot, or bunch of cases; and I could not on reading the report, nor can I now, discover what difference is made between the two kinds, sorts, varieties, aggregates, groups, batches, lots, or bunches.

It was my mistake, no doubt; but I had no idea that what the reporters objected to was the system of calling medical witnesses *en bloc* as witnesses of the court. The objections to this course certainly do seem to me real, great, and manifest. Structural alterations would be required in the courts. Either the witness-box must be enlarged or additional witness-boxes must be provided. The simultaneous examination and cross-examination of several witnesses must inevitably confuse the court, jury, counsel, and each other. I cannot doubt that the plan of calling the witnesses one after the other is much to be preferred, and this is the plan that I have always seen followed in court; but it seems that the practice must have been altered since last I gave evidence, for Drs. Scott and Burrows assert that "in no cases are expert witnesses expressing divergent opinions called one after another." It must be bad enough to call simultaneously witnesses who express similar opinions, but to have several experts simultaneously expressing divergent opinions must turn the court into a bear-garden, and I am surprised that the judges allow it.

I abhor ambiguous expressions and cannot but feel humiliated at being charged with using one. If I had

been charged with using ambiguously such expressions as "either" or "one after another," I do not know how I could have survived the exposure; but when I am told that the expression, "reported cases," is ambiguous, I may, perhaps, be permitted to clear up the ambiguity by substituting the expression, "cases reported in the *Times* newspaper."

Lastly, the reporters pin me down with a definite question, and ask me if I should "care to sustain the theory that no criticism could be passed, say, upon the trial and conviction of men charged before justices for summary offences of indecency under the Vagrancy Acts." Well, Sir, I must admit, as the chairwoman admitted when she was asked for a character, "There you 'ave me." The difficulties are so numerous and stupendous that I give it up at once. The question planks me down in a new and unknown world, and leaves me completely at fault. To begin with, I do not know what a summary offence is. Summary jurisdiction I know, and summary conviction I know, but how am I to know whether or not an offence was committed summarily unless I was there to see? Again, that passing criticism or not passing criticism can be a theory gravels me; and I hasten to say that it would gravel me just as much to find a theory in passing hypercriticism. The only way that I know of to sustain a theory is by adducing evidence in its favour, and where and how am I to find evidence that no criticism can be passed upon this trial? It was a trial and conviction of unspecified men, charged at an unspecified time and place, before unspecified justices, and they were charged for offences, and summary offences into the bargain. I am not told even how much they were charged for their offences—their summary offences. The whole system of criminal jurisprudence seems to have been revolutionized since I frequented the courts, and it seems that we have gone back to the Saxon system of *wer-geld*, and charge the offenders so much for their offences. No, Sir, I do not care to sustain the theory. There is no need for Drs. Scott and Burrows to shoot. I will come down.—I am, etc.,

Parksstone, July 17th.

CHAS. A. MERCIER.

THE SUPPLY OF MEDICAL MEN.

SIR,—“A. M. E.’s” letter in the BRITISH MEDICAL JOURNAL of July 3rd should not be allowed to pass without a protest. He evidently is well satisfied with the position in which he finds himself owing to the war, and this has led him to think he possesses the faculty of summarizing the positions of many different classes of medical men of whose private matters he must be absolutely ignorant. His classification of “mankind” (which includes only the *English*) is extremely narrow, and necessarily most unjust to many. He seems to forget that of the many medical men “who had given up lucrative practices” some, at least, have done so—(a) because they had to as officers of certain units; (b) because they foresaw the effect of the war on their practices, and the war enabled them to tide over the time; (c) because, having made their bit, they could well afford to go. If “love of the country” is to transcend “all else,” then surely, indeed, the war would leave many widows and orphans, and increase the liabilities of the State. It is quite easy for young unmarried men and very young married men to accept the generous rates given for a temporary lieutenantcy with the R.A.M.C.; but it is rather hard that married men who could not afford to accept those rates without loss and incurring bankruptcy should be regarded as unpatriotic because they wish to be clear of debt, and thereby help their country. If “A. M. E.” still holds the opinion he does, he should publicly state he is willing to pay all expenses above the war rates of those of his classes whose expenses exceed the pay offered by the War Office.—I am, etc.,
July 17th.

COMMON-SENSE.

SIR,—Our experience in West Sussex makes us wonder whether the shortage of medical officers in the army is a fact. Some weeks ago a meeting of practitioners in West Sussex was addressed by the Director of Medical Services of this district, and they were asked to help by giving whole or part time service as far as they possibly could. As a result of several further meetings a certain number of

medical men were enabled to offer their services for a stated period.

Recently about 1,000 troops were quartered in this town and were placed under the medical care of a local doctor. After a short time he was superseded by an officer of the R.A.M.C. If such an officer can be spared to do such work in a town where there are upwards of twenty practising doctors, it would seem that the “shortage” has been exaggerated.

Are we to be guided by the spoken words or by the action of the Director of Medical Services?—I am, etc.,

FRANK HINDS,
Chairman, Worthing and Chichester
Division, B.M.A.
Worthing, July 15th.

TEMPORARY RANK IN THE R.A.M.C.

SIR,—In support of your correspondent, “A Forty Year-Old Lager,” may I say that the authorities have made a great mistake in giving us temporary R.A.M.C. officers any substantive rank whatever—it is most misleading? Juniors of the rank and file and other corps believe that being subalterns we are mere makeshifts of no professional standing, and, what is worse, our patients think the same. In the Boer war, through which I served as captain (two medals, seven clasps) in an irregular corps, temporary officers were either civil or consultant surgeons—that is, general or special practitioners, as in civil life. “Way-back” practitioners, of no military training whatever, are being enrolled from obscure practices in far-away colonies, and arrive here as captains. I, with almost twenty years of commissioned life in a colonial militia, though also from such an obscure practice as I suggest above, having gained promotion by examination and trained on R.A.M.C. lines, travelled at my own expense for two months across the world, and have been rewarded with a lieutenantcy. The R.A.M.C. has not adopted the present plan because it assumes that we have no professional standing—are, in fact, mere embryonic practitioners—but because we have no special military training, and are, most of us, incapable of successfully taking command of ambulances, hospitals, boats, and companies. Therefore we should have no substantive rank. But as we have, in the name of sense let us be graded sensibly—say, as honorary or brevet captains—so that we shall assume no superiority over those who though junior in rank, are trained lieutenants and recently promoted captains.

Then, too, let me speak of that absurd age limit which as yet prevents the vigorous hard-riding athletic man of 46 from going to the front and doing the work he is physically adapted for, whilst the staid, artistic idealist of 40 is sent instead, whose pluck leads him into dangers from which his physique provides no means of escape.

Also, why are we in base hospitals on the northern side of the Channel not to receive the “honours of war”—medals which will be given to those who are just as stung at bases on the southern side or on hospital boats? It is through increase of well-earned public esteem that we alone can expect to balance our losses—and we have lost heavily, and will lose more. Any man who loyally and voluntarily leaves his work, whatever it may be, and devotes his whole time to purely military work, be he surgeon, cook, or clerk, should receive his medal. As we now have rank, we surgeons, let us be at least captains. I am an old M.D., and answer to the name of “Mister” now, and in selecting us for duty at base or front let the personal equation be considered. One man working with me has been kept back because his vision does not meet a stereotyped and archaic test long known to be useless. I have seen him operate without glasses and count cattle at over two miles.—I am, etc.,
July 17th.

OVER FIFTY.

SIR,—“Temporary Subaltern,” in his letter of July 10th, strikes the right note, only not quite strong enough. I sympathize with him, also with myself. This is my case: In August last I resigned a good permanent appointment to offer my services at the earliest moment. I was kept waiting for weeks, and at last obtained a lieutenantcy, R.A.M.C.(T.), with the assurance that I would be promoted to captain’s rank in a month’s time, but no promotion yet. I have served overseas, and am now engaged at depot work, not looking for or caring much for promotion

any longer, but intending to "pull out" when my year is up, as the position is *infra dig.* and humiliating. If only young enough, I would much rather serve as a private. I see Colonialists and others who have started with rank of captain—good men, no doubt, but not better than many senior and efficient men who have to masquerade as lieutenants and subs. with a paltry star or two. I have the Queen's medal with four clasps for service in South Africa, where, I will say in justice to myself, I made good. Although gazetted in October last, I have not received my ordinary allowances up to date; it was nearly six months before I could extract my pay through the "proper channels," apparently because I had moved about, having been willing to go anywhere or do anything in the way of duty. It is all very well for the War Office to appeal to the patriotism of the profession, but I fear we have made ourselves too cheap, and are treated accordingly. This is my first grumble, but not necessarily my last.—I am, etc.,

July 6th.

GROWLER.

A SCALE OF FEES FOR MEDICAL EXAMINATIONS FOR LIFE INSURANCE.

SIR,—In the report of the Council to the Representative Meeting the attention of the latter is drawn to the question of fixing a scale of fees for medical examination for life insurance, and emphasis is laid upon the fact that this matter has been more or less under consideration since 1904. I think that this statement is a proof of the difficulties that militate against any satisfactory settlement of the question, and hope that the meeting will consider very closely the possible result of any decision it arrives at. We have a recent example of an attempt to get unanimous action throughout the profession in the passing of a resolution by the Representative Meeting which fixed the fee for referee work under the Insurance Act at 10s. 6d., and many of us are aware of the ethical questions that were created by that resolution, and by the attempt of those who loyally obeyed it, to bring to book those who failed to do so. A far worse state of things will arise if an attempt is made at present to enforce a certain scale of fees for life insurance work, and until those affected are agreed upon unanimous action, while a resolution of the Representative Meeting which is to be only a pious opinion, to be generally disregarded by those concerned, will, I fear, be very little helpful. When we realize that in every town each of the large insurance companies doing both "ordinary" and "industrial" work employs one or more local practitioners, who are often men of good class practice, to examine their cases at fees varying from £1 1s. to 2s. 6d., and that frequently the larger fees so far outnumber the smaller ones that the examiners express no discontent with the scale of pay for the work they do, then I think we must first of all secure the co-operation of those interested before passing any resolution in either the Divisional or Representative Meetings, which will oblige loyal members of the Association to either resign the appointments they hold from the insurance companies, with the knowledge that other men will be found who are less scrupulous, or alternatively resign their membership.—I am, etc.,

July 12th.

S.

BRITISH AND FRENCH SALVARSAN PRODUCTS.

SIR,—In the BRITISH MEDICAL JOURNAL of July 10th Dr. C. F. Marshall, commenting on the occasional toxic results of salvarsan injections and the manufacture of the British product, states: "Whether English salvarsan is more or less toxic than the German product is immaterial, considering that this drug is not essential in the treatment of syphilis. The labour and ingenuity expended on its manufacture would be better applied in the production of high explosives," etc. Salvarsan is not essential in the sense that it is the only drug with which we can treat syphilis, but it is essential in that it is by far the most powerful antidote to syphilis which we possess, and that a proper course of treatment consisting of salvarsan and mercury not only gives better results but takes up far less time than one of mercury alone.

The duration of the course of treatment is of extreme importance, particularly at the present time. The number of soldiers who contract syphilis is considerable. It is not only desirable but essential that their course of treatment

should be short as well as efficient, so that no unnecessary delay may take place and prevent them from joining their units abroad. Salvarsan and mercury can do more for them in nine weeks than mercury alone can do in two years. From this point of view alone, therefore, salvarsan must be looked upon as a most essential drug, and the labour and ingenuity expended on its manufacture and control as fulfilling a national necessity and worthy of every encouragement. I have now given 123 intravenous injections of the British preparation, kharsivan. The two batches used, 49 and 54, have given rise to no toxic effects, and have proved every bit as good as the original German preparation. I hope members of the medical profession who deal with these injections will comply with the request of the National Research Committee, published in the BRITISH MEDICAL JOURNAL of June 26th, and forward to them accurate records of their results, paying particular attention to the points mentioned in the communication.—I am, etc.,

H. C. LUCEY, Lieutenant, R.A.M.C.,
Specialist in Venereal Diseases, Royal Herbert
Hospital, Woolwich.

Woolwich, July 18th.

SIR,—Great as is Dr. C. F. Marshall's reputation as a syphilologist, it is not well that he should make a statement "that this drug (salvarsan) is not essential in the treatment of syphilis" without being invited to produce at the same time the evidence on which he bases his remark.

His letter is an open invitation to us to discard the use of salvarsan; but the mere weight of Dr. Marshall's opinion, unsupported by data from his own experience in the use and administration of this drug, will not be sufficient to convince those of us whose favourable opinion of salvarsan is founded upon first-hand observations of its value. The advice of Arctæus the Cappadocian should be remembered: ἀγαθὴ δὲ διδασκαλία ἢ πείρα, χρῆ δὲ καὶ αὐτὸν πείρα. εἰλαβὴ γὰρ ἀπειρή (which Adams translated for us, "For experience is a good teacher; one ought, then, to try experiments, for too much caution is ignorance.")—I am, etc.,

Clifton, Bristol, July 12th.

J. A. NIXON.

THE SO-CALLED "NEW DISEASE" (STREPTOCOCCAL NEPHRITIS).

SIR,—I do not know who is responsible for labelling a streptococcal nephritis "a new disease," but it seems to me strange to do so. It has been well known to me—and I imagine to most other clinicians—for many years that nephritis may follow non-specific sore throats. Before the days when it was customary to look for the particular micro-organism this was surely well known, but in recent years I have often ordered vaccines to be prepared for the treatment of such cases of nephritis dependent upon various infections of the throat. Moreover, it is a familiar fact that streptococcal infection anywhere may give rise to nephritis, meningitis, endocarditis, osteomyelitis, and so forth, so that there is not only nothing new in this particular disease, but it is merely an illustration of a quite well known pathological process. In these circumstances your correspondent's references to ancient history are out of place; instead of referring to the records of ancient Nineveh, he might have looked into some modern textbooks.—I am, etc.,

Birmingham, July 19th.

ROBERT SAUNDY.

NERVE SUTURE AND BULLET WOUNDS.

SIR,—In his letter of July 5th, which appeared in the JOURNAL of July 10th, Captain Roth has accused us of serious error in stating in our paper on nerve suture for bullet wounds that "within two months of the operation there was good voluntary power of contraction of the flexor carpi ulnaris." This is not a serious error, but a serious fact. Knowing that it is generally considered that a three months' interval, at least, is necessary for the recovery of function in muscles whose nerve supply has been cut, we nowhere stated that this return of power was due to the suture of the nerve, though it may be hard to explain it otherwise. Certainly Captain Roth's simple anatomical explanation cannot be correct; we mentioned that "the proximal end of the nerve was freed up to the internal condyles," and if there had been branches passing from this part of the nerve into the flexor carpi ulnaris we

would have mentioned it; there were no such branches. It is possible that the supply came from the ulnar nerve in its course in the upper arm, but if so, it is difficult to explain the paralysis of the muscle—it could scarcely have been the "paralysis of disuso or concussion" which lasted for four and a half months, during the last month of which the case received daily massage and electrical treatment.

With regard to the question whether or not an operation for suture should be performed where there is a septic wound, we did not wish to dogmatize, merely stating our preference, to await healing as a rule. In individual cases much must depend on the degree of sepsis and the other complications which may be present.—I am, etc.,

Dublin, July 16th. R. ATKINSON STONEY, F.R.C.S.I.

THE TOURNIQUET IN WAR.

Sir,—Your issue of July 17th seems to me to raise, incidentally, a very important question, and one of which the importance is not quite as generally recognized as some would think desirable.

Briefly, the point is the utility or otherwise of the tourniquet in war and of teaching the soldier the use of this means of arresting haemorrhage.

May I contrast the following statements from your last issue:

1. This is from a review of a pamphlet entitled *Instructions for Rendering Immediate Aid*, by Major Maclure, and reads as follows:

Over 120,000 copies of the leaflet had been supplied gratuitously to regiments on service, and Sir Frederick Treves has stated that 15 per cent. of casualties had been saved thereby from bleeding to death.

2. These two quotations are from your account of the annual meeting at Brussels of the *Deutsche Gesellschaft für Chirurgie*, and are as follows:

Professor Garré: The use of elastic bandages (for the arrest of haemorrhage) should be avoided as much as possible, as their timely removal was often not feasible.

Herr L. Rehn: Much harm had been done, particularly in the beginning of the war, by the improvised use of straps, belts, etc., by soldiers for the arrest of haemorrhage.

3. This is from your *précis* of the experience of Dr. F. Demmer with the Austrian amicus:

Here he was struck by the frequency with which the arms had been injured by bandages, which had been applied too tightly on account of haemorrhage, either by a comrade in the trenches or at a first dressing station.

Dr. Demmer is also reported as saying that, although he worked at the front on three occasions, he never once had to apply an Esmarch's bandage or to ligature a vessel for haemorrhage.

The experience of British surgeons in this matter has not, so far as I am aware, formed the subject of discussion in the medical press. I can only quote my own to the following effect. I never put on a tourniquet (even at amputations, when I preferred to find the artery and tie it at the point of amputation rather than do anything to risk the vitality of the leg above). I invariably took off immediately every tourniquet which had been applied, and never had any occasion to regret this practice. I often thought, and still think, that these constricting bandages had been of no use and very often of active harm to the wounded. This harm occurs for three reasons or in three sets of circumstances—namely:

- (a) If not tightly enough applied, they prevent venous return, although allowing arterial supply to continue. I have known this to be the apparent cause of death on more than one occasion.
- (b) If properly applied, they often stay on too long—in some cases being covered with a neatly-applied bandage, which gives no hint of their presence. I cannot see how this is to be prevented when there is a rush of wounded, say, 500 in the day.
- (c) The onset of sepsis, which is very rapid and accompanied by swelling, accentuates the evils referred to.

Consequently, I have always in lectures to soldiers emphasized the point that they are on no account to use tourniquets, but rather to apply pressure to the bleeding point if this be particularly necessary, as is very seldom the case. This advice I had long ago from my former teacher, Mr. W. G. Spencer, of the Westminster Hospital,

and experience in France has convinced me anew of its wisdom.

One would very much like to know on what grounds Sir Frederick Treves formed the opinion attributed to him and also the views of others on what is really a very vital matter. This is not a question of whether the tourniquet is a good thing, but whether it is useful and often required in war time.—I am, etc.,

GORDON WARD, Capt. R.A.M.C.(S.R.),
Military Hospital, Lydd, July 19th.

THE PREVENTION OF GAS POISONING.

Sir,—I have read many suggestions as to the treatment for soldiers poisoned by German gases. I have vainly searched for suggestions as to the prevention of such poisoning by the use of other gases.

Would not a liberal supply of oxygen to the trenches, to be used in the event of a gas attack, overcome the horrors of their chlorine and cyanide poisons and so annul their effect?

I have sometimes wondered whether it would be possible to drive the gases back by water hoses as in case of fire, but the water might not be attainable. The oxygen could be made so.—I am, etc.,

Bewley, July 8th. JANET G. HORWOOD.

THE IRISH APOTHECARIES' HALL AND THE GENERAL MEDICAL COUNCIL.

Sir,—Adverting to certain comments made at the General Medical Council which suggested leniency on the part of the examiners in medicine of the Apothecaries' Hall, may I be permitted to point out that, according to the returns for 1914, just published by the General Medical Council, the percentage of candidates who pass our examinations is smaller than at any other examination in Ireland:

Medicine.	Passed.	Rejected.	Percentage Rejected.
Apothecaries' Hall, Dublin...	17	11	39.28
University of Dublin	60	34	36.17
Irish Conjoint Board	59	28	32.18
University of Belfast	47	23	32.33
National University of Ireland ...	53	21	28.38

—I am, etc.,
J. C. McWALTER, M.A., M.D. LL.D., D.P.H.,
Dublin, July 9th. Governor, Apothecaries' Hall.

Medico-Legal.

UNREGISTERED PRACTITIONER FINED.
BEFORE the Sheffield magistrates on July 16th William Williams Abwick, of 8, Underwood Road, Woodsteads, was summoned for that, not being a registered medical practitioner within the meaning of the Medical Acts of 1858 and 1886, and not being a person recognized by law as a physician, surgeon, licentiate in medicine, or an apothecary, he did unlawfully pretend to be, and take and use the title and description of, a surgeon on three different occasions.

Mr. Neal, who, instructed by Messrs. Hempsons, appeared to prosecute on behalf of the Medical Defence Union, said, according to the report in the *Sheffield Daily Telegraph*, that the defendant had attended a soldier and members of his family. He had rendered bills calling himself M.B. New York, M.D. Lond., a registered dental surgeon, and a surgeon. As far as could be ascertained the defendant had no title at all and was not on the *Medical or Dental Register*.

The police officer who served the summons stated he had known defendant as a doctor for over fifteen years.

Defendant, who put in a dental registration form dated 1895, said he was a registered dental surgeon as far back as 1875, but had not been on the *Register* because he had not troubled about it. He had been assistant at different times to several doctors, but he had never pretended to be a doctor. He attended the soldier as an ordinary man without any medical knowledge.

Mr. Neal said that in 1906 defendant had been fined £5 for forging a death certificate.

The magistrates being satisfied that the case had been proved imposed a fine of £10 in each of the three cases, with the alternative of one month's imprisonment. The defendant was allowed time to pay at the rate of £1 a week.

Universities and Colleges.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMMITTEE was held on Thursday, July 15th, Dr. Frederick Taylor, the President, being in the chair.

DUTY OF MEDICAL PRACTITIONERS IN CASES OF CRIMINAL ABORTION.

A report was received from the Censors Board on the duties of medical practitioners in cases of criminal abortion. After discussion the report was finally adopted as follows:

Report.

The College is of opinion:

1. That a moral obligation rests upon every medical practitioner to respect the confidence of his patient; and that without her consent he is not justified in disclosing information obtained in the course of his professional attendance on her.

2. That every medical practitioner who is convinced that criminal abortion has been practised on his patient, should urge her, especially when she is likely to die, to make a statement which may be taken as evidence against the person who has performed the operation, provided always that her chances of recovery are not thereby prejudiced.

3. That in the event of her refusal to make such a statement, he is under no legal obligation (so the College is advised) to take further action, but he should continue to attend the patient to the best of his ability.

4. That before taking any action which may lead to legal proceedings, a medical practitioner will be wise to obtain the best medical and legal advice available, both to ensure that the patient's statement may have value as legal evidence, and to safeguard his own interests, since, in the present state of the law, there is no certainty that he will be protected against subsequent litigation.

5. That if the patient should die, he should refuse to give a certificate of the cause of death, and should communicate with the coroner.

EXAMINATION IN PRACTICAL PHARMACY.

A report was received and adopted from the Committee appointed to report upon the examination in practical pharmacy. It contained the following general recommendations:

1. That for the title "Examination in Practical Pharmacy" be substituted the title "Examination in Materia Medica and Pharmacology."

2. That the examination be *à la voce*, as at present, but that the time for each candidate be extended from ten minutes (the present time) to a quarter of an hour.

3. That candidates be not examined upon the experiments by which the actions of drugs have been determined.

4. That all questions on therapeutics be excluded.

5. That the examination form part of the second examination (that is, of the examination in anatomy and physiology). [The object of this recommendation is to keep the subsequent period free for the study of medicine, surgery, and midwifery.]

6. That no change be made in the status of the examiners nor in the method of selecting them.

UNIVERSITY OF OXFORD.

Degrees.

THE following degrees have been conferred:

B.M., B.Ch.—C. M. Burrell, R. J. Inman, R. C. Fairbairn, O. H. Goteh, J. M. Guilfoyle, H. A. B. Whitelocke, R. W. J. A. Cushing, J. B. Cavenagh, A. H. Southam.

Examinations.

The following candidates have been approved at the examinations indicated:

FIRST M.B. (*Organic Chemistry*)—E. H. Cluver, F. B. Dutton, R. Ginzburg, H. F. Hodge, J. G. Johnston, W. N. Robinson, E. A. Woods. (*Anatomy and Human Physiology*)—E. A. I. Mackenzie.

SECOND M.B. (*Materia Medica*)—F. L. Apperly, J. N. L. Blamey, G. K. Bowes, C. M. Burrell, J. B. Cavenagh, J. L. P. Cavenagh, J. C. Crow, W. S. Dawson, G. Perkins, A. Traill, S. C. Varley, D. M. P. Whitcombe, C. D. Wood. (*Forensic Medicine and Hygiene*)—C. M. Burrell, J. B. Cavenagh, A. G. East, L. Gannon, G. T. Ginnette, O. H. Goteh, J. M. Guilfoyle, R. J. Inman, H. S. Jeffries, M. R. Lawrence, H. M. Oddy, J. F. West. (*Pathology*)—F. L. Apperly, C. M. Burrell, J. M. H. Campbell, G. I. Evans, G. T. Ginnette, H. S. Jeffries, T. E. Mickletham, A. Traill, S. C. Varley, D. M. P. Whitcombe, C. D. Wood. (*Medicine, Surgery, and Midwifery*)—F. L. Apperly, C. M. Burrell, J. B. Cavenagh, R. W. J. A. Cushing, R. C. Fairbairn, O. H. Goteh, J. M. Guilfoyle, R. J. Inman, J. B. West, H. A. B. Whitelocke.

UNIVERSITY OF BRISTOL.

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B. (*Part D*)—Hilda Kate Evans, D.P.H.—A. Seemple, R. E. Thomas.

UNIVERSITY OF EDINBURGH.

The following candidates have been approved at the examinations indicated:

THIRD M.B. (*Pathology*)—J. Aitken, Janet C. P. Alison, L. G. Allan, H. M. Anderson, G. Baisilich, C. G. Booker, C. C. Boudou, J. S. Bow, R. M. Bowman, W. D. Brunton, J. C. Burns, Gladys Carleton, Isa Thuan Chan, D. C. Chalmers, G. C. Clark, W. Crawford, P. C. Datta, T. S. Duncan, D. W. Dunlop, J. W. C. Fairweather, D. T. P. Gay, J. A. Hadfield, N. K. Henderson, N. Hirschman, A. Joe, Ying C. Lee, V. St. C. Lucas, D. MacEachran, R. D. Mackenzie, I. F. MacLeod, A. MacRae, R. Miller, A. Maja, J. B. Martin, A. B. Matheson, C. J. van der Merwe, J. H. Neill, R. B. Okholm, R. D. Osier, F. W. Poole, H. B. Renton, A. Robertson, S. A. Robertson, S. S. Roseenthal, L. C. Rudd, R. Sandilands, J. Schneider, S. N. Seal, J. M. H. Smellie, J. O. P. Smith, Janet Smith, J. H. R. Smith, R. B. Smith, S. L. Smith, D. G. Sinton, A. Strachan, J. H. H. Spykens, D. R. Thapar, A. Ba Thaw, J. M. Tyrrell, L. Walker, R. Walker, W. A. Weatherhead, D. H. Williamson, J. Wolfson, J. W. van Zyl.

FINAL (*Foroens Medicin*)—C. B. C. Anderson, J. Bennet, K. P. Brown, W. Brownlie, A. J. Caird, R. D. Cameron, Yun Y. Chan, J. E. Chow, A. H. Chu, F. W. Clark, C. T. I. Clarke, A. Cleland, D. Colomboth, T. F. Corhill, J. A. Crawford, B. C. Crawford, A. L. V. Davin, J. Dick, J. Dickson, A. V. Dill, D. G. Duff, J. J. B. Edmond, W. H. Ferguson, A. M. Ferrie, G. H. Fraser, J. S. Galvin, A. K. Gibson, G. W. Grant, W. S. Green, C. Harris, F. J. Hauptfleisch, C. S. van Hercken, W. Helming, W. Hendry, C. E. Hill, R. L. Inper, J. M. Johnstone, H. B. Kirk, A. C. Kirtou, Marjorie L. S. McGregor, I. Mackenzie, J. A. Mackenzie, Isobel M. MacLulich, Annie M. Madin, P. T. Majumdar, J. C. J. O. Mearns, J. de Vos Meiring, E. A. Mills, H. S. Moore, E. O. A. Singer, N. H. Smith, E. D. Sölerström, M. Stuart, M. D. Thakore, D. R. Thomas, W. E. Thompson, J. de Villiers, W. Waddell, Gladys Ward, R. A. Waters, H. W. Williamson, W. Williams, D. Wilson, H. D. Wright, W. Ngai-Yow.

FINAL (*Public Health*)—C. B. C. Anderson, J. Bennet, K. P. Brown, W. Brownlie, A. J. Caird, R. D. Cameron, Yun Y. Chan, A. H. Chu, F. W. Clark, F. W. Clark, C. T. I. Clarke, A. Cleland, J. A. Crawford, B. C. Crawford, J. Dick, J. Dickson, A. V. Dill, D. G. Duff, J. J. B. Edmond, H. F. Ferguson, A. M. Ferrie, G. H. Fraser, J. S. Galvin, A. K. Gibson, G. W. Grant, W. S. Green, F. J. Hauptfleisch, C. S. van Hercken, W. Helming, W. Hendry, C. E. Hill, H. H. Inper, J. M. Johnstone, H. B. Kirk, A. C. Kirtou, I. Mackenzie, J. A. Mackenzie, Isobel M. MacLulich, P. T. Majumdar, Annie M. Madin, J. Manuel, J. de Vos Meiring, F. H. van der Merwe, E. A. Mills, C. Milne, J. Milne, H. S. Moore, G. Morris, J. L. Owen, M. S. N. Panikar, A. M. Paterson, D. H. Paterson, A. Prentice, K. S. Ray, W. Richards, P. A. Rostant, A. J. D. Rowan, B. J. Rytic, G. C. Salgado, E. G. Schuller, Eng S. Seah, J. S. Shannon, H. S. Weatherston, W. Williams, D. Wilson, H. D. Wright, C. W. Ngai-Yow.

UNIVERSITY OF GLASGOW.

SPECIAL GRADUATION.

A SPECIAL graduation ceremony was held on July 14th at Glasgow University for the "capping" of medical students most of whom had accepted commissions in the Royal Army Medical Corps.

Principal Sir Donald MacAlister, who presided, said that the casualties and the distinctions of the Royal Army Medical Corps which were already recorded in the roll of honour testified to the peril and glory of that service. By the application of medical science to prevention as well as to cure it had doubled the efficiency of the fighting forces. In no previous campaign had the losses from disease been so small, the operations and the recoveries from wounds so large a proportion to the total casualties.

The following degrees were conferred:

M.B., CH.B.—I. M. Macfie, J. D. Milligan, H. S. Weatherston, R. S. Gibson, M. W. Cantor, J. K. Ronnie, W. F. Shanks, W. Cunningham, R. M. Lang, D. S. Campbell, W. Campbell, J. Gilchrist, C. B. Gilmour, Janet F. Henderson, Helen I. W. Kerr, J. A. Leiper, R. Lyon, D. J. Sandilands, F. M. Inghis, G. Maclean, P. D. MacLeod, D. MacLeod, D. McNeill, F. W. Morrison, Mary A. Noble, A. Scott, J. T. Smith, Isabel S. Thomson, A. J. van der Spuy, J. D. Watson, R. J. Wilson, Mary F. Wood, A. Young.

B.Sc. (*In Zoology*)—T. Rogers.

* With honours.

† With commendation.

QUEEN'S UNIVERSITY OF BELFAST.

At the graduation ceremony on July 22nd twenty candidates received the degree of M.B., B.S. of the University in the reserve of officers and some have passed the Officers' Training Corps, and will very shortly seek admission to the temporary service in the R.A.M.C. One candidate got leave as a combatant for three months, and now returns to the front as a medical officer. Mr. E. G. B. Calvert obtained first-class honours, and Mr. R. L. Rea and Miss F. S. Walker each second-class honours. Mr. Calvert gained a scholarship of £20 for being first in medicine, and another of £30 for being first in medicine. Mr. Rae gained a

scholarship of £30 for being first in surgery, and Miss Walker a scholarship of £30 for being first in obstetric medicine. Dr. Harold Black and Dr. John Gibson received the degree of M.D., the former with commendation, and the latter with a gold medal for his thesis on heart-block. The degree of D.Sc. was awarded to Major McCarrison, I.M.S., M.D., F.R.C.P., Lond., an old Queen's man, for his original work on the etiology of endemic goitre.

CONJOINT BOARD IN ENGLAND.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE (*Part II, Practical Pharmacology*).—J. H. Allan, E. R. Audrene, W. G. Barnard, W. E. Barnes, K. L. Bates, L. M. Billingham, L. G. Blackmore, E. J. S. Bonnett, J. Brooks, W. H. Butcher, A. J. Chappie, W. Colborne, A. I. Cox, W. Davies, T. H. Dobrashi, F. S. Drewe, W. F. Eberl, B. Graves, J. C. N. Harris, M. L. Hatch, S. Hazeldine, T. R. E. Hillier, A. B. Isaacs, J. Jackson, T. James, L. P. Johns, E. F. J. Jones, J. W. Jones, L. K. Leitch, P. Lindsey, Louisa M. Lister, T. D. Llewellyn, J. M. J. MacDonnell, G. B. McMichael, F. K. Marriott, W. H. Handling, J. S. Moore, E. C. de M. Moreau, C. P. Naganamitti, W. W. Newton, C. Nicory, A. E. Parkes, J. Peter, R. B. Powell, R. H. Robinson, J. A. M. Ross, M. M. Sheeh, J. A. D. Skinner, N. L. Smith, E. A. Sparks, I. H. Syed, R. H. Oo Tha, B. Whitehead, Gladys M. T. Williams, H. W. M. Williams, P. E. Williams, W. R. Wilson, R. Wolf, P. V. Wynne-Verrill, C. Young.

SECOND COLLEGE (*Anatomy and Physiology*).—G. V. W. Anderson, K. A. Anklesaria, H. C. Apperly, E. R. Batho, J. C. Blake, H. W. Breeze, R. Calco, F. Cameron, G. W. Coombes, J. R. Cox, James Crawford, L. P. de Abrew, H. E. Ekanayake, F. M. T. Flintan, M. Gourevitch, T. C. Higgins, M. Ibrahim, A. Ismail, A. K. I. Jones, D. J. H. Jones, Lillian Lewenstein, K. McFadyen, L. H. McLeod, H. L. Martine, P. H. Meehan, W. R. M. O'Connell, M. J. Milandis, H. Palmer, C. S. Parker, A. Peime, P. Randall, C. G. J. Rayner, C. C. Rowland, R. J. Saunders, I. Shwartz, Flora Singh, F. H. Scottford, C. H. Warner, G. A. O. White, G. Winter S. To Wong.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—J. H. Scott, R. E. Hopton, J. K. Steel, D. Mackay. (*In Physics*).—T. R. O'Keefe, W. Gibb, D. Gilmore, E. J. Allan, J. B. Singh. (*In Biology*).—W. Gibb, D. Gilmore, E. J. Allan, A. S. Irvine, W. S. Moir. (*In Chemistry*).—T. R. O'Keefe and W. H. Kerr.

SECOND COLLEGE.—L. L. Rupasingha, E. E. Bronstorff, Mahmood Ahsa of Kader Motreh, L. MacDuff. (*In Physiology*).—D. A. Walpole, J. B. Welby, A. F. Brighton, A. S. Hughes. (*In Anatomy*).—G. P. de Silva.

THIRD COLLEGE. Ethel M. Dukes, S. D. Vania, W. McElroy, I. Borrall. (*In Pathology*).—J. H. Brown, J. G. Murray. (*In Materia Medica*).—J. Meak, B. T. McColloch-Gasper.

FINAL.—J. L. Hendry, W. Ainsley, W. D. Bathgate, J. Baerman, W. A. Backhouse, M. McL. Bainbridge, A. C. Taylor, W. J. F. Craig, H. A. L. Guthrie, P. Chisholm, C. E. Meryon, J. M. Hiddleton, A. Burre. The following candidates pass in: (*Medicine and Therapeutics*).—Elivida H. B. Coahill, J. W. Robertson, J. S. Dickson, C. K. Carroll. (*Surgery and Surgical Anatomy*).—E. A. Neilson, J. Ross, D. C. M. Page. (*Midwifery and Gynaecology*).—E. C. Haller, E. A. Neilson, J. H. Blackburn, Elivida H. B. Coahill, D. C. M. Page, J. W. Robertson. (*Clinical Jurisprudence*).—T. D. Renwick, O. G. Evans, Z. A. Green, J. E. Kitchin, Phoebe Trapp, J. A. Tolmie, J. Jones, Martha Hoakings, J. S. David, S. Luther, A. Farker, C. K. Carroll.

The Services.

INDIAN MEDICAL SERVICE.

The result of the July examination was announced on July 16th. There were twelve candidates, the first seven being admitted as lieutenants on probation, with effect from July 16th, 1915. The names of the successful candidates, with the marks obtained by each out of a possible total of 5,100, are given below, together with their degrees and medical schools.

	Marks.
H. G. Alexander, F.R.C.S., L.R.C.P., Middlesex Hospital	3,363
O. Wilson, M.B., B.Ch. Belfast, Queen's University, Belfast	3,246
J. J. Liston, M.B., B.Ch. Cork, University College, Cork	2,961
K. R. Batra, M.R.C.S., L.R.C.P., Government College, Lahore, University College Medical School, London	2,679
B. H. Singh, M.R.C.S., L.R.C.P., Lahore Medical College, Middlesex Hospital	2,631
P. D. Chopra, M.B., B.S. Punjab, Lahore Medical College, University College, London, Middlesex Hospital	2,627
O. R. Unger, M.R.C.S., L.R.C.P., University College Medical School, London	2,599

Obituary.

COLONEL WILLIAM GEORGE HUME HENDERSON, Bombay Medical Service (retired), died at Kensington on July 15th, aged 64. He was born on May 16th, 1851, the eldest son of the late General Hume Henderson. He received his

medical education at the school of the Royal College of Surgeons, Dublin, and took the diplomas of L.R.C.S.I. and L.R.C.P. in 1875, and in 1889 that of F.R.C.S.I. He entered the I.M.S. as surgeon on March 31st, 1876, became surgeon-major on March 31st, 1888, surgeon-lieutenant-colonel on March 31st, 1896, and colonel on November 11th, 1905, retiring on November 14th, 1908. He served in the Burma campaign of 1887-88, and received the medal.

Medical News.

THE late Dr. Ernest Wilson Stoker left estate valued at £18,240.

AMONG the Justices of the Peace appointed by the Lord Chancellor for the County of London is Dr. T. A. Ives Howell, of Upper Richmond Road, Putney.

SURGEON-GENERAL RUPERT BLUD, of the Public Health Service, was elected President of the American Medical Association at the annual meeting recently held at San Francisco.

THE eightieth annual report of the Royal Medical Benevolent Fund for the year 1914, presented to the annual general meeting held on February 9th, has recently been issued. The chief event of the year was the incorporation of the fund: this was rendered necessary by the magnitude and importance of the charity. During the year to which the report refers the total sum distributed was £5,392 10s. 8d., an increase of £182 5s. 8d. as compared with the previous year. To this amount must be added £540 8s. 7d. distributed by the Guild, bringing the grand total expended in relief in 1914 to £5,842 19s. 3d. The working expenses are as nearly as possible 6.5 per cent. of the income. Full accounts of the objects and work of the Fund and Guild are given, and an earnest appeal is made for support in view of the rapidly growing demands made by the war.

THE usual monthly meeting of the Medical Sickness and Accident Society was held at the offices of the society on July 16th. Dr. Major Greenwood was in the chair. It was reported that the society had been allotted £5,000 in the new War Loan, which, together with the amount secured in the previous War Loan, makes a total of £15,000. The new business showed a falling away in comparison with last year, but the combined tables issued by the society are still much in demand, and constitute a good proportion of the total. The claims were less than in the previous month, and the first half of the year has been average in this respect. It was reported that three of the society's candidates were successful at the Epsom College election; one widow of a late member was elected to a pensionership, and two sons of late members to foundation scholarships. This shows the great benefit the members secure through the society's annual subscription to this college. Further information and particulars of the society can be obtained on application to Mr. Bertram Sutton, Secretary, Medical Sickness and Accident Society, 300, High Holborn, W.C.

IN a circular letter addressed by the Treasurer of the Royal Earlswood Institution to its supporters it is pointed out that, although it is thought best to abandon for this year of grave crisis the customary festival dinner, the maintenance of this large establishment is more costly than ever, and consequently the loss of the £2,000, or thereabouts, usually resulting from the festival will be seriously felt. An earnest plea for increased support from subscribers and others is therefore made, and, by way of strengthening the appeal, an admirably illustrated pamphlet has been issued, under the title of "What is being done at Earlswood." This has a striking frontispiece representing a Mongolian imbecile squatting in characteristic fashion, with an Oriental screen as background; and there are pictures of cretin and other patients at various stages of progress which have medical as well as general interest. Having but recently noticed the Earlswood annual report and set forth the excellent work done (which during its nearly seventy years' existence has supplied care and training for upwards of 5,000 patients), we need only express our entire sympathy with the object of the appeal for this national institution for mental defectives. Medical readers may help the cause by recommending paying patients, for whom there is special accommodation at Earlswood; the excess of payments beyond the cost of maintenance of those more well-to-do is applied to that of the poorer cases, which form the majority of the 500 now resident.

Letters, Notes, and Answers.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ATTENTIONS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR OF THE BRITISH MEDICAL JOURNAL, Medical, Westminster, London; telephone, 263, Gerard; (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; telephone, 263, Gerard; (3) MEDICAL SECRETARY, Medicæva, Westminster, London; telephone, 263, Gerard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

ES Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

STFOLK desires to get into communication with some member of the profession who served, shortly before the war began, as ship surgeon in the Atlantic Transport Line.

E. (Transvaal) asks for advice in the treatment of a patient who for the last fifteen years has, about every two months, suffered from eruptions of the upper lip. Arsenic has proved a failure. The patient is very susceptible to fugitive erythema, and diphtheria antitoxin on one occasion caused very troublesome urticaria. E. wishes to know if a vaccine would be of any use.

KELOID.

J. W. W. has under his care a woman, aged about 50, who some years ago was severely scalded on the left breast by hot fomentations applied during a heart attack. The whole of the breast and surrounding skin is now a mass of keloid, which causes great pain and inconvenience. He asks for advice in treatment.

COLD FEET.

D. asks for advice in the following case: A man, between 43 and 50, of spare habit, about 5 ft. 8 in., and under 10 st. in weight and very energetic, suffers, and has suffered for years, from cold feet. While in bed he is comfortable enough, but as soon as he gets up and has to stand, sores at home his feet and legs become cold and slightly clammy, and no external application gives relief. When he gets to his office the trouble becomes intensified, with a certain amount of mental depression. He is a moderate man in every sense—in eating, drinking, and in amusement. He keeps a horse and rides. The greatest attention has been paid to his shoes and stockings. His general health is well looked after, and is very good. The cardiac conditions are quite satisfactory and he sleeps well. All sorts of remedies have been tried—tonics, salines, and mild purgation with pil. hydrarg.—but without any good effect.

URINARY PIGMENTS.

R. K. writes: Testing the urine of a case with clay-coloured stools, I found no albumin and no sugar. The urine did not look bilious. On adding dilute acetic acid to the boiled urine a cherry colour resulted. I tried the test several times with different samples of acetic acid. What did the reaction signify?

Urine may contain various chromogens derived from food, drugs, or decomposition in the intestines, and the addition of acids brings out the colour. It is not possible to say which of these was the source of the pigment in this case; a fine red colour has been noticed on the acidulation of the urine of patients who have been taking copaiba, but this is only one of many examples which might be given.

BURNING AND PAIN IN THE PLANTAR REGION;

GLYCOSTRIA.

L. F. R. has a lady patient, aged 60, who has suffered for three years with burning pains in the feet. There were corns on the plantar aspect of the first and second metatarsophalangeal joints, which were cured, but the burning had continued. In the left leg an induration, without swelling, could be felt which the patient had noticed for years; she was sent into a hospital and treated by massage, which lessened the induration but did not relieve the burning pain. After the patient left the hospital sugar was detected in the urine, yet there was no polyuria nor wasting, nor thirst. The sugar disappeared after appropriate dieting and rest, but at this time with occasional polyuria, when the patient went back to her usual food. At present there are no corns or blisters on the soles, but the burning pains are as bad as ever. The patient has lost half a stone in weight in twelve months, but gained 3 lb. within the last two months. There are no general signs of diabetes, and the symptoms, though distressing, remain strictly localized. Our correspondent would like some suggestion as to a remedy for this condition, and any opinion about prognosis.

LETTERS, NOTES, ETC.

A WARNING.

We have now on quite a number of occasions been asked to warn medical men to be cautious in dealing with travellers who call with the object of selling sparking plugs. We are informed that such a person is now touring the Midlands.

FOREIGN BODIES IN THE RECTUM.

MR. G. RALPH COX, M.R.C.S., L.R.C.P. (Winchcombe) writes: A man, aged 35, was admitted to the Winchcombe Cottage Hospital complaining of irritation round the anus and a constant foul fecal discharge. There was no skin eruption but some bulging of the anus. On digital examination the rectum was found to be tightly packed with small sticks, jagged and sharp, about 1 in. to 2 in. in length and $\frac{1}{4}$ in. thick. They were removed and amounted to two handfuls. Slight hæmorrhage ensued, and an enormous evacuation of faeces—the accumulation of fourteen days—followed a dose of castor oil. The man returned to work in three days and no after-effects appeared. No history of how or why these sticks were inserted could be obtained, but the patient was a dull stupid fellow.

BERI-BERI.

DR. T. A. K. AIYAR (Sidiaram, Lower Perak, F.M.S.) writes that the theory that absence of vitamin in white bread or rice is probably the essential cause of beri-beri in people who live chiefly on them is certainly not borne out in his experience. There are, he says, thousands of certain classes of people in Southern India whose staple food is white rice, and in whom beri-beri is a rare disease. If polished rice or brown bread have anything to do in the etiology of the disease, it must be then that at least a small proportion of the people sustaining themselves on rice deprived of vitamin should suffer from it, or vice versa, which is not actually the case. It occurs in certain areas and in certain seasons, among people of all description, and it is therefore most likely that the disease is of microbic origin and infectious in its nature.

COFFEE AND BANANAS.

AN OLD MISSIONARY writes: Merely as a matter of possible interest to some of your correspondents who have written about coffee and bananas (March 13th, etc.), may I mention that coffee is, in Madras and its neighbourhood, a very usual drink at all times of the day, instead of tea? Both Europeans and Tamil and Telugu people use it freely, sometimes very weak. When you invite your Tamil friends to see you, coffee and bananas are usually served as light refreshments. I have observed no evil effects from either on people generally. Bananas (or plantains) are of so many kinds that possibly some one kind—perhaps the more highly flavoured—may contain some special toxin; but wherever they grow, they seem to be looked on as wholesome. It might also be remembered that the Boers, Belgians, and Swiss—all sturdy races—use coffee freely.

THE "FRIGHTFULNESS" OF THE STERILIZER.

AN interesting series of articles entitled "The First Hundred Thousand," dealing with the way a new army is hiked into shape, has been appearing in *Blackwood's Magazine*. In the number for April the author, who writes as "The Junior Sub," gives an amusing account of the difficulty of defeating one of the smallest but at the same time most irritating enemies the soldier is troubled with in camp:

"The only other architectural feature of the camp is the sterilizer, which has been working night and day ever since we arrived. No, it does not sterilize water or milk, or anything of that kind—only blankets. Those men standing in a queue at its door carrying their bedding. (Yes, quite so. When blankets are passed from regiment to regiment for months on end, in a camp where opportunities for ablutions are not lavish these little things will happen.)

"You put the blankets in at one end of the sterilizer, turn the necessary handles, and wait. In the course of the blankets emerge steamed, dried, and thoroughly purged. At least, that is the idea. But listen to Privates Ogg and Hogg, in one of their celebrated cross-talk dialogues:

"Ogg (examining his blanket): 'They're a' there yet. See?'"
 "Hogg (on optimist): 'Aye; but they must have gotten aw'fu' fricht!'"

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 8 0
A whole column	3 10 0
A page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association, at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-transit letters addressed either in initials or numbers.

OBSERVATIONS ON 685 CASES OF
POISONING BY NOXIOUS GASES
USED BY THE ENEMY.

BY

J. ELLIOT BLACK, ELLIOT T. GLENNY,

AND

J. W. McNEE,

LIEUTENANTS R.A.M.C., BRITISH EXPEDITIONARY FORCE, FRANCE.

*With a Note by*COLONEL SIR WILMOT HERRINGHAM,
CONSULTING PHYSICIAN TO THE FORCES OVERSEAS.

The following notes are founded on observations on 685 cases of gas poisoning which came under treatment in a casualty clearing station between May 2nd and May 7th, 1915. The patients were brought in by motor ambulance convoys from the field ambulances—a journey of about ten miles. Some arrived only six hours after being "gassed," while in other cases a much longer period had elapsed before they were brought in. They were detained in the casualty clearing station only until they were deemed fit to evacuate to the base. The slighter cases were sent down at the earliest possible moment, the majority were evacuated within forty-eight hours, while a number of severe cases were kept for several days while their condition remained critical. The total number of cases admitted during this period was 685. They were suffering from all degrees of asphyxia, but no good reason could be given why some cases were much worse than others from the same trench. It was, however, observed that the older men were almost all severe cases.

Extreme pressure of work made it impossible to make notes on each case, but the following general features have been observed with care, and it is hoped may be of interest and assistance to others.

The whole series could be roughly divided into two groups:

- (a) Those who seemed in imminent danger of death from asphyxiation—about 120 in number.
- (b) The remainder who, although suffering from the effect of the gas, did not appear in immediate danger.

Of the first group 33 died, giving a death-rate in the total number of cases observed of just under 5 per cent. It must be added here that many other cases died either on the field or at the field ambulances.

Of the 33 deaths:

- 16 died on the day of admission.
- 13 died on the day following admission.
- 2 died on the second day following admission.
- 1 died on the third day following admission.
- 1 died on the fourth day after admission.

It will be seen that 29 of the 33 deaths took place within thirty-six hours after admission, only 4 dying at a later period.

CONDITION OF CASES ON ADMISSION.

The first intimation that the urgent problem of asphyxia would have to be faced on a large scale was the arrival of the convoy, and it is difficult to convey the mental impression produced when the first batch were unloaded. It was 1.30 a.m. when they reached the casualty clearing station, the gas having been used against them about 7.30 p.m. on the previous evening. One man was dead before he could be removed from the ambulance. Most of the others were in a choking condition, making agonizing efforts to breathe, clutching at their throats, and tearing open their clothes. At one moment they propped themselves up to gasp, at another they fell back exhausted by their struggles. There was marked cyanosis, especially of the lips and ears, and in a few cases a light yellowish frothy discharge was escaping from the mouth and nose. Some, especially the older men, were in a condition of collapse; their faces and hands were of a leaden hue, their heads fallen forward on their chest. The majority of these cases did not rally. In addition to the asphyxiating effects of the gas, most of the men, although young

and robust, were greatly exhausted by continuous fighting against the poison.

All, except those moribund or collapsed, were fully conscious, and fighting desperately for life.

Fourteen men died out of the first batch of seventeen admitted.

Among the hundreds of cases subsequently observed, all degrees of asphyxia were evident, and it is difficult to convey a composite clinical picture of all of these. Certain common features, however, stood out so prominently that our purpose will be served by calling attention to them. Certain of these have been alluded to already.

The typical case was on admission cold, with a sub-normal temperature, conscious but restless, the pulse slow and full (except in the collapsed cases). The face was cyanosed, intensely so in many cases, and the expression was strained and anxious. The posture varied. In some cases the patient sat propped up, with head thrown back, gasping for breath; in others he lay on his side with his head over the edge of the stretcher in an attempt to aid expectoration. The respirations were jerky and hurried, often numbering forty a minute, and were associated with a choking cough, accompanied by a varying amount of frothy expectoration.

With each inspiration the chest was expanded to its fullest, all the auxiliary muscles being brought into play just as in an asthmatical paroxysm.

The percussion note over the chest was somewhat impaired without being actually dull. Auscultation revealed the presence of moist sounds of different qualities all over the chest.

PROGRESS OF THE CASES.

It was noticed that the patients who lived tended to pass through three more or less definite stages while under our observation:

1. The asphyxial stage.
2. The quiescent or intermediate stage.
3. The bronchitic stage.

Nearly all the cases on admission were in the first or asphyxial stage, which has just been described. This condition demanded immediate and energetic treatment, and was that which chiefly occupied us at the casualty clearing station. Grave symptoms appeared with startling suddenness, but if patients could be safely brought through this stage, recovery was the rule.

The first stage gradually passed off after some thirty-six hours, and the patient fell into a sleep from which he woke feeling much better. He continued in this state for perhaps half a day, and during this period every effort was made to evacuate him safely to the base.

After these few hours of comparative quiet, symptoms of bronchitis began to manifest themselves. In the majority of cases, as far as our experience went, these were not severe. In the cases, however, which had been kept alive with difficulty there was a very short quiescent stage, followed by intense bronchitis. Four of the most severe cases died in this bronchitic stage. Their symptoms, as compared with the first stage, were as follows: The frothing secretion gave way to thick greenish mucopurulent expectoration, consciousness was replaced by delirium, temperature rose from subnormal up to 104° F., and the pulse became of small volume, while its rate increased to perhaps 160. Respirations were less choking, but more shallow, and numbered up to 70 per minute before death.

TREATMENT.

As *post-mortem* examination showed that the patients died of acute congestion and oedema of the lungs, the aim of our treatment was:

1. To expel the excessive secretion from the lungs by emetics and stimulating expectorants.
2. To diminish the secretion.
3. To support the failing heart and reoxygenate the blood.

General Treatment.

On arrival the patients were placed in the open air, and, as they were very cold, extra blankets, hot-water bottles, and hot drinks were provided.

A little later on, as the weather was unsettled and to facilitate nursing, the worst cases were placed in a large, lofty room with open windows on opposite sides, giving a

through draught. Here about 120 out of the 685 cases were treated, the maximum number in the ward at one time being 30.

Special Treatment.

1. *Emetics.*—As a routine measure, the first 80 cases admitted were treated with emetics. Later on their use was confined to those cases which were obviously choked with secretion, and had not already been sick. The most successful emetic was salt and water, administered in 10 oz. doses, followed by large draughts of lukewarm water; vomiting was immediately induced by tickling the back of the throat with a soft brush, or by the patient using his own finger. In all cases marked relief was experienced, the patients bringing up quantities of yellowish frothy fluid. In fact, so pronounced was the relief, that many tried to make themselves sick again. *Vinum ipecacuanhae* and *apomorphine hydrochloride* were also tried, but were discarded, neither being so certain in their action as salt and water. There was no difficulty in getting the men to take the latter remedy, even in the most acute cases.

2. *Artificial Respiration.*—The action of the emetics was furthered in selected cases by the application of Schaefer's method of artificial respiration. The results at times were strikingly successful, notably in the case of one man, almost moribund, who was treated in this way on four successive occasions, and who ultimately recovered.

3. *Stimulating Expectorants.*—Every case was given ammonium carbonate gr. x every three hours, as a stimulant and expectorant. Later this dose was increased to gr. xv and *vinum ipecacuanhae* ℥ xv added. This mixture, although containing a somewhat large dose of ammonium carbonate, frequently given, gave very good results, producing copious expectoration followed by improvement in colour and general relief. In the 80 cases treated with emetics the expectorant followed.

4. *Posture.*—The action of emetics and expectorants was sometimes aided by altering the position of the patient, from sitting up to lying on the side, with the head low down to aid expectoration.

To Diminish Secretion.

In the hope of being able to check the excessive secretion in the lungs, atropine was administered to several severe cases, in doses of gr. $\frac{1}{2}$. We cannot say we found any beneficial result from this treatment; doubtless its administration was too late, but it might have been of use if given earlier—that is, in the field ambulance.

To Support the Failing Heart.

Venesection.—In view of the cyanosis and marked dyspnoea, venesection was attempted, 10 to 15 oz. being removed on each occasion. This proved very difficult to carry out satisfactorily as the blood clotted rapidly, and the relief given was very transient. It occurred to us that a more gradual and protracted depletion of the right heart would give better results. Accordingly leeches were procured. Sufficient suitable cases did not then remain, however, to enable an opinion to be formed as to their value.

Pituitary Extract.—Whenever the pulse showed signs of weakening—which was rarely seen except in cases approaching a fatal termination—1 c.cm. of pituitary extract was given, with marked benefit, the pulse becoming fuller and slower.

Oxygen.—As most cases presented marked cyanosis and dyspnoea, oxygen was given freely by inhalation; there was no doubt that temporary benefit resulted, the restlessness decreasing and the colour improving. Continuous inhalations appeared to give no more benefit than intermittent ones. In one or two cases oxygen was given by subcutaneous injection in the pectoral region, the amount being sufficient to cause a lump in each side of the chest about the size of a small football. This was absorbed very slowly, and no relief was apparent.

Benzoin Inhalations.—In milder cases, when the alveolar and bronchial secretion was not so marked as the irritation of the larynx and trachea, inhalations of steam impregnated with compound tincture of benzoin, in a closed tent, were tried with some relief.

Opium.—There was a type of case in which the mental strain was a more marked symptom than the pulmonary distress. This type was characterized by extreme rest-

lessness rather than by dyspnoea, and in these cases tincture of opium, ℥ v administered every half-hour until ℥ xv had been given, gave certain relief, the patients quietening down and falling into a peaceful sleep.

Other Remedies.—Other remedies, such as inhalation of chloroform and amyl nitrite, were tried, but without success.

Routine Treatment Evolved from Experience.

The routine treatment evolved from the experience gained was:

1. Abundant supply of air and warmth.
2. An emetic of salt and water if the patient was very cyanosed and had not already vomited, followed by the
3. Administration of ammonium carbonate gr. xv and *vinum ipecacuanhae* ℥ xv three-hourly.
4. Oxygen inhalation in cases of marked cyanosis and dyspnoea.
5. Opium ℥ v to ℥ xv in restless cases to allay the mental strain.
6. Pituitary extract (1 c.cm.) and brandy when the heart threatened to fail.

PATHOLOGICAL CHANGES FOUND IN CASES DYING FROM THE EFFECTS OF THE GAS.

Post-mortem examinations (10 in all) have been made in cases dying at periods varying from less than a day to five days after inhalation of the gas. Only relative differences were found, even in cases dying at different periods after the gas attacks, so that a general description is sufficient.

The most important changes were found in the lungs, but some changes of note were present in the heart and stomach.

Respiratory System.

In the larynx there was in several of the acute cases a distinct but not marked degree of oedema glottidis. The internal surface of the larynx was congested, even the epiglottis being involved, but not nearly to the same extent as the trachea.

The mucosa of the trachea showed in nearly all the cases intense congestion and oedema, and this could be traced down into the larger bronchi. In almost every case *post-mortem* the trachea and bronchi were filled with a thin, light yellow frothy secretion, which was found escaping from the nose and mouth of the cases when they were laid on the *post-mortem* table. This secretion was highly albuminous and solidified like white of egg when heated. The large bronchi only could be traced, the smaller being lost in a condition of intense congestion and oedema, which affected the lungs as a whole. The lungs *in situ* were in most cases voluminous, and bulged forward so as partly to cover up the area of pericardium normally left bare. The most notable characteristic of the lungs, when removed, was their increased weight, which was several times greater than the normal. The pleural surfaces of the lungs could be mapped out into patches of lighter grey and dark greyish brown, and the pathology of their appearance will be returned to in a moment.

There were subpleural haemorrhages in all but one case. These haemorrhages were small, but in some cases extremely numerous; the lung tissue when incised was found to be of deep maroon-red colour, and fluid secretion flowed in great abundance from the cut surfaces. The structure of the lung could scarcely be made out on the cut surface, the small bronchi being hidden amid the intense congestion. In one case considerable haemorrhage had occurred into one lobe, giving rise to an area about the size of an orange, resembling microscopically a large haemorrhagic infarction. A slice of lung cut from this area sunk in water.

To return now to the light grey patches on the surface of the lungs. These were most numerous along the margins of the lungs and on the diaphragmatic surfaces, but were present up to the very apices. They were found to be areas of actual acute emphysema, and air could readily be made to pass from one side of such an area to the other. In one case bullae of about the size of a small marble were present along the interior margins of the lungs. The emphysematous process did not extend in any area for more than a depth of half an inch into the tissue of the lung from the pleural surface. The margins of

these patches were clearly, but not quite sharply, demarcated from the lung tissue beyond, as the congestion was not at all marked in these emphysematous areas. In several instances the lymphatic channels below the pleural surface of the lungs stood out as prominent lines filled with opaque fluid, there being evidently considerable obstruction to the lymphatic flow.

The Heart.

The heart was in all cases seen to be distended even before the pericardial sac was opened. The dilatation affected all four chambers of the heart, but especially the right auricle and right ventricle. On opening the heart all the cavities were found filled with recent clot, no *ante-mortem* thrombus being found.

Abdomen.

None of the abdominal organs showed more than a condition of venous congestion, except the stomach. The liver in the case of one man who died five days after inhalation of the gas appeared fatty, but this observation has not so far been controlled by microscopic examination.

The Stomach.

The stomach when opened was in all cases found to be in a condition of marked catarrh. The mucosa was covered with a thick yellowish mucus, and submucous haemorrhages were present in nine cases out of ten examined. In one case the amount of submucous haemorrhage present was extreme, and covered almost half of the inner surface of the organ.

The Head.

The head was examined in the majority of the cases, but nothing beyond marked congestion of all the vessels, both of meninges and in the cerebral tissue, could be found.

Histology is pursued here under great difficulties, and in consequence microscopic sections have only been prepared so far from the lungs. The specimens are interesting, however, as they bear out all microscopic observations with regard to the areas of emphysema. The chief microscopic appearances were briefly these: The parts of lung tissue not affected by the emphysema showed marked congestion of the capillaries, and many alveoli, but not by any means all, were seen to be filled with an albuminous amorphous substance taking up the eosin stain. In this substance fibrin could be here and there detected, along with red corpuscles and a few leucocytes. A few alveoli were observed filled with preserved red blood corpuscles.

In the portions of lung affected by emphysema the microscopic changes were very different. Many of the alveoli were broken down, so that perhaps a group of five or six had run into one. The broken free ends of the alveolar walls appeared in the sections more or less bulbous shaped, with a darkly stained cap of amorphous appearance on the top. The alveoli not broken down were obviously much distended, being almost twice the size of the normal lung alveoli under the same magnification. This condition of distension had quite obliterated any tendency to congestion of the alveoli capillaries, the walls of the alveoli being found thin and practically free from blood corpuscles.

These facts account for the light grey colour of the emphysematous patches as compared with the rest of the lungs. The bronchi in the areas of emphysema were empty of contents, in contrast to the congested and oedematous lung tissue in other parts, where the alveoli were found filled with the amorphous eosin-staining material already referred to.

SUMMARY.

From the foregoing account, it seems desirable to emphasize certain points again. None of the cases remained in the casualty clearing station for more than five days after the inhalation of the gas. It is thus the acute stages only which are described in this paper.

On admission the cases were of two chief classes:

1. The acute asphyxial.
2. The subacute.

Of the first class almost one-quarter died. This class was characterized by orthopnoea and marked cyanosis. The subacute cases, on the other hand, showed dyspnoea never amounting to orthopnoea, and were cyanosed to a lesser degree.

It must be admitted that treatment of the acute asphyxial cases was unsatisfactory, which is not to be wondered at when considered along with the changes found in the lungs *post mortem*. The subacute type, however, responded well to treatment, and the cases, although distressed by constant coughing, all admitted the relief gained. The treatment found most satisfactory in such cases was the frequent administration of ammonium carbonate in full doses.

Now that respirators of an efficient type have been issued to the troops it is hoped that many cases requiring to be dealt with will conform to the subacute type, when treatment is of avail.

NOTE BY COLONEL SIR WILMOT HERRINGHAM, Consulting Physician.

I saw a large number of these cases myself and can confirm the report in every particular. Subsequent experience has shown that the milder cases, which are the large majority, recover fairly well. A medical officer of one battalion, who stayed with the battalion in the trenches through a fairly severe "gassing," is now back again in good health after about a month's convalescence.

The problem is how to prevent the severe cases.

I have not the least doubt that proper respirators properly used will almost entirely stop their occurrence. This was proved in the last attack. One battalion with a fairly good pattern of respirator, well used under the intelligent direction of its officers, stayed in its trenches and suffered hardly at all.

Accidental cases will now and then occur, however.

In experiments on animals, atropine given in the earliest stages undoubtedly prevents oedema. I have, however, been surprised to find that no field ambulance reports very favourably upon it. In fact, of the five or six field ambulances which have treated these cases and have told me their experience, no two recommend the same drug or the same method. This difference of opinion shows at least that no other drug appears to be of great value. I hope that if more gas attacks occur we shall be able to try the effect of atropine at an even earlier stage than the field ambulance, and to try it rather more systematically.

When the oedema has once set in there is nothing to be done but to aid the patient to expel the fluid and maintain his strength. The opinion at the casualty clearing stations is almost unanimous in favour of ammonium carbonate.

Only a few cases have remained in the stations, and therefore under my observation, to the stage of bronchitis and bronchopneumonia. These patients, who are dangerously ill, seem to do better with soothing than with stimulant remedies.

The later stages will, however, I hope, be described by medical officers of the base hospitals, who have seen far more of them than I.

It seems certain that the drift gas whose effects are here described is either entirely or almost entirely chlorine. The shells contain other poisonous gases.

MR. HEATH HARRISON, shipowner of Liverpool, has presented a sum of £10,000 to the university of that city for the endowment of the chair of organic chemistry recently established by the council, and filled by the appointment of Professor R. Robinson, of the University of Sydney.

We learn from *Nature* that Mr. C. W. Mally has published an account of the use of sodium arsenite in South Africa as a poison for flies. The bait used is made by dissolving one pound of sodium arsenite and ten pounds of sugar in ten gallons of water. The liquid is applied with a syringe to non-absorbent surfaces, to pieces of canvas, to manure heaps, and rubbish tips. Bunches of twigs, of trees the leaves of which, when plucked, do not crinkle and drop off, are dipped in the solution and hung up where the flies congregate; the flies drink the poison, and die, it is said, literally in heaps. In military camps the method has been applied with success, and, in the absence of suitable trees, pieces of canvas have been sprayed and hung up, and the bait has been sprinkled near manure heaps and other places where flies gather; the bait is, of course, a human poison, but in military camps there is no risk in its use. The method has proved extremely effective for the house-fly out of doors, and its use for fruit-flies has shown that an apparently reckless use of arsenite is not attended with risk to human beings.

PHLEBOTOMUS FEVER (SANDFLY FEVER)*

PHLEBOTOMUS OR SANDFLY FEVER.

BY

COLONEL C. BIRT, A.M.S.,

OFFICIATING A.D.M.S., 6TH (POONA) DIVISION.

SANDFLY FEVER is of scientific interest because its causation has been established by means of experiments on volunteers, experiments which were justified by the fact that the disease does not endanger life.

Newcomers to tropical or subtropical places where the phlebotomus abounds are attacked during their first summer of residence with a fever which incapacitates them completely for several days. After an incubation period of four to seven days the onset of sandfly fever is usually sudden, although sometimes the pyrexia may be preceded by lassitude for a few days. Chilliness may be complained of, but the severe rigor of the ague fit is never observed. The writer, who had suffered from both ailments, recognized at once that the shivering and chattering of his teeth, so violent that he was constrained to hold his jaw with his hands, which were the prelude of his first ague seizure, distinguished the attack from the sandfly infection which he had experienced previously. Giddiness, severe headache, most often limited to the forehead and the back of the eyes, which is aggravated by the least movement of the head, pains in the back and in the legs, and general stiffness of the muscles of the body, induce the patient to take to his bed. He is drowsy and resents being disturbed, but sleep is broken or absent. His face is deeply flushed, and his features are tumid. His eyelids are swollen and partially closed; the conjunctivae are injected, but there is no lachrymation; his eyeballs are sensitive to movement and gentle pressure. He has complete loss of appetite, with pain or discomfort in the epigastrium; vomiting and diarrhoea occur in about one-quarter of the cases, but constipation is the rule. The tongue is coated with a thin white fur, except at the tip and edges. There is often congestion of the fauces and palate on which vesicles may be seen. Epistaxis is observed in a fifth of the attacks, mostly towards the end of the illness. The skin is generally dry, but may be moist; beyond flushing of the face, neck, and upper part of the chest, no rashes are present except the effects of blood-sucking insects. The temperature rises rapidly until it attains 101° to 103° F. on the evening of the first day; it is not quite so high on the second evening, and falls gradually on the third or fourth day—hence the termination of the attack is very different from that of ague, in which the pyrexia abates suddenly amidst profuse sweating. The pulse does not rise in frequency with the fever and generally becomes slow. Leucopenia with relative decrease in the polymorphs is an almost constant sign which persists throughout the illness and the early days of convalescence. The eosinophiles are decreased during the fever, but are increased afterwards as in dengue.

Depression, lethargy, and dyspepsia often continue for a fortnight after an attack, but epidemics vary in this respect. Sometimes vigour is restored rapidly.

In Malta the duration of 20 per cent. of 243 cases of sandfly fever was two days or less, of 30 per cent. three days, of 23 per cent. four days, of 12 per cent. five days, of 9 per cent. six days, and of 5 per cent. seven or eight days. Wymberley's figures of his observations on 160 cases of sandfly fever at Nasheda, India, are—three days' pyrexia in 22 per cent.; four days' in 27 per cent.; five days' in 24 per cent.; six days' in 20 per cent.; and seven or eight days in 6 per cent.

The susceptibility of British troops is very high. Sometimes more than half a regiment has been attacked during its first hot weather. Ninety-five per cent. of all the cases occur in people who have resided two years or less in the endemic area. A high degree of immunity is afforded by the fever. Second attacks occur in only 5 to 10 per cent. of the cases. Relapses are sometimes caused by excessive exercise during convalescence.

* Papers read in the Section of Tropical Medicines at the annual meeting of the British Medical Association, 1914. Publication of these papers has been delayed owing to exigencies of space due to the outbreak of war.

Inoculation of non-immune persons with $\frac{1}{2}$ to 3 c.cm. of the blood or serum withdrawn from sandfly fever patients during the first twenty-four hours of the illness excites the fever without fail (nineteen experiments). Blood taken after the first day is harmless (five experiments). On fourteen out of sixteen occasions inoculation with infective serum which had been passed through a bacteria-proof filter induced the malady. In twenty-one experiments the bites of sandflies which had been fed seven to twelve days previously on sandfly fever patients during the first day of their illness gave rise to the disease. A single phlebotomus is sufficient to infect.

The disease is often called "summer influenza," but bronchitic symptoms are uncommon, and the influenza bacillus is not present. Atypical cases of the mosquito-borne dengue closely resemble sandfly fever; a dengue outbreak, however, is usually more explosive in character than a phlebotomus fever epidemic; rashes also are present in 70 per cent. of dengue patients.

Abortive attacks of enteric, paratyphoid, and Malta fevers may be mistaken for the sandfly infection.

In malarious climates it was formerly confounded with ague, and at the present time this still occurs. Bellile, writing in 1913 of the outbreaks of sandfly fever in Crete, states that the Cretans name it ague. In Malta, where endemic ague may be neglected, sandfly fever, which has caused much sickness among our soldiers and sailors quartered there, has been recognized during the last hundred years as a malady distinct from malaria.

In India, until ten years ago, sandfly fever was for the most part diagnosed "ague." Without doubt many of the cures attributed to quinine have been in times past nothing but the natural terminations of cases of sandfly fever. Since five or six thousand attacks of sandfly fever occur annually among the European and Indian troops, the amount of quinine which has been uselessly expended has been enormous. Great progress has now been made in the identification and classification of fevers in India. In a memorandum issued in 1913 by the Director of Medical Services of India instructions are given that the blood of every case of pyrexia is to be examined before the administration of quinine, by the thick film method, by which parasites can be detected in 94 per cent. of malarial patients. Leucocyte counts are to be made, including differential estimations. Serum reactions are to be undertaken every two days in order to trace the agglutination curve of the serum with the suspected microbe. Cultures of 5 to 10 c.cm. of the patient's blood are to be made in bile or tartrate media. The dejecta are to be investigated bacteriologically. Given a short fever in which the results of these examinations are negative, except the leucocyte estimation which shows leucopenia, in a locality where sandflies are numerous and culices and stegomyia are few, then the diagnosis of sandfly fever is correct. In another memorandum it is suggested that experiments on volunteers with the above-named mosquitos should be carried out if these insects are abundant, as they are the suspected carriers of dengue-like fevers which may be prevalent in the station.

The advance which has taken place in the recognition of sandfly fever in India appears in the following figures: In the year 1910 among the 71,000 European troops there were recorded 512 admissions for sandfly fever; in 1911, 1,393; and in 1912, 2,163. The laboratory facilities for diagnosis are not so great in hospitals for Indian troops as in those for British; 508, 114, 1,316, are the numbers of the admissions on account of sandfly fever among the 131,000 Indian troops for the above-named years. Many sandfly infections are recorded under the headings of "influenza" and "pyrexia of uncertain origin" tables of the seasonal prevalence of which are given, from which it is estimated that five or six thousand cases of sandfly fever occur annually in the European and Indian armies of India.

It is to be regretted that the heading "sandfly fever" does not appear in the annual statistical reports of the health of the navy. In the report for the year 1912 326 cases are registered "pyrexia"; it is stated that many of these were instances of the sandfly infection.

Quinine is without effect prophylactically or therapeutically in sandfly fever. Aspirin and pyramidon are of some use for the relief of pain. An antitoxin is present in the blood of persons immunized by an attack of this

fever, for Doerr found that 1 c.c.m. of virulent blood mixed with 1 c.c.m. of the serum of a man who had suffered from phlebotomus fever two years before, was innocuous when inoculated into a susceptible individual. McCarrison, moreover, injected four immune men with doses of 2 c.c.m. of virulent blood without exciting the disease. It seems probable, therefore, that the infection might be aborted by injections of the serum of convalescents.

Sandflies are widely scattered throughout the tropical and subtropical world. There is a close correlation between the number of sandflies and the fever. In Poona they are scarce and the admissions for sandfly fever are few. In the north-west of India these flies are abundant and the fever is very prevalent. The phlebotomus is so small and elusive that it often escapes notice at night. During the day careful search may find it resting in dark corners, behind clothes, etc.

In the *Transactions of the Society of Tropical Medicine and Hygiene* (1913, vol. vi, No. 7) a survey of our knowledge of the distribution of the phlebotomus and of the fever was made. We learn from the Army Medical Report for 1912, which has appeared since the date of this paper, that there were 104 attacks of sandfly fever registered among the British troops at Malta, 144 in Egypt, and 108 in North China.

The bionomics of the sandfly are being investigated by Howlett, the Imperial Pathological Entomologist of India, and by Marett in Malta. It breeds in caves and in the interior of rubble walls, and in collections of damp material, such as fragments of bricks and stones. *Phlebotomus minutus* feeds on the blood of the common wall lizard. King discovered the larvae of phlebotomus in cracks of the alluvial soil near Trinkitat on the Red Sea. Wenyon succeeded in keeping a sandfly alive in captivity for forty-six days. Doerr's observations tend to show that the summer epidemics of sandfly fever are bridged over by the virus being carried in the larvae, which hibernates in the winter.

The knowledge which has been acquired has been instrumental in reducing the incidence of sandfly fever among the British troops stationed in Malta from more than 300 attacks in 1908 to 104 only in 1912.

SANDFLY FEVER IN CHITRAL (N. INDIA).

BY

CAPTAIN G. F. GRAHAM, M.D., I.M.S.

DURING the three years 1911-13 I have had the opportunity of studying between 700 and 800 cases of this fever in its epidemic form in Chitral—a British outpost beyond the north-western frontier of India. Attention was first drawn to this fever in these parts in 1906 by Captain McCarrison of the Indian Medical Service, who called it the "three days fever of Chitral." It is now fully recognized as identical with sandfly fever, which occurs in many parts of India, especially in the north of India, Punjab, and Himalayan stations, and also in many other parts of the tropics and subtropics. As far as India is concerned, I shall have occasion to point out that probably this fever is by no means of recent appearance, but has previously passed under various names, as Peshawar fever, or pyrexia of uncertain origin.

Distribution of the Fever.

Sandfly fever appears to be a rare disease actually in the tropical zone, being much more frequently found in subtropical regions, and especially in stations at the foot of the Western Himalayas. Chitral itself, where this fever would appear to be most constantly and persistently prevalent, is a narrow valley in the Hindu Kush range of mountains to the east of Afghanistan beyond the Himalayan range. I may mention in passing that Chitral is about the same degree of latitude as the south of Spain. The disease is present throughout the whole of the Peshawar-Chitral Valley at all levels below 7,000 ft. It would appear that the sandfly cannot live and breed at any level over 7,000 ft. The highest level at which I have found it was 6,500 ft.

Climatology.

The disease is strictly limited to the summer months between May and September, more especially June, July,

and August. During these months alone are the sandflies prevalent in their active winged stage of development. In my experience of three successive annual epidemics a very dry season was most favourable to the spread and severity of the epidemic. During the months of June-August there is practically no rainfall at all in Chitral, which becomes exceedingly dry in parts. I found it very difficult to reconcile the necessity for moisture being essential for the life-history of the sandfly in its early development. The only water flowing through the Chitral fort in which the garrison were all quartered was a tiny brick-lined drain about one foot wide, with a very rapid flow of only a small quantity of water down the steep incline on which the fort is built. This drain was repeatedly searched for larvae or pupae, but invariably with negative results. No other open drains or tanks exist in the fort, in which and in similar buildings alone these pests were found. Heavy rainfall—which did occur on one occasion—appeared even to reduce the fever incidence somewhat, possibly by killing off some of the infecting sandflies. High temperatures up to 110° to 115° F. of the Punjab hot weather are favourable, but the cold season of the Himalayas stops breeding and development entirely. Apparently the temperature which is necessary for the imago to hatch out from the pupa is between 70° to 80° F. This temperature is reached as a shade maximum in Chitral about the end of May. It is almost certainly in the egg stage that the sandfly rides over the cold winter months, when the temperature frequently drops to 10° to 15° below freezing point.

Etiology.

It is now, I think, established beyond all possible question or dispute that this fever is spread by the agency of the sandfly, though the nature of the infecting virus is not quite certain. The sandflies, or Phlebotominae, belong to the family Psychodidae. The two special species which are known to convey the virus are the *Phlebotomus papatasi* and *P. minutus*, both of which species I have been able to identify in Chitral. These sandflies are of a light straw colour, with wings carried divergent and pointing backwards and upwards. The sexes are easily distinguished by the large and complex clasping apparatus of the male genitalia on the hinder end of the abdomen. The whole process of life-history from egg to adult fly lasts about one month, this period, however, varying with the surrounding conditions. The methods I adopted in examining specimens were as follows:

The sandflies, young and adult, were caught alive in small glass-covered entomological boxes. In this small cell they could be easily examined with a hand lens and the general characters of the specimen made out. If necessary it was transferred to a small glass cell and examined on the stage of a microscope with a low-power lens. Mounted specimens were also made by the following process:

1. Kill by inverting the small glass bottle in which they were caught over some cotton-wool or blotting paper soaked in a little chloroform, or, better still, over a board with some chloroform soaked into it.
2. Transfer the killed specimen to 60 per cent. alcohol.
3. Clear in oil of cloves.
4. Mount in Canada balsam, arranging the legs and wings carefully with a fine needle and cover over with a coverslip.

Large numbers of sandflies could easily be caught daily in the barracks of the Chitral forts during the summer months. Owing to their small size, they can easily pass through the meshes of an ordinary mosquito curtain used everywhere in India. This necessitates the use of one of much finer mesh to ensure their being unable to bite the individual while asleep at night. This, I need hardly point out, adds very considerably to one's discomfort, as circulation of fresh air through the curtain is greatly impeded by the fineness of the mesh. The flies exist in large numbers in all buildings, especially on the walls and near the ceilings or the roof of the building during the daytime. Towards evening they commence their search for food. The females alone are blood-suckers; they frequently feed by day, and are capable of easily biting through thin socks or cotton summer clothing. The males probably live on vegetables, juices, and other similar materials. The virus which exists in the blood of patients is only infective during the early stages of the fever, and the blood of patients, after being passed through a Berkefeld-Reichel filter, is still infective if injected into

the veins of another. No parasite or germ of any description has ever been identified in connexion with this fever, and if such should ever be shown to exist it will probably be ultra microscopic. The incubation period has been shown to be from two to four days; this was found to be more or less constant in many of my cases in which this point could be made out.

Racial Incidence.

This is peculiar. In Chitral it is remarkable that Europeans and Gurkha sepoys suffer to the extent of 60 per cent. to 80 per cent., while other details of the garrison who have lived previously for the most part in the plains of the Punjab have been practically free from the fever. The Chitrali people themselves do not appear to suffer from the disease except in early infancy. Doubtless they acquire a high degree of immunity in early childhood which protects them throughout later life. The existence of the disease in the Punjab will also explain the fact that while a hospital may be crowded out with Gurkha sepoys, who go down like flies before the epidemic, hardly a single Punjabi will be attacked. The Gurkhas have always previously lived in hill stations where the fever has not existed, while the Punjabis has come up to Chitral for his year's duty from the plains of the Punjab where he has acquired a high degree of immunity from previous attacks. The percentage of Europeans attacked is even greater than among the Gurkhas of the garrison. As a rule one attack confers immunity against fresh attacks, though this is by no means constant. I have seen fresh attacks to the extent of 5 per cent. of all cases, and have myself contracted the fever in each of two successive years. Even cases of third attack have been noted in the same epidemic, though these are rare.

Some epidemics are much more severe than others, and the circumstances which influence the type of the severity of an epidemic are difficult to make out. In the first of my three epidemics (in 1911) something over 200 cases occurred, being about 40 per cent. of all who had been exposed; while in 1912 exactly 400 cases occurred, that is, about 70 per cent. of total exposed, though the conditions in the two years were almost identical and the type of the actual cases of the two epidemics showed no marked difference.

Symptoms.

After an incubation period of from two to four days, during which there are usually no prodromal symptoms beyond slight headache and general malaise in some cases, the disease usually begins with a rigor. The temperature rises rapidly in a few hours, reaching a maximum varying from 103° to 105° or 106° F. by the end of the first twenty-four hours. The fever usually lasts two to three days, generally with a slight remission on the second day. The action of the virus manifests itself by general symptoms: Acute aching pains and stiffness all over the body, especially in the muscles of the back and limbs, severe frontal headache, and pain in the back of the eyes. Injection of the conjunctival vessels is also present, producing the "pink eye" described by some observers in Crete. Nasal and pharyngeal catarrh are occasional symptoms, but this catarrh never extends to the bronchi or lungs. Disturbances of the digestive system are invariably noticed; anorexia is a pronounced symptom, vomiting is not common, constipation is the rule. The spleen is generally unchanged.

Among the circulatory signs most noticeable is bradycardia. Many cases, even with a temperature of 103° or 105° F., will show a pulse-rate of less than 80, or even less than 70, and rarely over 100, and during convalescence this bradycardia is still more pronounced.

Blood changes are very slight. Leucopenia, with a relative large mononuclear increase, was found in some cases. No protozoal or other micro-organisms were ever found in any cases, though the blood of all cases was carefully examined microscopically with a high power. Epistaxis was a very common symptom, being noticed in over 20 per cent. of my cases. In some cases this epistaxis was a troublesome symptom and hard to control, possibly indicating a diminished degree of coagulability of the blood. No cases showed any sign of a rash, which has occasionally been noticed by other observers.

Treatment.

Treatment on the ordinary lines for pyrexia was adopted as a routine. Quinine has absolutely no effect on the fever. Aspirin I found of use; if given in fairly large doses the aching pains in the muscles and the severe frontal headache were considerably relieved. Given shortly before the usual hour for sleep, the use of this drug made all the difference in the night's comfort in many cases. Tincture of opium and salicylates were also used in many cases with gratifying results, at least from the former.

Diagnosis.

The diagnosis seldom presented any difficulty during the epidemic season. The sudden onset, with rapidly rising temperature and slow pulse, are characteristic.

Prognosis.

The prognosis is never serious. No cases terminate fatally, and complications or troublesome sequelae are exceptional, except the very marked degree of prostration, which lasts from ten days to a fortnight at least, and is very constantly present in almost all cases. It would appear that the virus has a marked depressing effect on the central nervous system, producing this severe prostration. Occasionally the temperature chart will show a sharp rise of temperature about three or four days after its return to normal. Such relapses, however, are not common; my figures only show 1 per cent. of such cases.

Prophylaxis.

Evacuation of localities where the disease is known to be present should be carried out where practicable. It is not always possible, however, to do this, especially in a frontier station where a fort has to be kept occupied.

Experience in Chitral has proved that if the troops of the garrison can spend the three or four special fever months of the hot weather under canvas at an elevation of anything over 7,000 ft. not a single case of sandfly fever will occur amongst such troops, while any troops remaining in the fort, which is situated at an elevation of just under 5,000 ft., will contract the fever to the extent of nearly 80 per cent. during the epidemic season.

Very early isolation of cases should be strictly carried out, inasmuch as inoculation experiments have shown that it is only during the early stage of the disease that the case can be considered infectious. All cases should be kept under a (fine mesh) sandfly-proof curtain erected over each bed. A similar curtain should, of course, be used by all persons living in an infected area. The demolition of all unnecessary buildings and old walls—ideal haunts for the sandfly—is desirable. Various drugs have been recommended for external use as repellents, but they have not proved of much value. Fumigation of rooms of barracks has been tried, with temporary good results in some cases by killing off numbers of sandflies. Destruction of sandflies by spraying the walls of buildings with some insecticide, such as formalin solution, has been recommended, but I have not given this method a trial in Chitral, as I do not consider that it could be conveniently carried out. Indeed, it must be admitted that very little reliance can be placed on any methods hitherto employed with a view to reducing the fever incidence by diminishing the number of sandflies.

In conclusion I should like to emphasize the fact that although sandfly fever is a very distressing type of fever, I do not think that of the 700 cases or more which came under my notice during the years 1911 to 1913 any one patient is now any the worse for his attack. The fever is not a serious one when compared with other tropical fevers, such as malaria. Recovery from sandfly fever may be considered to be absolute in all cases, and a considerable degree of immunity from fresh attacks usually results. But as a severe cause for temporarily rendering a large percentage of a unit inefficient it requires to be dealt with carefully.

SANDFLY FEVER IN PESHAWAR.

BY

CAPTAIN J. W. HOUSTON, M.B., R.A.M.C.

As long ago as 1899 Colonel Fooks saw an epidemic of short fever cases at Landi Kotal, in which he considered the sandfly to be the infecting agent, and later he described

an epidemic which he saw amongst the 15th Lancers at Sialkote in 1907, and was again of opinion that it was conveyed by sandflies. He considered this epidemic to be one of dengue, of a three-day and a seven-day fever type, but writing later, in 1911, he said that the disease would be known as sandfly fever; but although medical officers were cognisant of this fever, it was not until 1910 that the evidence was sufficiently strong to warrant its being officially recognized. In that year, under the heading of sandfly fever, we find that there were 103 admissions to hospital amongst the British troops in the division. In 1911 it is evident that the diagnosis was more readily made, as there was a sharp rise in the number of admissions to 782, and this was maintained in 1912 and 1913, when the admissions were 823 and 746 respectively. In the years previous to 1910 sandfly fever was doubtless recorded under various headings, the principal one being malaria, but influenza and pyrexia of uncertain origin also took a share.

With regard to susceptibility and incidence it would seem that all ages and both sexes are prone to be infected, but the disease has not been observed much here amongst women and children as they all depart to the hills at the commencement of the hot weather. Fresh arrivals from stations where the disease is not prevalent appear to be particularly susceptible, whilst the stay of a battalion or other unit in an infected station such as this is marked by a gradual rise in immunity. An example of this may be given.

The 72nd Battery R.G.A. arrived from Nowgong last cold weather. A perusal of their medical history sheets showed that none of their men had suffered from sandfly fever. They were quartered beside, and practically in the same barracks with, the 75th Battery R.F.A., who had been in Peshawar and district for over four years, and whose medical records show that 37 per cent. of their men have been infected at one time or another. During a period of one month after the appearance of sandfly fever in April, 1914, 19 cases occurred in the fresh battery, an incidence of 112 per 1,000. Amongst the old battery 8 cases occurred, an incidence of 61 per 1,000, or just about half. All these men were living side by side under practically identical conditions, so that it would seem that in the 75th Battery a certain degree of immunity has been established.

A perusal of the figures for the two British infantry battalions in the station gives a similar, though less marked, finding.

The incidence among the men of the 2nd King's (Liverpool) Regiment, a new arrival here, was, up to April 28th, 6 per 1,000, and during the month following that date 41 per 1,000; April 28th was the date on which half of each battalion left Peshawar for the hills. In the 1st Royal Sussex Regiment, who are old inhabitants, the rates of incidence before and after April 28th were respectively only 2 and 12 per 1,000, so that here again it seems probable that some immunity has been attained.

The incidence in the two batteries was considerably greater than in the two infantry battalions, and so far as can be observed, this coincides with the relative numbers of phlebotomi present in the various barracks. They are distinctly more numerous, and certainly occasion more complaints, amongst those inhabiting the gunner lines than amongst the residents in the infantry barracks. An interesting feature, too, is that the infection appears to cling more particularly to certain bungalows, and with the appearance of sandflies in April, cases of the fever begin to occur in these, which then form foci from which it spreads in all directions.

The varieties of phlebotomi commonly seen in this district are *P. papatasi* and *P. minutus*. *P. papatasi* is, however, by far the most prevalent and widely distributed, and, so far as can be judged, outnumbers all the others by at least 20 to 1.

The disease makes its appearance with considerable suddenness about the middle of April annually, and as this coincides with the yearly advent of numbers of phlebotomi, also as the usual type of fever seems identical with that described in other parts of the world as sandfly or pappataci fever, it is reasonable to suppose that they are identical in every respect, and that the *P. papatasi* is the vehicle of infection from person to person.

As well as the sandfly, the north-west frontier is the

home of several of the other blood-sucking diptera, but it does not seem likely that any of them will be found to be implicated in the spread of this particular fever.

The disease reaches its maximum incidence annually in May and June, though in 1913 this did not occur until August; the tendency for it then is to show a decided fall until October is reached, after which month practically no cases occur. The clinical manifestations of sandfly fever may be described as follows: The onset is sudden—a man goes to bed feeling either absolutely well or he may notice some chilliness or shivering in the evening. There is no rigor. He wakes up in the morning "with the fever on him," as he expresses it. Frequently it is ushered in with nausea and vomiting. Severe headache is almost always complained of, the main seat of pain being at the back of the eyes. Joint pains and aching pains and cramps, chiefly in the lower limbs, are usually present, and the patient feels ill and depressed. The face is flushed and the eyes suffused. A rash has not been noted. The temperature runs up rapidly, reaching 102° F. or 103° F., or even higher during the first day. It tends to fall gradually until the second day, when it is usually about 100° F. or 101° F. The third day it may be still falling and quickly reach normal, or show a slight exacerbation to 100.8° F. or 101° F., this being followed by a rapid, sometimes almost critical, fall to normal. It is unusual to find any fever at all after the third or fourth day. The pulse is full and compressible. The rate is not markedly increased, seldom being beyond 88, even when the fever is high.

The tongue is coated with a whitish fur, and a constant complaint of the patient is "a bad taste in the mouth." The bowels are, as a rule, constipated. No abdominal distension has been noted; the heart sounds do not change, and the lungs remain clear. There is no enlargement of the liver or spleen.

The blood picture is characterized by a leucopenia, the total leucocyte count averaging about 5,500 per c.m.m. Differential counts show that the polymorphs are usually below 60 per cent., while the mononuclears show an increase up to 15 per cent. or over. An increase in eosinophiles up to 5 or 6 per cent. has also been noted in a few cases, but it cannot yet be said whether this feature is at all constant or not. There is no diminution in the number of red cells, nor does there appear to be any blood destruction as evidenced by an examination of the urine. In other respects also the urine is normal. As soon as the temperature becomes normal the patient usually states that he feels perfectly well, but in many instances he finds that it is a considerable time before he fully recovers his strength. One attack does not appear to confer absolute immunity against the disease, as a second or even a third in consecutive years have been noted in a few cases. In a very small percentage two attacks in one year have been recorded.

There is another type of fever seen in this part of the country during the summer months which some observers also attribute to the presence of sandflies and designate sandfly fever. In it the duration of the pyrexia is longer and runs a course of seven days so consistently as to be known as the seven-day fever type, as opposed to the three-day fever type described above. The general symptoms resemble those of the three-day variety, but are much less marked, and in a considerable proportion of the cases there are practically no subjective symptoms, the only marked objective one being the pyrexia. A rash is also sometimes seen. In other words, these cases resemble the "seven-day fever" described as occurring in the large coast towns of India, but also seen in Poona, Bangalore, Belgaum, and various other places. They are well marked off from the classical dengue by their more sporadic appearance and much less epidemic character, combined with their general mildness of symptoms. Nor does the evidence in favour of their being a variety of sandfly fever appear to be strong, the main arguments against that assumption being again their rather sporadic appearance during the later warm months when phlebotomi are disappearing, whilst if we are to regard sandfly fever here as being identical with that occurring in Malta, Crete, and other places, there is the fact that when the disease has been produced experimentally it has never undergone any marked modification in the person artificially infected but has been of the original three-day type. As *Stegomyia*

are found here it is at least as likely that they may be a factor in the causation of this seven-day type of fever, as they appear to be now generally regarded as being the active agents in its propagation in other parts of the country.

THE BIONOMICS OF THE MALTESE PHLEBOTOMI.

By CAPTAIN P. J. MARETT, R.A.M.C.,
BETT MEMORIAL RESEARCH FELLOW.

It is places which are dark, damp, and usually inaccessible, and with a requisite temperature and a suitable food supply, that the phlebotomus flies select for their breeding grounds.

That darkness is the natural condition is to be deduced from an examination of the larvae, which are devoid of eyes, their place being taken in the adult larvae by two patches of pigment. A certain amount of moisture is necessary, for two reasons—the one, that, if placed in dry surroundings, the larva will shrivel up, and the other that the food of the larva being excretal matter, cannot be eaten when in a dry condition. Excess of moisture is equally harmful, as has been experienced in breeding experiments, where excessive spraying of a breeding dish resulted in the loss of all the larvae.

Quiet is essential, as the larval stage is somewhat lengthy, and if exposed to inclement weather during this period a fatal result is a foregone conclusion. The proper food supply of the larva has been found to be the excreta of the various insects and animals found in walls. Special attention has been paid to the excrement of woodlice, lizards and bats, and undoubtedly, in experimental breeding, the first—that of woodlice—gives the best results. The requisite temperature for active breeding is above 70° F.; below 60° F. larvae appear to roll themselves up in detritus, whilst the higher the temperature is above 70° F. and up to 86° F. the more rapid is the life cycle.

All the above physical conditions are to be found in the interior of rubber walls, in crevices of caves, artificial embankments, and, in Malta especially, in the interior of the old bastions, many of which contain long disused chambers. In searching these places, of which only the interiors of the first three have been examined, the number of specimens of larvae and pupae found has not been in proportion to the quantities of flies prevalent, but this has been found to be due to the fact that the larvae bury themselves, and that of the pupae, in nature, only those adhering to stones have been found. In experimental breeding only about 5 per cent. of pupae so attach themselves, the remaining 95 per cent. lie free on or under the detritus.

Newstead, in his article on the Papatasi flies (Phlebotomus) of the Maltese Islands, describes three varieties: *P. papatasi* Scop, *P. perniciosus* Newstead, and *P. minutus* Rond; of these *P. papatasi* is the largest, *P. minutus* the smallest, whilst *P. perniciosus*, as regards the size of its body, resembles *P. papatasi*, but its legs are not nearly so long. *P. papatasi* breeds out in caves and in embankments, whilst *P. perniciosus* and *P. minutus* breed chiefly in the rubble walls and in bastions, the result being that the two latter species are seen more often in dwellings, unless caves and embankments are in close proximity.

Flies appear about the middle of May, in small numbers; they gradually increase, and by the end of June they are numerous; during July, when the breeding grounds are somewhat dry, their numbers decrease, and only on the onset of the damp sirocco, about the middle of August or beginning of September, do their numbers rise once more, when they appear in far greater numbers than earlier in the year, and persist till the onset of the rains and wind, about the middle of November. They can still be found in their breeding haunts in small numbers during December.

The latest date on which a fly was seen was January 14th; this was in a breeding ground where the temperature kept up to 70° F. till January; on the temperature falling to 60° F. no flies were seen. There is thus an interval of about four months during which the adult fly is not to be found; that is to say, the fly does not hibernate, but the winter is passed in the larval stage.

The causes for the fluctuations noted in nature have been worked out experimentally; it is found that dryness of surroundings prolongs the length of the various stages, and on the other hand, that with suitable moisture and heat the various stages are passed through rapidly; in the former the complete cycle takes up to four to five months; in the latter, the shortest time has been found to be thirty-four days.

A summary of the length of life of the different stages, for wild flies and for tame flies, is best given in tabulated form.

Summary of the Length of Life of the Different Stages, for Wild Flies and Tame Flies.

Stage.	Duration of Stage:	
	Wild Flies.	Tame Flies.
1. Pregnancy stage ...	Unknown	7 to 10 days.
2. Egg stage ...	(a) 6 to 9 days (b) In dry weather up to 20 days	(a) Average, 8.4 days. (b) Shortest in incubator at 30 C., 5 days. (c) Longest in October at room temp., 10.1 days.
3. First larval stage ...	14 days	(a) Shortest, 6 days. (b) Longest, 14 days.
4. Total larval stage ...	Up to 5 months	(a) Longest, 140 days. (b) Average longest, 92 days. (c) Average shortest, 24 days.
5. Pupal stage ...	11 to 16 days	6 to 16 days.
6. Length of life of fly	8.4 days	Females: (a) Shortest, 7 days. (b) Longest, 25 days. (c) Average, 12.5 days. Males: Average, 4 days.

The above data are gathered from breeding experiments. Of tame flies from the middle of August, 1913, to the end of March, 1914, four generations were bred out.

The eggs are white, but rapidly darken; they are marked with distinct patterns (36 μ by 12 μ). The larvae on hatching are minute and with a dull white body, the head and the two tail hairs being a shiny black; at two days old the size of the larva is 0.4125 mm. and the length of the tail hairs 0.5 mm.; total length, 0.9125 mm. They rapidly increase in size and take on the brownish colour of their surroundings; on moulting, which they do once, they once more become white, and shortly after the head and tail hairs assume the black colour, but now the larva has two pairs of tail hairs. The larva is motile and eats voraciously; when about to pupate (its size is then about 4 mm. and tail hairs 1 mm.; total length, 5 mm.) it becomes motionless, empties its intestinal canal, and its head curves over till it touches its abdominal surface.

The colour of the pupa, which is obtectate, is on emergence a dull white, having its terminal segments covered by the remains of its larval skin. In a couple of days the eyes show their black pigment, and about two days prior to emergence the wings, body and legs take on their pigmentation, brownish to jet black. The size of the pupae varies with species and with sex; in *P. papatasi* the males are 4 mm. long and are thin in comparison to the female flies; the females are 3 mm. The extra length of the males is due to the claspers, which are held fully extended. Pupae are more resistant to the action of water than larvae.

When a larva is about to pupate, it comes up to the surface; if the surface of the detritus, however, is dry it will remain in the depths, so that under these conditions, when the fly hatches, it has to work its way up to the surface. The fly emerges from its pupal case through a sagittal slit at its anterior extremity.

Flies are sexually mature within a few hours of emerging, thus it is impossible to state the duration of pregnancy in the wild fly.

Tame flies usually feed before pairing, the females alone suck blood; when pregnancy is short (for example, seven days), the eggs are more likely to be fertile, and when this is the case, the eggs are all laid within twenty-four hours, and the fly is found dead by the last of her eggs—this is the usual course with wild flies.

With the tame fly, where eggs are laid and the fly dies

after ovipositing, the eggs are usually fertile; where flies do not lay their eggs all at the same time, they do not succumb till some days later and the chances of their eggs maturing is much lessened.

Examples.

In the third generation of laboratory-bred flies, one fly hatched on January 18th, 1914, and died on the 25th of the same month, having completed oviposition, a length of life of seven days; from her eggs 40 larvae hatched on February 1st and 2nd—that is, all eggs were fertile. Another fly of the same generation, hatched on January 19th, 1914, laid eggs from the 28th of the same month for some days; the first lot of eggs produced 2 larvae on February 3rd, and the fly died on February 5th. Here out of all the eggs only 2 were fertile.

The longest life of a fly in these experiments was 25 days, and all her eggs were unfertile.

The average length of life of female tame flies is 12.5 days, of males 4 days.

The average longevity of both sexes of wild flies in captivity has been worked out at 4.2 days, and is inferred to be one half the viability. In this experiment, which was continued for a month, the true viability works out at 8.4 days.

On warm sirocco nights the flies appear just before sunset; leaving their haunts, they are attracted to uninhabited dwellings, where they cause annoyance by their persistent biting. Flies bite both warm and cold blooded animals. At sunrise they disappear, either to their breeding haunts, which they can be seen to enter, or they retire to dark corners of rooms, where they are to be found seeking shelter behind hangings; on windy nights they do not leave their haunts. The flies dislike sunlight, but are attracted by artificial light, and are to be found in considerable numbers on and around paraffin lamps.

The only way in which the distance of their flight has been worked out has been from a knowledge of the habitats of the different species—that is, knowing that *P. papatasi* bred out in a certain cave, it was found that this fly was present in dwellings within fifty yards of the cave, but only rarely beyond this limit. They do not fly high, and the top rooms of houses which are not shut in by high walls are comparatively free from flies.

In the course of breeding experiments it has been found that abnormalities occur, the most noticeable being varying degrees of malformation of the male claspers, up to complete transposition of superior and inferior claspers. At present the males are identified by their claspers and by the number and arrangement of hairs thereon; these minute details being inconspicuous characters are stated to be uninfluenced by adaptation; however, the fact of these abnormalities occurring is rather against such a classification. Among the females there is a gradual loss of fertility, due probably to in-breeding; the eggs of such flies assume abnormal shapes, but the pattern of the reticulations does not appear to be altered.

The fly possesses one fairly common ectoparasite, a mite, which hatches out in the woodlouse excreta, and is to be found hanging on to the thorax of the fly; apparently it is not a true parasite, as it lives in dishes in which no flies have been present and it does not injure the larval stage. On the other hand there is a minute pseudoscorpion which does injure the larval stage.

Work is being done in the bacteriology of the various stages. Mention will here be made of a fungus only. This fungus is pathogenic to the fly and is provisionally called *Empusa papatasi*. A fly so infected is recognized by the fact that ingested blood appears to remain in the thorax, causing it to appear nearly as red as the abdomen. On dissection of such a fly the salivary glands show motile forms, "swarm spores," whilst the mycelial form is seen in the intestines. When such an infected fly is dipped in absolute alcohol and flamed till the wings and legs are burnt off and is then emulsified in 10 per cent. citrate, a flocculent growth is obtained, consisting of mycelium and spores. Subcultures from the citrate on to Sabouraud's medium and on to glycerinated egg medium give rise to a white fungus; in this stage spore formation is by intercalary formation. When the growth in citrate is subcultured into N.N.N. highly motile forms are seen, corresponding to those seen in the salivary glands. Experimental inoculations with the motile forms into rabbits and guinea-pigs give rise to symptoms. The white fungus under certain conditions gives rise to yellow bodies (ascospores); here apparently spore formation is by aecrogenous segmentation, which would allow of its being

included in the Entomophthoraceae, to which family the *Empusae* belong.

In conclusion, it is thought advisable to make a note of the effects of inoculation, as this *Empusa* appears to have pathogenic properties, and involuntarily the thought arises that it is quite possible that the *Empusa muscae domesticae* may be the cause of infantile diarrhoea.

NOTES ON THE TRANSPORT OF CASES OF FRACTURED THIGH.

By C. MAX PAGE, M.S., F.R.C.S.,
CAPTAIN, R.A.M.C.(S.R.).

The provision of satisfactory methods of fixation for cases of fractured femur has proved most difficult in the present war.

It is not surprising that adequate results have not always been secured in these cases, for all the appliances in common use for fractures of the femur have been developed in order to deal with cases under stationary conditions and, in general, for simple fractures.

It is true that reasonable comfort of the patient is usually secured by the administration of morphine. On the other hand, in the later course of these cases a good many amputations have been necessary, and the mortality has proved surprisingly high. It seems probable that the complications of severe infection and haemorrhage—both reactionary and secondary—should be attributed in some degree to the unsatisfactory fixation of the injured limb during the necessary period of transport. Laceration of muscles and vessels is bound to occur under such conditions, and, unless efficient extension is exerted on the limb, any wound, unless very large, becomes plugged by ruptured muscle. This obstruction to free drainage in the early days of the injury obviously assists the development and spread of any infection present in the wound track.

It is noticeable that the patients themselves seldom complain of great discomfort during the journey. This is undoubtedly due to regular and proper use of morphine. Yet the position of the limbs in such cases by the time they reach the base generally leaves much to be desired. The foot is usually rotated inwards, and the thigh is commonly telescoped owing to the lack of proper extension.

I propose to show that the method in common use of fixing these cases in some form of long outside splint is not satisfactory, and that in the majority of instances a modified form of Thomas's knee splint gives much better results.

Requirements to be Fulfilled.

If one defines the ideal requirements of a method of fixation suitable for use in the transport of these cases from the field ambulances to the base and thence to England, one would set down the following requirements—the first four apply to the present conditions in relation to the rapid handling and transport of large numbers of wounded; the last two are more purely surgical:

1. The splint should not be cumbersome, and should be standardizable.
2. The standard pattern should be easily adapted to all varieties of individual cases.
3. The application of the splint should be simple, and effected with the least possible disturbance of the patient.
4. After application of the splint, movement of the patient and his transfer from stretcher to bed should not displace the splint.
5. The apparatus should secure steady extension in the long axis of the limb; the fulfilment of this requirement presupposes fixation in the natural position, and secures the comfort of the patient.
6. When the splint is in position, access to any part of the limb for the purpose of changing dressings should be possible. Nursing duties should be rendered simple.

At the present time, for the transport of cases from the front to the base, an interrupted or bracketed long outside splint with an adjustable foot-piece is generally used. If one compares the features of this apparatus with the

standard above set out, it may be said to conform to the first requirement, and very imperfectly to the second.

As to the third, in order to apply the splint, considerable movement of the patient's body is involved, and to fix it properly an anaesthetic is necessary.

It very frequently fails to comply with the fourth

Fig. 1.—The skeleton splint, padded.

requirement in practice, as the upper end of the splint tends to rotate forward on the trunk.

The fifth important requirement, of extension of the limb, is seldom attained with this splint; theoretically it is effected by the use of a perineal band, but this appliance is usually very uncomfortable, and seldom efficient in its action; moreover, the fixation of the thigh is not in the natural position—any outside splint is bound to lateralize the fragments. The splint is firmly attached to the foot and leg, and so to the lower fragment, but as its hold of the upper fragment and trunk is at the best approximate, and is often unsatisfactory, such an arrangement often fails to prevent rotation of the foot and lower section of the leg.

As to the sixth requirement, of accessibility, the fixed interruption by no means gives free access to all wounds, while the splint is in position. The use of the bedpan is an awkward problem.

Method Recommended.

I will now detail the features of the modified Thomas's knee splint which I described in the BRITISH MEDICAL JOURNAL (May 15th, 1915). This splint is made from the standard aluminium material supplied in the regulation

Fig. 2.—The splint padded and with slings in position for application.

field fracture box. It has, with slight modifications, been in use for the majority of the cases of fractured femur admitted to this hospital since January last, both for their treatment here, and for their transfer to England.

Reports of the medical officers of hospital ships, and from the hospitals at home, support the value of the method.

The form of the splint is shown in the figures (Figs. 1, 2, and 3). As before described, it is made by joining together two standard lengths of splinting suitably bent. The only material addition is that of a wide based prop, attached as shown in figure. This prop is bent, when necessary, so as to project inwards and downwards, so that, in spite of the sagging of the canvas of the stretcher, no rotation of the splint takes place.

Jaconet covering of the tow padding on the crutch has not proved durable. If, instead, a length of Panl's india-rubber intestinal tubing is rolled on like a cricket bat handle, the result will be found good.

As stated in the first article, for application of the extension stirrup, a plaster-of-Paris bandage gives satisfactory results, but if that or an ordinary adhesive extension are not available, a simple ankle strap will give sufficient hold for a few days.

This splint will be found suitable for use in any case of fractured femur in the lower four-fifths of the thigh.

One can enumerate its claims to comply with the above requirements as follows:

1. The splint is made and its application can be completed from the materials supplied in the Standard Field

Fracture Box, with which all the units concerned are equipped. One of two standard sizes of the splint can be adapted to fit any case. A certain stock can be made and padded ready for use in times of pressure.

2. The malleability of the material and the system of staples by which the pieces forming the splint are joined together make it possible to fit any case accurately.

3. For the application of the splint the only movement of the patient called for is a slight raising of the injured leg from the stretcher. The application is completed in two or three minutes as follows: An extension stirrup is fixed to the injured leg; long axis traction is then made on the limb, and it is steadily raised through about 30 degrees. The splint, with slings in their approximate place, is then laid below the leg, the crutch of the splint is bent open, and made to abut against the ischial tuberosity. The limb is then lowered on to the slings. The crutch is moulded round the hip and the lateral limbs of the splint are bent in so as to support the leg evenly. A webbing strap is applied round the bottom notch of the splint and the extension stirrup. The slings are then adjusted so that the limb lies comfortably in

Fig. 3.—The splint applied. The extra strap passing across the front of the thigh is unnecessary.

about the midplane of the splint. Two webbing straps are carried across the front of the limb, one between the extremities of the crutch and the other just below the knee. These two straps need only be tight when the patient is being moved about or rolled on his side for dressing; the extension strap should always be kept taut.

4. The splint does not become readily displaced when once applied if the above directions are carried out—the continuous fixed extension, acting between the notch of the splint and the stirrup and countering against the ischium, makes a single manageable unit of the limb and splint.

5. As above described, steady fixed extension in the natural line of the limb is provided. The amount of tension necessary to secure the limb for transport is not very great, but sufficient pull to prevent any shortening of the leg during treatment is easily obtained. The position of the leg in the splint is the natural one, and so lateral displacement of the fragments cannot occur. The question of flexion of the fragments is alluded to below.

6. Dressing of wounds in any part of the leg is easily accomplished owing to the detachability of the slings and the ease with which the patient can be rolled on his side. The side members of the splint can be bent so as to avoid

Fig. 4.—The splint applied and held in flexed position.

any lateral wound. Use of the bedpan is simple owing to the mobility of the trunk.

As before stated, this splint is suitable for fractures in the lower four-fifths of the femur. For injuries near the hip-joint it can be used if there is no wound where the crutch would lie. The latter, so long as it bears centrally on the tuberosity of the ischium, can be bent downward or arched forward in order to avoid wounds in its vicinity.

In some cases of high fracture, flexion of the upper fragment of the femur may be present, though this is not as common in gunshot injuries as in those due to indirect violence. For purposes of transport this will not affect the satisfactory action of the splint. In such cases, when the patient is stationary, the fragments can be brought into line by bending the splint at the level of the knee as in a Hodgen's splint. The leg should thereafter be suspended, as in fact it usually is during hospital treatment in straightforward cases.

REMARKS ON THE MOVEMENT OF THE DIAPHRAGM IN EARLY PULMONARY PHTHISIS.

BY

HUGH WALSHAM, M.A., M.D.CANTAB., F.R.C.P.LOND.,
MEDICAL OFFICER IN CHARGE OF THE X-RAY DEPARTMENT AT
ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE
CITY OF LONDON HOSPITAL FOR DISEASES
OF THE CHEST;

AND

WALKER OVEREND, M.A., M.D. OXON.,
CHIEF ASSISTANT IN THE X-RAY DEPARTMENT, ST. BARTHOLOMEW'S
HOSPITAL; LATE PHYSICIAN TO THE PRINCE OF
WALES'S HOSPITAL, LONDON, N.

A DIMINUTION in the extent of the inspiratory depression of the diaphragm accompanies many diseases of the lungs and pleura, including pulmonary phthisis. This loss of movement in tubercle occurs at an early stage on the affected side, and is known as Williams's sign. It is by no means universal.

1. The origin has been attributed to several causes, and it will be profitable, in the first place, to subject each of these to a brief examination. (a) It is assumed that there is a diminished power of retraction or loss of contractility in the tissues of the implicated lung. (b) The diaphragm may be intimately connected with pleuritic adhesions, which hinder its excursions. (c) The terminal branches of the vagus are involved, being unduly exposed to the effects of pressure or strain. A reflex follows which inhibits inspiratory movements or stimulates broncho-constrictor fibres. (d) The phrenic nerve becomes invested in pleuritic thickenings at the apex of the lung. This idea was more acceptable some years ago, when hilum phthisis was little regarded. (e) Toxicæmic conditions arise as the result of the disease.

2. *Average Position of Diaphragm.*—In the erect posture the highest point of the arch in front lies near the upper border of the fifth right and lower border of the fifth left rib. In recumbency the position is slightly higher—namely, the lower border of the fourth right and upper border of the fifth left rib. Behind on standing, the level is about the lower border of the ninth right and lower border of the tenth left rib; in the horizontal position the lower border of the eighth right and lower border of the ninth left rib. In quiet normal breathing the amount of movement is practically half an inch; in deep inspiration about two inches, being rather more on the left side in both conditions.

3. A reduction in the amount of shortening, after extension of the elastic fibre, or a condition of atony in the unstriped muscle will be followed by an increased volume of the lung, since the force of contraction of the diaphragm during the act of inspiration, which opposes the stretching of the elastic tissue, will be less restrained. On relaxation, moreover, the vigour of the elasticity which apparently assists in the preservation of the convex outline of the diaphragm being lowered, the height of the latter is diminished. The neutral position will be depressed, and during quiet breathing the excursions will be deficient. But there is no such general downward displacement of the diaphragm; on the contrary, it may be somewhat higher during the pause than in the normal. A jerky or stammering movement is occasionally observed. In some endothoracic growths—lymphosarcomata, etc.—at times an expiratory fluttering also is noticed, and some of these cases appear to exhibit a diminished elasticity.

4. Diaphragmatic pleurisy manifests itself either as a marked prominence in the curve during inspiration, or as a series of small irregularities in the contour. But in

cases where Williams's sign is obvious the shadow of the diaphragm is often quite smooth and regular.

5. The vagus is a nerve endowed with great possibilities. The area of its distribution is extensive, and it is the motor (cranial autonomic) as well as the sensory nerve of the lung and pleura. It transmits from afferent end organs—the nature of which is still unknown—inspiratory and expiratory impressions to the medullary respiratory centre. It is possible that the inspiratory inhibiting impulses differ from the purely expiratory. When the central stump of the vagus is excited with weak stimuli inspiratory movements are inhibited, partially or completely, producing either small movements or—in a condition of narcosis—complete cessation of respiration with the thorax in a state of passive expiration.¹ It has also been suggested that the nerve-endings of the vagus may become hyperæsthetic in inflammatory conditions like pneumonia,² and produce rapid breathing by affecting both halves of the respiratory centre. Where small unilateral lesions exist a similar condition of hyperæsthesia of the terminal fibres may arise, producing a greater reaction during the inspiratory dilatation of apical alveoli; or vagal branches caught in diseased and enlarged glands within the hilum and along the extra-pulmonary bronchi may be subjected to increased pressure or tension during the same phase of respiration. The vagus also contains broncho-constricting fibres. Afferent impulses from the nasal mucosa produce reflexly broncho-constricting effects. In the same manner irritation may be transmitted from sensory areas of the lung and pleura. On the other hand, efferent vagal branches, situated in the immediate vicinity of enlarged glands, may be affected directly by pressure. Irritation of the sympathetic (dorsolumbar autonomic) is followed by bronchial dilatation. It is also conceivable that excitation of afferent vagal branches during inspiration, either by pressure of glands or on account of pleuritic adhesions at the apex, might induce a reciprocal expiratory reflex with cessation of the inspiratory act before its full completion is reached.

6. Paralysis of the phrenic on the same side has been mentioned. But the effect of division of the nerve results in a unilateral paradoxical movement of the diaphragm; moreover, it is difficult to see why the nerve should be implicated at all. Conditions of toxæmia would influence both sides equally and indiscriminately.

7. The elasticity of the lung appears to play a passive part only in the act of expiration.³ During this phase a hardening of the upper part of the rectus may be felt.⁴ When a healthy individual is breathing quietly and deeply, the extent of movement of the diaphragm can be estimated by means of the fluorescent screen. If now, after a long pause following expiration, both mouth and nostrils are closed, and an attempt be made to inspire, the halves of the diaphragm move scarcely at all, or move in the reverse direction (paradoxical movement). There is an inhibition of the diaphragm, due, it has been asserted, to the production of a negative pressure within the pleural cavity. As a matter of fact, this negative pressure is produced by the contraction of the inspiratory muscles themselves, and is the effect, not the cause. On further investigation it will be found, first, that the sterno-mastoids, scaleni, and intercostals harden, and the muscles closing the glottis also come into play; secondly, that the auxiliary muscles of expiration commence to contract, and, so far as can be ascertained by the fingers, at the same period of time. These are the recti, obliqui, and inner intercostals. Moreover, both sets of muscles continue to contract with the perseverance of inspiratory effort, so that there is here no question of reciprocal reflex action. The result must be an inhibition of the diaphragm.

It is an error to suppose that the auxiliary expiratory muscles are easily exhausted, since in reality the recti and obliqui, at least, pass into a state of tonic activity whenever the erect posture is assumed and maintained. In cases of unilateral extensive pleuritic adhesions, hypertrophy of the abdominal muscles on the same side is sometimes observed. These facts may assist in the explanation of certain signs of early phthisis, and of the behaviour of the diaphragm in the various types of pneumothorax.

8. In the hilum and peribronchial phthisis of children there is occasionally noticed towards the end of a deep inspiration an apparent retraction—really an incomplete expansion—of the lung on the diseased side. This is

most apparent in the two upper interspaces near the sternum, and has been termed the dimpling of the hilum.⁴ At the same time the scapular and sterno-mastoid of the same side—incidentally of both sides—may be seen to contract. Simultaneously, with care, a unilateral hardening of the rectus and obliqui may be felt. This sign may be suggested as a test for the determination of the presence of incomplete expansion of the lung. A sudden rigidity of the intercostals may also occur (Pottenger's sign of early phthisis). In conditions of insufficient pulmonary dilatation there appears to be a struggle between opposing muscular groups—the sterno-mastoid, scalene, external intercostals and diaphragm on the one hand, and the rectus, obliqui, and internal intercostals on the other.

9. In hilum phthisis some impairment of expansion exists at least in the terminal areas supplied by the three chief upper bronchi. These should correspond to the inner and outer ends of the superior interspaces anteriorly and to the apex of the lower lobe behind at the fourth rib, near the spine of the scapula. In ordinary and in stereoscopic radiograms we have been able to trace conspicuous linear shadows to these three areas.⁵ In addition to venous and lymphatic stasis induced by the pressure of enlarged glands (often the right tracheo-bronchial group) on vessels at the root of the lung, there may be a condition of partial atelectasis in these situations produced by pressure on the bronchial wall. Before the absolute termination of a deep inspiratory movement, when the limit of expansion is prematurely reached, the auxiliary inspiratory muscles are called into activity, but their contraction will be readily overcome by the auxiliary expiratory muscles, since the inspiratory impulse is now on the wane and rapidly approaching its normal conclusion. In other words, if mechanical conditions forbid further dilatation, the expiratory muscles contract forcibly. The resistance of the chest to further expansion probably excites end organs within the tendons of the inspiratory muscles, the effect of which leads to the reflex contraction of the recti, obliqui, and others. Moreover, in a similar manner, a very small difference of pressure within and without the lungs renders inspiration impossible.⁶ Dr. Steuart, late chief assistant in the x-ray department at St. Bartholomew's Hospital, found in some cases, which exhibit the sign, if the breath be held for a few seconds after a deep expiration, the movement of the diaphragm in the succeeding inspiration is apparently normal.⁷ The explanation appears to be that during the longer pause the blood within the centre itself becomes increasingly loaded with carbon dioxide, so that the next inspiratory discharge becomes excessive. Reinforced by the inspiratory reflex from the pulmonary vagus itself this is able, under suitable circumstances, to overcome any expiratory muscles which might otherwise prove efficacious in curtailing the diaphragmatic movement. If the experiment fails, a real mechanical hindrance to full dilatation is present.

10. It has been stated that when the locus of disease is situated posteriorly, the diminished excursion is more evident in the dorsal half of the arch.⁸ In other words, the spinal part is affected more than the sterno-costal. The muscles which oppose the crural fibres may be the deeper muscles of the back and possibly the quadratus. In any case, the effect of this reflex must be a reduction in duration and amplitude of the ordinary inspiratory wave, and its object the attainment of a definite measure of rest and protection for the diseased area of the lung.

NOTE.—In this communication the occurrence of an early expiratory reflex (preceeding from nerve-endings of the vagus in alveoli or in unstriated muscle in the manner described) is not sufficiently emphasized. The necessary condition is the presence of diseased and hypersensitive areas within the lung. Actual proof might be afforded by the determination of the time relations of the antagonistic muscles by means of tambours and a revolving drum. When the loci become quiescent, the second and later expiratory reflex, under suitable conditions, would still persist.

BETA-NAPHTHOL POISONING OCCURRING DURING THE TREATMENT OF ANKYLOSTOMIASIS.

BY WILLIAM BRYCE ORME, D.T.M. AND H.CANTAB.,
PRINCIPAL MEDICAL OFFICER, BRITISH NORTH BORNEO.

AN obvious instance of this complication has recently been the subject of inquiry at Sandakan, British North Borneo. As it is only one of a series coming under the writer's notice, the time is apparently ripe for a word of warning.

Beta-naphthol was introduced at a much later date than thymol and eucalyptus, Nicot probably being one of the first to use it on a large scale in Natal (*Transvaal Medical Journal*, June, 1910). Beta-naphthol was particularly welcomed as by reputation it was safe, and in 1911 it was common to see it exhibited in the Federated Malay States in three doses of 20 grains each, preceded and followed by Epsom salts. Among thousands of cases treated with these doses, in the writer's memory only one fatal case occurred. Of late, however, it has become the fashion to use it in enhanced doses, three portions of 30 grains each being quite usual, and even larger being exhibited by some. We are inclined to deprecate such large doses as a routine administered by dressers in native hospitals. In the fatal case about to be recorded the medical officer, had he been at hand and able to see the patient two or three times daily, would have reduced the dose. I may add that two other fatal cases have come under my notice, though, unfortunately, notes were not recorded; both resembled the present case very closely.

L. T., a Chinaman, 28 years of age, was admitted on August 26th, 1914, into the Gaol Hospital, Sandakan, for a trivial abscess on the knee, and being somewhat anaemic his faces were examined for ova, the result being recorded as follows: Ova of *Ankylostoma*, of *Clonorchis*, and of *Trichuris trichiura*. On the same evening 5 grains of calomel were given. Half an ounce of Epsom salts was administered two days later, and on August 29th 30 grains of beta-naphthol were taken at 7 a.m. and at 9 a.m., and again at 11 a.m. At 1 p.m. the patient took Epsom salts, and the resulting stool contained seven ankylostomata.

The treatment was repeated on August 30th. When the dresser visited the hospital at 7 a.m. on August 31st the patient was given his first dose of the beta-naphthol mixture, but as he began to vomit shortly afterwards the second and third doses were not administered. Whenever the gaol dresser has finished his morning duty he leaves, in order to take up the non-working hours at the Sandakan Civil Hospital—namely, 11 a.m. to 2 p.m. and 4 p.m. to 7 p.m. This being the case, second and third doses are left in charge of an attendant, who in this instance did quite correctly in not giving the second and third doses, but unhappily did not mention this fact to the medical officer nor call his attention in any way to the patient.

At 6 p.m. another dresser was at the Gaol Hospital and recorded the patient's temperature as 102.8° F. On the morning of September 1st the fever had fallen to 99° F. Vomiting continued, the urine became extremely dark in colour, and slight jaundice showed itself. In the morning the medical officer found the patient in so collapsed a condition that $\frac{1}{10}$ grain of strychnine was ordered at 11 a.m., 4 p.m., and 9 p.m. The temperature in the evening, however, again rose to 101° F., and in the early hours on September 2nd the patient died.

On the bed head ticket being examined, it was found that, as usual, before such treatment the urine had been tested, the record being: Specific gravity 1010, acid, cloud of albumin.

It is felt that the presence of albumin is of paramount significance, as it was also found in the other fatal cases mentioned above.

At the *post-mortem* examination it was found that the liver weighed 3 lb. 5 oz., was deep yellow in colour, and contained numerous *Clonorchis sinensis*. The right and left kidneys weighed respectively 4 and 5 oz. The capsule peeled off without tearing the tissue beneath. The most characteristic feature was the colour of the cortex on section. It had much of the aspect of the liver itself, though it was less deeply stained and was rather narrow. The cut surface was quite dry, and appeared somewhat fatty. A sample of urine which was removed after death

was highly albuminous, very dark, partly owing to bile pigments, but partly no doubt to the beta-naphthol. Microscopic examination showed a quantity of debris and a few scattered red blood cells. No spectroscopic examination was made.

Conclusion.

These cases teach us that in individuals suffering from diseases of the kidneys beta-naphthol should be used with the utmost caution, if at all. Probably it would also be wise to go back to the old Egyptian rite of leaving an interval of a full week between any two treatments.

Dr. J. E. A. Ferguson of British Guiana administers to patients with ankylostomiasis 10 grains of thymol in a cachet every night for many weeks, and finds that it cures the disease completely without any ill effects on the kidneys. Perhaps other physicians who have had experience in this thymol treatment may publish their results in the JOURNAL, especially noting its effect on kidneys.

One more observation, which may be interesting to those in charge of hospitals in the tropics, is that in the writer's experience, whereas in *Necator* infection one treatment is usually sufficient to dislodge all the worms, in infection with *A. duodenalis* three are generally necessary. Can it be that the more formidable mouth parts of the latter are responsible for this difference?

A FURTHER CONTRIBUTION TO THE DIAGNOSIS OF GOUT.

By J. B. BERKART, M.D.,

LATE PHYSICIAN TO THE CITY OF LONDON HOSPITAL, ETC.

A PAINFUL inflammatory swelling of the big toe, apparently of constitutional origin, or pain only, which soon after the consumption of a glass of generous wine is felt in a small bone of the hand or the foot, is commonly regarded as pathognomonic of gout. If that term is meant to denote a specific pathological process, of which a deposition of urates is supposed to be the exciting cause of its clinical manifestation, then its indefinite application to all cases presenting such symptoms is not only misleading, but, for more reasons than one, mischievous also in its consequences. For there are numerous cases called gout in which, when they happen to come to *post-mortem* examination, not a trace of a uratic deposit can be found. If, nevertheless, the clinical diagnosis of them is upheld, as is frequently done, it is on the alleged ground that the urates have been absorbed. This explanation would have some validity if it were conclusively established that the urates had been previously deposited. As it is, there is nothing to support it but the tacit yet unfounded assumption that the region above referred to has a singular immunity from other pathological processes except the one connected with uric acid. There is proof, however, of its inadequacy; for whether a deposit of urates acts as a mechanical irritant or as a toxic agent, invariably it leaves behind it indelible changes in the articular cartilage in which it has taken place; whereas, in the unanimous opinion of those who advanced it, there are numerous instances in which the articular cartilage appears on *post-mortem* examination to be perfectly normal.

The fact is that there is a pathological process of frequent occurrence which gives rise to clinical phenomena closely similar to those commonly called a gouty paroxysm, but which is not due to uric acid. The habit of looking for the cause of the painful swelling to the surface of the joint has diverted attention from its other constituents. Yet if the corresponding bone be carefully examined, it will be found that very often take place within it, silently and almost imperceptibly, changes which in their last stages fully account for those symptoms. Such examination discloses in the first metatarsals, and occasionally also in the phalanges, a cystoid degeneration, which starts in the epiphysis, extends to the articular cartilage, and after perforating it allows the discharge of the cystic contents into the joint, thus producing an acute "perforative synovitis." The resulting fistulous openings are generally minute (Figs. 1, a; 3, a), and readily escape detection, as do the cysts themselves so long as

they are of small size and concealed by the fat marrow; but when the bone is fully prepared for microscopic examination they are easily recognized, and are found to be either isolated in their earlier stages (Fig. 1, b) or

Fig. 1.—Section through the subchondral portion of a first metatarsal bone. a, Fistulous opening through the articular cartilage; b, b, softening of connective tissue and formation of cysts; c, c, c, areas of fibroid tissue; d, transverse section of an artery.

multiple (Fig. 2, a), and gradually coalesce so as to form a macroscopic excavation (Fig. 3, b).

Of the contents of those cysts little is definitely known, as they rarely, except in accidents or surgical operations, come under anatomical observation. They appear to consist, when of comparatively recent origin, of a conglutinal substance (Fig. 2, b), which later on softens and becomes serous or haemorrhagic. So long as the canal thus formed remains pervious, or when its calibre becomes enlarged, the necrotic matter periodically passes into the joint and gives rise to periodic attacks of synovitis; only in the cases which are not here under consideration, where the cysts are situated near or within the diaphysis without reaching to and perforating the cartilage, it accumulates within the bone, which then is gradually expanded by its pressure.

Fig. 2.—Section through the epiphysis of a first metatarsal bone, of which the articular cartilage was worn off. a, a, a, Cysts; b, b, conglutinal substance; c, c, fibrous tissue.

From the histological details of the affected epiphyses it may with safety be inferred that this cystoid degeneration originates from an anomaly of the vascular and osseous systems. Conspicuous amongst them is the abundance of dilated and thin-walled veins which are here and there studded with emigrated blood corpuscles.

There is consequently evidence of a state of chronic congestion under the influence of which the trabeculae are decalcified and the adjoining fat marrow becomes fibrous. From both these sources are formed patches of fibrous

tissue (Figs. 1, c, 2, c, and 3, c) which owing to thrombosis of the neighbouring vessels soften and are converted into cysts. To this abnormal vascularity also must be attributed the pain which some individuals feel in the smaller bones of the hands or feet after the consumption of even one glass of a generous wine. This pain is commonly regarded as a sign of gout and attributed to uric acid, whereas in reality it proceeds from an undue relaxation and consequent over distension of the vessels which are deprived of their normal support by the osseous trabeculae.

Fig. 3.—Section through the epiphysis and adjoining part of the diaphysis of a first metatarsal bone. a, Fistulous opening through which a glass rod has been passed into a cyst b, which has formed in the area of fibrous tissue, c.

deflected outward. A frequent complication of this condition is a lymphangitis, and the whole leg may thus become the seat of a leucophlegmatic oedema. It is easily intelligible what mischief may be done if an obscure affection of some internal organ be supposed to be due to "misplaced gout," and if on the advice of some authorities the alleged materia peccans is then directed by mustard poultices to its supposed normal place of exit by the big toe. Such naive practice presumes that the redness due to the irritation by mustard is equivalent to an attack of gout and serves to relieve the blood of its contained impurity.

This cystoid degeneration is readily distinguished from gout by the absence of swelling of the regional lymphatic glands. It may, however, become gouty if from a concomitant disease of the kidneys uric acid is retained and accumulates in the blood. The tissues, especially those of an inflammatory or a metaplastic nature, then undergo hyaline degeneration, and favour the deposition of uratic crystals.

Such change in the type of the disease is then shown by the accession of the diagnostic element of gout—namely, the enlargement, as just mentioned, of the regional lymphatic glands, which have also become hyaline, as I have already pointed out.¹ My observations of the involvement of the lymphatic system in these circumstances have been confirmed by Minkowsky, who apparently was unaware of my statement to that effect, which had been published ten years before the appearance of his work on gout.

REFERENCE.

¹ Vide *Lancet*, December 16th, 1895, Fig. 3.

WE learn that work has been begun on the hospital which is to form part of the School of Tropical Medicine in Calcutta, and that it is hoped that the building of the hospital will be completed next year, the necessary funds having been collected.

The United States Public Health Service has recently set on foot an active campaign of education for the prevention of typhoid fever. The proportion of typhoid cases in the United States is said by the *Bulletin* of the Service to be from two to five times that in many European countries where systematic preventive measures are enforced. The number of deaths from the disease in the United States last year is stated to have been 30,000, while 400,000 persons were incapacitated. During the last forty years, although there has been a considerable reduction in the prevalence of the disease in some cities, the United States as a whole are a generation behind the time in respect to the reduction of the typhoid rate.

THE CARE OF THE ILLEGITIMATE BABY.

BY

A. DINGWALL FORDYCE, M.D., F.R.C.P. EDIN.,

EXTRA PHYSICIAN, ROYAL HOSPITAL FOR SICK CHILDREN,
EDINBURGH.

I AM UNWARE of any reports of investigations into the welfare of poor illegitimate babies throughout the early years of life, and consequently the results of an investigation undertaken in Edinburgh in the early part of 1914 may be of interest.

The object of the investigation was to trace the history of illegitimate babies in the city for three years after birth in order to gain an idea of the care bestowed upon them as compared with legitimate babies of their own class. Several ladies very experienced in social work most kindly assisted me in the work, and their aid proved invaluable, as is evident from the very considerable number of cases in which a thoroughly satisfactory and first-hand history was obtained.

Conditions in Edinburgh.

Illegitimate infants born in the Royal Maternity Hospital, Edinburgh, January 1st to June 30th, 1911, and their history for three years—that is, till June 30th, 1914:

(a) Dead-born or died practically at birth...	14
(b) No trace of mother or child ...	38
(c) "Reports" about ...	7
(d) Satisfactorily traced ...	82
Total ...	141

Of 82 cases traced for three years:

Child known to be alive and cared for ...	54
Child presumably cared for ...	9
Cases in which child died and mother known to have been good ...	6
	69

So that in 69 out of 82 cases the babies had fair attention.

Cases in which baby died in questionable circumstances ...	5
Cases in which the conditions prior to death were uncertain ...	8
	13

What do these statistics show?

1. It was possible to trace 82 cases for three years after the birth of the child out of 127 cases in which the child survived birth.

2. Of these 82 cases, the mother afterwards married in 36 cases.

3. In 69 out of these 82 cases the baby had fair attention.

4. Forty-five cases could not be traced satisfactorily, or at all.

It would seem that of cases under heading 4 a certain number could not be traced because of shame on the part of a good mother, but in many cases it was certainly because an undesirable mother wished to leave no tracks. It may be taken that in 75 per cent. of cases the illegitimate baby received fair attention, and that in 40 per cent. of cases the unmarried mother later married.

It seems reasonable to conclude that an illegitimate baby in 1 out of 4 cases does not receive the ordinary attention given to his legitimate brother. This does not mean that 3 out of 4 are properly attended to. At best it means that 3 out of 4 receive the ordinary treatment of legitimate children of that class. In the out-patient department of any sick children's hospital in a large city the time of the physician is to a very large extent occupied by attending to children under 3 years of age who suffer from preventable diseases. Their mothers are well-meaning and kindly, but, either from ignorance on their part or the effect of an unwholesome environment, or both combined, the children become unhealthily. But, distinct from these well-meaning though ignorant mothers are most of the unmarried mothers. In some cases they are as unselfishly devoted to their child as any mother could be. More commonly they are fond of their child, but the times of stress they have been through have left their indelible mark; they are laden, overborne, oppressed by the difficulties of their situation, they recognize the claims of the child on them and would respond if they could; but they cannot, and though they sincerely regret it, there seems little hope

for the future except by the death of the child. Other illegitimate babies there are who are brought to the hospital when practically moribund, in whose cases death is obviously wished for, and the doctor is looked upon not as a curer of disease, but as a necessary means of securing a death certificate.]

Let us not save our conscience with the unctious that three out of four illegitimate babies are properly attended to. They are not. But all I have been able to show is that one out of four is improperly attended to.

In Hungary since 1903 every homeless child—every child for whom there was no obvious means of suitable support—has had a right to support by the State, and has been so supported.

The result has been that during the years 1904 to 1908 the number of births in the country increased by over 2 per cent., while the number of illegitimate births decreased by over 4 per cent.!

In Edinburgh an infants' home was opened in 1912. Unmarried girls with their first illegitimate baby are admitted to it on quitting the maternity hospital, and on signing a promise to remain in the home for at least two months, and to suckle their babies. Each girl pays 5s. weekly for the first two weeks, and thereafter 2s. 6d. weekly. Girls who spend three months in the home may leave their babies there at a charge of 5s. weekly until they are a year old. The mothers of babies who have been left in the home visit them almost invariably twice a week, and stay to bath, feed, and put them to bed.

The home saves many girls from finding themselves in a hopelessly difficult position on leaving the maternity hospital at the expiry of ten days. Some have no home, and others are forbidden by their relations to return with their babies to the home they have disgraced. The only course open to them is to board out their young babies with the first person who offers, and to seek work, however unfit physically they may be. In the home they have a refuge. A certain amount of the money in payment is sometimes obtained at first from the father of the child, and otherwise the amount is usually obtainable from relatives, or, if necessary, from charitable sources.

The babies are cared for and nursed by their own mothers. They usually thrive well and become strong and healthy. When the baby cannot later go with his mother or to her relatives, the mother has time and the assistance of the matron to find a good home, where he may be boarded out or adopted. This "good home" is, however, extremely difficult to find.

As regards the mother, the first object of the home is to strengthen and develop her character generally, so that when she leaves she may be able to lead a better life.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PLUMBISM IN A BRANCH OF THE HOSIERY INDUSTRY.

THE following brief report may lead, in other places where the making of military pants is carried on, to the detection of further cases of plumbism.

A. K., a man aged 28, came to see me on May 31st, 1915, complaining of abdominal pains, so severe at times that he could not sleep at nights. On the night of May 30th he was "up all night" in pain. He had been very constive for some weeks. There had been no vomiting, but his appetite was poor and he had lost flesh lately. He referred the pain to the umbilical region. The abdomen was flaccid, not tender to touch; in fact, the pain was somewhat relieved by pressure. He had also "rheumatically" pains in the left arm and leg during this period of poor health, of some weeks' duration. There was a typical blue line on the gums, but no ankle or wrist drop.

The condition at once suggested plumbism, but his employment, which he described as that of cotton spinner in the hosiery trade, seemed at first to negative this possible source of the poison. On closer inquiry, however, he explained that, in passing the cotton through a rolling machine, it was impregnated with a dry ochre pigment, which gave the pants the regulation tint.

In visiting the "blowing room" where he worked, it

was seen that a cloud of this pigment pervaded the room in the neighbourhood of the machine, and even at some considerable distance from it, covering the walls and roof. The workers stated that they were frequently spitting up the pigment "from their lungs." The strong air draught from below upwards is necessary in order to drive the cotton into the machine. Since a new machine had been introduced some weeks previously the dust had been much more dense. There had also been a much heavier pressure of work owing to large Government orders.

Two other rooms in the same factory have similar machines, and many of the operatives within the dust radius, including some women, are reported to have had poor health lately.

A sample of the ochre revealed the fact that it consisted of "almost pure basic chromate of lead." This induced me to make further inquiry.

A. K. rapidly recovered from his acute symptoms under treatment, while absencing himself from work, and has now returned to the blowing room.

Another worker, G. S., a man aged 40, was seen by me at his home on June 20th. He had been under another medical man's care for some weeks for symptoms similar to those of A. K., accompanied by marked loss of weight and weakness. When I examined him I found a well-marked blue line on his gums.

As no other source of plumbism could be discovered (the water supply of Nottingham being now above suspicion) both cases were notified to the Home Office.

Subsequent inquiry was made by the Medical Inspector of Factories, and I learn from A. K. that precautions are being taken by using another pigment.

Nottingham.

Reports of Societies.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE annual meeting of the Oxford Ophthalmological Congress was held on July 15th and 16th in the Department of Human Anatomy of the University of Oxford, by the kind permission of Professor Arthur Thomson. Notwithstanding the inevitable absence of some of the regular attendants owing to military duties and other regular connections with the war, a good number were present during the proceedings, which were opened at 9 a.m. on July 15th by a hearty welcome from the Master, Mr. Sydney Stephenson. The morning of this, the first day, was devoted to addresses by Sir ST. CLAIR THOMSON, Sir MACKENZIE DAVIDSON, Lieutenant-Colonel R. H. ELLIOT, Messrs. W. H. H. JESSOP, HARRISON BUTLER, and STEPHEN MAYOT. The subjects chosen were of considerable interest, and each address was followed by discussion. Lieutenant-Colonel ELLIOT prefaced his remarks with words of congratulatory welcome to Mr. Sydney Stephenson on his first appearance as Master of the Congress in place of Mr. Robert W. Doyne, now the Past Master. The afternoon was spent at the Oxford Eye Hospital, where interesting cases were shown by Messrs. P. H. ADAMS, WILLIAM ROBINSON, N. C. RIBLEY, E. H. EDWARDS STACK, and B. CRELDAN. Messrs. RIBLEY, STACK, and MADDOX also gave demonstrations. The whole of the second day (July 16th) was occupied by a discussion, opened by Dr. FRANK SHUFFLEBOTHAM, on *Industrial diseases and accidents*. The subjects dealt with comprised coal-miner's nystagmus, eye injuries caused by occupation with their prevention and first aid treatment, industrial cataract, plumbism as it affects the eye, siderosis, and the rarer industrial diseases and injuries of the eye, and were introduced by Messrs. PRICIVAL J. HAY, EDGAR COLLIS, WILLIAM ROBINSON, S. McMURRAY, J. GRAY CLEGG, and SYDNEY STEPHENSON respectively. The papers were extremely interesting and evoked considerable discussion, in which many members took part. During the two days demonstrations were given by Mr. SYDNEY STEPHENSON, Lieutenant-Colonel R. H. ELLIOT, Messrs. J. BURDON COOPER, R. J. COULTER, W. H. H. JESSOP, F. H. ADAMS, N. C. RIBLEY, J. GRAY CLEGG, C. T. REES WOOD, and S. E. WHITNALL, comprising pathological specimens, apparatus, and instruments of much interest. An exhibition of ophthalmological instruments and apparatus was open daily. The official dinner of the Congress took

place on the evening of July 15th in the hall of Keble College, and was well attended. The chair was occupied by Mr. ROBERT W. DOYNE, and amongst the guests present were Sir St. Clair Thomson, Sir Mackenzie Davidson, Surgeon-General Sir Frederick Bradshaw, K.C.B., the Rector of Exeter College, the Bursar of Keble College, and others.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE seventy-fourth annual meeting was held on July 22nd at the rooms of the Medical Society of London under the presidency of Dr. DAVID G. THOMSON of Norwich. The annual meeting is usually held in London or in one of the large provincial centres, and two days are devoted to the business of the association and to the reading and discussion of scientific papers. In this abnormal year, however, it was decided that the annual meeting should be of a purely business character, and it was bereft of the festivities which are its usual accompaniments. Following the lead of other societies, no change was made in the personnel of the officers, council, or special committees. The annual report of the council shows that the membership is 731, and in it sympathetic reference was made to the passing away of Sir Thomas Clouston after a membership of fifty-three years. Satisfaction was expressed at the knighthood conferred on Sir Frederick Needham, a former president and an honorary member. The President was heartily thanked for the manner in which he entertained members and conducted the meeting at Norwich last year. Reference was also made in the report to the fact that many members of the association had joined the forces of the Crown for the duration of the war and to the valuable work done by members in arranging for the reception of wounded soldiers in various asylums. Prizes for papers read at divisional meetings were awarded to Dr. Dunlop Robertson and Dr. Maxwell Ross.

Reviews.

MEDICAL SERVICE IN CATALONIA.

CATALONIA consists of the eastern strip of Spain, from Lérida in the north to Alicante in the south, and includes the Balearic Islands, the old kingdom of Majorca. The Catalan language, an offshoot of the Romance tongue of Southern France, is a Spanish dialect quite distinct from the Castilian and Portuguese dialects spoken in the remaining portions of the Iberian peninsula, and it has had a distinguished literary past in the Middle Ages. After that epoch, Catalan became obsolescent, remaining in eclipse until about a hundred years ago, when it experienced a renaissance; and this renaissance is still vigorously in evidence, as is witnessed by the publication of a scientific yearbook¹ detailing the work of the Biological Society of Barcelona.

This yearbook consists of thirty-one papers read before the members of the society, with brief notes of the discussions to which they gave rise. The papers are mainly on medical and physiological subjects; six deal with the electro-cardiograph, three with various aspects of Basedow's disease, two with pneumothorax, and others with such subjects as the diagnosis of taeniasis in dogs by fixation of the complement, McDonagh's views on the leucocytozoon of syphilis, anaphylaxis, the morphology of tubercle bacilli in sputum, and the fixation of complement in experimental tuberculosis. A paper on the presence of *Dryopithecus* in the upper miocene of the Catalan Pyrenees, at the end of the volume, will, no doubt, be of interest to palaeontologists.

A new theory of Basedow's disease, advanced by J. Marimón, endeavours to explain the fact that certain patients exhibit signs of myxoedema, or hypothyroidism as it is called, at the same time as they show evidences of Basedow's disease, which is commonly believed to be an example of hyperthyroidism. Marimón argues that

myxoedema is an expression of the organism's failure to elaborate or utilize iodine, while Basedow's disease illustrates the harmful action in the body of iodine-containing compounds that have not been elaborated by the thyroid gland.

As a language Catalan is not difficult to read for anyone with a knowledge of Spanish, helped out with Latin and French. Such Catalan dictionaries as are available in London appear to be old-fashioned, and they are not very helpful for the reason that the spelling of Catalan appears to be in a stage of transition; the result is that many of the words looked up cannot be found in their modern forms.

The Biological Society of Barcelona is to be congratulated upon its varied medical and physiological activities, and we wish it a prosperous career in the future. The world nowadays is thought to look unkindly on the smaller nationalities of Europe, threatening them either with economic absorption on the one hand, or on the other with active suppression, at any rate so far as Central Europe is concerned. The cultivation of a distinct national speech is always taken as evidence in favour of the existence of a distinct nationality; witness the courage with which Irish and Welsh are being pushed in various parts of Great Britain, and the lamentations still raised over the disappearance of the Cornish tongue at the death of Dolly Pentreath. Catalan, to judge by the promise of the year-book now before us, should have a future not unworthy of its past.

AMOEBIASIS AND THE DYSENTERIES.

*Amoebiasis and the Dysenteries*² is the title of an up-to-date and useful little work by Dr. LLEWELLYN POWELL PHILLIPS, Professor of Medicine in the Egyptian Government School of Medicine, Cairo. Various hooks on the subject have appeared from time to time, the most recent being those by the late Dr. Carnegie Brown and by Sir Leonard Rogers. The work done on dysentery has, however, advanced considerably since the date of these works, so that there is plenty of room for another manual on the subject. Dr. Phillips classifies the different forms of the disease as follows: (a) Protozoal dysenteries and those caused by other animal parasites—(1) Amoebic (amoebiasis); (2) ciliate (balantidiasis); (3) flagellate (lamblia, tetramitus, etc.); (4) bilharzial dysentery. (b) Bacillary dysentery. In addition he mentions that dysenteric symptoms are sometimes recorded in connexion with kala-azar and with malaria, and that a spirochaete has been held responsible by some. The book contains twelve chapters, a bibliography, and an index; six of the chapters are devoted to amoebiasis, one to ciliate dysentery, one to flagellate dysentery, one to bilharzial dysentery, and three to the bacillary form of the disease.

The book is well written and the information it contains is accurate. For example, the manner in which the somewhat intricate subject of the protozoal organisms is dealt with is specially good. Dr. Phillips has, of course, had unique opportunities of seeing cases of bilharzial dysentery. Finally, the chapters on bacillary dysentery give an up-to-date account of what is known of this variety. The only real fault of the book is the absence of illustrations, but the author explains in his preface that there would have been considerable difficulty in providing these under the present conditions of the war, and he has therefore reluctantly omitted them. As he states also, his account of the subject is rather condensed, but in some respects this is an advantage, especially as the main points are all given. This will largely conduce to giving to those who have not first-hand knowledge of the disease a clear conception of it. The bibliography is sufficiently full. One rather curious mistake, especially coming from the pen of Dr. Phillips, has occurred in the spelling of Looss's name; at pp. 90 and 134 it appears as "Loos." Looking at the book as a whole, it may be said that it is excellent, and that the author has shown great skill in presenting his points so clearly in such a short compass. It can therefore confidently be recommended to all interested in the subject of dysentery, and even those who know the subject might do worse than study its pages carefully, while to students it should prove invaluable.

¹ *Travaux de la Societat de Biologia. Any Primer, 1915.* Publicats sota la direcció de A. Pi Suñer. Vol. I. Publicacions de l'Institut de Ciències. Barcelona: Institut d'Estudis Catalans. 1914. (Med. 8vo. Pp. 265. Illustrated; 10 plates.)

² *Amoebiasis and the Dysenteries.* By Llewellyn P. Phillips, M.A., M.D., F.R.C. (Camb.), F.R.C.P. (Lond.), F.R.C.S. (Eng.). London: H. K. Lewis, 1915. (Demy 8vo, pp. 158. 6s. 6d. net.)

BUCCO-FACIAL PROSTHESIS.

In publishing at this moment their treatise on bucco-facial prosthesis Messrs. MARTINER and LEMERLE have rendered opportune service. No surgeon or dentist can read their book without being inspired with a new and reasonable hope for those distressing cases of deformity following destructive wounds of the face which war makes so frequent. They will find, also, on reading the experiences of Michaels, hope for at least some of the cases of shattered limbs—those in which though the bone is shattered the circulation is still efficient.

Apart from this, the book will be of permanent value. With perhaps the exception of Case's latest form of cleft-palate obturator, which we think the authors do not sufficiently appreciate, every serious contribution to the subject is described and dispassionately criticized. Some of these methods, especially such as refer to artificial noses, ears, etc., have, as the authors allow, become of historical value only since the introduction of Henning's plastic restorative material and special fixing substance. The authors, however, have been right not to exclude the description of these methods. They are associated with the name of Claude Martin, of Lyons, whose every word is for the authors, and indeed for all who have studied surgical prosthesis, an inspiration. Deserved and generous homage is paid to his name, and his works are freely quoted.

The book is well planned and clearly written, but the authors admit a certain amount of repetition, pleading that their great object, which was the delimitation of the different procedures and their proper classification, could not otherwise be attained.

The properties of cicatricial tissue, the prevention and reduction of cicatricial deformity, the materials best tolerated by the tissues, the form most suited to permanent retention, are carefully considered, and it is interesting to note that Martin could find no evidence of recurrence of malignant growth due to the presence of the artificial apparatus. The details given as to the apparatus for replacing upper or lower jaws, noses, the bones of the extremities, for use in cleft palate, for dilating cicatricial naso-pharyngeal obstruction, for artificial larynx for fractured jaws, are short and clear. The differences between immediate and permanent restorative procedures on the one hand, and temporary followed by late permanent restorative apparatus on the other are well set out. The lower jaw is little suited to immediate permanent restoration, and the temporary appliance must be mechanically fixed to the bone remaining till the whole wound is covered with epithelium, a period of perhaps six or eight months, during which suppuration is more or less profuse. A removable permanent apparatus is then made, the usefulness of which depends on the fact that cicatricial contraction has been avoided.

The general remarks on cleft palate are worth the attention of all interested in this subject.

TWO MUSEUM GUIDES.

THE Council of the College of Surgeons, acting on the advice of the Conservator, Professor Keith, has arranged the issue of catalogue guides to the collections which make up the famous museum. A guide to the obstetrical and gynaecological specimens appeared in 1912. Mr. ARTHUR H. CHEATLE is the author of the second publication of this series. It is, as professed by its title, a *Guide to and Catalogue of Specimens Illustrating the Surgical Anatomy of the Temporal Bone in the Museum of the Royal College of Surgeons of England*.¹ It is a complete descriptive catalogue. Most of the bones have been sectioned in a vertical manner behind the meatus through the antrum, mastoid process, and some part of the labyrinth; and where it is of special interest, horizontal section has been made as well. The guide portion of this manual is written after a convenient though somewhat unfamiliar plan. It is an alphabetical list

of names of parts concerned in the surgical anatomy of the temporal bone, and demonstrated by the specimens, the corresponding numbers being indicated. Thus we find "Diploë, apical replaced by dense bone, 629, 1 (R. and L.)," and "Occipital bulla, 634, 1 (L.)." The value of this guide may perhaps best be understood by the reader when we add that, for instance, under "Sulcus jugularis" the heading is carefully subdivided under "left larger than right," "marked discrepancy in size," "relation to facial nerve," "to the posterior semicircular canal," and so on. Such an index guide greatly adds to the value of a catalogue, and reflects high credit on the distinguished authority who has taken so much trouble to prepare it. We understand that other similar guides to the College Museum are in preparation, though until peace returns little can be done to hasten their publication. The public already know the advantages of study at the Natural History Museum, where special analytical guides, compiled by experts, are at hand and on sale. A complete series of similar publications would make the museum of the Royal College of Surgeons even more useful than it is at the present time, thanks to the exertions of Owen, Quekett, Flower, Stewart, and Keith.

The compiler, Dr. MAUDE ABBOTT, of the *Descriptive Catalogue of the Medical Museum of the McGill University*,² states that the volume now issued is the first portion ready for publication, although the fourth in the order of the museum classification, thanks to the activity of Professor Grauer, Sir William Osler took the initiative in raising a fund among the graduates in medicine of the university, ten years ago, pointing out the necessity for a good catalogue in order that the wealth of material in the-museum might be properly utilized. The response to the appeal was immediate, 1,200 dollars being subscribed within a few weeks. The fire of 1907 interrupted the work and led ultimately to the substitution of this volume for that which was originally intended to be published as Part I, illustrating the circulatory system, an instalment already in course of preparation. The system of compilation is that which is already in use in University College, London, and other English museums, with certain modifications. The specimens are very systematically described, with the assistance of various clinical and pathological experts on the teaching staff, and, as in most current catalogues, great pains have been taken about microscopic examinations. Twelve instructive plates adorn the catalogue. Among these are a specimen of lymph nodes in lymphatic anæmia and of milary tuberculosis of the spleen, and microscopic drawings by Dr. Grauer of the bone marrow of a young adult showing erythroblastic and leucoblastic reaction. The photographs of a spleen from a case of Banti's disease are highly successful, and the centimetre scale placed along the side of each illustration greatly aids those who cannot visit the museum itself in gaining a correct idea of the specimen. The series in this fasciculus includes spleen, thymus, bone marrow and lymph nodes, and the collection seems very rich. Not many years ago the most famous museums in Europe were very deficient in specimens such as are included in this series. The general introductory notes at the head of each subsection—rather eccentrically termed "didactic"—have been prepared with great pains by Dr. Grauer. The numbering is, as indicated in the title page, arranged on a modified decimal system.

NOTES ON BOOKS.

THE author of *The Campaign Against Syphilis*³ pleads for the extirpation of the disease by means of both cure and prevention. He indicates, by excerpts from the first volume of the evidence before the Royal Commission, some of its principal directions; and argues the need of better instruction of the young in these matters, and of higher ethical and spiritual enlightenment, in order to avoid the pitfalls which beset them. A useful popular summary is given of the nature and effects of venereal diseases, while

¹ *Traité de restauration bucco-faciale et traitement des fractures des maxillaires*. Par Professor P. Martinier et Dr. G. Lemerle. Manuel de Chirurgien-Dentiste publié sous la direction de Ch. Godon. Paris: J. B. Baillière et Fils. 1915. (Pout 8vo, pp. 360; 174 figures, Pt. 2.)

² *Descriptive Catalogue of the Medical Museum of McGill University: Arranged on a Decimal System of Museum Classification*. Edited by Maude E. Abbott, B.A., M.D., Curator. Part IV, Section 1. The Haemopoietic Organs. Catalogue and Didactic Introductions by O. C. Grauer, M.D. Oxford: The Clarendon Press. 1915. (Roy. 8vo, pp. 253; 12 plates, 10s. 6d. net.)

³ *The Campaign Against Syphilis*. By F. W. Giles, M.B. Durham. London: P. S. King and Son, Ltd. 1915. (Demy 8vo, pp. 19. 6d. net.)

³ *Guide to and Catalogue of Specimens Illustrating the Surgical Anatomy of the Temporal Bone in the Museum of the Royal College of Surgeons of England*. By Arthur H. Cheatle. Issued by order of the Council of the College. London: Adlard and Son. 1915. (Demy 8vo, pp. 177.)

the later portion of the pamphlet deals with the questions of responsibility, treatment, and prevention. Mr. Giles is a member of the White Cross League Council, and his pamphlet is well adapted to its purpose.

Muter's Analytical Chemistry, which has now reached its tenth edition, is probably as well known to pharmaceutical students as any textbook of the subject. In inorganic analysis it covers the usual ground of such a book, the arrangement of a great deal of the matter in tables materially increasing its usefulness in the laboratory. Special attention is given throughout the book to pharmaceutical chemicals and tests; but volumetric and gravimetric analysis of metallic salts are included. A short section is devoted to ultimate inorganic analysis and many of the principal processes of the analysis of water, food and urine are described in a useful manner, though somewhat briefly. The present edition follows the lines laid down by the late Dr. Muter with the necessary alterations and expansions to bring the matter up to date.

It is in times like the present, when the world is full of wars and rumours of wars, and the nations of Europe are fighting for existence, that a book such as *Pot-Pourri Mixed by Two*⁸ fulfils its true purpose by distracting its readers for a little while from the grim realities of everyday life. The pot-pourri so skilfully mixed by Mrs. C. W. EARLE and Miss ETHEL CASE diffuses a refreshing fragrance and should act as a tonic on minds depressed by the misery and suffering of the day. It is a pleasing medley of gossamer hints, antiquarian notes, and recipes for vegetable dishes, with a running commentary on passing events made by a shrewd and kindly observer of the frailties and inconsistencies of human nature. Mrs. Earle is a very gentle critic of the "amiable weaknesses of humanity," and her book breathes an atmosphere of peace and tranquillity which is none the less soothing because it now seems strangely unfamiliar and remote. Her many friends will welcome this further proof of her inexhaustible activity, and their gratitude should be extended to the gifted lady whose clever collaboration has done much to ensure the success of a very pleasant volume.

⁷*Muter's Short Manual of Analytical Chemistry, Qualitative and Quantitative—Inorganic and Organic*, Edited by J. Thomas, B.Sc. Lond. Tenth edition. London: Baillière, Tindall, and Co. 1915. (Roy. 8vo, pp. 251; 56 figures, 6s. net.)

⁸*Pot-Pourri Mixed by Two*, by Mrs. C. W. Earle and Miss E. Case. London: Smith, Elder and Co. 1914. (Demy 8vo, pp. 468; two illustrations. 7s. 6d. net.)

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held July 13th, twenty-six cases were considered, and £261 was granted to twenty-three of the applicants. The following is a summary of some of the cases relieved:

Widow, aged 39, of L.R.C.P. and S. Edin. who practised in Ireland, and died in 1912. Applicant recently been suffering from prolapsed uterus, and operated upon. Prior to operation just managed to make a living in a small sweet shop. Has three children, ages 11 to 14, all at school. Voted £10.

Widow, aged 40, of M.R.C.S. Eng. who practised in the West Indies, and died in 1909. Applicant manages to earn a living by nursing, and requires assistance for the education of her only son, aged 10 years, whom she hopes to get into Epsom next year. Voted £5, and referred to the Guild.

Widow, aged 70, of M.D. St. Andrews who practised in London and died this year, and who has been in receipt of a pension from the Fund. Applicant left entirely unprovided for, and only income a few shillings a week from son. Too old to obtain work. Voted £12 in twelve instalments.

Daughters, aged 57 and 49, of M.D. Aberd. who practised at Luddenden. Joint income £40. The eldest suffering from incurable deafness, and the younger from chronic bad health, and neither able to work. Relieved twice, £20. Voted £18 in twelve instalments jointly.

Daughters, aged 42 and 44, of M.R.C.S. Eng. who practised at Poplar. Endeavour to earn a living by keeping a boarding house in Cornwall, but owing to the war last season was unsuccessful, and they find it difficult to get along. Relieved twice, £20. Voted £10.

Widow, aged 63, of L.R.C.P. Edin. who practised at Burnley as a Conductor. For some years kept house for brother-in-law, who died last year, and was left without any means, and is too old to undertake work. Has recently been appointed to an almshouse and £12 per annum. Relieved once, £10. Voted £12 in twelve instalments.

Widow, aged 68, of M.D. Glasg. who practised at Dennistown. Endeavours to make a living by taking in lodgers, but not successfully. Her son, who is a medical man, pays rent and rates, and applicant has £12 a year from another charity. Relieved seven times, £56. Voted £12 in twelve instalments.

Daughter, aged 59, of L.R.C.P. Edin. who practised at Holloway. Suffering from chronic bad health and quite unable to work. Only income a pension from another charity of £40 per annum. Relieved eleven times, £91. Voted £12 in twelve instalments.

L.R.C.P. and S. Edin., aged 59, who practised at Leith and is suffering from locomotor ataxia. Only income his wife's dividends, £48 per annum. Relieved once, £18. Voted £18 in twelve instalments.

Daughter, aged 58, of M.R.C.S. Eng. who practised at Laycock. Joint income £24 per annum from dividends, and applicant makes a little by taking an occasional boarder, but, owing to the war and the high price of food, is unable to manage. Relieved twice some years ago, £20. Voted £10.

Daughters, aged 53 and 50, of M.R.C.S. Eng. who practised at Kingscliffs. Only certain income £20 each from dividends. A little extra made by acting as companions when they can obtain posts, but have not succeeded recently. Relieved once, £5 each. Voted £9 in twelve instalments each.

Daughter, aged 52, of M.R.C.S. Eng. who practised in East London. Health thoroughly undermined as a result of nursing her mother through a long and serious illness. Total income, £46 per annum. Requires a little help towards a short holiday. Relieved once, £5. Voted £5.

Daughter, aged 54, of M.D. Duhr. who practised at Hillingdon and British Guiana. Applicant is suffering from tuberculous glands and quite unable to work. Lives with her stepmother, whose income is only £50 per annum. Relieved ten times, £80. Voted £10.

Daughters, ages 51 and 43, of L.S.A. Lond. who practised at Sydenham. Joint income £45. The younger suffers from epilepsy, and the elder is a confirmed invalid. Relieved seven times, £77. Voted £18 in twelve instalments.

Daughter, aged 44, of M.R.C.S. Eng. who practised at Redcar. Is suffering from tuberculosis, and sleeps in the garden in a shelter kindly provided for her. Has a pension from another charity of £20. Her mother, with whom she lives, has very limited means and suffers from heart trouble. Relieved four times, £42. Voted £10 in four instalments.

Widow, aged 65, of M.D. St. Andrews who practised at Stepney. Since death of her husband in 1903 has endeavoured to earn a living by letting rooms, but never with great success, and now age and indifferent health make it much more difficult. Has four daughters, all married and unable to assist. Relieved twelve times, £144. Voted £12 in twelve instalments.

Widow, aged 47, of L.S.A. Lond. who practised at Leyton, and died in 1911. Applicant left totally unprovided for with five daughters ages 9-17. Requires a little help towards their education. Relieved twice, £15. Voted £10.

M.R.C.S. Eng., aged 81, who practised at Kensington. Is practically blind. Only income a pension from another charity and the old age pension. Lives with son, who is also almost blind. Is already a recipient of help from the Fund, and asks for a little additional assistance in consequence of the high price of food. Relieved twice, £19. Voted £5.

Widow, aged 57, of M.R.C.S. Eng. who practised at Wellingborough. Was left totally unprovided for at husband's death in 1911. Suffers from acute rheumatism, which prevents her taking regular work. Relieved four times, £44. Voted £12 in twelve instalments.

Widow, aged 49, of L.R.C.P. Edin. who practised at Stamford Hill. Applicant suffering from cancer and had breast removed, and too ill to undertake any work. Partly supported by son, who has now joined the army. Relieved three times, £56. Voted £18 in twelve instalments.

The claims of the Fund are steadily increasing, largely in consequence of the war, and, though the ordinary subscriptions remain at much the same level, there is a constantly-increasing adverse balance. At the last meeting the committee was faced with an overdrawn account of £92, which was increased to £292 in July, which, with the amount of £261 spent in grants at that meeting, left a total deficiency of £533 upon the current account. To meet this the Committee has had to draw upon its limited reserves, and, unless increased support be rapidly forthcoming, its work will have to be seriously curtailed.

Subscriptions may be sent to the Honorary Treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild appeals for gifts of secondhand clothing, boots, and shoes in good condition, also household linen. The gifts should be sent to the Secretary, Royal Medical Benevolent Fund Guild, 43, Bolsover Street, W.

The Local Government Board in England has issued a circular (W.R. 7) to Local Refugee Committees dealing with the finding of employment for Belgian refugees, and strongly recommending that refugees should be encouraged to take advantage of the openings for industrial employment available for them in this country, and assisted in adjusting themselves to the conditions of such employment. Copies of the circular can be obtained through the Local Refugee Committee.

British Medical Journal.

SATURDAY, JULY 31st, 1915.

THE ASSOCIATION AND THE WAR EMERGENCY.

MEMBERS of the Association, when reading the report of the two days' session of the Annual Representative Meeting, published in the SUPPLEMENT this week, will probably look first to see what was done with regard to the war emergency. We believe that the action taken will be generally approved. A mixed committee, with a very wide reference, was appointed to take up the matter at the point to which it has been brought by the work of the Council and the Committee of Chairmen of Standing Committees. The war began a few days after the last Annual Meeting ended, and at that time, of course, the Association had not set on foot any organization for dealing with the unforeseen call upon the resources of the profession.

The full magnitude of the call could only be appreciated gradually as the general demands made upon all classes of the community for the new armies grew. The drain upon the resources of the profession due to the immediate mobilization of the Territorial Forces was, however, felt in some districts at once. This was especially the case in Scotland, where are many districts in which even in peace the number of resident doctors is barely sufficient for the needs of the population. The Scottish Committee of the Association, at the instigation of its Chairman (Dr. Hamilton of Hawick), took the matter up at an early date, and eventually a Joint Committee for Scotland was formed comprising representatives of the universities and medical corporations, as well as of the Association, with Dr. Norman Walker as convener. This Scottish Medical Emergency Committee, as our readers are aware, has done most valuable work in organizing the profession in Scotland to meet the demands of the military services of the Crown by setting free fit men from their civil engagements, and by making arrangements to obviate, as far as possible, loss to them and inconvenience to the public.

The considerations which led the profession in Scotland to appoint a joint committee were mainly that the emergency affected all branches of the profession, from the professor to the newly-capped graduate, and that it was necessary therefore that any steps taken should command general approval, including that of the medical teaching institutions and examining bodies. The same considerations have influenced the Representative Body in setting up a joint committee similarly constituted for England and Wales and Ireland. The work of the Scottish Committee will not be disturbed, but what it has done for Scotland the new Committee will seek to do for the other three countries. We say for the countries advisedly, for this organization of the medical profession to meet the great emergency concerns not only members of the profession, but every member of the public and all local administrative bodies.

The new War Emergency Committee for England, Wales, and Ireland will comprise, when complete, twenty-two members. It will consist of the President, Treasurer, Chairman of Council, and Chairman of

Representative Meetings of the British Medical Association; of four members specially elected by the Representative Meeting—namely, Sir Clifford Allbutt, Regius Professor of Medicine in the University of Cambridge and President-elect of the British Medical Association; Sir William Osler, Regius Professor of Physic in the University of Oxford; Dr. A. E. Shipley, the Master of Christ's College, Cambridge, who has done so much to organize the work of that university to meet the strain on its resources both in men and money; and Dr. T. Jenner Verrall, who has just resigned the Chairmanship of the Representative Body after holding office for three years—of four members (Dr. Buttar, Major Russell Coombe, Captain W. J. Greer, and Major Albert Lucas) elected from among itself by the Representative Body; and of the following four members appointed by the Council of the Association (Major James Galloway, Lieutenant-Colonel R. A. Bolam, Mr. N. Bishop Harman, and Lieutenant-Colonel Sir James Barr). The sixteen members of the Committee thus chosen will meet this week, and are empowered to co-opt not more than six other members representing universities, colleges, and other medical bodies.

The reference to the Committee is wide. It will be its duty to organize the medical profession in England, Wales, and Ireland in such a way as will enable the Government to use every medical practitioner fit to serve the country in such a manner as to turn his qualities to the best possible use, and to deal with all matters affecting the medical profession arising in connexion with the war. It would appear that the work of the Committee will fall under two general heads—the organization of the civil profession so that it may yield as many men as possible to the military medical services, and the safeguarding of the interests of those who join the army or navy, both in respect of the practices they leave and of their position and prospects in the service they join. Under the latter head the Association has already made representations to the Army Council, and it has been announced within the last few days that the War Office has decided to promote all lieutenants of the Special Reserve and of the Territorial branch of the Royal Army Medical Corps with six months' mobilized service to be captains. There is reason also to hope that the case of junior medical officers with temporary commissions who have done good service will be favourably considered. It will be remembered that all lieutenants of the regular R.A.M.C. were promoted captains a few months ago; the difference in pay is very small, but in the army rank affects an officer's position and his power of doing efficient work in many ways not obvious to the civilian. A number of other matters of this nature remain over and will, we have no doubt, receive the careful consideration of the new War Emergency Committee at an early date. Under the other head the work will be difficult and complicated. The medical war register now being formed by the Association, which it is expected will, within a few weeks, embrace three-fourths of the profession, will place much valuable information necessary for its task in the hands of the Committee, and will enable it to take a comprehensive view of the situation. In addition to laying down some general principles, it will, perhaps, find occasion to indicate districts where more may be done to set free doctors of military age. The adjustment of details must, of course, be carried out by local action, and already in some districts plans for carrying on the practice of absent colleagues, so that they and the public may suffer as little as possible, have been completed, while in others good

progress has been made; in some others it is believed that much remains to be done, and it will doubtless be one of the first cares of the War Emergency Committee to stimulate activity in such areas.

When all is done that can be done in both these directions there will remain the unfortunate certainty that many of those who have left their civil practices to meet the country's call must suffer financially in the future as well as in the present. The Chairman had to tell the meeting that it must not entertain any idea that pecuniary help for such men was to be expected from the State, because the Government held that it could not discriminate between members of the medical profession and other professions which had been affected by the war. This view, which naturally commends itself to the Treasury, raises arguable points, because, for one thing, the call upon members of the medical profession to give their professional services to the military has been more extensive and insistent than that upon any other profession. There does not seem to be any very sanguine hope that the Treasury will yield to arguments that can be adduced for anything of the nature of a *post-bellum* annuity, or even for a gratuity which would afford any adequate compensation for loss of capital. The meeting asked the Council to consider whether it would be feasible to establish by voluntary subscription a fund which could be used to assist cases of special hardship. The amount required would be large, and it has to be remembered that many of those who were accustomed to respond most generously to appeals to give money to help their brethren who had met with ill fortune, are themselves suffering serious loss of income.

FLIES IN FRANCE AND GALLIOLI.

In temperate climates weather conditions largely decide whether the year is to be "a fly year" or not. In cold, damp summers flies are few and far between, and do not seem to live long, whereas in hot, dry weather they multiply enormously and become a pest. As far as the present summer has gone there has been no excessively hot weather, and as a result there have not been many flies. If these cool conditions persist this will not be a fly year in England, Flanders, and the north of France. In subtropical regions, like the south of Italy, Greece, and the Dardanelles, the necessary conditions of temperature are always present in the summer and early autumn, and as a result flies are now becoming numerous in such places. From many private communications we have received, and from letters of newspaper correspondents, it is clear that flies are the great pest of existence in the Gallipoli peninsula; their numbers are described as amazing; food is black with them the instant it is set on the table; they fill the tents and shelters, settle on the refuse of the camp, on the unburied dead, and by their annoyance multiply the sufferings of the wounded, and spoil the tempers of the hale. There is no exaggeration in this, for similar conditions may be seen in parts of Italy at any time of the summer.

Hordes of flies are an annoyance and constant source of irritation, but worse may follow, for the pests may disseminate disease. Three of the great epidemic diseases—cholera, typhoid, and bacillary dysentery—can be and very often are spread by the agency of flies, and this happens especially when large numbers of people are herded together in masses, and where the disposal of their excreta presents difficulties. In the South African war flies were mainly held responsible for the large number of cases of enteric and bacillary dysentery that occurred there,

and it is quite possible that they will act in a similar way in Gallipoli now; moreover, the danger of the other great epidemic disease—cholera—has to be guarded against. It existed in Turkey, Southern Russia, and Austria last autumn. There appears to have been a serious recrudescence in the Austrian Empire this spring, affecting especially Bosnia-Herzegovina, Croatia, and Hungary, with a considerable number of cases in Austria proper, and last week Vienna was officially declared infected.

The transference of these three diseases by flies forms one of the simplest examples of the part insects play in the spread of disease. The general belief, until quite lately, has been that the fly settled on infected excreta and carried the specific germ of the disease on its legs to the food of man. More recently, however, evidence has been obtained that the contaminated matter is really sucked up by the fly and then regurgitated on to food, or wherever else the insect alights. The essential is, then, that the fly should have access to infective material, and unless the latrine arrangements for the disposal of faeces are perfect, this is easy. However good these arrangements may be on our own side, they are certainly not likely to be very excellent on that of the Turks; and the trenches are not far apart. Whether any of the diseases mentioned will be transmitted will depend upon whether carriers of such are present in the troops on either side to supply the infected faeces.

So far very few cases of typhoid have occurred amongst the British troops in France. This fortunate state of things is attributed in large part to the protective effect of antityphoid inoculation and to the efficiency of the sanitary arrangements in the field. The task of the Army Medical Service in the Dardanelles is more difficult, but it is certain that its magnitude is fully appreciated by the medical officers there. Cholera, as just stated, is certainly to be feared; recent reports state that it has broken out seriously in Galicia, and it is very likely to spread thence to Austria generally. In the last Turkish war the disease was met with both amongst the Bulgarians and the Turks, and was very bad at the Tchataldeba lines, from which troops are said to have been moved to Gallipoli. There is one consoling factor, however—namely, that this disease is more generally water-borne than fly-borne, so that careful attention to all water supplies may prevent its appearance, or at any rate curtail its spread. Bacillary dysentery is a serious disease and may cause as large an amount of invaliding, though it is not so deadly, of course, as cholera, nor does it last so long as typhoid fever. Amongst other maladies attributed to flies are various types of diarrhoea, different forms of conjunctivitis, often purulent, while unprotected wounds may quite easily be contaminated by them.

In considering what can be done to prevent the plague of flies, or diminish their numbers, the first consideration is that their breeding grounds are manure, especially horse manure, and other forms of refuse. The best way to deal with manure and refuse is to incinerate it, or to see that it is properly buried; if this be not possible, then to soak or cover the refuse with chlorinated lime, borax (which is said to be very efficacious), cresol, or other strong disinfectant. The careful removal of all suitable breeding places will quickly cause a great diminution of the flies. Latrines must, of course, be carefully attended to, sanitary buckets or other arrangements with lids being used to prevent the ingress of flies. This has no doubt been already seen to, and is in as efficient a state in the Dardanelles as it is in France. If flies irritate the healthy, active man, they must be a still

greater torment to the severely wounded man, often unable to move a limb or in any way to look after himself. The only way in which this trouble can be dealt with is to make all places in which wounded are detained fly-proof. By proper screening and a system of double doors this is quite easy, and mosquitoes and all other noxious biting insects are kept out as well. Transports conveying wounded from the Dardanelles to Egypt, Malta, and other places should also have fly-proof accommodation for the wounded. Of minor means of warfare on flies, sprays of different kinds, formalin vapour, and traps of various makes may be used. They all have their uses, but are all subservient to the major method of screening. Wherever a permanent building is established, proper screening, in the manner adopted with such success in the campaigns against flies in the United States, should be employed.

In addition to the non-biting flies—*Musca domestica*, etc.—to which the foregoing remarks apply, there are the biting flies—*Stomoxys calcitrans*, *Haematopota pluvialis*, and other *Tabanidae*. The first of these, very like an ordinary house-fly in appearance, is found in the vicinity of stables and horses. If numerous, this fly is a great nuisance, for it gives a severe bite. So far, though suspected, it has not been, we believe, certainly proved to spread any disease. *Haematopota* are generally found in wet, damp areas, and very likely will be very troublesome in parts of Flanders and Northern France. These flies inflict a severe bite, and if numerous are not easy to avoid. *Tabanidae* are very common in woods, and in some instances occur in such numbers that transit through such places is almost impossible. Another fly, the *Phlebotomus papatasi*, a sandfly, is pretty certain to occur in the Gallipoli peninsula, and if it does, then cases of three-day fever are pretty sure to occur. Fortunately, three-day fever, or sandfly fever, is a minor malady, which only lasts for the period stated, and is attended with no mortality.

In some of the British trenches in France blue-bottles and other flies of a similar nature occur in great numbers. They are attracted by the many decaying corpses, on which they lay their eggs, maggots quickly developing from them when the weather is hot. These flies are unpleasant and must be carefully kept off meat, as otherwise they will lay their eggs upon it and so contaminate it. Apart from this they are not specially dangerous to man.

CHAIRMANSHIP AND DEPUTY CHAIRMANSHIP OF REPRESENTATIVE MEETINGS.

THE decision of Dr. Jenner Verrall not to permit himself to be nominated again for election to the office of Chairman of Representative Meetings was received with universal regret, but was understood to be final. Dr. Verrall has been Chairman during three strenuous years, and discharged the duties of the office with ability and devotion beyond all praise. It would, indeed, be difficult to add anything to the eloquent tribute made to his services by the Chairman of Council, who truly expressed the opinion held by all those who have been associated with Dr. Verrall in the business of the Association, or to those uttered by Dr. Douglas, who has been a member of the Representative Body since its initiation, and Mr. Turner, Dr. Verrall's successor in the chair. We may, however, add this much, namely, that the duties of the Chairman are by no means confined to the actual sessions of the Representative Body. We may, indeed, accept Dr. Verrall's own statement that he has thoroughly enjoyed these meetings; Napoleon once,

when he was starting from Paris for the seat of war, said to Bourrienne, pinching his ear, as was the great man's embarrassing habit when he was pleased, "Now for a holiday," the real work having been done during the many months of preparation. Something of the same is true of the Chairman of Representative Meetings; he is an *ex officio* member of all committees of the Association, and it is important that he should attend most of the meetings of many of them. Dr. Verrall has not only been assiduous in this respect, but has served for various periods as chairman of some of the most important, including the Insurance Act Committee and the Committee of Chairmen of Standing Committees, to which, since the outbreak of the war, the Council committed the study of many military questions by which the medical profession is affected. All those who know Dr. Verrall will be glad to see the terms in which the Representative Body embodied the feelings of respect and affection in which he is held by every one who has worked with him. Mr. E. B. Turner, the Representative of the Kensington Division, who has been Deputy Chairman for the last three years, was elected Chairman without a contest. Mr. T. W. H. Garstang was elected Deputy Chairman. Mr. Garstang, who is a graduate in arts of the University of Oxford, is medical officer of health for several districts in Cheshire, Chairman of the Local Medical and Panel Committees for that county, and has been for some time Chairman of the Medico-Political Committee of the British Medical Association. This committee is one of the most important and hardest worked of the standing committees of the Association, and Mr. Garstang as a member, and afterwards as its Chairman, has shown qualities which ensure his success in the new and distinguished office to which he has been elected.

THE COMMOTIONAL SYNDROME IN WAR.

NUMEROUS cases of cerebral traumatism comparable in many ways to "commotio cerebri" have occurred during the war. In these there is no external injury to the brain, but the cerebral functions are very seriously upset in various manners. Quite recently¹ forty-eight patients exhibiting the "commotional syndrome" have been studied at Montpellier by Mairat, Piéron, and Bouzansky. These authors divide its nervous signs and symptoms into six groups, as follows: First, sensation is most commonly affected, usually in the direction of diminution or abolition of function—blindness, deafness, loss of taste and smell, partial or complete anaesthesia, have all been noted; usually the distribution of the disturbance is asymmetrical. Various degrees of hypoaesthesia, hypoaesthesia, loss of sensitiveness to pressure, heat, or cold, limited to zones or areas of the body, or affecting (as is most common) only one side of the body, perhaps with the loss of the superficial reflexes, are all more frequently seen than the hyperaesthetics, which involve as a rule the existence of areas painful on pressure. Secondly, these authors describe on the motor side increased reflex excitability of the tendons and muscles, oftentimes unilateral, in rare cases going on to the production of hysterical or epileptiform attacks; less often paresis or paralysis of groups of muscles, with or without contracture, has been recorded. Thirdly, vasomotor disturbances have been very general in these patients; chilliness and cyanosis that may be unilateral, dermatography, and cardiac irregularity are mentioned under this heading, and it is added that headache is almost constantly present, perhaps with nausea or vertigo. Fourthly come perturbations of the affective functions; altruism and family affection are lost, egoism comes boldly to the fore in the shape of causeless irritability or rage, causeless fear, or even terror. Fifthly are placed associative troubles or disturbances of the intellectual faculties; retrograde amnesia, or loss of memory for the events preceding

¹ Bull. de l'Acad. de Médecine, Paris, 1915, 3. s., LXVIII, 654.

the shock, is very common—the patient may forget his own name, his home, the faces of his friends—speech may be lost or halting, intellectual inertia to the point of stupor may be found. Alternatively, indeed more usually, the patient's imagination is unduly active, making him the victim of dreams, nightmares, hallucinations, sleep-walking, even delirium, in which bygone battle scenes are re-enacted. Sixthly and lastly, the authors describe disturbances of the perceptive functions: the patient retains no recollection of the shock itself or of the events following it for a shorter or longer period, and is left with a permanent lacuna in his memories. In addition, he is often unable to concentrate his mind on any subject, such as reading, or is very readily fatigued thereby. From this analysis of the possible symptoms it is clear that the phenomena presented by the victims of the commotional syndrome can be very various, so that the patients may readily be classified under the heading of some predominant trouble, such as blindness, aphemia, or the like. But the large number of cases studied by the authors of this paper seems to justify their proposal to group all instances of nervous shock together under a single heading, and their term "the commotional syndrome" appears to be as suitable as another.

MEDICAL FAME.

At the present time, when so much is heard of the work of the medical profession among the sick and wounded, and the praise of the doctor is deservedly in all men's mouths, it may be well for us to remember that the public memory is short, and that the unparalleled part played by medical science in the greatest war the world has ever witnessed will soon be forgotten when the silence of peace has fallen over the battlefields. It is a chastening thought that the healer whose high mission it is to save life and limb has an infinitely lower place in the opinion even of those to whose sufferings he ministers than the professional slayer of men who, with his drums and trappings, as Sir Thomas Browne would say, is regarded as the very symbol of glory. In our American contemporary *Science*, Mr. Edward C. Pickering gives some interesting particulars as to the relative place held by leading men in various spheres of intellectual activity in the opinion of the people of the United States. That opinion is, according to him, most accurately reflected in the elections to the Hall of Fame, the American Valkalla. Three elections have already been held—in 1900, 1905, and 1910. Mr. Pickering tabulates the votes recorded on each of these occasions. Politicians head the list. Next come authors. It is significant of the value of popular judgement that while of eleven writers of fiction nine were elected, of ten authors who dealt with serious subjects, only three gained the *arbitrium popularis auri*. Next come soldiers and sailors. Doctors hold a low position, but this is not surprising, as medicine is not a profession which leads to popular fame among Anglo-Saxon peoples. What is surprising is that in a country like America which swarms with inventors, and where the cult of the "almighty dollar" is generally believed to be so prevalent, engineers and business men are nearly at the bottom of the list. "Philanthropists" stand lowest of all. The list suggests some curious reflections as to the mentality of the American people, but it would be rash to draw any definite conclusion from the figures. The system of voting is probably accountable for the strangeness of the results, for till now the judges have been literary men who may be assumed to have been more familiar with the work of authors than with that of men whose activity was displayed in other fields. Even allowing for this, it is remarkable that among so practical a people fiction should hold the place of honour in literature; and it is hard, as Mr. Pickering says, "to believe that there are . . . twelve authors more famous than any American missionary, physician, engineer, or business man."

DEATH BY LIGHTNING.

On July 23rd a party of men belonging to the 2 2nd London Field Ambulance, R.A.M.C., comprising 77 of all ranks, with four wagons, were practising stretcher drill on Martlesham Heath, when a thunderstorm took place. Some of the men took shelter, but others remained in the open, and one man was killed and eight injured. According to the evidence of Captain Hubert Charles Phillips, R.A.M.C., at the inquest held in Ipswich on July 24th, as recorded in the *East Anglian Daily Times*, the following were the appearances presented by the body of the man who was killed. There was a severe jagged scalp wound on the left side. The chest and right side of the thorax and abdomen were much burnt. There were several incised wounds on the front of the right thigh, leg, and between the big toe and the second toe. The skin was burnt off the left thigh, and adhered to the clothing. On his chest the identity disc had made a red mark, as also had the string by which it was suspended. His glasses were shattered and his belt torn to pieces. None of the metal was fused. The watch on his wrist was not stopped. Death was undoubtedly due to lightning. The corporal in charge of the party said that the men were returning to camp as quickly as possible when a flash of lightning struck him on the right forearm; he was unable to move for a few minutes, and when he recovered himself saw several men lying on the ground. One of these was a lance-corporal, who had been riding a horse which was killed. The witness said that his right arm still gave him great pain when moved. He was about twenty yards from the deceased when he was struck.

INDUSTRIAL AND SCIENTIFIC RESEARCH.

A MEMORANDUM has been issued by the President of the Board of Education stating that in consequence of a strong consensus of opinion among persons engaged both in science and in industry that a special need exists at the present time for new machinery and additional State assistance to promote and organize scientific research with a view especially to its application to trade and industry, the Board had prepared a scheme to establish a permanent organization. It was well known that many industries have since the outbreak of war suffered through inability to produce at home certain articles and materials required in trade processes the manufacture of which had become localized abroad, and particularly in Germany. This had occurred because science had there been more thoroughly and effectively applied to the solution of scientific problems bearing on trade and industry, and to the elaboration of economical and improved processes of manufacture. The scheme now promulgated provides for the establishment of a committee of the Privy Council responsible for the expenditure of any new money provided by Parliament for scientific and industrial research, and of a small Advisory Council composed mainly of scientific men and others actually engaged in industries dependent upon scientific research. The Privy Council Committee will consist of the Lord President, the Chancellor of the Exchequer, the Secretary of State for Scotland, the President of the Board of Trade, the President of the Board of Education, and the Chief Secretary for Ireland, together with other members, the first of such being Lord Haldane, the Right Hon. Arthur H. D. Acland, and the Right Hon. Joseph A. Pease, M.P. The President of the Board of Education, who will be the Vice-President of the Committee of Council, will be responsible to the House of Commons for the expenditure. The Advisory Council will consist of Lord Rayleigh, O.M., Mr. G. T. Beilby, LL.D., Mr. W. Duddell, Professor B. Hopkins, Professor J. A. McClelland, Professor R. Meldola and Mr. R. Threlfall, with Sir William S. McCormick, LL.D., as administrative chairman. All the members of the Advisory Council with the exception of

the administrative chairman are members of the Royal Society, and it is recognized that it is essential that the Council should act in intimate co-operation with that society, and with other scientific or professional associations, as well as with the universities, technical institutions, and other institutions in which research is, or can be, efficiently conducted. The Royal and other scientific societies will be asked to initiate proposals for the consideration of the Advisory Council, and the duties of that Council will be to advise the Privy Council Committee on proposals for instituting specific researches for establishing or developing special institutions, or departments of existing institutions, for the scientific study of problems affecting particular industries and trades, and for the establishment and award of research studentships and fellowships. One of its chief functions will be to prevent overlapping between institutions or individuals engaged in research, and it will be at liberty to initiate proposals and to institute inquiries preliminary to preparing or eliciting proposals for research. In this way it is hoped that the Council will be able to concentrate the interests of all persons concerned in the development of all branches of scientific industry on problems requiring solution.

We are asked to state that as the General Medical Council has to vacate its present building (299, Oxford Street) towards the end of November, 1915, and as the new premises in Hallam Street will not be completely prepared for the occupation of the Council by that date, it has been arranged that the autumn session shall begin on November 2nd in the old building. The Executive Committee will meet on Monday, November 1st. It is expected that the business of the Registration Office will be transferred to 44, 46, and 48, Hallam Street, by November 25th.

Medical Notes in Parliament.

Lieutenants R.A.M.C. (Special Reserve and Territorial).—Sir Clement Kinloch-Cooke asked the Under Secretary for War whether he could now say if the War Office had arrived at any decision regarding the question of pay and promotion of special lieutenants in the Reserve and Territorial Force Royal Army Medical Corps. Mr. Forster said that it had been decided to promote to the rank of captain all lieutenants of the Special Reserve and Territorial Force Royal Army Medical Corps who had given six months' mobilized service, with effect from April 1st last, and steps were now being taken to carry out this decision. Sir C. Kinloch-Cooke asked whether the same privileges would be extended to qualified dentists now holding the rank of lieutenant. Mr. Forster replied that he thought the dentists were serving under a special engagement. He did not think they were included in the officers to whom the question referred.

Total Casualties, Navy and Army.—The following are the figures supplied by the Prime Minister as to the casualties amongst the British Forces in all fields of operations, excluding German South-West Africa, up to the latest available date:

NAVAL (to July 20th).			
	Officers.	Men.	
Killed	499	7,430	
Wounded	87	787	
Missing	29	274	
	615	8,491	
	9,106		
MILITARY. (France).			
	Officers.	Men.	
Killed	3,293	48,402	
Wounded	6,807	156,435	
Missing	1,207	53,375	
	11,307	258,212	

Dardanelles (including Naval Division).			
	Officers.	Men.	
Killed	562	7,537	
Wounded	1,375	28,508	
Missing	154	8,486	
	2,091	44,531	
Other Theatres (excluding German South-West Africa).			
	Officers.	Men.	
Killed	145	1,445	
Wounded	248	3,247	
Missing	22	641	
	415	6,333	
TOTAL.			
	Officers.	Men.	
Army:			
Killed	4,000	57,384	
Wounded	8,430	188,190	
Missing	1,383	62,503	
	13,813	308,076	
Naval casualties	615	8,491	
	14,428	316,567	
Grand total...	330,995	

Casualties at Tanga.—Mr. Tennant, on July 27th, informed Sir J. D. Rees that the total amongst the 2nd Battalion of the Loyal North Lancashire Regiment and the British officers serving with the Indian troops during the fighting at Tanga last November were as follows:

	Officers.		Other Ranks.	
	British.	Indian.	British.	Indian.
Killed	19	11	25	247
Wounded	16	15	58	236
Missing	2	3	27	140
	37	29	110	623

Recoveries from Casualties.—Mr. Asquith stated, in reply to Sir G. Scott Robertson on July 21st, that the percentage of the sick and wounded who returned to duty remained approximately at 60 per cent.

Nerve Strain on Active Service.—In the House of Lords on July 26th Lord Newton, in reply to the Earl of Lytton, said that cases of nerve strain not certifiable under the Lunacy Acts were treated in the neurological sections of the military hospitals. In addition, accommodation was available at two institutions which were formerly responsible to the Lunacy Board of Control. Neurological cases had been divided into four classes: (1) Cases of nerve injuries caused by wounds; (2) cases of men who were quite insane; (3) cases of a minor character; (4) cases of epilepsy. The treatment in each was special. There was no intention to treat the men as ordinary lunatics. There was no foundation for the allegations which had been heard in various quarters against the War Office on this particular question. Viscount Knutsford said that the arrangements made by the War Office for dealing with men and officers suffering from nerve or organic shock were particularly good. The War Office had engaged neurological departments at twenty-three hospitals, and if the men were too bad or needed a change of surroundings, they were sent either to the Military Hospital at Liverpool or to the Springfield Hospital, Wandsworth. It had been made a grievance that at certain hospitals soldiers were treated by men who had made mental disorders their special study, but these doctors bitterly resented the agitation which had been got up against them and the representation that because they were alienists every man who went to them was necessarily insane. The suggestion that a stigma attached to soldiers treated at institutions which were formerly asylums is baseless. The Marquess of Lansdowne said that he was satisfied that it was the policy of the War Office that the treatment of nerve-shaken soldiers should in no sense resemble that of ordinary lunatics. On the same day Mr. Tennant stated in the House of Commons, in reply to Mr. Onthwaite, that every consideration was given by the responsible officers

to the cases of soldiers whose nerves had given way under the strain of active service conditions, and that the Field-Marshal-in-Chief with the Expeditionary Force was sending back men who, in his opinion, were unable to stand the strain of active service.

Health of the Troops in the Dardanelles. Mr. Tennant stated on July 27th, in reply to Mr. Joynson-Hicks, that there was a certain amount of enteric and dysentery among the troops in the Dardanelles.

Health of Troops in Mesopotamia.—Mr. Chamberlain, in replying to Sir G. Scott Robertson on July 26th, said that the health of the troops in Mesopotamia was good. During June, 27 cases and 9 deaths from enteric fever had occurred, but there had been no special prevalence of the disease at any time. Every effort had been made to minimize the effects of the heat, which had been intense. The troops had been supplied with spine protectors and goggles, mosquito nets and veils, ice, mineral waters, and fresh vegetable food from Bombay. Electric lights and fans had been fitted in buildings where possible. It had been found practicable to give some of the men a change in India during the unhealthy season. There was ample hospital accommodation and a good supply of comforts for the sick.

Nurses in Casualty Clearing Stations.—Mr. Tennant informed Mr. Walter Roeh, on July 22nd, that seven nurses were employed in each of the twenty-seven casualty clearing stations in France.

Wounded Soldiers and Hospital Location.—Colonel Yate asked, on July 21st, whether arrangements could be made for wounded soldiers who desired it being transferred to hospitals or convalescent hospitals as near as possible to their homes as soon as they were fit to travel, and if they could not be sent there direct on arrival. Mr. Tennant said that as far as was possible every endeavour had been made to send to hospitals in the neighbourhood of their homes all sick and wounded on arrival in this country. It was, of course, easy to appreciate that in many cases this was quite impossible, and often for the sake of the patients themselves, who might be so severely wounded as to necessitate their admission into the nearest hospital in which accommodation was available. In the case of those men sent to hospitals remote from their homes the War Office endeavoured to arrange for the transfer, to hospitals in the neighbourhood of their homes, of all cases which were likely to be unfit for duty for any period over six weeks, and which were, therefore, unlikely to be able to proceed to their homes on furlough within that period. Cases that were referred to the War Office were dealt with strictly on these lines. Suitable cases which were likely to be fit for duty within six weeks were treated in convalescent hospitals, so far as accommodation in them was available. At present all these hospitals were in the South of England, but as others were opened in other parts of the United Kingdom it would be arranged, as far as possible, to send cases to convalescent hospitals in that part of the country in which their homes were situated. In reply to a subsequent question by Colonel Yate, Mr. Tennant said he thought that medical officers in charge of hospitals already gave transfers to hospitals or convalescent hospitals as near as possible to the patients' own homes without reference to the War Office. Mr. Tennant stated, on July 26th, in reply to Sir Archibald Williamson, that every endeavour was made to send our patients, arriving from overseas, to hospitals in the neighbourhood of their homes, but, owing to the fact that men were sent from the port of disembarkation in ambulance trains, each carrying 100 or more patients, it was not always possible to do so. In many instances it was not to the advantage of the patients themselves that they should be sent on a long railway journey on arrival in this country. There was great difficulty of sorting out all cases and putting the right man in the right place. Much depended upon the nature and condition of the wound.

Badges.—In reply to Mr. Anderson, who on July 22nd asked a question as to badges for dental mechanics, Mr. Forster said that the whole question of the issue of badges

was under consideration between the War Office and the Ministry of Munitions. Mr. Tennant on July 26th stated, in reply to Mr. Bowerman, that the question was under consideration for supplying a distinctive badge to soldiers invalided out of the service, who might have returned to civil employment.

Motor Operating Theatre.—Mr. Tennant stated, in reply to Mr. Lynch on July 26th, that, so far as he was aware, no offer of a motor operating theatre had been made to the War Office, but the question of sending motor operating theatres to the front had been brought to notice, and had been carefully considered in communication with the expert advisers overseas, with the result that it had been decided not to send any motor operating theatres to the front, as the opinion of the expert advisers on the spot was that their provision would not diminish the rate of mortality of abdominal wounds.

Sick Leave and Inoculation.—Mr. Tennant informed Mr. Wing, on July 26th, that preference as regards leave was given to men who had been inoculated, but there were, he understood, about 300 inoculated men who had had no leave.

Rest for the Troops.—Mr. Joynson-Hicks asked the Under Secretary of State for War on July 21st, whether having regard to the number of new troops ready and anxious to go to the front, he would consider the advantage to the army of sending back the remainder of the original Expeditionary Force for a compulsory rest of, say, two or three months. Mr. Tennant said that the Secretary of State for War would consider the proposal.

Schools for use of Troops.—Mr. Tennant, in replying to Mr. King on July 21st, said that no general reports had been furnished upon the sanitation, ventilation, and general conditions of schools placed at the service of the War Office for hospitals, honing of troops, and other purposes, though the suitability of the buildings was considered before they were taken over. The sanitary and other requirements in the case of a building in continuous occupation were not the same as in the case of one occupied for a few hours daily.

Retired Civil Medical Officers.—Sir P. Magnus asked, on July 26th, why a difference was made between the total amount of remuneration granted to retired medical officers and others receiving civil superannuation allowances who had accepted fresh service under the military authorities and the amount of remuneration, including superannuation allowance, granted to retired naval and military officers who had similarly undertaken new duties in either of the two services. The President of the Board of Trade (Mr. Runciman) said that the issue of superannuation allowances to retired civil servants who were reappointed to any civil office was governed by the provisions of Section 20 of the Superannuation Act, 1854. The differences in the regulations applicable to naval or military service, on the one hand, and the civil service, on the other, were due largely to historical reasons, and the conditions of the services were too dissimilar to enable any useful comparison to be drawn in this respect. Colonel Yate asked if the question of giving an officer who was to be employed his full pension without question, and make his pay equal to the difference between that and the amount he was drawing when last employed, had been considered. Mr. McKenna said that he would have to have notice of that question.

Unregistered Dental Surgeons.—In reply to Mr. Hogge, on July 26th, Mr. Tennant said that registered dentists only were employed by the War Office, because to be registered a dentist must have complied with conditions which implied a prolonged, practical, and skilled training, tested as to its results by examination. In the interests of the troops it was essential to know that the dentists who treated them had been properly trained. It was not proposed to alter the present practice. In reply to a subsequent question by Mr. Watt, Mr. Tennant intimated that there was a sufficient supply of registered dentists to meet the War Office demands.

The Naval and Military War Pensions Bill was introduced into the House of Lords on July 23rd, and met with a good deal of opposition, partly on the ground that sufficient time had not been given to consider the changes in its structure made in the House of Commons, and partly because it had not sufficient regard to voluntary effort. The debate was adjourned, and resumed on July 26th, when the Marquess of Crewe said that the Government fully appreciated the value of the work done by the Soldiers' and Sailors' Families Association, and that if it was desired that the representation originally given to that body on the proposed Statutory Committee should be restored, no objection would be raised. The Government was also willing to place two representatives of the Soldiers' and Sailors' Help Society on the Statutory Committee. With regard to local committees, the Government was prepared to insert an amendment in some such terms as these: "That in constituting the local committees regard should be had to the representations of the society or association which has hitherto undertaken the duties prescribed by this Act." He resisted the proposal to postpone the final discussion of the bill until after the recess. Lord Balfour of Burleigh objected that the bill did not distinguish sufficiently between the provisions which were to have a permanent effect and those which were temporary in character. After some further discussion, during which divergent opinions were expressed, the Marquess of Lansdowne asked the House to pass the bill before adjourning; if it did not, there would be a delay of at least six weeks, and during that time there would be no provision for supplementing pensions for widows, orphans, and disabled men, and the flat rate which they would receive, although liberally conceived, would be inadequate in many cases to meet their wants. Unless the bill was passed there would be no means of giving effect to the policy laid down in the report of the Committee presided over by Sir G. Murray on the provision of employment for soldiers and sailors disabled in the war, so that they might be enabled to earn a livelihood. On a division the motion for the adjournment of the debate was carried by 44 to 31.

Scottish Universities Emergency Powers.—A bill was introduced into the House of Lords on July 15th authorizing the University Courts of the four Scottish universities to submit to the King in Council a joint representation to the effect that it is expedient to modify or suspend ordinances in their application to graduates, students, or intending students, who are, or have been, engaged in naval, military, or other public service connected with the present war. The bill, which was read a second time on July 20th, provides that any such application shall be referred to the Scottish Universities Committee of the Privy Council.

Old Age Pensions in Scotland.—Mr. Montagu stated on July 21st, in reply to Colonel Yate, that the number of old age pensions payable in Scotland on the last Friday in March, 1914, and 1915, respectively were 97,294 and 96,895.

Optical Glass.—Dr. Addison, the Parliamentary Secretary to the Munitions Department, stated, on July 26th, in reply to Sir Philip Magnus, that important steps had been, and were being, taken to increase the supply of optical glass and optical munitions generally. As, however, negotiations were now in progress with this end in view, any statement as to the measures which it was proposed to adopt would be premature and inexpedient.

Rhodes Scholarships.—Mr. King asked the Prime Minister, on July 26th, whether he had consulted with the authorities of Oxford University with a view of some arrangement being made whereby funds for the Rhodes scholarships held at Oxford by German subjects nominated by the German Kaiser might be diverted during the war; and whether any action would be taken in this direction. Mr. Asquith said that the scholarships were in abeyance, and nothing had been or could be paid in respect of them during the war. It would require special legislation to divert these scholarships to other purposes, which in present circumstances he was not prepared to initiate.

Deductions from Accounts.—Mr. Hancock asked the Chairman of the Joint Committee of Insurance Commissioners, on July 27th, to state the reasons justifying the deductions insisted upon by the National Health Insurance Commissioners (England), in circular I.C.L. 124, of one-third of the quarterly accounts of panel practitioners, chemists, and institutions, after services had been rendered and an agreement had been entered into by each party. Mr. C. Roberts said that there was no question of any deduction from or abatement of the remuneration payable under the agreements alluded to. The circular in question had reference only to the subject of advances on account of that remuneration, and indicated the extent to which such advances might safely be made without risk of exceeding the sums which would ultimately prove to be due under those agreements. Mr. Hancock also asked why there had been no advance on account nor adjustment of the deductions of 10 per cent. made in the accounts of doctors, chemists, and institutions for the year 1914; and whether the Government would instruct the Commissioners to deal with the deductions owing to enlistments upon a less arbitrary and more generous basis by a temporary increase of the Treasury Grant, if necessary, considering that the medical profession had undertaken the free treatment of soldiers' wives and families and other dependants, and had lost the most healthy portion of their panel. Mr. Roberts said that the final settlement for 1914 had been unavoidably delayed by certain difficulties arising out of the present state of war. The balance due (which was considerably overestimated in the question) would be ascertained and paid as soon as practicable. In the case of the chemists, who might otherwise have suffered hardship, steps were taken in April last to effect an emergency settlement which was now in progress. In reply to the second part of the question, he could not admit the implications of the hon. member's epithets, or his suggestion that a further sum should be provided by the Exchequer.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS. The following subscriptions to the Fund have been received by the Treasurer, Dr. Des Voeux:

Thirty-fourth List.		£ s. d.	£ s. d.
Dr. A. B. Olsen ...	1 1 0	Leeds and West Riding	
C. A. S. ...	50 0 0	Medico-Chirurgical	
Dr. McCrea ...	1 1 0	Society (per Dr.

In the list published on June 19th an anonymous subscription of £163 was acknowledged from Christchurch, New Zealand, which had been paid through the Bank of New Zealand. A letter has now been received from Dr. L. S. Manning, of Christchurch, saying that the money had been cabled by him as treasurer of the fund instituted by the North Canterbury Division of the British Medical Association.

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS. Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

THE WAR.

CONFERENCE ON ARTIFICIAL LIMBS FOR DISABLED SERVICE MEN.

AN international exhibition of artificial limbs was held at Roehampton House, near Barnes, from Tuesday to Friday of last week. Roehampton House, through the kindness of Mr. Kenneth Wilson, its owner, is being utilized as one of Queen Mary's Convalescent Auxiliary Hospitals for soldiers and sailors who have lost their limbs in the war. About twenty-four firms, many of them American, and one or two others Scandinavian, exhibited. It was announced that the Directors-General of the Navy and Army Medical Services, together with the President of the Royal College of Surgeons of England, and a committee of English, Scottish, and Irish surgeons, would judge the exhibits with a view to deciding what appliances should be adopted as standard patterns. The actual judging took place in private, but subsequently a conference was held, at which the awards were announced.

Sir W. Watson Cheyne, who presided, pointed out that long delay in fitting artificial limbs after amputation often led to wasting of the muscles and loss of strength. On this account such an institution as Roehampton House was doing an invaluable service by ensuring that a man was fitted with a proper limb as soon as the stump was ready for it, and that in the meantime his muscular tone was maintained. The fitting of artificial limbs was, naturally, more difficult in military than in civil practice, for in the latter the operation could usually be designed so as to preserve the best possible stump. Amputations in war, on the other hand, very often could not be made on set lines if as much of the limb as possible was to be saved, with the result that the scars and flaps which covered the stump were sometimes much more tender and much less fit to bear weight than after the ordinary amputations. The fitting of a limb was thus a more troublesome business, and any uncomfortable pressure quickly wore down a man's spirit and energy.

Sir Arthur May, Medical Director-General, R.N., said that in ordinary peace conditions the number of men who lost their limbs in the navy was much greater than in the army. In war, however, this relation had been reversed, and there were twenty or thirty times as many cases of loss of limbs in the army as in the navy. Still, the cases in the navy were much larger in number than before the war. The number was so large that delay in provision was inevitable, yet the longer a man went without his artificial limb, when once he was ready for it, so much the worse for him.

Surgeon-General M. W. Russell, Deputy Director-General A.M.S., after expressing the regret of Sir Alfred Keogh at his inability to be present, said that the aim of the conference was to focus the present position of the artificial limb industry. The supply of artificial limbs in war time was quite a different matter from the supply in peace; the question for consideration was how the expansion in demand might be met by a corresponding expansion in supply.

A resolution was carried asking the orthopaedic surgeons who had been called into consultation to draw up a report advising as to the most suitable artificial limbs for various amputations.

Mr. T. H. Openshaw made an interim report on the judging, and announced the awards of medals which had been offered by Mrs. Gwynne Holford and Mr. C. H. Kenderdine. The gold medal for the greatest advance in mechanism was given to an exhibit by the Carnes Artificial Limb Company, of Kansas City, U.S.A. This took the form of an arm which, in the case exhibited, was attached to the stump at the middle of the humerus, and enabled the man who wore it to command such movements as are involved in lighting a cigarette or even, it was stated, "pulling out a hair." The silver medal in the same section was given to Messrs. Mayer and Meltzer, of London, for a leg, opening laterally, of simple mechanism, and readily adjustable by the wearer. Another gold medal for exhibits of best general excellence was awarded to the J. F. Rowley Company, of Chicago, the chief feature of their exhibit being a leg which was so adaptable that its wearer could run upstairs and downstairs, and even dance and jump. The

silver medal in the same class was awarded to Mr. W. R. Grossmith of London. It was proposed to award a further gold and a further silver medal for the exhibits of mechanisms which best fulfilled the requirements of the soldier, the question of expense being taken into account. The decision on this point, Mr. Openshaw said, would be deferred for further consultation.

GERMAN EXPERIENCES OF WAR SURGERY.

(Continued from p. 137.)

THE following notes on the proceedings of the Deutsche Gesellschaft für Chirurgie which met in Brussels on April 7th are published in continuation of those which appeared last week:

WOUNDS OF THE SKULL.

Professor Tilmann admitted that recent wars had not taught military surgeons to treat wounds of the skull on any generally accepted principles. In the present war he had learnt to operate on a straight bullet wound of the skull only when aseptic treatment of the wound could be guaranteed. Bullet wounds of the skull inflicted at close range were usually fatal on the field or during transport, and almost all the cases of penetrating bullet wounds of the skull which came under his observation were inflicted by bullets with low velocity. When the wounds of entry and exit were small, it was sufficient to apply a simple aseptic dressing. When the wound of exit was large, it was advisable to remove splinters of bone, to sponge the surface of the brain, and to apply a tampon. He had seen eighteen severe penetrating wounds of the skull heal under this simple treatment. In other cases, terminating fatally, the necropsy showed infection of the track of the wound, where surgical treatment could not be employed. Operative treatment was admissible only for haemorrhage, which was a rare complication. Secondary haematoma was also rare, and the symptoms were usually due to encephalitis. An attempt should be made to remove a bullet only when its position could be located by the x rays. It was, however, necessary at some time or another to remove the bullet or any other foreign body from the brain, as encephalitis otherwise usually ensued. Tangential bullet wounds of the skull were frequently inflicted in close-range fighting, and were the most common of all bullet wounds of the skull requiring treatment. Operative treatment was necessary in all such cases, for splinters of bone were driven inwards and caused suppuration, encephalitis, paralysis, pressure symptoms, etc. The groove made by the bullet must be exposed, and splinters of bone removed from the substance of the brain. Even when the injuries to the brain were extensive it was advisable to dispense with plugging of the wound, and merely to apply gauze to the surface of the wound. In wounds inflicted by ricocheting bullets, the fracture of the skull was uncomplicated, as a rule, by injury to the dura. A furrow was ploughed in the bone or a dent formed in the outer table. But slight as these wounds appeared, they were often associated with alarming general symptoms, and even paralysis. The pressure exerted on the brain by this indentation of the bone actually caused almost a more alarming reaction than a direct wound of the brain substance. It was, therefore, necessary in the case of ricocheting wounds of the skull to expose the bone and the dura as soon as cerebral symptoms developed. Every operation could be performed under local anaesthesia, and no narcotic was necessary when the patient was already unconscious. Sometimes paralysis following penetrating wounds of the skull, from which the bullet had escaped, disappeared of themselves. Hemianopsia had also been found to disappear after fragments of bone had been removed from the occipital lobe. Meningitis, when it occurred, usually developed within the first few days. Lumbar puncture was useful both for diagnosis and treatment, and should be repeated whenever headache became severe. Only in the serous and haemorrhagic forms of meningitis was there any prospect of recovery. Encephalitis played an important part, and was either reactive or purulent. In the purulent form, there was stupor, a slow pulse, and progressive paralysis. In the reactive form, and also in softening of the brain, there was, as a rule, no fever. Abscess of the brain was difficult to diagnose; it was usually accompanied by

prolapse of the brain, which ceased when the abscess was drained. Reactive encephalitis was frequently followed by the formation of cysts and large scars, and the ultimate fate of the patient was often disappointing.

Professor Enderlen had observed 311 bullet wounds of the skull since November. Of these, 149, or 44.7 per cent, had terminated fatally. Many of the patients died in a few days, and encephalitis and meningitis were frequent. Post-traumatic softening was more rare. Every wound of the skull should be examined, and by the help of an early operation it was possible to avoid secondary infection. Bullets should be removed at once only when they were superficial, and could be accurately localized, with or without the *x* rays. Migration of the bullet had to be taken into account when its removal was attempted at a later stage. The operation should be undertaken only when the further transport of the patient could be deferred for three or four weeks. The operation should be thorough but simple; plastic operations of the skull and dura should be discouraged, and when the wound was simple, drainage and suture of the dura were alone sufficient.

Herr Best had found ocular symptoms in more than two-thirds of the 92 cases of skull wounds under his observation. Papillitis was very common, hemianopsia was observed in every sixth case, and mind-blindness in every seventh case. When the bone was not shattered, and the symptoms were due to bruising or a haematoma, papillitis was seldom seen, whereas it was observed in about four-fifths of all the cases of penetrating wounds.

Professor Bier insisted that it was most difficult to remove a bullet from the interior of the brain, but that if the head were placed with the wound of entry lowest, and were then knocked, "the bullet walked out by itself"!

WOUNDS OF THE ABDOMEN.

Professor Körte had found the length of the interval between the infliction of an abdominal wound and an operation the most important factor. If this interval were more than twelve hours the prognosis was bad, particularly if the patient meanwhile had been transported over rough roads. Of 312 wounds of the abdominal cavity, the majority had been inflicted by bullets, and only two by the bayonet. Thirty-eight of these patients died at the first dressing station, and 274 reached hospital alive. Of these, 121, or 46 per cent, recovered; 146, or 53 per cent, died; while the fate of the remainder was unknown. Of the 17 cases in which an operation was performed for prolapse of the intestine or omentum, recovery was effected only in two cases. Expectant treatment was adopted in 257 cases. These patients were, as a rule, admitted to a field hospital from the sixth to the eighth day, and were passed on about a fortnight later. The mortality was 51.4 per cent., while the percentage of recoveries was 47. Of the 10 patients who had subsequently to be submitted to operations for prolapse of the omentum or abscess, including liver abscess, four recovered and six died. Taking the 312 abdominal casualties as a whole, the proportion of recoveries to deaths was 40 to 60. Necropsies often showed that perforations of abdominal organs had been overlooked at the operation. In many cases a bullet wound of the bladder had been sutured, but a wound of the rectum had been overlooked. A recovery had been effected in fifteen out of twenty-three bullet wounds of the liver. Two out of three bullet wounds of the spleen and three out of seven bullet wounds of the bladder had terminated fatally.

Comparative Merits of Operative and Conservative Treatment of Abdominal Wounds.

Professor Körte said that at a recent meeting in Lille, the speakers, with the exception of Enderlen, were opposed to operations for bullet wounds of the abdomen. The same was also the case at a meeting in Lothz. Recently, however, there had been a movement in the opposite direction; and Rottor, whose results had previously been unfavourable, had lately recorded six consecutive abdominal operations, all of which were successful. Under favourable conditions, Professor Körte said, a simple perforation of the intestine might heal of itself, but it was not known how often this occurred. It was difficult to ascertain whether the intestine had been wounded or not; if it were, an operation should be performed within the first twelve hours, provided that the patient had not, in the meantime,

been transported a great distance, and that his general condition was not very bad, and provided also that there was sufficient time, and that it could be done under aseptic conditions.

Professor Schmieden said that his experiences concerned trench warfare almost exclusively. He had expected that 50 per cent. of the penetrating abdominal bullet wounds would heal of themselves, but he had been grievously disappointed; spontaneous recovery was exceedingly rare. The prognosis was far worse than for wounds of the chest and skull. The old teaching that the intestinal mucosa formed a plug which automatically closed a perforation of the intestine was erroneous. Possibly the small Japanese rifle bullet caused less fatal perforations of the intestine than those observed in the present war, and he believed that when abdominal wounds healed under conservative treatment the intestine and stomach had in most cases escaped injury. The principles of conservative treatment could not be carried out, and in no case could the transport of the wounded be avoided. In his opinion laparotomy should be performed when the wound had been inflicted not more than twelve hours earlier, when the general condition was not hopeless, and when there were adequate facilities for operating. Appliances for irrigating the abdominal cavity were essential. Among 198 abdominal casualties, the gastro-intestinal tract had been perforated in 157 cases. An operation was performed in 58 cases, 37 of which terminated fatally; recovery occurred in 16 cases; the fate of the remaining 5 patients is not recorded. Among 94 cases in which no operation was performed, there were only 4 recoveries. In the absence of perforation of the gastro-intestinal tract, the mortality from abdominal wounds was about 50 per cent. Of late he had been able to advance his operating theatre to within about four kilometres of the trenches, and was thus in a position to perform a laparotomy half an hour after the infliction of a wound. Bullet wounds of the liver should not be closed when the wounds of entry and exit were fairly large. The damaged liver substance was thus enabled to escape, and the formation of late retention abscesses was prevented. In one case, in which the thorax and abdomen were simultaneously wounded, the spleen was prolapsed, and it was impossible to replace it on account of the adhesions which had formed. It was cauterized every fortnight, and the patient ultimately recovered.

The Mortality from Abdominal Wounds at Various Distances from the Front.

Herr Friedrich had compared the results of abdominal wounds treated at a first dressing station, a field hospital, and a home hospital. At the first dressing station, among 33 patients, there was a mortality of 44 per cent. within twenty-four hours and of 85 per cent. within two days of the infliction of the wounds. Only 5 patients survived. Among 34 cases treated in a field hospital on absolutely conservative lines, there were 11 deaths, or a mortality of 32 per cent. Among 46 patients treated in a home hospital, many of the wounds being recent, the mortality was 38 per cent. Under conservative treatment the prognosis was worse for wounds of the colon, and it improved the higher the wounds were inflicted. Thus, the prognosis was best when a wound of the gastro-intestinal tract affected the stomach. The prognosis for wounds of the liver was also relatively good.

Operations for Abdominal Wounds.

Herr Enderlen reported 89 cases in which operations had been done for bullet, shrapnel, and shell wounds of the intestine. About 30 per cent. recovered. As many as 12 perforations of the intestine were found in a single case; in some instances it was necessary to resect part of the intestine, and in 3 such cases the patient's life was saved. In 5 cases, in which the wounds of entry and exit clearly indicated perforation of the abdomen, no wound of the intestine could be found, and all 5 patients recovered. Since November the transport of the wounded from the trenches had been accelerated, so that an operation could be performed within the first four to ten hours. Early in the war he had operated eighteen to twenty hours after infliction of a wound, but he had invariably found purulent peritonitis, without adhesion of the abdominal organs, or any sign of a mucous plug in the perforations. All his cases of prolapse of the abdominal organs had terminated

fatally. Experience had taught him to operate, time and other factors permitting. Professor Sauerbruch also endorsed the policy of operation in abdominal wounds, and by this means he had saved 23 out of 54 cases.

WOUNDS OF THE LIMBS.

In dealing with wounds of the limbs complicated by fractures, Professor Payr said the wound healed most satisfactorily when the fracture was properly set, and the fate of the fracture was similarly dependent on the favourable course of the wound. Suppuration was common even in simple penetrating wounds inflicted by bullets; in shell wounds he was inclined to advocate immediate incisions and exposure of the track of the wound as a matter of routine. The treatment of fractures due to bullets by primary dissection and exposure gave more satisfactory results than deferring the operation till severe sepsis had supervened. When subfascial gas-phlegmon had developed, very deep incisions were necessary, and when this treatment failed to give definite relief after twelve hours, amputation was inevitable. He was opposed to the practice of plugging wounds with tampons, and he preferred to keep them open with lightly rolled gauze. It was advisable not to interfere with traumatic osteomyelitis till the necrosis was complete. Permanent irrigation was too elaborate to be satisfactory and, as a rule, there were not adequate facilities for a permanent bath, excellent though this treatment was. When a joint was wounded, and infection or an increase of the effusion into the joint were detected, it was advisable to puncture, to irrigate with a solution of carbolic acid or collargol, and to immobilize the joint. Extension of the limb in such cases was not advisable, and an attempt should be made to extract a bullet only when the functions of the joint were impaired. He had found it necessary to do this only in 8 out of 220 wounds of the knee-joint. The course of infection of a wounded joint was usually insidious; it was often latent for as long as ten days.

The Faults of Plaster of Paris Splints.

Herr Goldammer most emphatically disapproved of plaster of Paris splints for first aid in the field. Their use implied far too much stationary treatment and waste of time. They should be used only when the patient could be kept under observation for at least twenty-four hours. Treatment by extension was, no doubt, the best, as it alone prevented shortening; but owing to the difficulties of transport, the surgeon had to be satisfied with simple immobilization. But as soon as the wounded were admitted to hospitals, whence they were not likely to be further transported, treatment by extension should be instituted.

SURGERY OF THE BLOOD VESSELS.

Professor Bier said that he had operated on 102 cases of aneurysm. Early in the war arterial aneurysms had been most common; recently they had been less frequent than arterio-venous aneurysms, which had been observed in 28 out of 33 cases of aneurysm of the femoral artery. Varicose aneurysms were most rare. The length of time the aneurysms had existed ranged from eight days to five months. In most cases the diagnosis of aneurysm was easy, and they were rarely confused with abscesses. The aneurysms usually developed soon after the infliction of a wound, but in many cases not until the patient had returned to active service. He considered it necessary in every case to dissect out the artery before attempting any suture. If this precaution were neglected and the operator attempted to excise the whole sac of the aneurysm, so much of the artery was removed that it was usually impossible to suture the blood vessels satisfactorily. He much regretted that this procedure was still generally followed, for it was apt to destroy the most important collateral vessels. Among his 102 cases, suture was performed in 74 cases, in 38 of which the more simple, lateral anastomosis was effected. When, however, a considerable portion of the artery had to be removed, a transverse resection was inevitable, and ordinary suture had to be performed. It was more difficult to operate on arterio-venous aneurysms; in these cases also it was necessary always to undertake a preliminary dissection of the vessels before attempting excision and suture. Venous transplantation was always superfluous. The operations on aneurysms were much facilitated by Momburg's method of inducing anaemia of the limb, which never suffered

from this treatment. Sepsis was the only contraindication to suture of the blood vessels; even lateral anastomosis should not be attempted in an infected wound for fear of secondary haemorrhage. Suture was superfluous for aneurysm of minor arteries, which were best treated by simple ligation. Among his 102 cases, ligation was performed in 28 cases, in which small arteries had been wounded. Eight of his patients had died, and 4 of these deaths had been in connexion with aneurysm of the subclavian artery, of which there had been 9 cases.

OPERATIONS IN THE PERSIAN GULF.

DISPATCHES.

The *Gazette of India* of June 26th publishes the official reports of the operations in Mesopotamia up to March 31st in dispatches from Lieutenant-General Sir A. A. Barrett, K.C.B., commanding Indian Expeditionary Force D, dated December 29th and March 31st. The following medical officers are specially mentioned in these dispatches. The dispatch of December 29th contains the following:

Captain D. Arthur, I.M.S., was particularly conspicuous in attending Captains Daunt and Otter when exposed to heavy fire and throughout the action.

Sub-Assistant Surgeon Pundit, I.S.M.D. During the attack on Muzaira'ah on December 7th, 1914, Rifleman Ghos Merhammad was shot by an Arab who was hiding in one of the huts. Sub-Assistant Surgeon Pundit called on a Sepoy of another regiment to enter the hut and clear it. The Sepoy seemed reluctant to do so, and the sub-assistant surgeon took his rifle and bayonet, entered the house, and closed with the Arab. The Sepoy followed, and between them they killed him. He has also shown exceptional bravery in attending wounded under fire.

The field ambulances under Major E. Bennett, R.A.M.C., worked with great devotion on the 7th, and were under shell fire for a short time that night.

The dispatch of March 31st contains the following:

Colonel P. Hehir, M.D. As senior medical officer he has done much to promote the general efficiency of the force by his unceasing care for the physical welfare of the troops and followers and for the treatment of the sick and wounded. He possesses great administrative ability, and is an extremely valuable officer.

The following staff and regimental officers are also worthy of special commendation:

Arthur, Captain D. M. (I.M.S.).
Barber, Captain C. H. (I.M.S.).
Collins, Major D. J. (R.A.M.C.).
Donegan, Lieutenant-Colonel J. F. (R.A.M.C.).
Horton, Major J. H., D.S.O. (I.M.S.).
Irvine, Lieutenant-Colonel G. B. (I.M.S.).
McCreery, Captain A. T. J. (R.A.M.C.).
O'Keefe, Major D. S. A. (I.M.S.).

The following officers are especially brought to notice for gallantry in the field:

Captain H. E. Shortt, I.M.S. In the operations from Muzaira'ah on the left bank of the Tigris, on January 30th, this medical officer displayed great devotion and courage in attending wounded in the open in face of rifle fire at comparatively close quarters.

Doctor Arthur Bennett, of the American Mission Hospital, has helped us greatly by undertaking the treatment of wounded Turkish and Arab officers and men.

MILITARY HONOURS.

The supplement to the *London Gazette* of July 24th records the award of a number of decorations to officers and men serving in Flanders and in the Dardanelles; four V.C.s, twelve D.S.O.s, and thirty-three Military Crosses. Two medical officers are among the recipients of the last.

Lieutenant William Kelsey Fry, R.A.M.C. For conspicuous gallantry and devotion to duty at Festubert, between May 16th and 18th, 1915, while carrying out his work under heavy fire. He was himself wounded while attending to others.

Lieutenant David James Sheires Stephen, M.D., R.A.M.C. For conspicuous gallantry and devotion to duty in attending to the wounded under heavy shell fire on several occasions, notably on the night of April 23rd, and on May 8th, 1915. He has usually performed his gallant work single-handed, and by his cheerfulness and pluck has encouraged all around him.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

Captain Michael Foster Reaney, of the Indian Medical Service, was killed in action at the Dardanelles on July 2nd. He was born on April 15th, 1878, educated at the London Hospital, and took the M.R.C.S. and L.R.C.P. Lond. in 1900, the M.B.Lond. in 1901, and the M.D. in 1914. In 1904 he gained the Carmichael prize for an essay on *The Medical Profession*. After filling the posts of house-physician and of clinical assistant for medical out-patients and in the skin and aural departments at the London Hospital, he entered the I.M.S. as lieutenant on February 1st, 1905, becoming captain on February 1st, 1906. Previous to the war he was serving in civil employment in the Central Provinces, but was recalled to military duty, and on October 16th, 1914, was posted to the 5th Gurkhas, with which regiment he was serving when he was killed. He is deeply lamented by many former students of the London Hospital, where he was clinical assistant to several special departments and also house-physician. Dr. Arthur Keith, then a teacher at the hospital, considered that he was an able anatomist of high promise. Captain Reaney was 38 years of age, and leaves a widow to lament his loss.

Major David Robert Taylor, R.A.M.C. (T.F.), was killed in action in the Dardanelles on July 14th. He was educated at Edinburgh University and at the Royal College of Surgeons school in that city, taking the Scottish triple qualification in 1893. After qualifying, he settled in practice at Ayton, in Berwickshire, where he was medical officer of the post office and visiting physician to the Millerton Hospital for Infectious Diseases since its foundation. He was also a member of the British Medical Association. He was for five years an officer in the 2nd Volunteer Battalion of the King's Own Scottish Borderers, and on August 8th, 1906, became lieutenant and medical officer in the 4th (Territorial) Battalion of the K.O.S.B., becoming captain on April 1st, 1908, and major on December 18th, 1914. Major Taylor was twice married, and leaves a widow and five children.

Captain Andrew Wallace, of the 4th (Border) Battalion of the King's Own Scottish Borderers, was killed in the recent fighting in the Dardanelles on July 12th. He was the eldest son of Mr. James Wallace, head master of Prestonpans school, and was educated in Edinburgh, at George Heriot's school and at the University, where he took the M.B. and C.M. in 1896. After acting as an assistant in Leicestershire he served for some years as a surgeon on the Glen line of steamers, and was surgeon of the *Glen Avon* when she was wrecked off Hong Kong. He settled in practice some fifteen years ago at Coldstream in Berwickshire. He took a combatant commission in the 4th K.O.S.B. about twelve years ago, and attained the rank of captain on April 11th, 1906.

Wounded.

Captain A. J. McC. Morrison, R.A.M.C. (temporary), (Dardanelles).

Captain J. D. Lithgow, R.A.M.C. (temporary), (Dardanelles).

Lieutenant C. S. Black, M.B.Glas., 6th H.L.I. (Dardanelles).

This is the second time that Captain Morrison has been reported as wounded; his name appeared in the casualty list of June 29th, and again in that of July 22nd.

DEATHS AMONG SONS OF MEDICAL MEN.

Five cases of sons of medical men killed in action have been reported in the past week, to which are added three others of an earlier date.

Bull, G. J. G., Lieutenant 2nd Field Company, East Lancashire R.E.T., son of Colonel W. H. Bull, K.H.S., A.D.M.S. (T.F.), of Stony Stratford, killed in the Dardanelles on July 8th. He was educated at Wellington, and at Magdalene College, Cambridge, where he took a degree in the first class. He got a commission as lieutenant on June 10th, 1913, went to Egypt in September, 1914, and to the Dardanelles in May, 1915.

Evatt, G. R. K., Captain Middlesex Regiment, who was killed in France on November 13th, 1914, was the son of Surgeon-General G. J. H. Evatt, C.B.

Henderson, Andrew Hubert Millin, 2nd Lieutenant 14th King's Own Scottish Borderers, eldest son of Dr. Percy J. Henderson, 9, Church Street, Galashiels. He was killed in action at the Dardanelles on July 12th, 1915. He completed the first year of

his medical career at the University of Edinburgh just before the war broke out. He was a lieutenant in the Royal Scots Cadet Corps, and resigned this on getting his commission in the 4th King's Own Scottish Borderers in the spring of 1913.

Morton, Sidney, Major India Army (24th Punjab), only son of the late Surgeon-General G. E. Morton, I.M.S., killed in action in the Persian Gulf on June 14th, aged 39. He entered the army on January 22nd, 1896, joined the Indian army on March 31st, 1897, and became major on January 22nd, 1914. He served on the North-West Frontier of India as Provost-Marshal of the First Brigade in the Malakand and Buner campaigns of 1897, and took part in the defence of Malakand, the relief of Chaldara, the actions at Landakari and at the Tuga pass, and the operations in Bajour and the Manand country, alval with clasp; also in China in 1900, in the relief of Peking, and the actions of Peitsang and Yangtsun, when he was mentioned in the dispatches in the *London Gazette* of May 14th, 1901, medal with clasp.

Porter, Alwyn, Lieutenant Lancashire Fusiliers, son of Dr. J. E. Porter, of Helmsley, Yorkshire, killed in the landing on Gallipoli beach in the Dardanelles, early in May 1915. He got his commission as second lieutenant on July 18th, 1911, becoming lieutenant on November 27th, 1914.

Ross, Ronald Forbes, Second Lieutenant 3rd (Reserve) Battalion of the King's Own Royal Lancaster Regiment, son of the late Dr. Forbes Ross, of London, killed at Zillebeke, near Ypres, February 20th. He got his commission on August 15th, 1914.

Sparrow, Eric Walter, Private 7th Battalion Rifle Brigade, second son of Dr. W. B. Sparrow, of Burton-on-Trent, killed in action in France on June 30th, aged 36.

Stewart, J. S., Second Lieutenant 5th Battalion Argyll and Sutherland Highlanders, son of Dr. W. Stewart, of Gourcock, killed in the Dardanelles, aged 20. He was a medical student, and got his commission on November 6th, 1914.

NOTES.

THE HEALTH OF THE FLEET.

The Archbishop of York, in an article on his ten days' visit to the Grand Fleet contributed to the *Times*, speaks of the cheerfulness of the men in spite of their monotonous life, and in spite of the strain of being always ready for any emergency. "Thanks," he says, "to excellent food, fresh air, exercise, and the absence of shore temptations the health of the fleet is admirable. When I was with the largest section, the rate of sickness (including accidents) was just under 1 per cent. The men at work on board ship are a vision of smartness and alacrity. They are all splendidly 'fit' in body and spirit."

GERMAN RED CROSS.

In a recent issue of the American Red Cross monthly magazine, Dr. Kimmle, Secretary of the German Red Cross, gives an account of the work of that organization during the present war. From an abstract which appears in the *Boston Medical and Surgical Journal* of July 15th, we learn that it was mobilized at the same time as the army, and has now some 5,000 nurses in the field. The nurses are divided into three classes, the first being the Red Cross sisters, who for years have carried on the profession of nursing. The second class consists of volunteer auxiliary sisters, who undergo one-half year's training, pass an examination, and are called out from time to time for further instruction and practical service in military hospitals. The third class comprises the volunteer helpers of the Red Cross. They are employed only in the home military hospitals under the supervision of experienced nurses. More than 60 per cent. of the Red Cross nurses—about 5,500 in all—are now in the field, war, and base hospitals. The remainder are at home, nursing not only sick and wounded soldiers, but also men, women, and children of the civil population. Besides the female personnel, there is a male staff of stretcher-bearers and sick attendants. They are trained in the First Aid Detachment of the Red Cross, the Red Cross Association of Voluntary Attendants, and the Samaritan Societies of the Red Cross. At the beginning of the war these organizations numbered from 70,000 to 80,000 men, and this number has since been materially increased. They are, says Dr. Kimmle, uniformed and equipped according to regulations, and form an army of "Caritas." About 20,000 men have been sent to the front or base, where they do service in army hospitals and in the depôts, while a still larger number do service in army hospitals and Red Cross trains and the home military hospitals. They have army, Red Cross, and auxiliary hospital trains and ambulances, these last being complete ambulatory field hospitals, with all the comforts afforded

by a stationary field hospital. The War Department hospital trains, classified by numbers, and the Red Cross trains, classified by letters of the alphabet, are about the same. They consist of fourth-class vestibule cars that allow the physicians and nursing corps to get quickly and easily from one end of the moving train to the other. The wounded lie on stretchers, on which, in the Red Cross trains, are mattresses, and are protected from cold by blankets enclosed in washable linen cases. The central committee of the Red Cross had completed ten such hospital trains shortly after mobilization, and there are now several dozen in the entire organization of the Red Cross.

THE CANADIAN HOSPITAL AT LE TOUQUET.

J. P. C. writes that he has grateful memories of the good work of the Canadian Hospital (No. 2 Stationary), Le Touquet, North France. "In January last," he says, "the battalion was encamped at Etapes, outfitting for the firing line. The weather was about the worst that could be imagined, and I, as medical officer of the battalion, had to send batches of men to hospital every day in the week, as many as 40 a day on the sick list, suffering from rheumatism, tonsillitis, influenza, eczema, bronchitis, and some had cuts of some feet. At length my own turn came—cold shivers, pains in back and limbs, relaxed throat, loss of appetite, and general malaise with high temperature were all unmistakable symptoms. I hung around on duty in pain, cold, and misery for three days that seemed as long as ten, unwilling to report sick; but eventually a kind brother medicotook me in hand and saw me safely to 'The Canadian,' as the institution known in that section. I was shown to a real bed in a nice cheerful room, with a blazing coal fire in one corner, which helped materially in restoring the chilled circulation. My temperature was found to be 103°, and I felt so shaky I did not care to venture a warm bath, but had a hot foot-bath instead, hot drinks, plenty of blankets, aspirin (10 grains) and—rest. I saw some poor fellows terribly frost-bitten, principally in the feet and hands, others in a lesser degree, the condition known as 'water-bite,' caused by standing for hours or days in liquid mud. The medical officers, nurses and attendants are all Canadian; Colonel Shillington, the able and popular chief of staff, is well seconded by Captain Young, and kindness and efficiency seems to be their motto. The requirements of religion are not forgotten, there being Church of England and Catholic chaplains on the staff. When I essayed a walk abroad I discovered that this immense building, which before the war was the Golf Hotel, was only ten minutes' walk from the sea, right in front through the golf links; on the right sand-dunes principally; left and at the rear a dense forest of primeval pines; it is an ideal situation, a lovely land, beautiful even in winter."

MEDICAL OFFICERS WANTED.

2/3rd West Riding Field Ambulance.

Five medical officers are required to complete the establishment of this unit at the war station. Applications to the Officer Commanding, Race Course, Beverley.

Ireland.

BELFAST MEDICAL SCHOOL AND A HOSPITAL IN FRANCE.

DR. THOMAS HOUSTON, in charge of the vaccine therapy department in the Royal Victoria Hospital, Belfast; Dr. J. E. MacIlwaine, assistant physician; and Mr. P. T. Crymble, F.R.C.S. Eng., surgical registrar to the same institution; and Dr. McCloy, assistant tuberculosis officer under the Belfast Corporation, have left to take charge, with other doctors, of the St. John Ambulance Brigade Hospital at Etapes, a few miles south-west of Boulogne. The former three will rank as captains and Dr. McCloy as lieutenant. Mr. Crymble's brother, Mr. C. R. Crymble, D.Sc., also a distinguished scholar and graduate of Queen's University, Belfast, was killed in the earlier phases of the war while serving as lieutenant in the 3rd Battalion Royal Irish Fusiliers. The hospital contains 520 beds; the bacteriological laboratory is under the direction of Dr. Houston; Dr. MacIlwaine is taking an electro-cardiograph with him; Mr. Carson, of Messrs. Lizars, who helped to put up one in the Royal Hospital, has gone with Dr. MacIlwaine to aid in its installation in France.

WAR WORK FOR WOMEN STUDENTS IN THE QUEEN'S UNIVERSITY, BELFAST.

At a special meeting of the Senate of the Queen's University of Belfast on July 20th a committee was appointed, on the motion of Dr. Calwell, seconded by Dr. Leslie, to consider whether and in what way provision

should be made for the training of women students in ambulance work, sick nursing, and other similar subjects. By a previous resolution of the Senate the men students are all required to attend a course of physical and military training, and these subjects are to be added to the various faculties that are already in existence. The time to be devoted will not in either case unduly interfere with their ordinary studies.

PROPOSED AMALGAMATION OF NORTH AND SOUTH DUBLIN UNIONS.

Last week a deputation organized by the Dublin Citizens' Association was received by Sir Henry Robinson and the members of the Local Government Board for Ireland. The deputation, which represented practically all the industrial, mercantile, and trading interests in Dublin, stated that all were handicapped by the weight of general taxes and the appalling local rates. To get some relief from the latter was the object of this appeal to the Local Government Board to use its powers in giving practical effect to the proposed amalgamation of the Dublin unions. The administrative fusion of the Dublin unions was a definite matter of practical local reform, which, it was confidently believed, would, without any hindrance to a general reform hereafter, secure better treatment for the destitute and infirm, and at once lighten the Dublin ratepayers' burden. He was glad the Local Government Board had the power to amalgamate the unions without the consent of the guardians concerned, though, of course if the guardians could be brought to see their real duty in the matter, it would be more satisfactory.

The memorial stated that shortly before the operation of the Old Age Pensions Act the cost of the North and South Dublin unions for the entire areas of both institutions was £164,054, whereas the total demands for the current financial year (1915-16) were £167,595, and this notwithstanding (1) a recent statement at a meeting of the North Dublin Union Board that the number of inmates then in the union was the lowest for thirty years; (2) the fact that old age pensions had benefited the poor of Dublin to the extent of £131,000; and (3) that the National Health Insurance Act in sickness, disablement, maternity, and sanatorium benefits had returned to Dublin as a whole practically £55,000 a year for the last two years, and that of the latter amount it was computed that a third, or, say, £20,000 a year, had gone to persons who would otherwise be chargeable on the poor rates. These facts and considerations had convinced the association the deputation represented that the practical reform needed in order to obtain adequate local advantage from the legislative benefits set out was to amalgamate the North and South Dublin unions. Unity of government and management and an efficient classification of inmates would effect a large reduction in the cost of administration, even after due provision had been made for compensation to disemployed officials. The merging of the two unions would also facilitate such treatment of pauper children as would allow of their being removed at the proper time from an environment calculated to mar their status as citizens to surroundings in which they could be fitted mentally, physically, and morally to face the battle of life successfully and avoid a dependent existence. It was mentioned that in Belfast, which has a larger population than Dublin, but only one union, the poor rate had fallen from 1s. 2d. to 11d. in the £ since the coming into operation of the Old Age Pensions and Insurance Acts.

Sir Henry Robinson (Chairman of the Local Government Board), in reply, admitted that his Board had full power without special legislation to amalgamate unions, and that, as a matter of fact, several such amalgamations had been carried out in Ireland. At the same time, it would facilitate the Board's action if both the Dublin unions were consenting parties to the proposal. He asked the deputation to help the Board by indicating in detail the plan outlined in the memorial. He rather favoured the idea of one large establishment for Dublin. The Viceregal Commission of 1906 had suggested one union for Dublin city as it now exists, but he believed that a grouping of the unions of Dunslaughter, Celbridge, and Balrothery, thus broadening the contributory area, would be preferable. He assured the deputation that the Board would give very careful attention to the matter.

THE BELFAST TUBERCULOSIS SCHEME.

We have received the following letter:

Tuberculosis Institute,
91, King Street, Belfast,
26th July, 1915.

Sir,—I should be much obliged if you would give me a few lines of your valuable space to correct some errors into which your Irish correspondent has fallen in your issue of 24th July in his news of the public health of Belfast.

Dealing with the tuberculosis scheme, he says it "does not appear to prosper." That, of course, may be a matter either of opinion or of fact. On the 2nd June the scheme had been in operation for a little over a year, and during that time upwards of 2,000 new patients had been examined, whilst upwards of 7,000 visits of old patients had been paid to the institutes. During the same period the nurses connected with the institutes paid upwards of 13,000 visits to the homes of patients. In addition to the above, 232 patients have been examined in the union infirmary since the 1st October, 1914. Taking all this into consideration, and with the attendant work involved in keeping records and in carrying out the administrative work of a new department, I think your correspondent's criticism is hardly justified.

Again, he states "£10,000 a year has, for the time, been lost, apparently owing to failure to come to an agreement with the Insurance Committee." Does he realize that the work which it would have been necessary to do for this amount would, in all probability, have cost a great deal more than £10,000 a year? If he had regretted the loss to the patients through want of centralization I should have readily agreed with him.

He goes on to say that some "£13,000 a year was to have been obtained from the Government for the enlargement of the Whiteabbey Sanatorium [?] . . . this has been held up, and now it may be taken for granted that no Government will expedite the giving of such a sum." Apart from the slight mistake that the money was for the enlargement of Whiteabbey Sanatorium, it may interest him to know that—so far from the money being "held up," or the Government failing to "expedite the giving of such a sum"—the Government are as prepared as ever to grant the money for building operations in connexion with the tuberculosis scheme, and the corporation will shortly avail themselves of the opportunity of spending it.

He then says: "A large number of medical appointments have been made representing payments of over £2,000 a year." I am not sure whether he intends the emphasis to fall on the number of the appointments or on the size of the aggregate salaries, but considering that the appointments number seven, and the average salary therefore something like £300 a year, I think that in the present state of medical employment he will hardly say that the staff are overpaid; and considering that the dispensary staff numbers three—working in a population of 400,000—he can scarcely say that the staff is too large.

Finally, he makes the comment that "the council cannot get rid of their obligation to the guardians' officers, Dr. Hall and Dr. Rankin." So far as I know, the council have never sought to rid themselves of any obligation under the agreement with the guardians by which they have undertaken, "as far as practicable and convenient to themselves, to take over the services of all officers, attendants, nurses, and servants employed in the Abbey Sanatorium." Nor is he correct in saying that Dr. Hall's relations with Dr. Gilliland have not been set forth, since they have both mutually agreed as to their respective duties.

Should your correspondent at any time visit this corner of the kingdom, or should he desire any information regarding the scheme for the prevention and treatment of tuberculosis in Belfast, I shall at all times be at his service.—I am, yours faithfully,

ANDREW TRIMBLE,
Chief Tuberculosis Officer.

Scotland.

THE PREVENTION OF TUBERCULOSIS.

DR. JOHN GUY, the tuberculosis officer for Edinburgh, has presented a report on the work of the Sanatorium Benefit Committee for 1914; it deals with 309 cases—190 males and 119 females. Sanatorium treatment was granted in 266 cases, domiciliary in 21 and dispensary in 22. Among the questions discussed by Dr. Guy is that of overcrowding

in the home. He has taken the census standard of overcrowding—namely, more than two persons to one room, and had applied this to the houses (299 in number) from which the applicants for sanatorium benefit had come (there were 309 in all, but 10 cases from common lodging houses were excluded). By far the majority of these were of the two-roomed type, and whilst 157 of them had through ventilation, 142 had not. The result, as regarded overcrowding, given in tabular form, is as follows:

Accommodation.	Ample.	Overcrowded.	Total.
1 room... ..	16	22, or 58%	38
2 rooms... ..	64	62, or 49%	126
3 rooms... ..	60	11, or 15%	71
More than 3 rooms... ..	61	3, or 5%	64
	201	98, or 31%	299

The census standard of overcrowding is not the legal standard, so that, whilst many of the houses did not conform to the census standard, they could not be dealt with legally as overcrowded, for they satisfied the requirements (400 cub. ft. per inmate). In the case of the one-roomed houses there was overcrowding in 58 per cent., and in the remainder there were two persons living in each. Dr. Guy expresses the opinion that, though this may satisfy the legal requirements, yet whenever a case of pulmonary tuberculosis occurs in a one-roomed house that house becomes at once overcrowded. The housing question is a vital point in dealing with the problem of tuberculosis, and Dr. Guy agrees that too much has been said about sanatoriums and too little about the houses. He inclines to the belief that if the money which has been poured out on sanatoriums had been spent on improvement in housing conditions the results would not have been less satisfactory. Improper or insufficient feeding also played, he thinks, an important part; in many of the houses from which the patients came it was no uncommon thing for there to be no properly cooked food at any time of the day. Dr. Guy suggests that out of the fund for educational purposes at the disposal of the committee a cook should be engaged to go into the houses of the people and instruct them in the use and preparation of cheap yet nutritious and wholesome dishes. During the year very few cases were granted domiciliary treatment, yet it was a much appreciated benefit. The housing condition had to meet with the approval of the medical officer of health, and so unless a separate bedroom could be given to the patient the benefit could not be received, but it seems a great pity that this inability, through poverty, to provide a separate bedroom should penalize a person in respect of domiciliary treatment. In conclusion, the tuberculosis officer gives a chart showing the decrease in the death-rate from pulmonary tuberculosis in Scotland generally and in Edinburgh from 1875 to 1914; whilst in 1875, out of every 10,000 living persons 25 died of pulmonary tuberculosis, in 1914 only about 11 perished. It is particularly noteworthy that the Edinburgh curve, whilst it has a more irregular course, follows in the main that for the whole country approximately, neither better nor worse. If the fall continues in the future as it had in the past, in forty years the disease will have disappeared.

England and Wales.

TREATMENT OF TUBERCULOSIS IN LONDON.

AMONG the reductions in annual maintenance voted sanctioned by the London County Council at its meeting on July 20th was one of £7,000 in connexion with the treatment of tuberculosis. The Public Health Committee reported that, although difficulty had been experienced in securing residential accommodation for tuberculous persons owing to the number of beds reserved for wounded and sick soldiers, yet, by a fortunate circumstance, the number of adult tuberculous patients requiring treatment in hospitals and sanatoriums had been smaller than was expected, and they recommended that on the

vote of £33,620 for residential and dispensary treatment of tuberculosis there should be a reduction of £7,000. This was agreed to by the Council, as was also a recommendation from the Asylums and Mental Deficiency Committee to the effect that the maintenance vote of £86,320 should be reduced by £12,032, the purpose in respect of which the reduction is to be made being that of asylum buildings for pauper lunatics.

THE NEED FOR WOMEN DOCTORS.

At the annual prize distribution of the Manchester High School for Girls on July 22nd, at which Professor Tout presided, an address was given by Mrs. Scharlieb, M.D., M.S. London, on the field that exists for women doctors. Miss Burstall, the head mistress, in her report described the many ways in which the girls had been working in connexion with the war. Four of the staff were absent on leave for special war work, and many of the girls had entered banks and public offices to fill the places of men on military service. Three of the sixth form science girls were working in laboratories on Government work, and many of the old pupils were serving as nurses and helpers in military hospitals. In introducing Mrs. Scharlieb, the Chairman said that one result of the war had been a wider recognition of the work done by women in the profession of medicine. Mrs. Scharlieb said that it was pleasing to find that many of the prejudices and difficulties that had stood in the way of schoolgirls in taking up their life work, especially if it happened to be the profession of medicine, were now melting away, and that the women medical students were now cordially welcomed and kindly judged. For some time past there had been great need for women doctors in India, and she strongly commended the scheme of the late Lady Hardinge for sending out more medical women, and even for training some in India. She was confident, too, that there was a great field opening out in this country for more medical women. They were wanted everywhere, and she could not hear of a single unemployed woman doctor. She urged girls to choose the medical profession for their life work. Even from a selfish monetary point of view it was a good choice. Within a few years of qualification a young woman doctor could earn four or five hundred a year, and by the time she was a woman of any standing she could earn a thousand a year. Many of them were earning even more than that. Those of them who had a more scientific turn of mind, and despised this world's profits, would find that plenty of research work was languishing for want of workers, while those who were humanitarians would find in the work of the woman doctor unlimited scope for their sympathies. At the close of her address, Mrs. Scharlieb distributed the certificates and prizes to the successful pupils.

India.

THE ST. JOHN AMBULANCE ASSOCIATION.

At the half-yearly meeting of the Indian Council of St. John Ambulance Association at Simla, the Commander-in-Chief presided, and Surgeon-General Sir Pardee Lukis, in presenting a report on Red Cross work, said that the Regum of Bhopal had generously subscribed Rs. 14,000 towards motor boats for the Persian Gulf in response to an urgent appeal from the A.D.M.S. He also alluded to the Indian Council's fleet of motor ambulances, three of which had been supplied from Assam, thanks to the efforts of Lady Earle. Sir Arthur Ker presented the accounts of the St. John Ambulance Red Cross War Fund, which gave details of the financial position. The Indian Council had Rs. 35,000 at fixed deposit, as a reserve, and a substantial working balance; when it was remembered that about five years ago the total assets of the Indian branch were only Rs. 300, this progress could be described as absolutely amazing. On the motion of the Commander-in-Chief, Sir George Roos Keppel, Raja Bahadur Singh of Raghogarh, Sir Sassoon David, Lieutenant-Colonel Jennings, I.M.S., and Rai Bahadur Karam Chand were elected honorary councillors. The Commander-in-Chief presented a preliminary statement with reference to the offer of the St. John Ambulance War Hospital in connexion with the 2-ray institution at Dehra Dun, showing that the hospital will

be organized, maintained, and equipped by the Indian Council. It has been offered to the Government of India for the reception and treatment of special cases of wounded officers and soldiers from overseas. The Council has been fortunate in securing Major Walter, I.M.S., an expert in medical electricity, as commandant of the hospital. The hospital will provide 2 beds for British officers, 2 for Indian officers, and 20 for rank and file. The estimated total cost per bed is Rs. 2,000 per annum. The estimated total cost per annum is half a lakh. At the hospital the following apparatus will be available: (a) Rapid exposure and single-flash radiographic apparatus, (b) special methods of localization of foreign bodies, (c) full-length electric baths and Schnee's four-celled bath for the administration of galvanic, faradic, sinusoidal, and rhythmically interrupted currents, (d) Bergonie's treatment; ionization for the treatment of sinuses, stiff joints, etc., (e) vibratory massage, (f) treatment by radiant heat and light, (g) high frequency and diathermic treatment.

BENGAL AMBULANCE CORPS.

The members of the Bengal Ambulance Corps, who have been in training during a short time only, have made themselves highly efficient, and are to leave Calcutta very shortly. The commandant is Colonel Nott, I.M.S., and the corps, it is believed, will be employed on field service connected with a hospital on the lines of communication in Mesopotamia. The amount originally promised for the scheme of one hospital flat is being satisfactorily realized, and the honorary secretary of the movement, Dr. S. P. Sarbadikbary, frequently receives offers of additional donations if they are found necessary.

Correspondence.

STUDENT DRESSERS IN VOLUNTARY HOSPITALS.

Sir,—I am directed to forward to you the enclosed copies of correspondence, with a request that you will be pleased to publish them in your columns. The first letter is one addressed to the three examining boards in London; the replies to that letter follow.

The request made by the West London Hospital appears to be reasonable and of urgent necessity in these days of war emergency. One examining board recognizes this emergency and grants the request. The other two refuse it, and, perhaps wisely, state no reason for their refusal.

Emergency has cut much red tape of late; even trade union rules have gone. But our examining boards still "bind heavy burdens and grievous to be borne, and lay them on men's shoulders, but they themselves will not move them with one of their fingers."—I am, etc.,

N. BISHOP HARMAN,
Vice-Dean.

The Post-Graduate College,
West London Hospital, Hammersmith,
July 20th.

Dear Sir,—Owing to the necessity for releasing medical men of military age, there is increasing difficulty in obtaining the necessary skilled assistance for the satisfactory working of general hospitals. The difficulty has been acutely felt at the West London Hospital. At the present time we are able in some degree to meet it by obtaining the assistance of senior students who are as yet unqualified, who work under the direction of the resident medical officers as dressers for surgical cases. These men are paid for the work, and found in board and lodging. To make this work really suitable for them without delaying the date at which they would ordinarily be able to proceed to their final examinations, I am authorized to make application to you for the official recognition of this hospital as a place of clinical study for men who have passed their intermediate examination. The hospital is at present recognized as a place of study for post-graduates and for men reading for higher professional qualifications. There is ample clinical material of all kinds, and full facility for personal teaching by the staff, both resident and visiting. We have at the moment two men acting as dressers in the surgical wards, and I shall be glad if your council will be pleased to grant the request made in this letter, that you will make it retrospective, so as to apply to these two men. The application for this recognition is for the duration of the war only.—I am, yours faithfully,

N. BISHOP HARMAN,
Vice-Dean.

June 19th.

Society of Apothecaries of London.

Blackfriars, London, E.C., 24th June, 1915.
Sir,—I am requested to inform you that the Court of Examiners are willing to recognize work done at the West

London Hospital for clinical teaching during the war "for students who have passed their examination in anatomy and physiology."

Would you be good enough to send me the names of the two students who are acting as dressers?—Yours faithfully,
FRANK HAYDON,

N. Bishop Harman, Esq., M.B., F.R.C.S., Secretary,
West London Hospital, W.

Examination Hall,

8 11, Queen Square, Bloomsbury, London, W.C.,
24th June, 1915.

Sir,—I have submitted your letter of the 19th inst. to the Committee of Management of this Board, and I am desired to inform you that they do not see their way to comply with your request.—I am, dear Sir, yours faithfully,

N. Bishop Harman, Esq., F.R.C.S., Secretary,
F. G. HALLETT,

University of London,
South Kensington, London, S.W.,
15th July, 1915.

Dear Sir,—I regret to inform you that, after consideration of your letter of June 19th last making application for the temporary recognition of the West London Hospital for clinical study for the purposes of the M.B., B.S. Examination, and of reports thereon from the relevant committees of the Senate, it was resolved by the Senate, at their meeting on 14th July, 1915, that the application be not acceded to.—I am, dear Sir, yours faithfully,
P. J. HARTOG, Academic Registrar.

The Vice-Dean, Post-Graduate College,
West London Hospital, Hammersmith, W.

ARE CASES OF CONGENITAL SYPHILIS BECOMING RARER?

SIR,—The annotation in the JOURNAL of July 17th on the exceedingly interesting report to the Local Government Board by Dr. Paul Fildes from the bacteriological laboratory of the London Hospital is worthy of wide attention. This report seems to give striking corroboration to the impression that many experienced clinicians have of the lessened frequency of congenital syphilis in London, as evidenced by observation in the wards and out-patient departments of hospitals set apart for children and babies.

I had occasion some time ago to inquire whether any notable diminution of this disease had been observed by my colleagues on the staff of the East London Hospital for Children where, during the twenty-four years from 1874 to 1898, such cases of unquestionable character may have been said almost to swarm both in the wards and among the out-patients. There was no limit of age for treatment or admission, and there were often many cases among the newborn in both departments. I was, last year, informed by Dr. Gossage, in answer to my inquiry, that the number of cases of congenital syphilis had diminished very remarkably; and that it was by no means easy to find marked cases for the purpose of illustration. Similar replies were given me by other observers elsewhere.

Dr. Paul Fildes suggests, as a general conclusion from his extensive observations, that the ravages caused by this disease among infants are sometimes exaggerated.

It is surely to be hoped, as you, Sir, have remarked, that further investigations on the lines of Dr. Fildes's work, and further clinical inquiries, may throw more light on the question of whether the frequency of congenital syphilis is actually diminishing.

For the purpose of duly comparing the present frequency with the past—for instance, with the period of twenty-four years that I have just mentioned—it must be remembered that neither the Wassermann test nor the specific sprochaete was known at the earlier time; and that the observed diminution of frequency to which I refer concerns especially such cases as are easily detectible without any test. It seems that the solution of this question will not be materially affected by any change or modification of treatment that may possibly have prevailed during the last seventeen years.—I am, etc.,
H. BRYAN DONKIN.

London, W., July 24th.

TARTAR EMETIC IN KALA-AZAR.

SIR,—The translation of the article of Dr. G. Di Cristana and G. Caronia in the May 15th number of the *Journal of Tropical Medicine*, reporting the successful treatment of the Mediterranean form of kala-azar by means of tartar

emetic intravenously, has just reached India. I therefore write to place on record the fact that I had previously commenced precisely similar treatment of the India form of kala-azar with most promising results. As a matter of fact, I had arranged to try this plan of treatment as far back as October last (1914), quite independently of any other worker, and even before I was aware of the success of Gaspar Vianna in the case of cutaneous leishmaniasis in Brazil, basing my hopes that it would very possibly prove to be a cure for kala-azar on the success of antimony treatment in some cases of the closely-allied sleeping sickness. Unfortunately at that time I was unable to obtain any suitable opportunity of trying it, and for over six months I actually carried about sterile solutions of tartar emetic put up in glass capsules ready for intravenous injection before I was able to use it.

I have, however, already treated ten cases, verified by spleen puncture, and have noted in several of them very marked and rapid decline of the temperature, together with some gain in weight, diminution in the size of the spleen, increase in the number of the leucocytes, and decrease in the number of the parasites found on spleen puncture—all most promising signs, although it is still too early to speak of any cure having been effected.

I may therefore claim to have originated the intravenous use of tartar emetic in kala-azar quite independently of any other worker, and to have obtained a considerable degree of success with it before any others' results came to my knowledge.—I am, etc.,

LEONARD ROGERS,
Lieutenant-Colonel, I.M.S.

Calcutta, June 28th.

THE SULPHUR MINES OF SICILY AND THE PHARMACOLOGY OF SULPHUR.

SIR,—I was much interested in your reviewer's excellent notice of Dr. Alfonso Giordano's work on the physio-pathology and hygiene of (sulphur) miners in Sicily, particularly as your reviewer has himself visited the mines in Sicily.

I had heard a good deal about the mines from an aged military patient who visited them in the old brigandage days, and for a considerable time I have wished further information with respect to what has been alleged about the multifarious properties of sulphur in therapeutics and which might be cleared up by studying the case of the sulphur miners.

Recently the discussion as to the effects of sulphur in rheumatism, etc., has cropped up again, and Sir Lauder Brunton¹ cited the case of a lady patient with rheumatism who achieved a "cure" by wearing sulphur in her stockings in bed.

Your reviewer might kindly say if Sicilian sulphur miners suffer from "rheumatism" in any or all of its forms.

It will be noticed that he states that the mine water frequently contains SH₂—Harrogate and Strathpeffer on a large scale—and that the air inhaled contains discrete sulphur particles, while, further, there must be abundance of SO₂ from oxidation. Another noticeable point is the presence of malaria, tubercle, and ankylostomiasis, in spite of the powerful parasiticide in the shape of the sulphur fumes and solution of sulphides present in the mines.

Such a method of studying therapeutics on the big scale may be fallacious from the possibility of a given disease being developed from or in spite of more than one cause or condition present, but may at times be useful. Thus, a number of years ago, Dr. Murrell of the Westminster Hospital, if I am not mistaken, pointed out that the creosote workers at Silvertown were wonderfully free or immune in respect of bronchial affections; while a couple of years ago, when lime water for rheumatoid arthritis was under discussion, I asked if it were possible for persons habitually using hard water to contract the malady, or whether, if so contracted under that or other conditions, they would not be cured if lime were a "cure"! Last year I saw a case of an elderly lady wheeled in a chair from effects of rheumatoid arthritis, living in a low damp neighbourhood, but where the water was extremely "hard." I merely cite this to show that one must take a number of factors into account in such questions. Still I think your reviewer and Dr. Giordano may be able to

enlighten us on the much discussed question of rheumatism and sulphur on the vast scale.—I am, etc.,

JAMES CAMERON, M.D. Lond. and Edin., etc.

Edinburgh, July 10th.

We have referred this letter to our reviewer, who writes: "During my stay in Sicily I did not observe any case of rheumatism among the sulphur miners. Giordano gives in his monograph a long list of diseases from which miners died; rheumatism, in any of its forms, is not mentioned. It is an interesting fact that notwithstanding the bactericidal and other properties of sulphur, ankylostomiasis a few years ago was extremely prevalent among the sulphur miners of Sicily. Although rheumatism is seldom met with, such physical defects as stunted growth and spinal curvatures are common owing to the boys carrying heavy loads of ore on one shoulder. I wrote to the Italian lady who translated Dr. Giordano's book for me. She is a sulphur mine owner, and her reply, which is as follows, confirms my opinion.

No, it has never come to my notice that sulphur miners, whether men or boys, suffer from rheumatism; you never hear about it nor see any one suffering from it. And yet, they often work with their feet in damp soil.

HEMERALOPIA OR NYCTALOPIA?

SIR,—In the annotation in the JOURNAL of July 10th headed "Hemeralopia amongst soldiers" I notice that the term is employed as a synonym for "night-blindness," which I venture to think is inaccurate. Hemeralopia is, of course, a coined word invented in contrast to nyctalopia, which, if the accepted derivation be correct, namely, *νυκτός-ἀλαπίς* (*álapis*, blind; *ἄψ*, the eye) can only mean "night-blindness," and therefore hemeralopia (*ἡμερίας-ἀλαπίς*) must signify "day-blindness." Yet by some confusion of ideas hemeralopia has come to be used in the sense of "day-vision" instead of "day-blindness," and the "night-blind" is called "hemeralope" because he can only see by day, which, were he really "hemeralopic" he could not possibly do. Apparently the force of the root "*ἀλαπίς*," which occurs in each word, is no longer observed. Such confusion has become so prevalent that certain distinguished ophthalmologists have suggested that both "nyctalopia" and "hemeralopia" should be left out of the *Nomenclature of Diseases* in order to avoid ambiguity. Although I am not prepared to agree to this proposal, at least so far as "nyctalopia" is concerned, it must be admitted that there is ample excuse for an ambiguity which dates from the days of Hippocrates and Galen. It was partly Galen's fault, and partly that of a careless transcriber of Hippocrates.

Hippocrates originally defined *νυκτάλαψ* as *ὁ τῆς νυκτὸς ἀπὸ ἄραυ*, but the copyist left out the "*ἀπὸ*." Now, Galen must have been acquainted with the correct version, for in his "Glossary" of Hippocratic terms he defines *νυκτάλαψ* as *ὁ τῆς νυκτὸς ἀπὸ ἀραυ*. Nevertheless, in his own works, Galen describes two precisely opposite conditions under the heading "*νυκτάλαψ*."

In Book XIV, p. 776 (Kühn), he says: "They call them nyctalopes when they see dimly by day, more clearly when the sun goes down, and still better by night. Or, conversely, when they see little by day, but not at all in the evening or by night." Obviously he is describing hemeralopes in the first and nyctalopes in his second definition. In Book XIV, p. 435, he says: "*νυκτάλαψ* is a complaint or condition of the eyes, the cause of which is not plain. It happens to those so constituted, that they cannot see by day, but can do so by night." Here again, he describes hemeralopes as nyctalopes, and practically contradicts the Hippocratic definition of *νυκτάλαψ*, which he himself gives in the Glossary. One can only conclude that owing to the discrepancy in the MSS. he was divided in mind as to what Hippocrates really meant by *νυκτάλαψ*. As a Greek, he must have known that it could not possibly imply "night-vision," yet out of respect for Hippocrates (almost the only authority for whom he had any respect), he endorsed the spurious version (*ὁ τῆς νυκτὸς ἀπὸ ἄραυ*) until he came upon the genuine text.

Aristotle gave rise to further complication in the question. In his *De Animalium Generatione*, Lib. V, p. 1137 B, he does not use the term *νυκτάλαψ* at all, but *νυκτάλαψης* (pl. *νυκτάλαψες*). This literally means "night-fox," but is rendered *Luscitiosus* by the translator of the 1629

edition. *Luscitiosus*, according to Lewis and Short (Latin Dictionary, 1886), is "one that cannot see in the dusk, or by lamp-light," and according to Isidorus Hispalensis, "*Qui vesperi nihil videt*" (*Etymologicæ*, Book X, p. 52). Hence it appears that *νυκτάλαψ* and *νυκτάλαψης* were regarded as synonymous, each meaning "night-blindness." Yet Aristotle does not define *νυκτάλαψης*.

He only says that it occurs in "black-eyed persons, and is caused by excess of moisture, and therefore chiefly affects the young." Now it is difficult to see how words of such different derivation as *νυκτάλαψ* and *νυκτάλαψης* could be regarded as synonyms. May it be that Aristotle gave the name of "night-fox" to those who, like foxes and other beasts of prey, see best at night? If so, it is possible that Galen's ambiguity was partly due to his including the "night-sighted" of Aristotle (*νυκτάλαψης*) with the "night-blind" (*νυκτάλαψ*). The confusion thus created still exists, but the preponderance of opinion amongst early writers such as Palladius and Aetius is in favour of the view that nyctalopia means "night-blindness," which is totally different from hemeralopia or "day-blindness." Indeed, there does not seem to be any necessity for retaining the term "hemeralopia." Such a condition as "day blindness" does not exist, as far as I know, except in cases of photophobia induced by some kind of inflammatory affection, and these were probably the cases which Galen described as "seeing more clearly after the sun goes down," and Aristotle as *νυκτάλαψες* or "night-foxes." If it is necessary to provide a word which implies vision by day but blindness by night, it should be "hemeralopia," but certainly not "hemeralopia."—I am, etc.,

LEONARD GUTHRIE,

Honorary Secretary, Nomenclature of Diseases Committee, R.C.P.

London, July 11th.

THE SUPPLY OF MEDICAL OFFICERS.

Temporary Rank in the R.A.M.C.

SIR,—I desire to enter an earnest protest against the letters appearing under this heading in your issue of July 17th. Whilst multitudes of men over 40 would gladly give up great prospects to serve in any humble way in the forces of the Crown, but find the door closed to them in ordinary cases, we of the medical profession have the inestimable privilege of serving our country under what I consider to be generous conditions. Let us consider separately the two questions of pay and rank.

As regards pay, we receive an allowance which is much higher than that which, under normal circumstances, would be granted to a lieutenant; and, though it will mean financial loss to some, yet that is not worthy to be compared with the loss of professional men in other callings, whose only avenue to service for their country may be through the ranks, or by becoming a second lieutenant at a comparatively small salary.

But the main question before us is that of rank. I consider it a high honour to sign myself "Lieutenant, R.A.M.C.," and, although I am 50 years of age and have only had three months' service, I have not found that my rank has hindered me from using any powers which I possess in the best way. I am on the staff of one of the home hospitals, which, with two exceptions, is worked by lieutenants, each of whom has a large measure of responsibility, and, so far as I have seen, we have better professional work than those of higher rank who are largely concerned with administration.

The idea that age should be the test for advance in rank in spite of want of experience is most unreasonable. It would hold in no walk of life. The man who wishes to attach himself to any new undertaking when over 40 will inevitably find that he must play second fiddle to juniors. It is so even in our own profession.

Your correspondents write as if to serve in the army as a medical officer was quite on all fours with general or any other kind of civilian practice. Obviously it is not, and if there is any cause for complaint it would with much more justice come from the regular officers of the R.A.M.C. or of the Territorial Force, who have seen us new recruits admitted to the service on a specially favoured footing.

I hope we may soon see an end of these grumbles. I do not think they are worthy of our great profession, which is certainly not wanting in patriotism. No one is bound

to serve his country in this special way if the conditions seem too difficult, but if we do so, let us do it cheerfully.—
I am, etc.,

July 22nd.

A TEMPORARY LIEUTENANT OF FIFTY.

P.S.—Although this letter is only posted to-day, and I have since read the letters in your issue of July 24th, I do not see reason to modify my comments. I will only add that I see in the orders published yesterday that temporary lieutenants, on receiving their agreement, will become temporary captains if their record is satisfactory.

July 27th.

“In consequence of the appointment by the Representative Meeting of a War Emergency Committee to deal with all matters affecting the medical profession arising in connexion with the war, letters addressed to the Editor on this subject will for the present be referred to that Committee.

INDEMNITY DEFENCE POLICIES.

SIR,—Attention has been called to the following statement that was made in our annual report, to which statement the Medical Defence Union have taken objection:

In comparing the indemnity provided by this society against costs of the other side and damages awarded against members, with the indemnity provided by other societies or insurance companies, it is important to remember that this society indemnifies against costs of the other side when actions are brought by the society on behalf of members (as, for instance, when an action for libel is brought on behalf of a member), whereas other societies or companies limit their indemnity to cases in which actions are brought against members as defendants, no indemnity being provided for costs of the other side where the member is the plaintiff.

The statement, so far as it refers to the Medical Defence Union, was made upon a statement contained in their annual report of 1914, p. 41, and was as follows:

The liability of the “Yorkshire Co.” shall be confined to damages which may be awarded and taxed costs of the other side in losing defensive actions only, or to the agreed damages and costs where the actions have been compromised.

We now for the first time understand from the Secretary of the Medical Defence Union that the words “defensive actions” “include cases where a member has been libelled and slandered and he is a plaintiff, and in respect of which we take action for his defence against unfounded allegations.”

We therefore accept the explanation of the construction of the words “defensive action” as now given by the Medical Defence Union, and will, of course, give this explanation in our next report.—I am, etc.,

HUGH WOODS,

General Secretary of the London and Counties Medical Protection Society, Limited.

London, W.C., July 21st.

WOMEN NURSES FOR MALE ASYLUMS.

SIR,—The male attendants of military age employed in asylums have as a class not been backward in their duty to their country. Many of them enlisted at the beginning of the war, being encouraged to do so by the loyal attitude of asylum boards and committees as regards pay, etc., and the vacancies created by these absentees have since been largely filled by men who are ineligible for military service. There are still, however, at the present time very many able-bodied young men employed as attendants on the insane. The presence of some of these is necessary, but the number required can be considerably reduced by the substitution of female nurses, especially in place of those attendants engaged in nursing the sick in the male hospitals and male infirm wards of asylums.

Fifteen years have now elapsed since the experiment of employing women on a large scale to nurse male patients in an asylum was tried in Scotland. All that was then said as to the advantages of female nursing for insane men under certain limitations has since been proved true by many observers, and the fears of the early opponents of this system have been found to be negligible, for the dangers that they prophesied have by forethought and care been avoided. The system is now, from the practical experience they have gained of its benefits, very strongly advocated by the Scottish Board of Control, and

their judgement can be accepted without reserve. It has been all but universally adopted by the Scottish asylums.

As there is every indication that all eligible males who can be spared will soon be wanted for our military forces, I take this opportunity of directing the attention of the medical superintendents and the members of boards and committees of asylums in England to this system, as it has up till now scarcely been introduced into English asylums. Not only will they be doing a patriotic duty by introducing these female nurses to enable more of their male attendants to enlist, but they can be assured that they will at the same time be adding to the comfort and well-being of the sick and infirm male patients under their charge.—I am, etc.,

The Royal Asylum,
Morningside, Edinburgh,
July 21st.

GEORGE M. ROBERTSON, M.D.,
Physician-Superintendent.

THE ACTION OF DIGITALIS ON THE BLOOD VESSELS.

SIR,—Will you permit me to state that by a *lapsus calami* in the report of the Cameron Prize Committee, the date of Sir Lauder Brunton's thesis on digitalis was stated to be 1868 whereas it should have been 1866? As a question of priority in the discovery of the action of digitalis on the blood vessels is involved, you will oblige me by publishing this note in the JOURNAL.—I am, etc.,

THOMAS R. FRASER,

Chairman of the Cameron Prize Committee.

Edinburgh, July 26th.

Public Health

AND

POOR LAW MEDICAL SERVICES.

THE NOTIFICATION OF BIRTHS EXTENSION BILL.

DR. R. R. RENTOU (Liverpool) writes: The above bill proposes to make the Notification of Births Act, 1907, apply to all areas in the United Kingdom. Some of its points require careful attention. Unfortunately, it neglects to provide for the payment of any fee to the person notifying. When we consider that all vital statistics, insurance of life calculations, and many other national questions are placed upon doctors, and that no fee is paid to them for notifying and certifying, we can see that the limit of medical charity has been passed. A fee of 3s. 6d. should be paid out of the public funds. A most important point is that the bill is most defective in regard to a practical definition of “stillbirth.” Section 1(5) of the 1907 Act states that only stillbirths of and over the age of 7 months' intrauterine life shall be notified. The defect is further emphasized, when we see that the definition given by the Central Midwives Board is, “a child is deemed to be stillborn after being completely born if it has not breathed or shown any sign of life.” Here no intrauterine age is mentioned, and so the midwife may notify only fully developed infants. I would suggest the following clause be added:

Every stillborn child in which the external sex organs—that is, from the fourth and a half month and upwards—of intrauterine life shall be notified by the medical practitioner, or midwife, or person present at the birth. The age and sex of the child shall be notified, and whether the child is dead or not at the time of the birth. The fact shall also be notified as to whether the child was alive during its birth, or showed symptoms of death in the womb for some hours or days before birth. Only one form of official notification form shall be used, such being supplied free by the Registrar-General's offices. Each year a return showing the number of stillbirths notified, with their age, sex, legitimacy, and appearance of life or death, shall be laid before the three Registrar-Generals of the United Kingdom before Parliament.

The present war compels us to afford more protection to the intrauterine child. It is quite easy to criminally prevent an infant during its birth from breathing, and both criminal abortion, feticide, and infanticide are on the increase. I would almost prefer to have it made compulsory that every conception must be notified for this would give us insight into the real loss to England through children being stillborn.

In 1890 I found that at 71 burial board cemeteries in England 6,321 stillbirths had been interred in one year alone. The late Dr. Cameron, M.P., called attention in the Commons to these statistics and then moved for a full return. It was granted during 1899 the following figures were returned in England and Wales: 17,335, and that 4,562 had been interred without a doctor's certificate. It will be noted this return did not include any cemeteries other than those belonging to public burial boards, probably about 10,000. In 1895 a further return, “Stillbirths in England and other Countries,” was issued. It is most unfortunate that the larger the child and the later the marriage of parents the more likely is the child to be stillborn, and further that more male than female children are stillborn. This imposes a great loss to the country in future husbands and men.

Obituary.

EDMUND OWEN, LL.D.(HON.) ABERDEEN, D.Sc.(HON.) SHEFF.,
M.B.LOND., F.R.C.S., CHEVALIER DE LA LÉGIION
D'HONNEUR.

CONSULTING SURGEON TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL
FOR SICK CHILDREN; SURGEON TO THE FRENCH HOSPITAL;
SURGEON-IN-CHIEF ST. JOHN AMBULANCE BRIGADE.

(With Portrait on Special Plate.)

We regret to have to record the death of this distinguished surgeon, for many years so well known to the profession in London for his handsome presence, his brilliant social qualities, and his zeal for his profession. On July 13th, when walking down St. James's Street, he had a sudden attack of right hemiplegia, and was taken to Charing Cross Hospital. He never regained consciousness, and died on Friday afternoon, July 23rd.

About one hundred and thirty years ago Daniel Owen, on leaving school in London, obtained an appointment with a mercantile house at Halifax, Nova Scotia. He married there, and had a large family, mostly sons. One of these was William Bay Owen, who was sent to Edinburgh as a young man to qualify as a surgeon. After serving the apprenticeship then customary and passing the examinations, he set up in practice at the exceedingly picturesque village of Finchingfield, about ten miles from Braintree. About 1840 he married in London Mary Blackett, by whom he had eight children. The third of these, born April 7th, 1847, was christened Edmund Blackett. His father, W. B. Owen, remained at Finchingfield till 1860, building up, thanks to his skill, integrity, and great personal popularity, a very large country practice. Finchingfield was, however, in the wilds of Essex, and in the interests of his young family, then consisting of five sons and two daughters, he decided to go to London, and in the year mentioned he bought a practice and took up his residence at Cleveland Square, Hyde Park, where he continued to practise for many years.

Edmund Owen, on leaving school in 1862, entered as a student at St. Mary's Hospital in 1863, the intention being that he should eventually assist in his father's practice. From the beginning, however, anatomy and surgery appealed strongly to him, and he decided to abandon the idea of general practice in favour of pure surgery. He was resident medical officer to St. Mary's Hospital in 1868 and studied for a time in Paris. He took the diplomas of M.R.C.S. in 1868 and of F.R.C.S. in 1872. At the end of the year 1868, as he had shown himself to be a good anatomist and an able teacher, he was elected demonstrator of anatomy, holding that office until 1875. He was appointed lecturer on anatomy in 1876 and retained that position until 1888, when he was made lecturer on surgery. In June, 1871, he was elected surgeon to out-patients, becoming full surgeon in 1882. Twenty years later, in 1902, he retired and was made consulting surgeon; he had resigned the lectureship in surgery in 1896.

Edmund Owen was on the staff of the Hospital for Sick Children, Great Ormond Street, for many years, as assistant surgeon in 1877, and full surgeon in 1885. On his retirement in 1898 he was made consulting surgeon.

Edmund Owen was elected a member of the Council of the College of Surgeons in 1897, holding his seat after a re-election, until 1913, and was twice Vice-President (1905-6 and 1906-7). As Bradshaw Lecturer in 1905, he named his discourse "Cancer: Its Treatment by Modern Methods." He expressed regret that it was out of his power to call attention to any modern method of treatment of cancer which could honestly and confidently promise a cure, but he believed that the results of experimentation held out hopes for the future. The Hunterian Oration, delivered by him in 1911, was the last in the first centennial of these famed biennial discourses, for as the lecturer announced, the century then lacked but two years of completion since Dr. Matthew Baillie and Sir Everard Home, John Hunter's executors, in their desire to show a lasting respect to his memory, provided for the delivery of an Oration on February 14th, his birthday. His audience agreed that Edmund Owen really succeeded in making his lecture a discourse worth listening to, for it was an analytical sketch of Hunter's life and labours.

Owing to his reputation as a teacher, Edmund Owen

held many examinerships in the course of his professional career. In 1883 he was placed on the Board of Examiners in Anatomy and Physiology at the Royal College of Surgeons, in 1884 on the Fellowship Board, and in 1899 on the Court of Examiners. In 1884 Edmund Owen was elected examiner in anatomy for the second examination of the Conjoint Board. He was also at various times examiner in surgery to the Universities of Durham, London, and Cambridge.

Owen was the author of several books on medical subjects. He published *A Manual of Anatomy for Senior Students* in 1890. In writing it, he was actuated by a desire to leave some permanent record of his labours during the twelve years that he held the chair of anatomy in the medical school of St. Mary's Hospital, such as might be of interest and assistance to senior students. The manual was carefully prepared, and included not merely that which is universally understood to be "surgical anatomy," such as the course of big vessels and the influence of muscles in displacing the ends of fractured bones, but also much relating to malformations, like talipes, and to visceral anatomy and other subjects previously studied in the medical, rather than in the surgical, wards of hospitals.

Edmund Owen's textbook on *The Surgical Diseases of Children* appeared in 1885. It was a model of condensation. At the date of its publication intestinal surgery was beginning to develop, and the bold procedures now so often undertaken were opposed on the principle that expectant treatment was safer than resection. We noted at the time how Owen made a very pertinent observation in reference to spontaneous recovery. "The report of one instance would attract much attention, whilst very possibly fifty children might have died of unrelieved strangulation without special record being made. Thus, Nature became accredited with a power of working a cure in internal strangulation, which, if misapprehended, is likely to involve great disappointment." This textbook went through three editions, and Dr. Laurent translated it into French, under the title, *Traité pratique de chirurgie infantile*.

In *Cleft Palate and Hare-lip: The Earlier Operation on the Palate*, published in 1904, Edmund Owen expressed his opinion that the most favourable time for operating on a cleft palate was between the age of 2 weeks and 3 months. He commended and followed Brophy's principle—that cleft palate should be operated on by the bold thrusting of the maxillary and palate bones together in the middle line. Owen urged that however wide a cleft of the hard and soft palate might be, it was advisable to operate on the entire cleft at once rather than to divide the operation into two parts, one for the hard palate and the other for the soft.

Edmund Owen's last work was *Appendicitis: A Plea for Immediate Operation*, issued in 1914. It was based on a paper which he had read a year previously at a meeting of the Medical Society, a memoir which led to much discussion and correspondence. A leader on that paper appeared in our columns on February 22nd, 1913, followed by no less than twelve letters in succeeding numbers of the JOURNAL. Owen, and most of the surgeons who discussed his memoir, were in favour of immediate operation, and by "immediate" they meant operation as soon as the diagnosis was made, and within the first twelve hours of illness if possible.

The article "Surgery" in the eleventh and current edition of the *Encyclopaedia Britannica* was written by Edmund Owen. It included a good summary of the history of surgical art and science, and the author was careful to award impartial credit to the ancients. He showed how among the Hindus surgery underwent important developments, though the relation of Indian to Greek and Chinese surgery was hard to determine since the antiquity of Sanskrit works on the subject was much disputed. The Arabs, on the other hand, did little more than preserve the bequest of the ancient world in medical lore, as in the arts and letters. It was not only the Arab fear of blood and the dread of prying into the secrets of anatomy that hindered the advance of surgery amongst the Spanish Moors: the main factor in the stagnation of surgical art and practice was the fact that the patients, acting on the principles of their creed, whilst accepting with equanimity the suffering that fell to them, declined the means of alleviation.

Edmund Owen

In November, 1898, Edmund Owen read a paper on "A Distinct Variety of Hip-joint Disease in Children and Young Persons" before the Royal Medical and Chirurgical Society; it is to be found in the eighty-second volume of the *Medico-Chirurgical Transactions*. He related his experience of a certain type of acute suppurative disease to be distinguished from the well-known tuberculous affection so common in the hip joint. It arose through the invasion by the micro-organisms not of tuberculosis, but of septic osteomyelitis, seated in the very active tissue at the upper extremity of the diaphysis of the femur. The paper gave rise to free discussion, especially as to treatment.

Besides the monographs that have been mentioned, Edmund Owen was active in delivering addresses and in reading papers before societies and joining in discussions.

In 1884 an International Health Exhibition was held in London, and the lectures delivered there were published in book form. Among them was a discourse on the rearing of hand-fed children, by Edmund Owen, which led to a friendly passage of arms with the chairman of the meeting, Dr. Charles West, characteristic of both men. Owen said that he felt uncertain as to the alleged increase or diminution of wasting diseases, such as rickets, in the present day, and referred the question to the experience of the chairman, who retorted that he was not Methuselah, and that the desired evidence would require an experience of hundreds of years, one long life being quite insufficient. Both Owen and West dwelt on the really serious question of feeding-bottles, agreeing that the "improved" modern patterns then in vogue were faulty, and should be rejected.

In the autumn of 1892, Edmund Owen read at a meeting of the Royal Medical and Chirurgical Society a memoir on the radical treatment of severe talipes equino-varus in children, published in the seventy-sixth volume of the society's *Transactions*. He denounced subcutaneous tenotomy as an anachronism, and insisted that the tendo Achillis should first be divided before the plantar fascia and the tendons of the tibials. He approved of Phelps's operation in these severe cases; after the tendo Achillis had been divided every resisting structure which was encountered was severed by a free vertical incision passing from the dorsum of the foot into the depths of the sole over the head of the astragals. An improved position of the foot was thus obtained by the lengthening of its inner, rather than its outer, border. Some surgeons of the older school, in discussing Owen's paper, strongly opposed the setting aside of subcutaneous tenotomy. It is instructive for the surgeon of to-day to bear in mind how much active discussion on this subject was current at the date to which we refer. In the same year, 1892, Mr. Walsham read at the annual meeting of the Association at Nottingham another important paper on the treatment of severe club-foot. It was published in the *JOURNAL* (vol. i, 1893, p. 339), and gave rise to much discussion in our pages. Walsham opposed operations such as Phelps and Owen practised, and declared that division of the tibial tendons was rarely necessary as, in his opinion, they had little influence in the production of the deformity.

In 1904 Edmund Owen delivered at the Leeds Medical School, at the beginning of the winter session, an address on William Hey and medical education. He dwelt on Hey's remarks on internal derangements of the knee-joint, and rightly gave the great Leeds surgeon the credit of having first described it. The lecturer, of course, referred to Hey's "well-known saws," but did not dwell on them specially, for he merely turned attention to the drawings in Hey's *Practical Observations in Surgery*, and those who care to look up that classic work will find that Hey himself admits that the saw was designed by another surgeon, named Cockell, and on reference to Scultetus and Parc, it will be seen that this well-known instrument was modified from an older type of skull saw.

Owen's Lettsomian Lectures, delivered before the Medical Society of London in 1890, were published in a volume entitled, *The Surgery of Infancy and Childhood*. Among the subjects dealt with in these lectures were heredity in hare-lip, congenital cystic hygroma, coloboma of the eyelid, and sterno-mastoid tumour.

Edmund Owen became a member of the British Medical Association at an early stage of his career, and, from the time when, in 1883, he was secretary of the Section of Surgery at the annual meeting in Liverpool, he took a

part in its affairs which grew steadily in importance. He was vice-president of the Section of Surgery in 1885 at the annual meeting in Cardiff, and president of the Section at the annual meeting in Swansea in 1903. In 1899 he was president of the Section of Diseases of Children at the annual meeting in Portsmouth, and delivered an address on "Ununited Fractures in Childhood." At the annual meeting held in Sheffield in 1908 he delivered the Popular Lecture on "Dust and Disease," in which he dwelt on the value of Pasteur's and Lister's researches, trade diseases, and the close relation of smoke to dust. It was a brilliant address, very well received. But undoubtedly his greatest service to the Association was rendered during the controversies which attended its reorganization in 1900 and the following years. As was inevitable, the proposals excited a good deal of feeling, and it was with great satisfaction that all friends of the Association heard that Edmund Owen had accepted the office of Chairman of the Constitution Committee. It was felt that he was a man whose impartial judgement and genial temperament made him well suited to compose differences, and in accepting the office he was doubtless influenced by the strong patriotic principles with which he was imbued, and his deep belief in the unity of the British Empire. He completed this part of his work for the Association by presenting the report of the Constitution Committee at the annual meeting at Cheltenham in 1901, in a speech full of wit and good humour, which many of those who heard it declared to be a masterpiece of persuasive eloquence. There is no doubt that his work on the Committee, and his presentation of its report, went far to convince many members of the Association that the new constitution should have a trial. The interest he was known to take in the Overseas Branches led to Mr. Owen's election to be Chairman of the Colonial Committee appointed by the Association in 1902, and in 1907 his popularity and the high opinion held of his business capacity and devotion to the interests of the Association led to his election to be Chairman of Council, an office which he held until 1910.

Edmund Owen was Honorary Associate and Knight of Grace of the Order of St. John of Jerusalem; President of the North-West London Boy Scouts' Association; member at one time of the Medical Board, University of Wales; member of Council of Queen Victoria's Jubilee Nurses' Institute; and member of the Committee of the Cancer Research Fund. He was Orator of the Medical Society in 1897 and its President in 1899, and also President of the Harveian Society, corresponding member of the Imperial Medical Military Academy (Petrograd), of the Canadian Medical Association, and the Association of American Orthopaedic Surgeons, consulting surgeon to the Paddington Green Children's Hospital, the Royal Masonic Institute for Girls, and honorary surgeon to the Royal Society of Musicians.

Edmund Owen, as has been said, was imbued with a high spirit of patriotism, and shortly after the outbreak of war he found thoroughly congenial duties as surgeon-in-chief to the St. John Ambulance Brigade. Here again he had an opportunity of exercising his powers of conciliation, for the relations between the St. John Ambulance Association and the Red Cross Society had for some years been strained. But difficulties were smoothed away, and last autumn a joint committee was formed and joint offices opened in Pall Mall, where Sir Frederick Treves on behalf of the British Red Cross Society and Edmund Owen on behalf of the St. John Ambulance Association worked amicably together in the selection of medical personnel and the organization and training of orderlies. Edmund Owen threw himself with all his old energy into this congenial work, and in a letter published in the *JOURNAL* of November 28th, he expressed the principle by which he was guided "that nothing is too good for our sick and wounded soldiers and sailors." This principle was illustrated by the fact which was the occasion of his letter, namely, that it had been made "as impossible for an untrained nurse to obtain work under the British Red Cross Society as it would be for an unqualified practitioner to get his name upon the *Medical Register*." He added that a certain number of women from the Voluntary Aid Detachments of the two societies were being employed to help in the work of the ward, the kitchen and storeroom, and that they had been given the title not of nurse, nor even of

probationer, but of woman orderly. It was while leaving his work at the joint office of the British Red Cross and the St. John Ambulance Brigade that Edmund Owen suffered the seizure which was so quickly to bring his useful and distinguished career to an end.

Edmund Owen married in 1882 Annie Laura Clayton, of Brynmallo, near Wrexham. She died a decade ago. A few years before her death he purchased a quaint old house at Malham Tarn, a lovely spot near Settle, in the Craven district, Yorkshire, which it was his delight to visit whenever his busy life afforded him the opportunity. Owen, as a student, took keen interest in cricket and football, being captain of the hospital football team. At Malham he devoted himself to his garden, but he was also an enthusiastic fisherman. He was a member of the Marylebone Cricket Club (Lords), at which he loved to spend a leisure hour watching his favourite game. He leaves four daughters. For the home of his boyhood, Finchingham, he always preserved a great affection.

The funeral service was held at the Golden's Green Crematorium at 10 a.m. on Thursday, July 29th.

Mr. HERBERT PAGE has favoured us with the following appreciation of Mr. Edmund Owen:

It came as a severe blow to hear of the sudden, mortal illness of Edmund Owen. If there ever were a man who seemed to be alive both mentally and bodily it was surely he, and it is hard to think of him save in the full possession of all his faculties. I met him for the first time in 1875, at a garden party at Mr. T. B. Curling's place near Stoke Poges, and even in our young days was attracted by his striking personality. Shortly afterwards I became his colleague, and from that time to this, at St. Mary's, at the College of Surgeons, and, as a fellow examiner, have been in constant touch with him and his work, and admiration for his strength, manliness, and high character has grown into real affection for him. I mourn the loss of a very dear friend. And what of his surgery? His works on the surgical diseases of children, on cleft palate and hare-lip, and on club-foot are of course known to every one, and in these departments he was a recognized authority. Here, as an operator, he was doubtless seen at his best, while in general surgery there was marked distinction in his work. There was nothing which he feared to undertake; and whatever arose was overcome by his courage and resourcefulness, and by his knowledge of anatomy, in which he had been a teacher for many years. If onlookers might criticize, they would perhaps have said that he gave too little thought to loss of blood, and he of all men, honest to the backbone, would have least liked that this should not be said if it were genuinely believed. At first he took up an attitude of opposition to Listerian antiseptic methods, and poured contempt, both oral and written, on the ritual of the spray. He even went further than this, and at one of the societies—I think the Medical—when Lister brought forward his open operation for fractured patella, Owen, with characteristic temerity, remarked, in parody of a famous saying, that it might be magnificent but was not surgery. His papers and addresses on innumerable subjects were always pointed and suggestive, while his little book on *Appendicitis: a Plea for Immediate Operation*, published only last year, was one of the best things he did. A lucid writer, gifted with a singularly charming and effective style, his work has, I do not doubt, had much influence for good, and is of lasting value. In the copy which he sent me this was written—"With kindest possible greetings of a former colleague and perpetual friend." Beautiful words, and just like Owen to write them.

The record of his long service to St. Mary's, both as surgeon and teacher, it is not easy to condense in words. An incisive speaker, having a marvellous store of apt illustration, he was a born teacher, as hundreds of students would amply testify. There was nothing anywhere quite like Owen's class in the theatre at the close of operations. By informed questions, by encouragement and sympathy, by veiled irony and gentle ridicule, by humorous invective, by instructive anecdotes of professional experiences, he seemed to draw all the boys unto him, and not even the most stupid of "chronics" was afraid to go to the class again. Then the transparent honesty of the man, shown not least in an impulsiveness which led him to hasty conclusions, soon to be put aside, so that he would vote

to-morrow against that which he had advocated to-day. You forgave, you laughed, and loved him the more. And now his life here is run, and we lay this garland on his hearse. His memory will long abide, as that of a fine Englishman, fearless, independent, straight, free from self-seeking, held in respectful veneration by countless students, trusted by his colleagues, and withal a most lovable man.

Dr. WARD COUSINS (Southsea), who was President of the Association in 1899-1900, writes: I am greatly grieved to hear of the sudden death of our very distinguished colleague, Mr. Edmund Owen, and the sad news will cause great regret through the length and breadth of the British Medical Association and the profession everywhere. His kindness of heart and very genial manner made him a great favourite with every one. As for myself I feel that I have lost one of my best and oldest friends.

Mr. J. H. MORGAN, C.V.O., writes:

Following closely on the decease of his predecessor, Howard Marsh, the death of Edmund Owen makes a marked blank in the ranks of British surgeons. The day before his fatal seizure he lunched with the writer at the Athenaeum, and spoke cheerfully and enthusiastically of his work in connexion with St. John Ambulance and the Red Cross, of which, with Sir Frederick Treves, he was the active and energetic organizer. Few would have guessed who saw him stride out of the club with his fine tall figure and handsome face that he would never enter it again. He had been talking of his work and a prospective holiday at his place in Yorkshire, where he spent many happy hours with his daughters, and where he revelled in the delights of his garden and an occasional day on the neighbouring stream, where he loved to stroll with his rod and reel.

Of his earlier career the writer is unable to speak from personal knowledge, but he rose rapidly through all the grades to the position of senior surgeon at St. Mary's Hospital, where he was deeply beloved by students and respected by his colleagues. At the Hospital for Sick Children he was always energetic, attending punctually in the wards and at the meetings of the committee. Kindly and enthusiastic, he was ever ready to reconsider his opinion, and would often after proposing a motion abandon it and vote for an amendment which was the direct antithesis of his own proposal. As a colleague he was always sympathetic and kindly, warmly supporting any scheme or suggestion which appealed to him. As an operator he was bold and forcible, but he was particularly interested in such delicate operations as those for hare-lip and cleft palate, on both of which he published articles. His handbook on *Surgical Diseases of Children* had a large circulation and was well received. As an examiner he was always kindly and sympathetic. He served two periods on the Council of the College of Surgeons, and became Senior Vice-President, and felt keenly disappointed when he was not elected to the office of President.

As a young man he sang in the choir of his church, and throughout life was enthusiastic on the subject of church music, attending the service at St. Paul's on Sunday afternoons. He was a prominent Mason, and held office in more than one Lodge. Although he professed to dislike it, he was a pungent and witty after-dinner speaker, and his appearance in that capacity at the annual dinner of the Medical Society was always warmly greeted. Besides his published works, he was a frequent contributor to the medical papers as well as to *Notes and Queries* and other periodicals. Both within and outside his profession he had many friends, who will mourn the loss of one who was always sincere and constant in his goodwill to others.

Mr. F. RICHARDSON CROSS, of Bristol, writes:

In the passing of Edmund Owen the profession of surgery has lost one of its leaders, respected for his uprightness and high sense of duty, and honoured for the active part he has taken in medical ethics, and in the progress and improvement of surgical practice and in its teaching. He was endowed with good health and a fine physique. His personality and ability as a student soon attracted the attention of his seniors, and he made an unusually early entry into important positions in the profession, for almost before he had taken his F.R.C.S. he

was elected on the honorary staff of St. Mary's Hospital and an examiner in anatomy at the College of Surgeons. This early recognition was not misplaced, for he rapidly became one of the most popular teachers both in anatomy and surgery. He was a well known figure in his earlier days at several meetings of the British Medical Association. I went with him to America on the occasion of the Congress at Washington in 1887, and ten years later to St. Petersburg, when we represented the Royal College of Surgeons of England at the celebration of the centenary of the foundation of the Russian Army Medical Service, and at which an enormous number of delegates from all parts of the world were present. We had the especial honour of being in a small party of European surgeons who were one by one received in conversation by H.I.M. the Czar and afterwards took lunch with General Kuropatkin. Owen was always in good spirits, courteous, and amusing, but not at the expense of others. I never remember him saying an unkind word of any colleague, and he showed no unfair bias against opinions he did not agree with. If he could not speak well or kindly of men or matters he did not discuss them. He was a hard worker. He wrote and spoke forcibly and well. Perhaps by nature somewhat impulsive, he carefully considered his subject with ability, shrewdness, and common sense, and, having formed his opinion, he was fearless and honest in expressing his views, which were usually sound and accurate. His work for the Royal College of Surgeons as an examiner and on the council was whole-hearted and of the highest value. He had been an active member of all the subcommittees, and the personal knowledge and long experience that he had of its affairs made him one of its most trusted leaders. He has been spared from old age, and has gone down at his post and in his work.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following degree has been conferred:

M.Ch.—A. H. Southam, Christ Church College.*

The following candidates have satisfied the examiners:

DIPLOMA IN PUBLIC HEALTH (Part D).—E. B. Argles, E. Clarke-Cohen, R. V. Shivashwarkar, A. K. Soutar. (Part LD).—A. E. A. Carver.

* Mr. Southam was, we regret, reported in last week's issue as taking the degree of B.M., B.Ch.; these were conferred on him in 1913.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

M.D.—BRANCH I (Medicine).—D. E. Morley, P. T. Patel, J. H. Suddow, Catherine V. Turner (University Medal). BRANCH II (Pathology).—A. Beesha. BRANCH IV (Midwifery and Diseases of Women).—Katie A. Platt. BRANCH V (State Medicine).—W. A. Broad (University Medal).

* Obtained the number of marks qualifying for the University Medal.

M.S.—BRANCH I (Surgery).—C. E. Shattock.
 SECOND M.B., PART II.—A. L. Abel, S. E. Barraza, E. V. Beaumont, Ursula P. Blackwell, J. C. Blake, A. O. Bolton, J. A. Boncaud, G. Bourne, J. N. Brash, R. B. Britton, Eleanor M. Burnett, F. Caldecott, D. Cameron, H. Carpenter, J. E. Carpenter, O. C. Carter, B. R. Chaudhri, H. J. C. Churchill, D. C. Clark, E. V. Corry, H. Das, F. de Robillard, Phyllis D. Dixon, E. F. Fernando, Harold Gazdar, Jehan G. G. A. Gier, T. N. Glover, L. B. Goldschmidt, R. C. Guenbert, B. R. Green, J. E. Howells, O. H. Hyman, N. R. Jenkins, N. Kanchara, G. E. Kidman, C. A. Kirtou, E. A. Levisour, K. McFadyen, T. H. McLeod, H. J. Martin, Cecily M. E. Maude, Annie S. Miles, Edith M. Newman, M. J. Panthaky, Sigrid Letitia S. Pearson, I. A. W. Peiris, S. H. de G. Pritchard, J. S. L. Roberts, H. Rowan, J. F. Ryan, B. Sacks, C. E. Seales, Charlotte A. Shields, K. L. Singer, E. C. Sizer, H. Theron, A. R. Tohill, J. A. Van Heerden, Gladys M. R. Webster, Kathleen S. Vine, K. T. K. Wallington, K. M. C. Woodruff, E. B. Woolf, Irene Yates, W. Yeoman.

* Distinguished in Anatomy.

† Distinguished in Surgery.

‡ Distinguished in Physiology.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates have been approved at the examinations held at the end of the fourth-eight session:

Miss G. J. Campbell, N. Wilson, Miss M. E. E. Smith, A. C. d'Ariafat, S. K. Valdy, V. L. Sathu, Miss J. A. Vaughan.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following candidates have been admitted to the Fellowship:

C. Burnham, C. Gibson, P. Greene, C. H. Hayton, Satya Sakha Maitra, A. Z. Phillips, J. C. Potter, V. L. Sathu, and W. D. Yuille.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—J. Lees, J. M. Speirs, B. McLaughlin, T. W. Stewart, T. T. Read, W. Grant, A. W. Buchan, D. C. Scotland, S. S. Barton, G. P. Walker.

SECOND COLLEGE.—A. B. Macdonnell, R. Smith, C. G. Magee, W. H. Duff, R. Austin, W. B. Lawson, A. P. Keith.

THIRD COLLEGE.—J. W. Morris, P. Hayes, W. A. Mein, W. Templeton, J. F. M. O'Flaherty, R. S. Watt, J. G. M. R. Macanlay, R. Woodside, H. G. Anderson, N. S. Bruce, A. Morrison, F. J. Jack, J. J. Mulvey, J. B. Misford, F. A. Rankin, A. D. Gorman, C. J. Middleton.

FINAL.—J. M. Farlane, C. Read, J. MacRae, D. A. Imrie, J. Crawford, W. M. Alpine, J. W. Irvine, Marion C. Fruit, Chenail V. Appandi, G. B. Hanna, J. P. Deary, H. V. Fitzcald, G. T. Makhijani, P. M. Saptarshi, N. B. Morris, P. Milnes, C. M. Bradley.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subject indicated:

SECRETARY.—F. W. Chamberlain, *H. A. Cottin, *H. N. Cozier, *K. M. Dyott, *N. Hoffmeister, *H. L. Hughes, *H. S. Jeffries, H. Morrison, *J. E. Rusby, *M. C. Stark.

MEDICINE.—J. A. A. Boddy, *K. M. Dyott, *J. E. Rusby, *M. C. Stark.

FORENSIC MEDICINE.—W. E. P. Briggs, W. Fox, H. S. Jeffries, J. G. T. Thomas.

MIDWIFERY.—G. T. Baker, J. Y. Dent, H. S. Jeffries, W. J. May, A. Trull, G. N. Younger.

* Section I.

† Section II.

The diploma of the Society has been granted to Messrs. J. A. A. Boddy, F. W. Chamberlain, H. A. Cottin, R. N. Cozier, K. M. Dyott, N. Hoffmeister, H. Morrison, J. E. Rusby, and M. C. Stark.

Medical News.

THE medical publishing business founded in 1844 by Mr. Henry King Lewis has been converted into a private limited company under the name of H. K. Lewis and Co., Ltd. Mr. E. J. Sowerby, Mr. J. L. Jackson, Mr. J. E. Simpson, and Mr. R. H. Smith, who have been responsible for the conduct of the business in the past, have been appointed governing directors. There will thus be no alteration in the proprietorship or management.

THE premises of the Royal Society of Medicine will be closed during the month of August. Owing to the war the number of meetings of Sections had been reduced to nine or two, with an average attendance of about thirty-one. Sir William Church, the senior honorary treasurer, announced that Mr. Lord, the accountant, estimated that the society would be £1,100 within its income this year; this, considering that subscriptions had diminished on account of the war, was regarded as very satisfactory.

A SPECIAL meeting of the Central Midwives Board was held on July 20th for hearing penal charges. Sir Francis Champneys presided. Fourteen women had been cited, and there were also six cases adjourned for reports from local supervising authorities. Of the former, ten were struck off the roll, of the latter four. In two cases no action was taken, and the other women were cautioned, and judgement postponed for reports from the local supervising authorities. The most frequent charges were, as usual, inability to take temperatures and pulses, want of scrupulous cleanliness, and failure to send for medical aid at times when according to the rules they should have done so. Unfortunately, in addition to these charges there were a large number of puerperal cases, some of which ended fatally and several cases of neglected ophthalmia neonatorum. The Board held another meeting to hear penal cases on July 21st. Sir Francis Champneys again presided. Eight cases were heard. Four women were struck off, judgement was adjourned in three of the other cases for reports in three to six months. One midwife was cautioned to obey the rules. At the monthly meeting, on July 22nd, the Standing Committee reported correspondence which included a letter from Dr. A. Stookes, one of the Board's examiners at the Manchester Centre, commenting on the propriety of allowing a midwife to undertake intrauterine manipulations as suggested by one of the questions set at the examination of June 15th. A reply was sent pointing out that such manipulations were only permissible in great emergencies, when there was dangerous haemorrhage and all other means had failed. The names of seven women were removed from the roll on their own application on account of old age, ill health, and inability to obey the rules.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atitology, Westminster, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisement, etc.), *Articulates, Westminster, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medicines, Westminster, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects in which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

VACCINE TREATMENT.

G. P. asks whether the vaccine treatment of chronic gonorrhoea and subacute rheumatism is satisfactory. A chronic gonorrhoea was latent in a man, aged 50. He now has epididymitis. (2) A girl, aged 14, has just recovered from a second attack of rheumatic fever and now has subacute recurrences.

HARE-LIP.

R. writes: Two cases of hare-lip. Two years ago Mrs. K. was attended by me in her fish labour. The child—a lusty, healthy male—was born with a single hare-lip involving the lip almost to the nasal septum. This month I attended her again, when she was again confined of a fine strong boy; this time a bad hare-lip was complicated with cleft palate. The mother's four previous children (three boys and a girl) are quite normal. The woman, a Jewess, is of a very nervous, hysterical temperament although strong and healthy. As she was to be expected, she was greatly upset by the birth of the first malformed child, and was in a state of nervous excitement during the period of subsequent operation and convalescence, and has looked forward with apprehension to the birth of the last child. The questions which naturally arise out of these cases are: (1) Has the neurotic temperament of the mother anything to do with these developmental irregularities? (2) In the event of subsequent births, is this condition likely to be perpetuated or increased by other abnormalities in development? (3) Can anything be done or suggested regarding future pregnancies?

WORK OF SCHOOL OCULIST.

S. O. asks for suggestions on an advanced textbook on the diseases of the eye, including errors of refraction, which would be useful as a reference book to a school oculist. He would also be grateful for a suggestion for a convenient portable lamp for retinoscopy.

The most widely read advanced textbook of ophthalmology is that of Fuchs, the professor at Vienna, but formerly of Liège; the translation by Duane of New York is now in the fourth edition. Next to that, Swanzy's well-known book may be recommended. There is no textbook that deals specially with eye work from the point of view of the school doctor, but Bishop Harman's little book *Aids to Ophthalmology* has a chapter on the subject, and the several chapters on errors of refraction and their correction are written with particular reference to such work as this, and after a long experience in training post-graduates at the West London Post-graduate College.

The most satisfactory portable lamp for retinoscopy is an ordinary acetylene lamp, a bicycle lamp minus the glass and reflector acts perfectly; the minute brilliant flame gives a most perfect reflex, and with it the results can be worked with a delicacy not to be equalled by the best focus electric lamp. A plain retinoscopy mirror must be used.

ANSWERS.

DEATHS FROM HEDONAL AS AN ANAESTHETIC.

D. J. will find much useful information on this subject in the thirty-sixth volume of the *Transactions of the Medical Society of London* (1912-15), beginning with Mr. C. M. Page's paper on "Hedonal Anaesthesia, its Uses in General Surgery," p. 30. Mr. J. F. Dobson's "Objections to the Use of Hedonal," p. 46, will be of particular interest to our correspondent. An abstract of these papers appeared in the JOURNAL, vol. II,

1912, p. 1310, and the same volume contains an article by Dr. Rawdon Veale on "Complications following the Administration of Hedonal," p. 347.

COLD FRET.

DR. ALASTAIR MACGREGOR writes in reply to "D.": The application of the diathermy current by what may be termed the "sole-to-sole" method seems to be strongly indicated in the case of "D.'s" patient. It produces, if the appropriate strength of current be used, an agreeable sensation of warmth, which gradually creeps up the limbs; this sensation lasts for a length of time, which increases after each successive application. The treatment may be given for fifteen or twenty minutes and repeated daily or thrice a week, according to the nature and progress of the case.

LETTERS, NOTES, ETC.

BERI-BERI.

DR. G. PRICE (Kington, Warwick) writes: At Christmas, 1908, the directors of the Saigon (Cochin China) branch of the Pasteur Institute very kindly demonstrated to me the results of their investigations into beri-beri. Their idea was that a micro-organism allied to a yeast found its way into the husk of growing rice, especially when the plant touched the earth as a result of heavy wind or rain. This germ multiplied in husk, but was prevented from reaching the grain itself by the lowermost layer of pericarp (the thin pellicle immediately surrounding the grain), which acts in a manner partly mechanical, partly chemical.

When the rice is polished these germs find their way into the grain and flourish, decomposing the starch and evolving poisonous products. Boiling the rice may kill the germs, but it does not neutralize the poisons produced by them.

The obvious prophylaxis against beri-beri is care in cultivation. The reaper should reject plants beaten to earth, and those whose fruit is obviously diseased. The grain should be stored dry, and preferably husked only as required. When infected grain is husked and stored in a damp place there is every chance for the beri-beri germ. The directors distilled this protective pellicle in alcohol, and administered it to their patients with good results.

They also showed me two fowls—one fed on beri-beri grain and the other on the same grain with the addition of the distillate of the protecting pellicle. The former was paralysed in both legs and one eye; the latter was healthy.

EARLY USE OF TINCTURE OF IODINE IN GUNSHOT WOUNDS.

DR. GEORGE FOY (Dublin) writes: As the value of iodine in the treatment of gunshot wounds is still on trial, I send the history of a case which is of more than historical interest. On September 16th, 1862, General John R. Gordon held the centre of General Lee's army at Sharpsburg. The first volley from the Northern lines sent a ball through the calf of Gordon's right leg, another soon after went through the muscles of his thigh, a third pierced his left arm, tearing asunder the tendons and mangling the flesh; a fourth went through his shoulder, leaving its base and a wad of clothing in the wound. Still no bones were broken, but whilst he lingered in the fighting line, a fifth ball struck him square in the face and passed through his neck, narrowly missing the carotid and jugular veins. Dr. Weatherly of the 6th Alabama Regiment had the colonel, as he then was, removed to a base hospital, and prescribed tincture of iodine to be painted on the wounds three or four times a day. The case was unpromising, for Gordon's eyelids were greatly swollen, one eye completely closed, the other almost so; his jaw was immovably clenched, and, to make matters worse, erysipelas set in on the left arm. Mrs. Gordon, his wife, as his nurse, putting a liberal interpretation on her instructions, painted the wounds very many times a day. Her care, her diligence, her love were rewarded. The patient survived. He outlived the war, became Senator for the Commonwealth of Georgia, represented the C.S.A. veterans at Grant's funeral, wrote his *Reminiscences of the Civil War*, 1903, and died in 1905. Mrs. Gordon still lives; she spends her declining years in visiting her children and grandchildren, who, in the words of Sir W. Osler, recall "the noble deeds she did amid the desolation, rescuing those who were ready to perish," and they love her.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0	5	0
Each additional line	0	0	8
A whole column	3	10	0
A page	10	0	0

An average line contains six words

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so accompanied by a reference.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-remittance letters addressed either in initials or numbers.

Presidential Addresses

TO THE
BRANCHES OF THE BRITISH MEDICAL
ASSOCIATION.

METROPOLITAN COUNTIES BRANCH.

SIDELIGHTS ON THE PRACTICE OF MEDICINE IN THE PAST FROM EARLY ENGLISH LITERATURE.

By MAJOR GREENWOOD, M.D. BRUX.,
D.P.H., LL.B.

The origin of the medical profession in this country is a disputed point. No literature throws much light on the subject, and the earliest evidence of the practice of the healing art in England and Wales is the existence of remains of medical instruments and appliances of the Roman period that have been dug up in various places. For at least three centuries England and Wales was a settled Roman province, containing many large and prosperous cities, and enjoying a civilization equal to that of their sister cities on the Continent. We know from Roman sources that this civilization included all that was then known of medical and surgical science. We learn, too, from the Civil Law, that there was a well recognized class or profession of *Medici*. The gleanings from old Roman remains in this country give ample evidence that these *Medici* came over here and carried on their profession. But in the fifth century came the deluge of barbarous tribes from the north of Europe, sweeping away the whole of Roman civilization, and with it no doubt most of the medical knowledge that up to that time had been enjoyed by the old population.

After the Saxon invasion, then, it would seem that medical and surgical science had to begin again, and it might be that our profession was slowly evolved *de novo*, possibly owing little or nothing to the Roman civilization that had preceded it. Whether any of the Roman *Medici* survived the invasion and were enabled to carry on their art through the troublous times that followed and develop a school at a more peaceful period is purely conjectural. But I cannot help thinking that we, like our sister profession the law, may owe much to that great people, whose influence in the civilization of the world has been so profound.

Sir Lawrence Gomme has shown that in the case of London customs there are many old survivals from Roman sources, and he suggests that the origin of our earliest lawyers must be looked for there.

In *The Village Community* he says:

Now the Order of the Coif (Serjeants-at-law) is the oldest association of lawyers in this country. There is no law for its first institution, no charter from a sovereign, nothing to show from whence it springs, except its remarkable parallel to Roman custom. If this custom could be regarded as evidence, then our present K.C.'s can show an unbroken descent from the *Jurisperiti* of ancient Rome.

These *Jurisperiti* flourished, together with the *Medici*, in the Roman cities of Britain, and if one class could survive the Saxon conquest it is difficult to see why the other could not. If custom can be made to evidence the descent of one from Roman sources, an analogous custom might also prove our Roman ancestry. It is a well-known rule of the Royal College of Physicians of London that Fellows of the College cannot sue for their fees—a rule recognized by law, and customary in the case of all members and licentiates before *Gibbon v. Budd*—and there is a similar custom in the case of barristers. It was a particular rule in the case of the *Jurisperiti* of ancient Rome that they should give aid to the poorest citizens without pecuniary reward. The old serjeant-at-law also was bound "truly to serve the King's people without fee or charge."

The commonly received view is that general practitioners of the present day are descendants of the old barber-surgeons and apothecaries. In a sense, no doubt, this is true, and the members of these guilds chiefly

administered to the medical and surgical needs of the people for a long period.

But this fact must not be overlooked. There is abundance of evidence to show that there were always recognized medical and surgical practitioners, altogether distinct from barber-surgeons and apothecaries. So that it may be our profession owes not a little to these other practitioners, who were neither barbers nor apothecaries. Who were these others?

I think they can be distinctly traced down from the Norman Conquest. Shortly after the Conquest William I organized a sort of national *Who's Who* known as the Domesday Book. In it we find the following entry:

Nigel—Medicus—5 Hydes of land in demenes in the hundred of Scipe.

"Medicus" could only mean a medical practitioner, and in the great national register of the landowners of the eleventh century a class known as *Medici* is shown to have existed. He was certainly not a "barber," "apothecary," or university graduate; neither was he a religious person. The writer of the Domesday Book would not have styled either of these "medicus."

The entry at least proves this, that at the end of the eleventh century there were recognized medical practitioners in this country distinct from barbers, apothecaries, or religious persons, and at a time anterior to medical faculties in universities.

Mr. Sidney Young thinks that as early as the reign of Edward II barbers were practitioners in the art of surgery; that at all events they performed the minor operations of the craft, such as bleeding, tooth drawing, and cauterization. But he admits there were other practitioners, for he records the admission of a surgeon, not a barber-surgeon, to the freedom of the city under the date 1312. Again, he recognizes that coeval with the Company of Barbers there existed in the City of London another fraternity or guild—that of the "Surgeons," in no way connected with the barbers, but like them existing by prescription, and unincorporated.

Mr. D'Arcy Power thinks these surgeons were military surgeons and formed the aristocracy of surgery. No doubt, in those days, when wars were so common and the habits of our ancestors so little peaceful, the work of all surgical practitioners largely consisted of attending to wounds and injuries the result of breaches of the peace. But whence came these surgeons, who were not barbers, and existed by prescription?

I can see nothing that forbids the hypothesis that they may have been lineal descendants of the old Roman *Medici*, neither do I think they confined their work to surgery pure and simple. In 1423 we learn of an attempt being made in London to form a united guild of surgeons and physicians, to be governed by a rector of medicine, two surveyors of the Faculty of Physik, and two masters of the craft of surgery; in short, a combined college of physicians and surgeons in the fifteenth century.

The members of this guild do not seem to have been numerous, but they were neither barbers nor apothecaries; and if the members who practised medicine did not also practise surgery, they would appear to have been physicians by prescription. In any case, I regard them as derived from the same source as their colleagues of the guild of surgeons. Some may have been doctors of physik and university graduates; but we learn from Chaucer that the Doctor of Physik practised both medicine and surgery, so that he must have been a general practitioner. Speaking of the latter in his prologue to the *Canterbury Tales*, he says:

In all the world ne was there non him lyk
To speke of Physik, or of Surgerye—

It seems probable that in early times there was little distinction between the practice of medicine and surgery. It was left to a much later representative of surgery to say, "That he thanked God he knew nothing of Medicine." Our predecessors, like the old *Medicus*, probably practised both.

If, as Mr. Sidney Young thinks, that up till the twelfth century the practice of medicine and surgery was entirely confined to the clergy, there is no evidence that among religious persons any distinction was made. The mediaeval monk was essentially a general practitioner; but when the practice of the two sister crafts became the appanage

of rival trading guilds it was not unnatural that distinctions should arise and that the barber-surgeon should be jealous of the encroachment of the apothecary on his field of practice, or vice versa.

From our early literature it would seem that the old medical practitioners were both surgeons and physicians.

In Langland's *Vision of Piers Plowman*, an allegory in which, as in the *Canterbury Tales*, all classes of the community are reviewed, there is reference to "physicians," but none to "surgeons" as a special class. This can only be because the writer included them under the generic term "physician." It is the same with Chaucer. Both law and medicine are represented among the pilgrims to Canterbury, the former by the "Serjeant-at-law" and the latter by the "Doctour of Physik."

Considering the importance of surgery at this period, it can only be explained by supposing that Chaucer regarded his "Doctour of Physik" as representative of both branches of the profession; and we shall not be far wrong if we assume that where early writers refer to physicians, they include all practisers of the healing art.

It is from our early literature alone that we get any idea of the social position of our predecessors in bygone ages. The London of Langland and Chaucer was not the same as the present metropolis, but as both of them were Londoners, the sidelights they throw on our profession in the fourteenth century are mostly drawn from observations in the metropolitan area of that time.

If Chaucer's "Doctour of Physik" may be taken as the type of the Plantagenet general practitioner, the character of his dress would suggest that his income compared favourably with that of his twentieth century successor:

In sangwin and in perse he clad was al,
Lined with taffata and with sendal.

This was a costly dress, and, at a time when dress was regulated by station, shows that the wearer held an elevated social position. Langland, also, in *Piers Plowman*, draws attention to the rich dress of the practitioners of medicine of his time, for he makes his allegorical personation of "Hunger" say, in his condemnation of gluttonous living to Piers, that if mankind would be satisfied with a simple diet,

Physic shall sell his furred robe to get his food withal,
And shall pawn for his dinner his Italian cloak.

Langland was anterior to Chaucer, and the picture he draws of society in the early years of Edward III is very mournful and depressing. He was no friend to the doctors, although he admits by inference that there might be good physicians, for in the *Vision of Lady Meed* he says:

Harlots and whores, and false physicians,
They ask their hire money ere they have deserved it.

By implication it would almost seem to be suggested here that *true* physicians only took their fees after they had cured their patients. If that were so, they must have been gifted with rare integrity, and showed scruples not conspicuous in their modern representatives. But there could not have been many of these bright stars, for Langland on the whole severely condemns the whole faculty. He is specially satirical on the examination of the urine of patients; for when the allegorical impersonation "Liar" is being sought for by the king's officers for immediate execution, he is offered shelter by the doctors:

Then the doctors heard of this, and wrote Liar letters
To come and stay with them, and study men's water—

There is no doubt he had rather a poor opinion of our brethren of those days, for he goes out of his way to make the following general charge:

For many doctors be murderers, (God mend them),
And men die through their drinks, ere destiny would
have it—

When we consider the nostrums of those days, some of us may think that there may have been a grain of truth in the latter accusation.

It is some consolation, however, that if we come under Langland's lash, the sister professions—the Law and the Church—fare no better. What he says against us pales into insignificance compared with his charges against the lawyers and clergy.

William Langland on the whole is not a lovable

personage. He was a keen observer, and devoted sympathizer with the poor and oppressed. Moreover, he was a cleric, and when speaking of his own cloth, he may have been nearer the truth than in his criticism of the lawyers and doctors. But I cannot help feeling regret that the great Chaucer, the father of English poetry, shared in Langland's disrespect for us. It is true he mostly poked fun; but none the less his satire was unmerciful, and clever enough to give the reader the impression of truth.

His picture of the mediæval physician is a masterly portrait, in spite of his sneers. We have an epitome of the medical practice of the day. We learn that the doctor practised both surgery and medicine. The horoscope and natural magic are depicted as part of his armamentarium, and the old doctrine of "humours" shown to be in full force. Medical practice, then as now, consisted largely in drugging, and the "Doctour of Physik" had his coterie of apothecaries to supply the drugs and electuaries. So it would seem he did not supply his own drugs, and Chaucer suggests there was a good understanding between the doctor and the apothecaries to make as much profit out of the public as they could.

He says:

For each of hem made other for to wyne:
Their freundschipe was not newe to begynne—

It has been asserted that such collaboration between doctor and chemist at the present day is not unknown. If so, it indicates that abuses in practice we are all acquainted with have a respectable antiquity. Constantly Chaucer accuses our profession of being too grasping over fees and of greed generally.

He says of the "Doctour of Physik":

For gold in phisic is a cordial,
Therefore he lovele gold in special—

This is only a touch of irony, but elsewhere in his works Chaucer is almost as outspoken as Langland against us.

In the *Romaunt of the Rose* he says of physicians:

They sell their science but for gain,
And ply their craft but to obtain:
Their gains such sweetnees have withal,
That if a man in sickness fall,
They are full glad their purse to fill:
For truly, if they had their will,
Then all to sickness would be brought;
And if folk die they think it nought:
And when their golden fees they take,
The patient's care they soon forsake:
For in their work they take no pains,
Except for covetousness and gain—

The poet then seems to think it is incumbent on him to give some reason for this diatribe, and he has the bad taste to put it in the form of a pun:

For phisic ginneth first with "fy,"
Physician also equally:
And since from "fy" to "ay" it goes,
To trust in them great folly shewes:
For unto this they ne'er agree,
To practise but for charity.

If this is the only explanation to be given for the rapacity of our predecessors, it would almost seem as though the poet were trifling, and could not be in earnest. As an admirer of Chaucer, I have always felt a little sore about his strictures on the medical profession. It is true that he lashes the clergy even more severely than the doctors. But they can forgive him after his beautiful description of the "Poor Parish Parson," who stood out as a shining example in the midst of the corruption of the mediæval Church. But he makes no mention of the poor parish doctor. Possibly, the "parson" was the only representative of a Poor Law service in his time.

There are one or two other points of interest to be noted in Chaucer's allusions to our profession.

He calls his type of the medical practitioner of the day, a "Doctour of Physik." Was this doctor a university graduate? According to Clenn the degree of M.D. cannot be traced earlier than the year 1384. But John of Gaddesden was a medical graduate of Merton College, Oxford, before then; so it would appear, Oxford gave a medical degree before Chaucer's time. It is also worthy of note that the title "doctor of physik," not doctor of medicine, was peculiar to this country.

The readers of Boswell's *Life of Johnson* will remember Dr. Johnson's inquiries of Dr. Lawrence, President of the

Royal College of Physicians of London, as to the right of a medical graduate to style himself "physician," and the answer given:

That Dr. of Physic (not Doctor of Medicine) was the highest title a practitioner of Physic could have.

It may be, then, that Chaucer implied that his "Doctour of Physik" was a university graduate; although it is difficult to imagine that the typical practitioner in those days would have been a university man. If not a graduate, Chaucer's appellation of "Doctour" may throw light on the origin of the courtesy title of "doctour" given by the public to all medical practitioners.

Another question of interest is, What part did religious persons take in the practice of medicine in the fourteenth century?

It is generally believed that most of the practice of medicine in early times was in the hands of the Church; that monks were the usual medical practitioners, and surgeons also, up to the date of the Council of Tours.

Such practice may have largely ceased in this country by the fourteenth century, for neither in Langland nor in Chaucer is any reference to medical practice by the clergy. All the doctors referred to appear to have been lay persons. Chaucer, speaking of the Doctour of Physik, says,

His studie was but litel on the Bible.

It is true that after the Doctor had told his tale, "oure host" compliments him, and says:

So mote I thee, thou art a propre man,
And y-like a prelat by St. Ruman!

This has been thought by some to imply that the Doctor was in "Orders," and gave more point to the charge of unbiblical studies. It seems to me, however, that it by no means proves that Chaucer's "Doctour" was in "Orders." Both doctors and lawyers who rose to any eminence were often sought after by the Church, and "oure host" may have meant only that the doctor was such a good fellow that the Church would possibly make a bishop of him.

Mr. D'Arcy Power, in his Harveian Lecture of last year, says the physician of this period was usually, but not necessarily, a Churchman, and gives contemporary examples. But all of them were attached to the households of great personages, and were hardly types of practitioners among the people.

It is interesting to note that Chaucer, like Langland, ridicules the examination of the urine.

In applauding the doctor, our host also says,

I pray to God to save thi gentil corps,
And eke thy nrmals.

No doubt there was much quackery mixed up with mediæval urinary pathology, and at a later age the term "water doctors" was one of opprobrium. In spite of popular contempt the practice had much vitality. It was evidently thriving in Shakespeare's day, for in *Henry IV*, Part 2, Sc. 2, Falstaff says to his page:

Sirrah, you giant, what says the doctor to my water?

To which the page replies:

He said, Sir, that the water itself was good healthy water, but for the party that owed it, he might have more diseases than he knew for.

It is curious to note that in pillorying a quack a urinal was sometimes hung about his neck as a mark of contumely.

In the Records of the City of London at the Guildhall, under the date 1382, appears the case of Roger Clerk of Wandsworth, who was condemned for quackery, and punished as follows:

It was adjudged that the same Roger Clerk should be led through the middle of the City, with trumpets and pipes, he riding on a horse without a saddle, a urinal being hung before him, and another urinal upon his back.

None the less these mediæval water doctors were not always quacks. There was a germ of science in their practice. As the old alchemists, in spite of their frauds and pretensions, laid the foundation of modern chemistry, so the water doctors may have assisted in paving the way for our later triumphs in renal pathology.

Before concluding, there is one other point of interest, especially to our sisters in the profession, which the records of the past cast some light upon. What do they tell us of the practice of medicine by women in early times?

There can be no doubt that in the past there have been women practitioners of repute, and even surgeons of eminence.

Miss Bateson tells us that there was an Ordinance in 1390 which mentions the practice of surgery by women, and it is there on record that Queen Philippa, wife of Edward III, had in her service a female surgeon, Cecilia of Oxford, a practitioner who derived her origin from no less a place than the academic centre of the kingdom. How did this lady obtain her professional training? Was it under the auspices of the Church?

Women were never greatly favoured by the hierarchy, but possibly, when by the Council of Tours the practice of surgery was forbidden to monks, the prohibition was not so stringently enforced in the case of nuns, and these women practitioners may have been the last surviving instances of the practice of medicine by religious persons in this country.

It is not difficult to understand the exclusion of women from medical and surgical practice, when these professions became vested in guilds and livery companies, such as the Barbers and the Apothecaries. We have plenty of liverymen with us still, but I do not think history records any instance of a liverywoman. After Plantagenet times we hear of no more female practitioners in high places. It is probable that medical practice by women was more or less suppressed, although there is reason to think that it continued to exist long after. There is extant the draft of an Act of Parliament, 9 Henry V., in 1422 (Pety's MSS., v, 33), in which occurs the following:

The sheriff shall inquire whether any one practises in his county contrary to the regulations; and if any one so practise he shall forfeit £40, and be imprisoned. And any woman, who shall practise physik shall suffer the same penalty.

This Act never had the force of law, but it shows that women endeavoured to practise medicine in the fifteenth century and came under the ban of the law-makers.

Again, in the next century, in the preamble 14-15 Henry VIII, cap. 5, in 1521, we read:

Forasmuch as the science and cunning of Physic and Surgery is exercised by a great multitude of ignorant persons, of whom the greater part have no manner of insight in the same, nor any other kind of learning, so that common artificers, such as smiths, and weavers, and women, boldly take upon them great cures, and things of great difficulty.

These statutes cast a sidelight on the practice of our profession in the fifteenth and sixteenth centuries, and make it probable that Cecilia of Oxford had other successors, but that they steadily declined in social rank, till they were more or less suppressed by man-made legislation.

STAFFORDSHIRE BRANCH.

THE PRINCIPLE OF ANOCI-ASSOCIATION APPLIED TO MEDICAL PRACTICE.

BY

F. M. ROWLAND, M.D., B.A.CANTAB.

AFTER a few introductory remarks the President proceeded:

Although the mental factor in medicine has long been recognized as a valued asset to the successful treatment of disease, it is only of late years that there has been any serious attempt scientifically to marshal its forces and to examine its possibilities as a legitimate adjunct to therapeutics, the field having been left open in the past—as it now, indeed, largely is, and will probably remain for some time yet to come—to the illegitimate blandishments of quackery and the quasi-spiritual enchantments of Christian Science and similar allied systems of unreasoning thought.

It is not my intention to-day to discuss this subject from the point of view of practical hypnotic suggestion as it may be legitimately utilized in the treatment of ailments. Rather do I want to call attention to a point of view in dealing with our patients which hinges on their mental outlook, and to which I believe I am right in saying that but little attention has been paid, at any rate in any scientifically defined way, or other than as that which is recognized as individual personality often exercised almost unconsciously by individual men.

I may, perhaps, the better explain my outlook if I take a lesson from surgery, and draw an analogy from Professor

Crile's principle of anoci-association, whereby is meant the exclusion of all noxious or harmful associations or stimuli from the field of operation, one of the primary factors of which involves a careful preparation and education for general anaesthesia in order to familiarize the patient with the procedure, and so, by minimizing the dread and apprehension, lessen the predisposition to shock. Furthermore, by cutting off the field of operation, and protecting the brain from impulses therefrom, by means of local anaesthesia an ideal combination is formed for excluding from the brain the stimuli of the special senses and the stimuli of common sensation. By thus avoiding the influences of emotion from the sight of the theatre, the spoken word of danger, the fear of the anaesthetic, and the influences of trauma at the site of the operation, the energy of the brain cells is conserved and shock reduced to its minimum.

While scarcely wishing to sketch out so practical an application of the principle involved as Crile intended for the surgeon, I think we may glean for our everyday dealing with the treatment of illness some very useful truths from the theory of anoci-association as understood to mean the exclusion of all noxious and harmful associations; and to this end I am desirous of pleading for the more systematic study and consideration of our patients' individual outlook upon life, not so much when in their normal health as when they are lying on a bed of sickness. At such times, I take it, the subconscious mind is more in the ascendant, altered in its sensitiveness, and likely the more easily to become the recipient of suggestions than in health, the mental attitude of a patient being so affected by an illness as to be altogether different from the mental attitude of the same person when in normal health. Those of us who have ever had the misfortune to lay aside the cloak of the physician for the bedgown of the patient, especially if our sufferings have resulted from some general toxæmia, will, I am sure, be in agreement as to the altogether disproportionate degree in which infinitesimal trivialities which would pass unnoticed in normal health become enormously exaggerated, and slight annoyances magnified into states of considerable mental anguish.

It seems to me, therefore, that it is all-important for us, when treating a patient, to make ourselves acquainted as nearly as we possibly can with that patient's view upon life at such a time—not so much the view which he may express in words as that view which I can perhaps best indicate as the resultant of forces operating in his subconscious mind, and it is only by a thorough knowledge and study of our patients, both in health and sickness, that we can hope to attain this end. In this connexion I cannot refrain from a veil of lamentation that our profession shows signs of drifting into new ideas of ethics in relation to our patients which are onsting the old-fashioned, but in this respect I believe really helpful, relationship between doctor and patient which is understood by the mention of the "family physician."

It is only by an experience, not otherwise obtainable than by years of intimate observation of the varying temperaments and idiosyncrasies of our patients, that we can judge even in the smallest degree of the lines of thought they will adopt at any given juncture, and by our knowledge so gained that we shall be enabled to some extent possibly to assist in influencing the course of their disease by the exclusion of all adverse subconscious tendencies, and by the furtherance of beneficial influences operating towards a cure. Although this aspect of the subject has been to a certain extent realized, as evidenced by the free choice of doctor principle in the profession's policy, the rapidly growing opinion among politicians in favour of a State medical service totally ignores the importance with which I consider it should be vested, and one has only to read the Fabian Tract No. 160 to see to what extent even a member of our own profession has lost sight thereof.

Were so infinitely personal a relation as that which, for the patient's psycho-therapeutical welfare, should exist between him and his doctor to become reduced to a system of service by whole-time officials with definitely fixed hours of work it would not conduce to the best results in treatment of acute illness, whatever may be said for its merits on the *preventive* side of medicine, which latter, I think, few would deny is essentially a matter for State

control under a properly constituted department guided by a Minister of Public Health.

It always seems to me foolish in the extreme to attempt to deal with complex human nature as if each individual were a standardized part of some huge machine, a point of view which a State medical service would tend to evolve, thereby entirely losing sight of the personal equation and infinite human diversity in temperament, and consequently I deplore very greatly this increasing tendency of the present day to ignore the operations of the subconscious mind in the treatment of disease.

Picture to yourselves the logical outcome of such a system of State service, if universally adopted as its advocates intend, in the case of a bad pneumonia requiring to be visited morning and night, with an eight-hours day in operation, when it is obvious that it is in the best interests of the patient that the same physician who saw him in the morning should see him again at night, since no written or verbal report—always supposing there would be one, which would be doubtful—could convey to the evening-visitant the all-essential though indefinable mental picture which the morning visit gave. It is here that it seems to me that this present tendency towards State interference, which must eventually culminate, if unchecked, in a State medical service, is objectionable and inimical to the best interests of the patient as far as promoting rapidity of cure is concerned, there being much to be said for the former status of the family physician who had attended the whole family for years and knew all the little peculiarities and idiosyncrasies of each member, a knowledge which often rendered him capable of foreseeing the various kinds of response to remedies, and the probable sequence of events, which might be expected to accrue under given conditions in each individual.

I am fully alive to the fact that in promulgating this suggestion that we should cultivate, even more than some of us may already be in the habit of doing, this principle of anoci-association by the avoidance and exclusion of all harmful associations in the everyday treatment of illness, it is difficult if not well-nigh impossible from the very nature of the conditions to lay down any definite line upon which treatment should be conducted. I must content myself, therefore, with merely pointing to some of the more generalized indications upon which we can, each one for himself, formulate a general process of action suited to each case.

If we are careful in our endeavours to obtain some understanding of the patient's mental outlook, trying to get a glimpse of his naturally warped perspective and general view of things, we shall then be able better to appreciate the many little ways in which we may be instrumental in warding off those harmful associations which might otherwise act detrimentally through the operations of his subconscious mind. Be it clearly understood in this connexion that many of the associations may be quite harmless in themselves, only becoming noxious when presented to a patient whose mental outlook is altered by the very fact that he is ill. How often has it not occurred to all of us to have wished that in some given case we had altered our phraseology or left unsaid some spoken word which has been seized upon in quite a different meaning from that which either we intended or in which a condition of health would have received it. It is just this study of the mentality during an illness which makes our experience of previous illnesses in the same patient a valuable asset, and although an intimate association during health may materially assist us in knowing what attitude to adopt, it is during the illnesses themselves that we must elucidate a plan of campaign which will be most on the defensive for our patient against harmful influences and associations.

In our daily visits I feel confident that the cultivation of punctuality will be fraught with a greater outcome of good to the course of an illness than we are apt to credit, and especially in acute and subacute cases do I consider it important, whenever possible, to mention a probable time for the next visit, and, when this is not possible, to let the fact that it is not possible be clearly understood, rather than leave without giving some idea to the patient when he may expect us again. Of course, I am quite aware that in certain circumstances surprise visits are of value, but with that class of case I am not now dealing. It may seem to some of you that this is advocating a counsel

of perfection rendered impossible of attainment by the very nature of our work, with its urgent calls and uncertainty of detention over any given case, but I think it will be found easier of application in the vast majority of instances, if given a fair trial, than many would imagine. Exceptions, I am aware, must of necessity be frequent, but these should not militate against the aim, and though possibly a little more exacting to ourselves, I feel certain that the resulting advantage to the patient will prove a real value in the treatment and course of the illness. Rightly or wrongly, we as a profession have acquired a reputation for unpunctuality, and I well remember the chaffing astonishment with which I was once received by the patient's friends at a night visit because I arrived at the time I had said I should, it being remarked: "Oh, yes, we know you said nine, but then, whoever expected a doctor to be punctual!"

Now it is the common experience of everyone that there is little else more irritating or depressing than to be kept waiting, and again I appeal to the memory of those who have ever been ill how much more irritating it is to be wondering when the doctor is coming than it would be in ordinary health. This cultivation of punctuality is a very potent means of influencing our patients' subconscious mind for good, at the same time avoiding those noxious associations which would inevitably result from unpunctuality.

Again, how frequently do we meet with cases in which we have to weigh in our minds the advisability of an evening visit for the sake of the physical needs, when we are aware that the mere fact of a second visit may act harmfully by making a nervous patient think that we regard his case as more serious than it is. In such cases it is all-important that we should as far as possible be in a position, by understanding the patients' mental outlook, to judge the probable subconscious effect, and so guard against any noxious influence by either eliminating the visit, or else affording some plausible reason calculated to counteract any harmful effect. In this connexion the reverse may obtain in a case where a second visit is not needed merely on account of the physical complaint, but in which our experience tells us that a second visit will be a comfort and not in the least an alarm, and consequently advisable as an assistance by auto-suggestion to the progress of the illness.

Individual cases will afford individual conditions, which only a study of the patient's mental outlook in the present and previous illnesses can anticipate and provide for, and innumerable opportunities for treatment by suggestion, unconscious to the patient, will present themselves which it would be impossible to enumerate or legislate for in any treatise or textbook. The much-derided "good bedside manner" is an undoubted therapeutic asset, for a greater success in the progress of his cases often attends the path of the cheerful optimist than accompanies the ministrations of the dour pessimist.

Hinging on this subject is the difficult decision we are often called upon to make as to how much in diagnosis and prognosis we are justified in telling to any given patient and how much to withhold, and even the very phraseology in which we clothe our statement will be affected by the intimate estimate we have been able to form of his mental outlook.

Consequently all this goes to show, in my opinion, that the attributes of the family physician should be fostered rather than discouraged, as is the tendency to day, since it is for the patient's good that his doctor should know him intimately both mentally and physically, and over as long a period of his life as circumstances will permit. How often cannot we each one of us recall instances where the fact that we have known patients for many years and attended them through several illnesses has been the greatest possible help in their later conditions; and I contend that in such instances we the better understand our patient's outlook upon his state, and consequently unconsciously to him and ourselves do we affect his subconscious mind for his own good in battling with his trouble.

Of equal therapeutical importance in this direction is the proper selection of suitable attendants, and when possible the choice of friends, and all of us can recall instances where the patient's litany may well have been "Deliver me from my friends," while in certain grades of

life the one idea of condolence and sympathy appears to take the form of an enumeration of gruesome experiences akin to the patient's ailment, or the cheerful greeting, "How ill you are looking!" More than once have I known the mental balance of a borderland case finally and directly upset by some such remark from a well-meaning acquaintance.

Each one of us must realize and be intensely grateful for the sense of relief and assurance afforded by the ministrations of a good nurse in attendance upon our patients—a nurse in whom we know that the patient has as much confidence as we have ourselves; equally, too, we must occasionally have experienced the sense of hopelessness for effective treatment afforded by the presence of a nurse to whom the patient has taken a dislike, or who we know does not possess his confidence. I consider that this aspect of the relation of nurse to patient as it affects the subconscious mental therapeutics is too much neglected by those responsible for the training of nurses, and I would urge upon matrons of nursing institutions the necessity for inculcating as part of the curriculum a definite ethical atmosphere and the need for careful consideration and study of the patient's mental outlook.

When in a serious case we telephone for the services of a nurse we are always anxious to secure one of whom we have had some previous knowledge, and failing this it must be within the experience of all of us how much we regard it as a lottery whether the stranger that may be sent us shall turn out a success.

So throughout the whole process of treatment and care of our patients I think we cannot overestimate the great importance, as a means to successful issue, of studying the mental outlook of those under our care.

Before closing this address, I should like for a few moments to detain your attention upon an entirely different subject, and to ask your consideration of an aspect of eugenics which, while always an absorbing subject of vital interest to the race, has become the more evident of late owing to the serious depletion of our best manhood at the front.

Recent legislation has shown signs that the State is awakening to the necessity of taking some practical steps to prevent a continuance of the altogether disproportionate increase in the number of the unfit as compared with the fit, a fact which cannot but give rise to anxiety when we realize that the only section of the population which prevents the birth-rate going lower, and which increases in proportion to the decline in other parts of the community, is that of the feeble-minded, so that, when to an already declining birth-rate there is superadded a proportional increase in the number of the unfit, the lasting powers of our race become largely a matter for mathematical calculation on a basis of geometrical retrogression.

While I intend just in passing merely to touch upon the question of how to deal with the existing unfit, the feeble-minded, and mentally deficient, my main object is to place before you some views for the betterment of the race by the exploitation of the existing fit, a point which has as yet received but scant notice as a powerful means of counteracting the declining birth-rate and a further continuance of the unfit. I shall not burden you with figures in statistical proof of the accuracy of unquestionable facts, but the problem must be faced, in order, if possible, to find a remedy, without violation of the Christian and utilitarian principles which underlie our whole social being.

It would appear that in such measures as the Mental Deficiency Act, etc., the State is fully alive to the need for the proper care of those unfortunates, but it does not seem to me that it is yet sufficiently alive to the need for adequate measures which will entirely prevent the possibility of procreation and the continuance of their stigmata among such members of the community as happen to be their offspring.

For those whose future is hopeless, in so far as they are ever likely to be able to take care of themselves, or to enter into ordinary relations with the world, complete segregation under care and supervision is obviously necessary; but for those whose disability is partial, and who in a limited sense might be allowed to control their own affairs and take up the duties of life in mixing with their fellow-beings, it appears to me that the costly process of segregation is unnecessary, nor is curtailment of their liberty

justifiable, as in many instances of this kind it would be cruel to curtail their liberty or to deny them the happiness and companionship of home life; but it is of paramount importance that some provision be insisted upon whereby the procreation of their kind is rendered impossible. Obviously any system of domiciliary inspection, boarding out, etc., would be totally inadequate for such a purpose; but the end in view could be best and fully accomplished by the production of sterility, either by operative procedure or the influence of *r*-rays, and a moment's consideration will emphasize the humanity of such a procedure for such individuals when compared with the alternative necessity of compulsory segregation or of permitting the birth of children whose only heritage is degeneracy, and who in turn would continue the series.

Coming now to my main theme—the exploitation of the existing fit—I have an indictment against our great departments of State, in that they do not appear to realize that before they should be concerned with their own individual specialities in naval, military, colonial, and home affairs, their departmental importance is an entirely secondary consideration to the primary importance of the State, and that their first solicitude should be for the welfare of the State as a whole, and not, as at present, for their individual departments.

It will be generally conceded that these departments of State are officered and manned by Englishmen who have been selected for their superlative mental and physical efficiency, and yet so far from any attempt being made by these departments to facilitate such men—the pick of the race—procreating their kind, matrimony is officially only half-heartedly recognized, and inwardly regarded as a nuisance, with a consequence that the families in this class are notoriously small.

Without interfering in the least with their efficiency as fighting units, without militating in the slightest against discipline, I contend that more consideration could be shown by the Admiralty and War Office to married officers and men in times of peace, whereby more shore leave could be granted, and whereby they would not be so liable as at present to be arbitrarily moved from station to station without any adequate compensation, and on all too short notice.

Had such departments the good of the State primarily at heart, there would be less grumbling in the services, less shortage of officers, and the birth-rate would have at least a better chance than at present of being augmented by the fit, while, putting the matter on its lowest footing, an increased expenditure in grants to married officers and men, to assist them in meeting the expenses of their families, would pay the country in the long run. The renting of houses where quarters are not provided being a serious drain on private resources, one would expect some sympathetic departmental solicitude, instead of the studied official indifference meted out to those who are anxious to obtain some idea upon which to base length of tenancies, etc.

Among soldiers a proportion of only 5 per cent. obtain leave to marry "on the strength," and the frequency with which, under the Local Government Board, boards of guardians, town councils, etc., notices of vacancies for joint married appointments openly state that preference will be given to those "without children," not only shows how utterly such departments fail to recognize their greatest responsibilities as being primarily in the interests of the community and for the amelioration of the State in the future, but also reveals the immorality of an attitude which places, as it inevitably must, a premium upon practices deserving the severest condemnation. I could quote you instance upon instance of this short-sighted attitude emanating from the Admiralty, War Office, Colonial Office, etc., but I will only mention one example typical of the whole position which occurred to my own knowledge in the case of a Local Government Board official, a man of splendid physique and moral character, and eminently desirable as a racial asset, who was informed when his third child was born that he would be dismissed if a fourth arrived, the threat being eventually carried out solely for that reason. Here, then, is an instance of a policy which, alas! permeates our great departments, and which, in my opinion, cannot be too forcibly condemned, no words being too strong for so criminal an attitude—criminal, because operating towards racial death.

I am fully alive to the fact that we cannot ensure perfect stock as long as no health restrictions are enforced upon two persons who get married, but as such restrictions are for the present, at least, out of the question, and can only come from a right sense of duty being developed in each individual, we can at least utilize the best material we possess to its best advantage, instead of, as we now do, discouraging the best, while permitting the degenerates unrestrictedly to do their worst.

The rebate on certain incomes allowed for children is a sign that the State is beginning to have a glimmering of its responsibilities in this direction, but there are hosts of other ways in which assistance could be given to those who are doing their best to improve the race, and I will instance only one of many directions in which the principle could be still further advantageously fostered. Surely it is a strange anomaly that the State does not in any way recognize the very different responsibilities of individuals, and claims from the man with a large family to bring up the same tax upon income as is exacted from the bachelor or married man without children, and here is a direction in which the financial burden could be eased for the former, thus directly affecting efficiency in the upbringing of offspring. Obviously a man, whose income is, say, £1,000 a year, with a wife and several children dependent upon him has greater responsibilities and is not so well off financially as a bachelor with the same income, so that the children should be taken into account far more than is done by the present rebate, which, by its very meagreness, is as much an insult as a benefit. It has been suggested, and it appears to me a sound proposition, that families should be classified for taxation purposes so that the man and his wife should count as one, and any two children should count as one adult for purposes of assessment. By this means a man with a wife and six children and an income of £800 a year, instead of paying as now full tax on the £800, would be assessed as four incomes of £200 apiece, which would entitle him to the very substantial rebate on the four smaller incomes.

I am fully aware that the whole of this suggestion is open to the objection that there is no guarantee that the fittest and best of the race will be the people having the large families, but that probably it will be the reverse; but here comes in my original plea that more encouragement should be given to those who are believed to be the fittest, as far as mental and physical examinations can determine, to procreate their kind, and I have but enumerated one or two of the hosts of ways by which such encouragement could come about and the future of the State as a State be benefited.

An interesting report on the work done at the Coolgardie Sanatorium in Western Australia by Dr. Henry A. Ellis, now acting as Tuberculosis Officer at Middlesbrough, contains some suggestive points which, if not altogether new, have, at any rate, been very fully investigated. The use of nitrites for the lowering of blood pressure, especially in haemorrhagic cases, the very free administration of calcium chloride, and the local application of iodine spray, have all been advocated in their turn, but few observers have pushed them to the same extent or claimed to have obtained such good results. A great believer in the value of von Pirquet's method, he believes that he has been able to gauge with some degree of accuracy the extent of lesions from the relative dilution needed to produce reaction, and suggests that the test should be applied to all persons aspiring to enter the public services. He points out, with truth, that a tuberculous person may not suffer from his tubercle if his general health be maintained. Any accession of disease may start the activity of the tubercle and the foreknowledge of its presence should enable the individual to guard against risks of infection by any other ailment which might rouse the tubercle to action. The von Pirquet reaction, except in the case of children, has gradually fallen into disregard in this country, owing to the large proportion of contradictory results obtained by various observers. The diagnostic importance of injections of tuberculin has proportionally gained in general estimation. It is to be feared that reaction to diagnostic injection would be too freely interpreted as indicating consumption in the present state of public knowledge or ignorance, and however useful it might be to the future health of the individual, it would not be likely to improve his present prospects.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY NITROGEN COMPRESSION.

[WITH SKIAGRAMS ON SPECIAL PLATE.]

BY

GEOFFREY LUCAS, B.A. CANTAB., L.S.A. LOND.,
SENIOR ASSISTANT PHYSICIAN, NORDRACH-ON-DEE SANATORIUM,
BANCHOBY.

So much has been written in this and other journals on the technique of the operation of nitrogen compression for pulmonary tuberculosis that I propose only to touch upon a few practical points of importance before proceeding to a recitation of the illustrative cases.

With regard to the preparation of the patient for operation, when possible I prefer the patient to be at absolute rest in bed for two days previously. On the second evening an aperient is given, and if the bowels have not acted satisfactorily, a simple enema is given early the following morning. The chest is then carefully examined, and three likely sites for puncture are chosen and painted with tincture of iodine to the size of half a crown. Three-quarters of an hour before the time appointed for operation 0.5 c.cm. of omopon-scopolamine is given hypodermically. Half an hour later, if the patient is not well under the influence of the drug, a further dose of 0.25 to 0.5 c.cm. is given. This procedure is found most beneficial in diminishing reflex sensibility, whilst the rate and depth of respiration is not materially affected. The proposed site of operation is again painted with tincture of iodine and a hypodermic syringe containing 15 minims of a solution of novocaine and adrenalin is taken, and the needle plunged through the skin at right angles into the intercostal space. It is pushed onwards gently until it is judged to have reached the parietal pleura (this can often be felt by a sudden feeling of resistance to the needle). Two or three minims of the anaesthetic are next injected, and the needle is gradually withdrawn, injecting slowly the while. In this way a track is anaesthetized along which the Saugmann's pneumothorax needle is subsequently passed. It is a practical point of some importance that no excess of anaesthetic fluid should be left immediately under the skin, as if it is there is a probability that the Saugmann's needle may be blocked and the manometric oscillations consequently interfered with. For the same reason it is of great importance that the Saugmann's needle should be absolutely dry, and for this purpose it is my practice to keep the needle in absolute alcohol until required for use. When taken out of the alcohol it is thoroughly dried over the flame of a spirit lamp, and hot air is blown through the needle by means of a small air bellows attached to the proximal end. At the first operation I prefer to use a needle with an opening at the end, but when a potential space has been established between the parietal and visceral layers of pleura I use a needle with a solid point and a lateral aperture at the end of the shaft immediately above the point.

With reference to the amount of nitrogen to be introduced and the alteration of intrapleural pressure to be brought about at the first sitting, some diversity of opinion exists. The two principal factors governing this question are—firstly, the presence or absence of pleural adhesions, and, secondly, the size of the chest. A point to remember is that one can proceed more rapidly with safety on the right than on the left side of the chest, as the normal position of the heart is less interfered with by introducing gas into the right than the left pleural sac. The use of x rays is of inestimable value in affording information as to the relative position of the intrathoracic organs, as percussio of the cardiac area becomes increasingly difficult and unreliable as the introduction of nitrogen proceeds. It has been my practice, in cases free from adhesions, to aim at producing a slight positive pressure (2 to 3 cm. of water) at the third of three successive sittings, which have taken place at intervals of a day between each. I have found that in chests of average capacity three separate injections of about 500 c.cm. of nitrogen each will bring about this result.

SELECTION OF CASES.
