road, Lambeth. It would seem probable that the murderer mistook his victim for another person, one Pullington, who worked in the same brewery with the murdered man. William Chester Minor is said to be a Member of the New York College of Surgeons, and to be a person of wealth. Papers found in his lodgings show that he has been an Assistant-Surgeon, and afterwards a captain in the United States army, and that on service he had suffered from sunstroke, which had left him unable to practise the Medical Profession. He is stated to be an artist of some merit, and came to England for the purpose of sketching English scenery. He brought with him a letter of introduction from a well-known American to Mr. Ruskin. It is to be sincerely hoped that further investigation of the case may prove Minor's insanity. His papers show that his mind was so affected by sunstroke in America that he was unable to practise his Profession, and it seems that he had come to Europe by Medical advice. On the other hand, there is a rumour that he had a pecuniary interest in Pullington's death.

We are indebted to Mr. Williams, of St. Thomas's Hospital, for the following notes of the post-mortem examination of George Merritt, sixty hours after death:—

"His external appearance was that of a muscular and well-developed man, apparently in the prime of life. On the anterior surface of the body, an inch above the right sterno-clavicular articulation, and about half an inch to the right of the median line, was a circular wound about a quarter of an inch in diameter, with its edges a little torn and discoloured. Over the right orbit there was a lacerated wound, by which the bone had been laid bare, and the nasal bones were fractured. The upper lip was contused externally, and lacerated on its internal surface. On the posterior surface a wound similar to that in the neck was observed, about an inch and a half to the left of the spinous process of the second dorsal vertebra. There was no other external injury. On passing a probe into the wound in the neck, and dissecting along its course, it was found that the sterno-mastoid was uninjured. The right common carotid presented two somewhat ragged perforations about two inches above the upper margin of the arch of the aorta; the anterior one, situated a little to the left, was less irregular in shape, and its diameter smaller. The subclavian artery was next found to be perforated, and both openings were larger and more ragged than those of the carotid. A wound was found in the upper lobe of the right lung, extending from the apex downwards and backwards, and emerging opposite the angle of the sixth rib, the upper edge of which was deeply grooved, and only an extremely narrow margin of bone maintained its continuity. In the middle of the subscapular fossa there was a starred fracture through which a foreign body might have passed. In the substance of the infra-spinatus muscle a conical leaden bullet was found, about half an inch in length and a quarter of an inch in diameter, weighing eighty-six grains. Blood was found to be extravasated in the connective tissue in the course of the wound; also in the mediastinum. The right pleura contained about a pint of dark-coloured blood. The course of the posterior wound was traced by means of the probe into the vertebral canal, and it was found that on the left side the lamina of the seventh cervical vertebra was fractured, and the lower margin of the lamina of the sixth cervical vertebra grooved. The membranes of the cord were perforated, and in its substance, within the arch of the sixth cervical vertebra, was found a bullet, much battered, weighing sixty-six grains. The substance of this part of the cord was completely disorganised. On opening the skull it was found that no fracture existed, but there was extravasation of blood over the posterior lobe on the left side of the cerebrum. The other viscera were healthy."

SANITARY STATE OF IRELAND.

SOME few weeks since we directed the attention of our readers to the very unsatisfactory state of sanitary regulations in Ireland. We are glad to perceive that this very deplorable state of things is likely to be remedied. The Lord Lieutenant, at the inaugural banquet of the Lord Mayor the other day, said: "In order to make clear and strengthen the administration of local governing boards and of sanitary measures in Ireland, it is proposed to consolidate, during the present

session, this administration with the Poor-law management which now exists." "This," says *Saunders's News-Letter*, "his Excellency believed would be of material importance, particularly with regard to sanitary matters, the present epidemic of small-pox furnishing a good example." As a matter of course, the Poor-law Medical Officers of Ireland will be constituted Health Officers under the extension of this Act. We recommend their attention to its provisions. The Poor-law Medical Officers' Association have, we understand, already taken the matter into consideration, and a scheme has been proposed with the intention of assisting the efficient operation of the proposed Act. The present necessity for the introduction of some well-devised sanitary measure for Ireland cannot for a moment be doubted; and we can hardly imagine a body of men better qualified to carry out the provisions of such an Act than Poor-law Medical Officers. The *Freeman's Journal*, in a leading article on the subject, forcibly portrays the evils resulting from the present unsatisfactory state of the sanitary organisation of the country, and insists upon the necessity of "centralisation," so far as sanitary laws and regulations are concerned. After showing that Practitioners connected with the Poor-law would constitute the best Medical Officers of Health, the *Freeman* makes the following very sensible and practical observations:—

"We are inclined to believe that there could not be any body of men better adapted to administer and give information as to the sanitary requirements of the country, and we have no doubt that in the event of legislation taking place in this direction these gentlemen will be appointed Health Officers, so combining the preventive along with the curative properties of this system. No doubt the extra duties that will be imposed upon them will call for extra remuneration. In the interest of the public we advocate a fair remuneration, for we do not believe in gratuitous sanitation. In their own interests these gentlemen had better look to it in time; they have before them the precedent of the Dangerous Lunatic Act—imposed 'without fee or reward.' The Poor-law Medical Officers' Association is not of very long standing, but during last session it gave evidence of great vitality. We would recommend them to perfect its organisation, and closely to watch what changes may be contemplated under the new Local Government Act."

SMALL-POX JOTTINGS.

IN the Whitechapel district three deaths had occurred from small-pox, and two new cases were reported during the past fortnight.—Three fresh cases of small-pox were reported in the Medical relief districts of Islington last week, as against seven the week before. There had been one death from the disease.—The Medical Officer of Health for Chelsea, in his last week's report, states:—"The existence of small-pox in the parish as an epidemic may be said to be now practically at an end. No deaths have occurred from this cause during the past six weeks, and a very small number of fresh cases can be ascertained to exist."—Dr. Lankester reported to the St. James's (Westminster) Vestry that in the past fortnight four cases of small-pox—all vaccinated persons—had been brought under notice.—In the Limehouse district twelve fresh cases were reported in the past fortnight; but there had been no death from the disease during that time.—The Aberdeen weekly return of small-pox cases up to the 15th inst. shows the total number of cases admitted in the Small-pox Hospital since the opening to be 85; new cases admitted on the 15th inst., 2; number of patients now in Hospital, 55; total discharged recovered, 17; dead, 13. The Convalescent Hospital is rapidly approaching completion, and will in all probability be ready for patients this week. In several country districts cases of small-pox—fatal in one or two instances—have occurred. These, however, have been readily traced to personal infection from the city, showing the necessity that exists for the most precautionary measures being taken.—Small-pox has assumed alarming proportions in Kirkaldy, and the town schools have been closed.—At the Hampstead Hospital during the last fortnight, 88

patients had been received, 25 had died, and 98 discharged, leaving 210 under treatment, against 245 at the date of the last report, thus showing a decrease in the epidemic in the Hampstead Hospital district.—At the Stockwell Hospital, during the same period, 52 patients had been received, 13 had died, and 85 had been discharged, leaving 149 at present under treatment, as against 195 at the date of the last report—viz., 98 in the Small-pox Hospital and 51 in the Fever Hospital. The decrease in number had been accompanied by a marked diminution in the type of the disease.—The Medical Officer of the Local Board of Lincoln having reported to the Sanitary Committee that two unvaccinated children suffering from small-pox were brought from Nettleham to the Hospital at the Lincoln Workhouse on the 12th inst., in an open cart, resolved that proceedings be taken against any person infringing the law for the future. Of the two children referred to, one died within twelve hours of admission to the workhouse, and the other on Thursday morning last. The father died only three weeks before in Sheffield of the same disease, in consequence of which his wife, being destitute, brought the children to her friends at Nettleham.—The report to the Cork Board of Guardians last week showed "that since the outbreak of the small-pox epidemic 232 patients had been admitted to the County Hospital, and there had been 35 deaths. Out of the 100 cases of non-vaccinated persons 32 had died, while of the 132 admitted who had been vaccinated only 3 died. Of the 100 that had not been vaccinated only 7 had the disease in a modified form, and of the other 93 cases of non-vaccination, of the most virulent form of the disease, 32 had died. Of the 132 cases that had been vaccinated, some imperfectly, there were 80 who had the disease in a mild form, and only 3 deaths. From these facts it will be seen that vaccination afforded protection from death and disfigurement from the disease, and that, although not relieving persons from the liability of getting small-pox, it did confine the disease to a mild form."—The weekly returns of the deaths registered in Dublin last week from small-pox show 47, against 45 in the week preceding. Eight deaths from the disease occurred in the North Union Small-pox Hospital; 4 of these persons had been residents in the city, and the residences of the remaining 4 were not given in the return.—Small-pox caused 12 deaths in Belfast last week.—Forty-eight persons died from small-pox in the metropolis last week. In the two previous weeks the deaths from the disease had been 52 and 68. The present week's return is lower than any week since December, 1870, when the epidemic began to prevail.—There were 46 deaths from small-pox in Rome during the first week of the present month.

SEWAGE AND FEVER.

SOME discussion has lately taken place with respect to the prevalence of fever amongst the men employed in the sewers of the metropolis. It appears from a statement made by Dr. Brewer, M.P., that in the metropolitan sewers 283 men are employed, whose ages range from 19 to 75, and the length of their service varied from seven weeks to fifty-two years. During the last year sixteen cases of fever occurred amongst them; of these eight were intermittent, which, it was considered, had nothing to do with the sewers. Sixteen cases, however, in 283 able-bodied men is a very large percentage indeed.

PAYING A FINE.

A STUDENT in the University, says the *Edinburgh Courant*, who was fined a guinea for disturbing his class last week, paid the greater part of it in halfpence, about a quarter of an hour being occupied by him in counting over the amount. This singular mode of "serving out" the Professor who inflicted the fine was carried out amid the laughter of the class, by whom the amount had been subscribed.

HEALTH OF CANTERBURY.

MR. G. RIGDEN, in his annual report of the health of Canterbury, says:—

“It must not, however, be imagined that, even when our drainage and water-supply are made complete, all, or nearly all, has been accomplished by our ruling authorities, or by our individual citizens, for the preservation of their health and prolongation of their lives; there will yet remain many removable sources of disease, foremost among which may be noticed the discreditable state of many of the cottages in which the poorer classes are obliged to reside, but which are totally unfit for human habitations, producing disease and mortality among the younger members, more particularly as may be remarked in the large proportion of deaths recorded at young ages in the city.”

HEALTH OF DUBLIN.

THE deaths registered during the past week were 231—111 males, and 120 females. The average number in the corresponding week of the previous eight years was 186. We refer to the deaths from small-pox in our “Jottings.” Fever proved fatal in nine instances in the Dublin registration district—viz., typhus in three, and typhoid in six. Two deaths resulted from scarlet fever, a like number from measles, and one each from diphtheria and croup. The deaths of eighteen children were referred to convulsions. Thirty-one deaths were caused by bronchitis, and three by pneumonia. Heart disease killed eight persons, and aneurism two. Two deaths were attributed to apoplexy, a like number to paralysis, and four to epilepsy. Twenty-four persons fell victims to phthisis, three to hydrocephalus, two to mesenteric disease, and one to scrofula. Two deaths resulted from accidental causes, and one was a case of infanticide. Sixty-three of the persons whose deaths were registered during the week were under 5 years of age, and forty-four were aged 44 and upwards.

SKIN-GRAFTING.

DR. THOMAS B. CLARKE, the Medical Officer of the Leicester Workhouse, in his report for the past year, says that a large number of cases of ulcerated legs had been admitted for treatment. With the hope of more effectually curing the same, and of preventing their recurrence, many of the sufferers have been induced to voluntarily undergo a newly introduced operation of skin-grafting, which consists in the transference to the ulcer of a number of small pieces of skin taken from other parts of the body. About twenty-five patients have been so operated upon, several two or three times in succession, with the best results in most of the cases. The progress of recovery has been remarkably accelerated, and a prospect of a recurrence of the ulceration greatly diminished.

THE LAW RESPECTING THE INTERMENT OF STILLBORN CHILDREN.

At an inquest held last week on the bodies of two “stillborn children,” at Liverpool, it appeared in evidence that a woman brought a box containing the bodies of two new-born female children to the cemetery in Vauxhall-road. The sextoness of the cemetery received it, and the woman handed her a certificate, of which the following is a literal copy:—“Feb. 10, Mrs. Griffiths midwife 073 Gordon St, delivered Mrs Dixon of a still born female child 705 Gordan St.” On inquiry being made, nothing was known of Mrs. Dixon at the above address, and Mrs. Griffiths knew nothing of the certificate. One of the children was born alive. The Coroner made some strong observations on the necessity of altering the law respecting the interment of “stillborn” children.

A FERTILE SOURCE OF DISEASE.

SEVERAL of the Medical Officers of Health of the metropolis have of late drawn attention to the injurious results of the accumulation of filth in dustbins, and some have suggested remedies for the abuse. The fault, it would appear, sometimes

rests with the authorities. At the last meeting of the White-chapel Board of Works, it was stated by the Sanitary Officer that the work of the dust contractors was performed in a most unsatisfactory manner; but it turned out that the authorities were unable to effect a remedy, as they had no power under the contract to inflict a penalty for neglect. The dust contractors, therefore, do as they like. This is really a disgraceful case of negligence on the part of the Board in drawing up their contract; and they must be held responsible for their loose way of doing business, for the occurrence of fever and other preventible diseases arising from the non-performance of their duties by the dust contractors.

FROM ABROAD.—THE FRENCH LIBERATION SUBSCRIPTION—CASE OF SPONTANEOUS HYDROPHOBIA—TURPENTINE IN PERITONITIS—EXCISION IN GUNSHOT FRACTURE OF THE HUMERUS.

THE Liberation Subscription which has been opened in France seems to have been commenced without sufficient deliberation, so that both the desirableness of instituting it and the possibility of realising a sum at all commensurate with the object in view have been canvassed in various quarters. Originating with ladies, as the idea did, it has perhaps, as with some measures which they have recently taken in hand amongst ourselves, been characterised rather by generous impulse than sound discretion; for even its complete and speedy realisation, in view of the present critical state of French finances, is considered by some of the economists as a very questionable advantage. However, of this, when the fearful amount to be exacted is considered, there is no danger, which indeed, in the opinion of many, lies in the other direction of the amount collected being absurdly small as compared with that needed. Those who are aware of the sustained exertions which would be required to raise by voluntary subscription even one million sterling for any purpose whatever may well be staggered when one hundred and twenty are in question. The Medical Profession, as such, has finally determined not to subscribe, leaving it to each member of this to contribute in his own locality to the common fund. This resolution has been hastened by the decision arrived at by the Council of the Academy of Medicine, and approved of by the Academy. At the meeting of the Academy on the 13th inst., the President, M. Barth, announced that the Council had agreed unanimously that the Academy should not subscribe as a separate body, and that it did not recommend any special subscription to be raised by the Medical Profession. The Council, however, warmly supported the general subscription itself, and besought all members of the Profession to contribute to it. The Committee formed by the wives of Medical men at the instigation of Madame Jeannel, and presided over by Mesdames Wurtz and Nélaton, will, in deference to this opinion of the Academy, of which so many of their husbands are members, cease to act as a centre for the collection of subscriptions exclusively from the Profession, and will form only one of the branches of the General Committee. We can but wish this generous enthusiasm may be crowned with success; but, as we observed above, grave doubts are entertained by very patriotic citizens whether the effort is expedient, and still graver of its success.

In the autumn of last year M. Guillery related an interesting instance of “spontaneous hydrophobia” to the Belgian Academy of Medicine, which is reported in the eighth number of its *Bulletin* for that year.

A vigorous old man, 71 years of age, a tailor by trade, who had always had the best of health, was attacked on February 5, 1871, with pain in the head, neck, and temporal region, which he attributed to cold. He thought little of it until he found, in the evening, on placing his hands in water for the purpose of washing them, that he was seized with a violent and painful spasm of the throat, and a great repugnance to repeat the immersion. Feeling thirsty, he tried to drink some water, tea,

and coffee, but at each attempt the spasm returned and prevented him. This state of things continuing, M. Guillery was called to him on the 7th, and found him quite calm, speaking of his malady more as a curiosity than a suffering. He swallowed some meat without difficulty, but dared not appease his ardent thirst. Introducing fluid into the mouth without seeing it, by means of a tube, had also brought on the spasms. Persuaded to try, he managed by an immense effort to get down two teaspoonfuls of coffee, but declared that he preferred enduring the thirst to repeating the painful attempt. The mere sight of liquid brought on the spasms, accompanied by paroxysms of intense and prolonged fear. The liquid once removed, he conversed calmly upon his strange malady. His pain of the head had disappeared; there was no fever or acceleration of pulse, and his tongue was only whitish. On the 8th, the symptoms described were found persisting and aggravated, cruel suffering having been produced by attempting to wash the hands. The only thing the patient could take was a few morsels of bread dipped in wine, which had to be conveyed from behind, so that he should not see them. Mere looking at a glass of water produced a fearful spasm. An hour after he died, declaring that the attempt to do this had killed him. No post-mortem was performed. It is quite certain that he had not been bitten by any dog.

At a recent meeting of the Paris Hospital Medical Society, M. Vidal took occasion to call the attention of his colleagues to the great value of turpentine as an external application in partial and general, and even in puerperal peritonitis. Trousseau, originally importing this remedy from England, employed it in large doses internally. In peritonitis, M. Vidal soaks a piece of flannel thoroughly in the turpentine, and having applied it over a large portion of the abdomen, covers it with gummed silk. It remains on until vesication is produced at several points, when the silk is removed in order to allow of the evaporation of the turpentine. Under this application he has in many instances seen patients, who were very far gone, rally completely and recover. M. Bourdon inquired whether this application of turpentine had been employed in any cases from the commencement, and whether leeches, cataplasms, &c., had been also resorted to. In this case the turpentine would have acted just like an ordinary blister, and it is well known that in advanced peritonitis advantage is sometimes derived from resorting to blisters and Todd's mixture. He also suggested that the turpentine might act in the same way as the castor-oil collodion employed by M. R. Latour, by preventing transpiration and the contact of air. M. Vidal believes, however, that turpentine does not act in this way, but as an energetic and diffused revulsive, while at the same time it undergoes absorption by the skin and respiratory organs. At first he did not employ it so exclusively in peritonitis as he now does, as he then used to apply also leeches. Now he resorts without hesitation to the turpentine at once. He generally combines with it the application of ice, or what might be termed compression by means of ice, and under certain circumstances he would still use leeches. M. Moutard-Martin, believing the action of the turpentine to be solely topical, asked whether comparative trials of it and of blisters had been made; but M. Vidal is convinced that it also acts internally. That it is speedily absorbed is shown by the odour of the urine; while, soon after its application, the patients seem as if a cordial had been administered to them, and their cyanosed lips soon recover their colour.

At a recent meeting of the Lyons Society of Medicine, M. Ollier read a memoir on "Excision of the Diaphysis of the Humerus after Fractures from Gunshot." This he had practised in three cases during the late campaign on the Loire, removing nine, seven, and six centimetres of the bone; and all the patients did well. In one of these the excision of six centimetres was performed on the upper third of the humerus, below the

head, which firmly united with the rest of the bone, and the uses of the limb were completely re-established, the shortening which remained being only twenty-five millimetres.

The cases of gunshot wound of the humerus, M. Ollier observed, in which his operation is indicated are comparatively rare, and expectation should be the general rule. It is in comminuted fracture, with denudation of the periosteum and contusion of the medulla, and especially when the projectile remains amidst or in the vicinity of the fragments, that intervention should take place. At a later period inflammation and pain may also render excision necessary; for one of the immediate consequences of the operation is the disappearance of the pains, to the great relief of the patient. M. Ollier's mode of procedure is entirely different from the old one for the removal of fragments of bone; for, in spite of the comminution, a true sub-periosteal excision should be attempted. Each fragment is successively seized and separated from its periosteum, so that at last a tolerably complete periosteal sheath is obtained, in spite of its lacerations opposite the seat of fracture. The bone, in fact, being a very compact body, is broken into a number of fragments completely separated from each other, while the more supple periosteum resists. It becomes more or less torn, and remains adherent to the soft parts and the fragments, especially in young subjects. The modifications produced in the periosteal adhesions by age are indeed considerable, and are very important as regards operations. When the splinters have been removed, the fragments must be excised to beyond the extent of the fissures. If, however, the fissure extends to the spongy tissue, and the subject is young, it need not be pursued if the soft parts are intact; but when it penetrates to a joint, an articular excision must be executed. After an excision, the ends of the bone should be brought nearer to each other, in proportion as there is little expectation of bony reproduction, which is less in proportion to the age of the patient. The silicated bandage favours the reparative process, and may require to be continued for months. In answer to a question as to the prevention of stiffness of the joints ensuing, M. Ollier replied, that so long as the inflammation persists, the bandage must be left on, it being indeed the best means of limiting the traumatic inflammation; and whenever it is renewed, movements should be imparted to the elbow and shoulder. The apparatus may, in fact, be left on without renewal for a month or five weeks, and ankylosis will usually be avoided, unless the fracture is too close to the joint. In conclusion, he repeated that expectation is the rule, and that excision is only suited for particular cases. It is especially indicated when, some time after the accident, complications arise; while, when there is intra-articular fracture, it should be performed immediately. The influence of age must also never be forgotten.

PARLIAMENTARY.—THE VACCINATION LAWS—METROPOLITAN WATER-SUPPLY—THE GOVERNMENT PUBLIC HEALTH BILL—SIR C. ADDERLEY'S BILL FOR CONSOLIDATING THE EXISTING SANITARY LAWS.

In the House of Lords, on Friday, February 16,

Lord Buckhurst gave notice that on Thursday next he would move for the appointment of a Select Committee to inquire into the operation and efficiency of the Vaccination Laws.

In the House of Commons,

In answer to a question by Mr. Stapleton, as to the impure state of the water recently supplied by some of the water companies,

Mr. Chichester Fortescue said the inspectors had been instructed to examine the reservoirs and filtering-beds of the water companies at least once a month, and to make a special report on the subject if occasion required it. The impurity of the water during January appeared to have arisen partly from the floods and partly from alterations which were being carried out.

Mr. Stansfeld brought in his Public Health Bill. Premising that it was a sanitary Bill and nothing more, and was founded on the report of the Sanitary Commission, he excused himself, on the score of urgency and want of time, from attempting to consolidate the existing laws, and from creating new Local

Boards. The Bill was divided into two main parts—the construction of local sanitary authorities, and the institution of new sanitary powers. With regard to the last, he showed, by a recapitulation of the principal sanitary Acts, that there were already ample powers in existence, and the first thing to be done, therefore, was to construct efficient machinery for working them. The essential parts of this machinery he defined to be a central controlling power, the institution of a definite local authority, and a definite responsibility cast on this authority, instead of mere permissive power. In the urban districts the local authorities would be Town Councils, Improvement Commissioners, and Local Boards, and the Boards of Guardians would be the authority in the rural districts—power being taken to combine different districts for sanitary purposes, such as the conservancy of rivers, the construction of sewage works, etc. As to the new powers, these Local Boards would be empowered to inspect drains, both inside and outside houses. As to pure water, power existed already for supplying water. He would ask for powers to test the purity of the water which was supplied by the water companies. A noble lord asked him the other day whether he proposed to deal with the adulteration of food and drugs. He did not propose to deal with the question of drugs. As to the adulteration of food, there were powers under the Nuisance Removal Act of dealing with unwholesome food, and he proposed to extend these powers specifically in certain directions. But he proposed also to make the local sanitary authority the authority for acting under the Food Adulteration Act of 1860. He proposed also to call upon the local sanitary bodies to provide Hospitals and all the appliances and Medical attendance for the treatment of epidemics. He also intended to ask the House to give to the Local Government Boards with respect to the country the same power which the Poor-law Board possessed in the metropolis, of requiring the institution of Poor-law Dispensaries and the provision of drugs for the treatment of paupers. He proposed, of course, to call upon the local sanitary authority to appoint sanitary officers, including Medical officers, who, as he thought, might or might not be Poor-law Medical Officers. With the assistance of these officers the Government hoped to secure those statistics of disease as well as those statistics of death which were now afforded to the Registrar-General. As to the compulsory registration of births and deaths, that would be provided for by another measure. He thought he had now stated in brief outline the provisions of this Bill. It reconstituted authorities and endeavoured to simplify them. It gave new powers and imposed distinct responsibilities. The Government entertained a confident hope that this measure before it left the House would assume a shape which would do credit to the House, and would be of lasting benefit to the health of the population of this country. The right hon. gentleman concluded by moving for leave to bring in the Bill.

Sir C. Adderley regretted that Mr. Stansfeld did not contemplate consolidation, without which any new legislation would be comparatively ineffectual, but he offered him all the support and assistance in his power to pass the Bill.

Mr. A. Johnston, Mr. F. Powell, Dr. Brewer, and others made some remarks, and the Bill was brought in and read a first time.

Sir C. Adderley obtained leave to introduce a Bill for consolidating and amending all the laws on public health and local government for England and Wales, exclusive of the metropolis.

REVIEWS.

A Practical Treatise on Bright's Diseases of the Kidneys. By F. GRAINGER STEWART, M.D., F.R.S.E., F.R.C.P.E.; Physician to the Royal Infirmary, Edinburgh; Lecturer on Clinical Medicine; formerly Pathologist to the Royal Infirmary, Edinburgh; etc., etc. Second Edition. Edinburgh: Bell and Bradfute. Pp. 334.

It is with pleasure we turn to this book, for it is a record of good work carefully and well done, impressed throughout with the marks of original thought. But it is more; for it contains, also, duly amalgamated, the conclusions of brother-workers on the subject. As Physician to the Royal Infirmary, Edinburgh, and as Pathologist to the same institution, Dr. Stewart has had great opportunities of studying any particular subject to which he may have directed his attention; and having for years studied this particular malady, he is fully entitled

to be listened to as an authority on the subject. Nevertheless, we shall take the liberty of applying to his work some kindly criticisms which Dr. Stewart, we dare say, will not take amiss.

The author describes three forms of kidney disease, which he includes under the title of Bright's diseases. These three are—tubular inflammation, whether in the inflammatory, fatty, or atrophic stages; amyloid degeneration, beginning in the vessels, but ultimately affecting the tubules; and the small gouty or contracted kidney. This classification is essentially pathological, and, we think, fails to mark certain clinical distinctions it is well to bear in one's mind.

In his introduction, Dr. Stewart discusses and rejects a classification given in Rosenstein of Groningen's excellent work on kidney disease—partly justly, and partly, we think, not indeed wrongly, but inconveniently. The grouping of the forms of Bright's disease given by that author is into Obstructive Hyperæmia, Catarrhal Nephritis, Diffuse Nephritis, and Amyloid Degeneration—Rosenstein wrongly refusing to recognise the gouty kidney, and Dr. Stewart rightly including it in his list of morbid conditions. That a form of Bright's disease with contracted kidney does exist most pathologists in this country will be prepared to admit. But we cannot agree with Dr. Stewart in refusing to acknowledge the first two varieties of Rosenstein. It is true that obstructive hyperæmia of the kidney arising from heart disease is not, technically speaking, a form of kidney disease; nevertheless, it gives rise to albuminuria and to certain changes in the kidneys. Whether these changes, especially the hardening, the increase in the connective-tissue corpuscles, and the changes in the epithelium, are enough to give it a specific place in the list of kidney diseases on a pathologic basis, is another matter. Clinically, we are fain to recognise it. The distinction between it and most other forms of kidney disease, in that the quantity of solids secreted by the kidneys is nearly normal, is of very great importance; and so we think it well to recognise the condition by a specific name—obstructive congestion.

So, too, is it with catarrhal as compared with diffuse or parenchymatous nephritis. We are quite prepared to admit that, pathologically, these are both forms of the inflammatory Bright's disease recognised by Dr. Stewart. Nevertheless, we hold it convenient to give a distinct name to a condition due to a causation incapable of setting up the more severe form of the malady. This gives rise to albumen in the urine, but does not greatly interfere with the excretion of urea and such-like waste products—in short, the condition called catarrhal nephritis bears somewhat the same relation to parenchymatous nephritis that capillary bronchitis does to pneumonia. We quite admit that strict accuracy is on the side of Dr. Stewart; we are quite sure convenience and no necessary inaccuracy is on ours.

There is another form of kidney which is still a bugbear to many, which Dr. Stewart has done well to sweep away—that is, the fatty kidney. Fatty degeneration may occur in any form of the disease, or even when there is no albuminuria, and so ought to be got rid of altogether as a distinct pathologic variety of Bright's disease.

Of the many excellent histories which follow we shall say nothing, though we should have been glad to have received from them a hint on more than one subject. We confess our mind has been filled with envy, on reading German cases, to note that day by day the *quantity* of albumen passed was given. Here we find nothing of the kind; and we sadly regret that we are not able to suggest any simple remedy for the deficiency. The estimation by the space occupied by coagulum in a test-tube is very fallacious, though commonly it is the only thing relied upon; and the process of drying and weighing is too tedious to be used out of the laboratory. Hoppe-Seyler says the Ventzke-Soleil polarisation apparatus gives, with light-coloured urine, fairly good results, but is useless if the urine is very dark. We have no personal experience of its use. As the same apparatus can be used for estimating sugar, its introduction into the Edinburgh Infirmary might be advantageous.

In explaining the conditions of the urine, local alterations of blood-pressure are duly acknowledged; but we hardly think that the difficulty of accounting for the presence of albumen with, at the same time, diminution of fluid—the two implying opposite conditions of pressure—has been made perfectly clear. We note, with regard to the amyloid form of the disease, that Dr. Stewart accepts an unnatural permeability of the blood-vessels as the explanation of the characters of the urine, and rejects the notion that it is obstruction from the diminished calibre of the vessels, with consequent increase of the blood-pressure, which is the cause of the polyuria and slight albu-

minuria. As to the true reason of the polyuria in the advanced stage of contracted kidney, Dr. Stewart is silent. Nevertheless, we think, having a view to the small kidney and the big heart, there can be but little doubt that increased pressure is the true cause.

There are so many points of interest in connexion with this subject that we have no time to touch upon them all. There, for instance, is the causation of dropsy, the origin of the nervous symptoms, and many others we should like to discuss, but forbear. As to the dropsy, where do we see it first? In parts where the subcutaneous connective tissue is loosest or contains no fat. It is a fact that most frequently in renal dropsy the effusion begins at some such elected spots—not, as in cardiac dropsy, where the circulation is weakest only; and this surely points to over-distension of vessels, and not to impoverishment of blood as the cause of the serous effusion.

We cannot, however, discuss every question which thus arises; but we think we cannot do better than refer our readers to Dr. Stewart's pages. We cordially commend his book to their careful study.

NEW BOOKS, WITH SHORT CRITIQUES.

Notes on Nuisances: Drains and Dwellings, etc. By W. H. FENNING, F.G.S.

. A short, popular treatise on a subject now engaging so much of public attention. It treats very ably of sewer-gas, gas, decaying organic matter, paper on walls, damp, smoke, and sundry nuisances; and there are chapters on ventilation, air-shafts, and on the prevention of nuisances.

Transactions of St. Andrews Medical Graduates' Association, 1870. Edited by Dr. L. W. SEDGWICK, J. and A. Churchill.

. A volume highly creditable to the Association, and containing several papers of great interest and importance.

GENERAL CORRESPONDENCE.

ELIMINATION IN SMALL-POX.

LETTER FROM DR. G. JOHNSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your correspondent "M.B." quotes my statement that the choleraic discharges "are as essentially curative as is the cutaneous eruption of small-pox," and upon this he proceeds to argue that if I believe this I ought to treat my small-pox patients "by closed doors and windows, roaring fires, etc.," the object of this highly rational treatment being, of course, to insure that the patient shall continually breathe an atmosphere charged with the poisonous emanations from his own skin. So, if I could convince "M.B." that the choleraic secretions are poisonous, he would obviously arrive at the conclusion that their expulsion from the bowels should be prevented, or, if this were found impossible, that the patient should be compelled to swallow them as rapidly as they are discharged. This is evidently the line of argument, and this is the logic of your correspondent, whose mode of reasoning and whose allusion to "taking up the gloves" suggest the inference that the initials "M.B." indicate, not a Graduate in Medicine, but a Master of Boxing. Why does he conceal his name, and shrink from the fame which is his due? I am, &c.,

Savile-row, February 20.

GEORGE JOHNSON.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 6.

Mr. HILTON, F.R.C.S., President, in the Chair.

MR. BALMANNO SQUIRE exhibited a patient the subject of Lupus in a very early stage. The same patient some years ago had suffered from lupus of the nose and chin; she was then very bad, and was ill for several years. At the present moment another attack was commencing. He had only seen one other case as early as this. The original sore had been healed since 1865. The one now present affected the middle of the right cheek, where it looked somewhat œdematous.

Dr. MOXON read a report on Dr. Greenhow's "Billiard-ball" Tumour. He thought it had grown, not by aggregation, but by true nutrition from the peritoneal juices.

Mr. HEATH showed a specimen of Fibro-cystic Tumour of the Jaw, removed from a patient aged 22, who had been the subject of the disease for six years. The cyst in its interior discharged into the mouth; but its size was the main inconvenience. He divided the jaw, and proceeded to remove the tumour by section of the tumour below the articulation. The patient did well. The tumour resembled that described by Mr. Wagstaffe last year. Its structure seemed glandular, with an apparent epithelium.

Dr. LIVEING exhibited a specimen of Diseased Liver taken from a patient aged 21, from whom no history of syphilis could be obtained. He suffered from diarrhoea and vomiting, and had caries of the skull. After death the liver was found large and dense, with puckering like those of syphilis on its surface, and some amyloid infiltration through it. The kidneys were small and amyloid. The spleen gave amyloid reaction with iodine. There were ulcers in the intestine, and the lung was affected with chronic phthisis. The urine was light in colour. In reply to Dr. Quain, he said there were no marks indicating communication between the intestinal ulcers and the liver.

Dr. MOXON said, with reference to the urine, that in amyloid kidney disease it was usually very light, but in one case he remembered it was dark-coloured and highly loaded.

Dr. GOWERS next showed a Large Liver, the enlargement being cancerous, from a patient at the Hospital for the Paralyzed and Epileptic. The mass had affected the lumbar glands, and there interfered with the functions of the cord. The matter in the liver was soft, almost diffuent, and seemed contained in something like cysts.

In reply to Mr. Hulke, Dr. GOWERS said the liver disease was probably secondary.

Mr. W. ADAMS asked, with regard to some cancer found in the breasts, if it was in both, as that was rare.

It having been elicited that nodules were found in both breasts, Mr. ARNOTT said he had seen eight or twelve instances of double mammary cancer in two or three years.

Mr. SIDNEY JONES had at the present moment two cases of double cancer under his care; and

Mr. JONATHAN HUTCHINSON had seen three where the cancer seemed primary in both.

Mr. ARNOTT had not been able to satisfy himself that it ever arises in more than one spot at a time.

Mr. HUTCHINSON exhibited a specimen of Malignant Growth removed by amputation above the knee. The patient, a healthy married woman, had for fifteen months suffered pain and inconvenience between the tibia and fibula on one side. He tried syphilitic remedies, but she got worse rather than better. He examined by incision, and found a mass extending up in front of the bones, which was deemed malignant. He removed the limb, and found the muscles infiltrated, but no direct communication with the bone, which was discoloured. In some muscles the new material was tolerably well isolated. He considered the growth infecting, and allied to medullary cancer, if not that growth. (Referred to the Morbid Growth Committee.)

Mr. SIDNEY JONES thought this was something like a periosteal swelling which occurred in his practice. It existed in the limb and in masses in the scapula and muscles. It proved to be syphilitic.

Mr. HUTCHINSON said he remembered that case. Was there any determination as to its being cancer or syphilis? This was not syphilitic.

Mr. MOXON said that in syphiloma of the liver the portal glands might be secondarily affected.

Mr. S. JONES agreed with this, as in gumma of the arm there may be swellings in the axilla. He could give no recent history of the case. He thought there was no return some years after.

Dr. THOROWGOOD exhibited a Biliary Calculus, which gave rise to no symptoms during life. It was heavier than usual.

Dr. KING exhibited an Aneurism of the Aorta, which had been perforated by a rib, and which gave rise to embolism of the cerebral artery. The patient, a male aged 42, in a street row got a blow, and fell. After this a swelling appeared below the clavicle, and a pulsating tumour could be discovered to the right of the sternum. There was no dyspnoea at first, but the tumour increased in size. One night, turning in bed, he became insensible, his breathing stertorous, and he died. Blood was effused over the brain, and the corpora striata were softened. The left middle cerebral was plugged with black clot. There

was an aneurism of the aorta in the first part of its course, and the sternum was eroded, as was the first rib, which had been fractured and united again irregularly. The fractured ends had perforated the true aneurism, and had formed a false aneurism. The first aneurism had its wall thickened from clots.

In reply to the President, it was stated that the upper portion of the bones only had united.

In reply to Dr. C. T. Williams, Dr. KING said the pupils, as observed during life, were even.

Mr. JABEZ HOGG showed a Madura Foot, in which the diagnosis had been made out moderately early. An abscess had begun on the sole of the foot. It was opened, and a poultice applied, on which some of the characteristic truff-like bodies were found. Madura foot was common in the village to which the man belonged. He had found some black, soot-like bodies in the tissues, which had a fungoid appearance.

Mr. ARNOTT asked if the fungus was the essence of the disease, or if it was only introduced. Most specimens were examined too late to determine this point.

Dr. MOXON recorded a case of Subacute Red Atrophy of Liver. He said this case shows very conclusively that there is a change of the liver towards which acute atrophy stands as a severe or violent degree of the same thing; so that this change itself, which is a red atrophy, is a slower or less intense degree of acute yellow atrophy. The liver was from the body of a woman who died in Guy's Hospital, having been under his care for jaundice, which lasted eight weeks. She was the mother of six children; but at the time of her seizure was living with a man who was not her husband. She was suckling, and not pregnant. Two bottles of brandy were found one day under her pillow, and she seemed drunk. She died five days after with symptoms of acute yellow atrophy of liver. The liver was partly bright yellow and partly deep blood-red—the latter colour about the great vessels chiefly. This red part showed great thickening of the vascular network, with semi-recent lymph; and pus-like cells were around the portal vein. In this country it has never been shown that acute yellow atrophy has chronic stages producing a red atrophy with inflammatory characters; but Waldeyer and Klebs, in Germany, have published cases. Dr. Moxon had met with three well-marked examples, drawings of all which were exhibited. There is a resemblance to the described effects of phosphorus on the liver; but it is not like Rokitansky's red atrophy, which should be called brown atrophy, from its colour. A drawing of this was shown.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 26.

Sir WM. W. GULL, Bart., M.D., F.R.S., President, in the Chair.

Mr. COOPER FORSTER read a paper "On Two Cases of Popliteal Aneurism," the treatment of which, though not novel, was calculated to elicit the opinion of the Society on a most important point of Surgical practice. The first case was that of a labourer, aged 35, sent to the author by Dr. Poole, of St. Paul's Cray. An intemperate man, with good general health, he had noticed, ten days before admission into the Hospital, pain in his left knee, followed in a few days by swelling. He came under notice with all the signs of popliteal aneurism. The treatment, which throughout was by means of instrumental pressure and flexion, extended over an interval of fifty-five days. In the first instance, this was applied by a dead weight on the artery in the groin, and by a screw-tourniquet, without chloroform. A Reid's compressor was subsequently used in place of the weight. The femoral current was by this means entirely arrested for some hours each time; but this failed to produce the desired effect, and chloroform was afterwards administered, while the pressure was kept up for periods which varied in duration from nine hours and a half to four hours. The sac gradually became smaller and harder, but pulsation had not finally ceased till December 23. The man left the Hospital well on January 3. The second case was that of a gentleman, aged 34, strong and hearty, given to athletic exercise, who felt pain in the calf of the right leg five months before he first came under notice; and two months later, he had pain and pulsation in the popliteal space. Two months more elapsed, during which time he walked about and took no notice of his leg, and then he consulted a Surgeon, who applied instrumental pressure to the sac itself. This gave excruciating pain, and no improvement resulted. When the author saw him, the popliteal space contained an aneurism the size of a

small orange, in which pulsation was very strong, and not arrested by flexing the leg to the utmost. Much swelling of the leg, moreover, existed, with excoriation of skin, the result of the previous treatment. The treatment was by pressure—instrumental for the first three days, by means of weights in the groin and a tourniquet in the middle of the thigh; this produced no effect. Digital pressure was then resorted to, three of the patient's friends compressing the femoral alternately for periods of ten minutes, the author of the paper sitting with his hand on the tumour to guard against the return of pulsation. The aneurism was cured by this means in three hours and a half. Mr. Forster thought that, to insure success, the great point to be attended to was that the current of blood through the sac should be completely arrested, and this in opposition to the view first held by Bellingham. Another question also arose as to when pressure, if adopted, should be discontinued in favour of ligature, and as to when it was unadvisable in the first instance. The author, from a review of of his whole experience in this disease, questioned whether pressure would not always be successful if tried with patience, and carried out with care. And for his part, he expressed the opinion that the disadvantages, even where chloroform was necessitated for long periods, were so insignificant, and the *prima facie* physiological arguments so strong in its favour, that he did not hesitate invariably to try it, and as yet he had done so always with success.

Mr. ERNEST HART said that the first object of the Surgeon was completely to control the circulation. The prevailing doctrine, that aneurism should be treated so as to obtain spontaneous cure by successive layers of lymph, had no real foundation. Surgeons should, he thought, discard the idea of the deposition of layers of lymph. It was in the effort to avoid pain caused by the complete stoppage of the blood that the Irish Surgeons tried to cure by the small current. There was now no reason why we should not aim at complete obstruction, aided, as we now are, by chloroform. There were now numerous cases of cure from complete stoppage of the circulation, thirty-four cases in which flexion had been successful, and in two of these all other methods failed.

Mr. CAMPBELL DE MORGAN said that cases treated by pressure varied, some aneurisms remaining uncured for months, even in cases in which digital pressure was applied for hours and hours together. He alluded to one case in which, after pressure was removed, the tumour existed much as before; and related a second case in which digital pressure was applied, but afterwards, when the man died, no layers of fibrine were deposited, and no outlet to the sac could be found. Some cases, no doubt, occurred in which pressure failed.

The discussion was adjourned until February 9 on the motion of Mr. HULKE, seconded by Mr. BARWELL.

FRIDAY, FEBRUARY 9.

E. H. GREENHOW, M.D., F.R.S., Treasurer, in the Chair.

The discussion on Mr. Cooper Foster's paper on the "Treatment of Popliteal Aneurism" was resumed by Mr. Barwell. In the middle of May, 1870, Mr. Barwell, and Mr. Cadge of Norwich, together with Dr. Beverly, treated a gentleman, aged 38, for a right popliteal aneurism due to violent exertion. Dr. Carte's apparatus was applied, and the screws carefully adjusted. No lowering diet or remedies were given; neither opium nor chloroform was administered. Chloral acted well the first time; but on a second trial so uncomfortably, that the patient declined to take it again. The patient was possessed of remarkable patience and fortitude. Nevertheless he described to Mr. Barwell that on the morning of the fifth day he felt that he could go on no longer; the artery throbbled violently and rapidly, the screws jumped with each beat, and he himself felt dispirited and exhausted, when the artery quite suddenly gave up the fight, and he felt quite comfortable and at ease. The cure thus effected in five days was confirmed by a fortnight's rest. The author drew attention to three points:—1. This cure was followed for three months by pain, and although the patient could in the same winter (1870-71) both dance and skate, yet walking at that time provoked pain. In one of the cases detailed at the last meeting by Mr. Forster, severe pain existed six years after the cure. This pain, Mr. Barwell believed, was a constant sequel, and yet no writer has mentioned it. 2. In reference to the choice between rapid and gradual cure by compression, he agreed with Mr. Hart that an aneurism cured in three hours and a half, in three-quarters of an hour, and, *à fortiori*, in twenty minutes, must, as far as danger from gangrene was concerned, be in the same position as one cured by

ligature; hence, in an old enfeebled constitution, the choice of method must be influenced by this consideration. 3. The peculiar exacerbation of pain and throbbing just before the cure of the aneurism gave occasion to compare this case with certain published ones of spontaneous cure as well as with some results of pressure treatment.

Mr. MAUNDER observed that the danger of gangrene under the rapid method was very slight. He believed that metropolitan Surgeons were not in the habit of tying the femoral artery for popliteal aneurism until pressure had been tried. The statement of Mr. Forster, that he had never required to ligature the femoral for popliteal aneurism, was more or less valuable according to the number of cases he had treated.

Mr. LAWSON related particulars of a case in which, after three-quarters of an hour's pressure, the patient, who was under chloroform, became faint and exhausted; and four hours afterwards the tumour-pulsation ceased entirely, and remained in this condition.

Mr. HULKE thought that Mr. Lawson's case was a mixed one, as compression had been tried three weeks before, by which collateral circulation may have been established. It seemed to him not so safe to have a loose black clot as a tough fibrinated one. He alluded to one case in which, after rapid cure, suppuration of the sac took place, and ended fatally; and other two in which recovery took place after amputation of the limb.

Mr. ARNOTT referred to the auxiliary means open to the Surgeon, of diminishing the heart's action by drugs.

Mr. JOHN CROFT expressed the opinion that the circulation in some, at least, of these cases was not completely arrested. He related a case cured in forty-eight hours, in which the clot was laminated and partly spongy, through which, however, a small passage ran.

Mr. HULKE asked if Mr. Forster, or any other gentleman present, had any personal experience of the treatment of aneurism by kneading, breaking up the fibrinous clot, and plugging up the distal end of the artery.

Mr. ERNEST HART said that in St. George's Hospital Museum there was a beautiful specimen of aneurism with a passage between the clots, in which the aneurism was cured, the man dying of another disease. The proportion of accidents occurring in the sac was less in rapid than in slow cures.

Mr. THOMAS SMITH had seen sudden swelling, with great pain, of an aneurism occurring, in which the symptoms were thought to be caused by the bursting of the aneurism, but proved to be really symptoms of cure.

Mr. DE MORGAN related two cases of spontaneous cure of aneurism in men, both of whom had been in great agony for a time, but shortly afterwards the pain suddenly left, and they were cured. He thought such cases were explained by the rapid increase in the size of the aneurism caused by its distension with blood. This was brought about by a detached clot, which acted like a valve to the opening of the aneurism, and closed at the end of each systole, thus retaining the blood which had been pumped into the sac by the systole. The distension become ultimately so great as to cause rupture of the aneurism. No bad results followed. In reply to Mr. T. Smith, he said that plugging of the distal extremity of the artery or aneurism would not explain the symptoms, for Brasdor's operation did not produce pain and swelling of the aneurism.

Mr. BARWELL, in reply to some remarks on his paper, observed that low dieting made the patient weak and irritable, and that Vanzetti used to give wine to his patients during operation.

Mr. COOPER FORSTER, in reply to Mr. Maunder, said that he could not at the moment recall the number of cases of popliteal aneurism he had treated, but they numbered at least seven. The principal object of his paper was to urge more confidence in the method by pressure, and to call forth opinions as to the length of time pressure is to be applied before ligature should be used. He wished to encourage the use of the pressure method until the operation was made always successful in popliteal aneurism, and also the method by flexion. In popliteal aneurism there was a long vessel, the femoral, where one could apply pressure easily and get a clot. The advantage of complete pressure was this, that a return current from the collateral vessels could be got. He did not at all approve of kneading the artery.

Mr. J. W. HULKE read a paper on "Cases of Cancer treated with Condurango" in the Middlesex Hospital. The author and his colleague, Mr. Campbell De Morgan, were enabled by the present of a parcel of condurango bark by an American Surgeon to begin, in November last, a second trial of this

reputed remedy for cancer. When this supply ran short, the trial was continued with bark bought of Messrs. John Bell and Co., and with a fluid extract very liberally placed at the author's disposal by its makers, Messrs. Bliss, Keine, and Co., of New York. After briefly noticing its natural history, and the physiological and therapeutic properties assigned to the condurango, the author proceeded to relate two cases of ulcerated hard cancer of the female breast, and one of rodent cancer of the face, in all of which the exhibition of the reputed remedy failed to modify favourably, or to retard the progress of the disease. The result of this trial confirmed the author's first one, made in August and September last, which showed that, as a remedy for cancer, condurango was absolutely inert.

Mr. DE MORGAN also read a paper containing a report of three cases treated at the Middlesex Hospital, showing the uselessness of condurango; and he mentioned others which had come to his notice, tending to prove the same thing. He considered it very important that the fact should be widely made known that this and other so-called remedies for cancer had really no effect on the disease, as statements of wonderful cures were inducing the public to put faith in them, and to waste time and money in their trial. Of the cases on which he had tried the medicine, two were advanced cancers of the breast, and one was uterine. The patients were suffering generally from the effects of the disease, and were considered fit cases on which to try the experiment. The medicine was given regularly and carefully in the manner directed. In no one instance was there the slightest improvement in the conditions of the local disease, which advanced at the same rate as before; neither was there any diminution of pain or discharge, or any change for the better in the characters of the ulcerations. There was not, moreover, any general improvement. For a day or two they thought they had a better appetite, but this was the mere transient change one always sees in cancer patients. None of the changes which were said to take place in the conditions of the urine or the perspiration had been observed. Mr. De Morgan's impression was that the downward progress of these patients had not been arrested for one instant by the agency of the drug.

Mr. ARNOTT, in remarking on the great value of these contributions, observed that Mr. De Morgan and Mr. Hulke, who had had so much experience in the cancer wards of the Middlesex Hospital, should make it distinctly known that there was no anatomical proof of a constitutional disease in cancer, and therefore we could not expect any general remedy to affect this local affection. He alluded to the cases which had by one or other of the various local means been cured.

Mr. THOMAS COOKE stated that Mr. Pearce, of the Westminster Hospital, had employed condurango in several cases, and had arrived at the opinion that the drug was a tonic, but quite ineffectual as a remedy in cancer.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, FEBRUARY 17.

Dr. DRUITT, President, in the Chair.

THE CHAIRMAN read a communication from John Dougall, M.D., of Glasgow, "On the Relative Powers of various Substances in Preventing the appearance of Animalcules in Organic Fluids." (a)

Dr. ALBERT J. BERNAYS, Professor of Chemistry at St. Thomas's Hospital, then read a paper "On the Precautions which should surround Toxicological Investigations in Medico-legal Cases, and on Evidence in Courts of Law." Speaking first of evidence in courts of law, Dr. Bernays little thought that such a commentary as that furnished by the cases of the Rev. Mr. Watson and Miss Edmonds would have been supplied by way of illustration. He must say that the manner in which the experts were received, especially in the latter case, was a disgraceful feature in the trial. Speaking as a student of chemistry, and as having considerable experience in toxicological analysis, he would put forward what precautions he considered ought to surround Medico-legal investigation. In all suspected cases he considered that the post-mortem examination should be conducted by an expert, in the presence of the local Medical man, that the truth might be established by two, if not three witnesses. These two gentlemen ought to agree beforehand on the method of proceeding, and nothing should be left

(a) This shall be given in our next number.—Ed. M. T. and G.

to haphazard. The evidence should be at once committed to writing, and signed by the witnesses. Next, as to the question of who is to make the analysis, and how it is to be made. All would agree that the work ought to be done by a practised hand. Very few Medical men could trust themselves to make an analysis, unless they devoted themselves to the practice of chemistry as a profession; neither had Medical men the time necessary. Analysis in cases involving life and death should not be left to one individual, whatever his talents. The work should be carried out by three persons, two of these being experienced in chemical analysis. The jury of experts that he would select would be the local Physician, a chemist with a Medical degree, and a practising chemist. Thus the work would be undertaken with a greater sense of responsibility than at present. An important question remained, as to who were the Physicians and chemists to be called in. Here Dr. Bernays entered a vigorous protest against the system of centralisation, by which all analytical work is given to two or three men, however able they might be. The selection should be made from a wider sphere. Why should not men of science be encouraged to settle in various parts of the kingdom, and opportunities be afforded them of enlarging their experience? The coroner ought to be able to call upon a competent person residing in his district. In case of dispute arising between two parties, it might be the interest of one party to prove death by poison (say of an animal grazing near mining works), and of the other party to prove natural death; ought the analysis to be left to one individual in such a case? The interests of both parties would be provided for by having three present. If the chemists were told what was the poison suspected, there would be a great saving of labour and expense. A point more important than all the rest was, How is the evidence to be given? Here Dr. Bernays made a severe commentary on the procedure in our courts of justice. In most cases the contention is for victory rather than truth. The richest man can secure the best defence. The evidence cannot be "the whole truth" when we simply tell *our* story. Too much liberty is given to counsel to suppress evidence. As regards scientific witnesses, the great object of opposing counsel is to confound them; and many of the most learned men were the most nervous and least positive on such occasions. For this reason Dr. Bernays thought a better mode would be, that experts should give their evidence in writing, and it should be published before the trial, so that no one might be taken by surprise. He thought that the examination of scientific witnesses ought to be left entirely to the discretion of the judge, and that counsel should be allowed only to suggest the questions to be put. In nuisance cases the matter ought to be referred to seven men, Medical and chemical, three to be selected by each side, the seventh to be appointed by both sides conjointly, and these seven to be exclusive of the Medical Officer of Health; and that only in cases of non-agreement should the matter be brought to public trial.

The CHAIRMAN read a letter from Dr. Letheby, in which he said he had been long convinced that the whole procedure of Medico-legal inquiries required amendment, and that this could be done, especially in the early part of such inquiries, under the direction and supervision of the Medical Officers of Health. They, and not the coroner's beadle, should set the coroner in action, be present at the post-mortem examination, should witness the results, and be able to add their unbiassed testimony.

Dr. Ross had found the necessity for a more competent referee in these cases. He mentioned an instance showing that provision was not made for the payment of such an analyst when grave interests were at stake.

Dr. BARCLAY agreed with Dr. Bernays as to the unsatisfactory manner in which evidence was taken, and especially as to the treatment scientific men were subjected to in courts of law. He objected to the affidavits of witnesses being so modified by the lawyers on either side as frequently to alter their bearing. Scientific men ought to be allowed to state their opinions in an independent and unbiassed manner. He did not think there was much hope of getting Dr. Bernays' scheme passed; but by agitating improvement might be brought about in course of time, perhaps in coroners' cases first of all. The first step would be the appointment of a public prosecutor.

Dr. LANKESTER thought Dr. Bernays' paper was very much in advance of the time. During his experience he had found great incompetency in ordinary Medical witnesses, and the fault he attributed, in great measure, to the teachers in Medical schools and the examining bodies. When he made application to Government for more skilled assistance, he was refused. He could only give two guineas to an analyst, and that was only

when the Medical man consented to relinquish his fee. He believed Medical Officers of Health might be made very useful in the coroner's court, although all were not equally competent to make toxicological examinations. He thought every coroner ought to be allowed an expert. In his district it could easily be done if the Medical men consented to give up the fees for post-mortem examinations. These amounted to £1500, and would pay the salaries of two experts, who would have quite sufficient occupation. While condemning the present legal procedure, he thought that a National Board of Assessors, consisting of from twenty-five to fifty of the most competent men in the country, would decide disputes more readily and more ably. Yet he confessed his plan in life had been to keep in the old groove, and let improvements and modifications be gradual. In answer to Dr. Ross, Dr. Lankester said that the initiative might well be left to the coroner's constable; the questions he had to ask were all drawn up for him, and he had merely to fill them in and bring them to the coroner. He considered it was the oath that gave substantiality to the coroner's court, and gave a case very much in point.

Dr. STEVENSON agreed with most of the contents of the paper, but thought, with Dr. Lankester, that changes should be gradual. Dr. Bernays' scheme would involve great expense.

OBITUARY.

THOMAS BENJAMIN PROCTER, M.D.

DR. PROCTER had for many years retired from the active pursuit of the Medical Profession. He died on January 18, in his 72nd year. He was born at Leominster, where his father had lived in practice as a Medical man for some years. After qualifying, he settled at Lieutwardine, in Herefordshire, where he practised successfully for about fourteen years, when he removed to Stockwell, and there practised until his ultimate retirement from the Profession, in the year 1850. He was a successful Practitioner, securing the confidence of his patients in a remarkable degree; a keen, intelligent observation, with great confidence and self-reliant decision, characterised his practice. A studious and well-read man, his mind was richly stored with information on many subjects outside the pale of his Profession. He was well versed in some of the collateral sciences, more especially geology and natural history, valuable collections of objects of interest in both of which sciences he accumulated. He enriched several museums both here and on the Continent with geological specimens especially from the Silurian strata. His principal published work was his "Treatise on the Sympathetic Nerve," a work which, on its appearance, was considered valuable as displaying considerable originality in the views he propounded. Dr. Procter married Susan, daughter of R. Woodhouse, Esq.; she survives him.

LEGAL INTELLIGENCE.

COURT OF QUEEN'S BENCH, GUILDHALL, FEB. 19.

(Sittings at Nisi Prius, before the LORD CHIEF JUSTICE and a Common Jury.)

JOHNSON v. CARPENTER.

THIS was an action for libel, brought by the Medical Officer of the district of Camberwell against another Medical man in the parish. The alleged libel was contained in a series of letters written by Dr. Carpenter to the Board of Guardians, in which he complained of the plaintiff, as Medical Officer of the Union, for neglect of duty.

Mr. Murphy was for the plaintiff; Mr. Morgan Howard was for the defendant.

The alleged libel appeared to have been contained in two letters addressed by the defendant to the Local Government Board, calling for an investigation to be had into the circumstances of a recent case of a pauper patient whom the plaintiff had attended, and stating that his conduct in that matter was but a specimen of some others with which the defendant was acquainted. The defence set up was that the communication in question was privileged.

Evidence was entered into at great length on each side, and both the parties were called as witnesses.

The Lord Chief Justice, in summing up, explained to the jury that in the case of a privileged communication it was incumbent upon the defendant to show that the allegations

he had made were not actuated by any malicious motive, and that he had such evidence of their truth as would induce a reasonable man to believe in it. It was not required for him to prove the actual truth of the circumstances. His Lordship then passed in review the different cases cited by the defendant of the plaintiff's negligence, and drew the attention of the jury to the circumstance that the defendant had not published a pamphlet or in any way unnecessarily made public his complaint, but had merely directed himself to the proper authorities—the Local Government Board. The jury were to decide whether in these matters the defendant had acted with entire *bona fides*, and in a way in which a person zealous for the public good, acting upon information which he might reasonably believe to be true, would act, or not.

The jury retired from the box, and after half an hour's deliberation returned their verdict for the plaintiff—damages, £5.

Mr. Marshall Griffith applied for a certificate.

Mr. Abbott (for Mr. Morgan Howard) applied for a stay of execution, on the ground that the verdict was against the weight of evidence adduced to rebut malice.

The Lord Chief Justice said that if he granted the certificate he would grant the stay of execution, but that he would consult his brothers and announce his determination.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the College on Monday, the 19th inst., the following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were granted licences to practise Physic, including therein the practice of Medicine, Surgery, and Midwifery:—

- Baber, Edward Cresswell, M.R.C.S., 34, Thurloe-square, S.W.
- Bland, George, who passed his examination in Medicine, October, 1871, and has obtained a recognised qualification in Surgery.
- Hammond, Robert Edward, M.R.C.S., 17, Booth-street East, Chorlton-upon-Medlock.
- Kiddle, John Nelson, M.R.C.S., Guy's Hospital.
- Ticehurst, Charles Sage, 11, Carlisle-parade, Hastings.
- Tweedy, John, University College Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, February 15:—

- Armstrong, Edward John, Wiesbaden.
- Price, Hugh Pugh Jones, Hulme, Manchester.
- Sloan, Ebenezer Erskine, Lisburn, Ireland.
- Smith, George Francis Firby, Northampton.

As Assistants in Compounding and Dispensing Medicines—

- France, Joseph, Rotherham.
- George, John, Kidderminster.
- Hannaford, William, Irthlingborough.
- Lingwood, William, Kensington.
- Parson, Henry James, Ely, Cambridge.

The following gentlemen also on the same day passed their first Professional examination:—

- Anderson, William Henry, St. Mary's Hospital.
- Boddy, Evan Marlett, Guy's Hospital.
- Johnson, Cottingham Greaves, St. Thomas's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- BARRY, JOHN COLLINS, L.F.P.S. Glasg.—Medical Officer, etc., for the Ballyduff Dispensary District of the Lismore Union.
- BONNEY, WILLIAM AUGUSTUS, M.R.C.S.E. and L.S.A.—Medical Officer for the North-Western District of the Parish of Chelsea.
- COLLET, A. H., B.A. Cantab., M.R.C.S., L.S.A.—Surgeon to the Worthing Infirmary.
- CRESWELL, J. C., Member of the Pharmaceutical Society—Non-Resident Dispenser at the Male Lock Hospital.
- DAVIDSON, M.A., M.B., Assistant-Physician to the Children's Hospital, and Lecturer on Pathology at the Liverpool School of Medicine—Physician to the Liverpool Northern Hospital.
- FRANKLIN, G. C., L.R.C.P. Lond., M.R.C.S.—Resident Medical Officer to the City of London Hospital for Diseases of the Chest, Victoria-park.
- GIBSON, DANIEL, M.R.C.S.E., L.S.A.—Medical Officer for the Western District of the Kingston-upon-Hull Incorporation for the Poor.
- ORCHARD, THOMAS N., M.B., M.C.—Assistant Medical Officer to the Workhouse of the Salford Union, Manchester.
- PETIT, JOSEPH, L.K.Q.C.P.I., L.R.C.S.I., and Licentiate in Midwifery—Medical Officer for the Dunshaughlin Workhouse.

MILITARY APPOINTMENTS.

- 6TH DRAGOON GUARDS.—Staff Assistant-Surgeon William Wakefield, M.D., to be Assistant-Surgeon, *vice* James Landale, M.D., promoted on the Staff.
- 16TH LANCERS.—Staff Assistant-Surgeon Robert Davidson Kemp, M.B., to be Assistant-Surgeon, *vice* James M'Cully, M.D., appointed to the Staff.
- ROYAL ARTILLERY.—Staff Assistant-Surgeon William Kippen Stewart, M.D., to be Assistant-Surgeon, *vice* Alexander Watt Beveridge, M.D., promoted on the Staff.
- 62ND FOOT.—Staff Assistant-Surgeon William Alexander Duke to be Assistant-Surgeon, *vice* Howison Young Howison, M.D., who exchanges.
- 78TH FOOT.—Staff Surgeon Alexander Watt Beveridge, M.D., to be Surgeon, *vice* Valentine Munbee M'Master, M.D., V.C., deceased.
- MEDICAL DEPARTMENT.—Staff Surgeon-Major Alfred Crocker to be Deputy Inspector-General of Hospitals, *vice* John Elliot Carte, M.B., C.B., who retires upon half-pay; Assistant-Surgeon Alexander Watt Beveridge, M.D., from the Royal Artillery, to be Staff Surgeon; Assistant-Surgeon Howison Young Howison, M.D., from the 62nd Foot, to be Staff Assistant-Surgeon, *vice* William Alexander Duke, who exchanges; Assistant-Surgeon James M'Cully, M.D., from the 16th Lancers, to be Staff Assistant-Surgeon, *vice* Robert Davidson Kemp, M.D., appointed to the 16th Lancers.
- BREVET.—Deputy Inspector-General of Hospitals John Elliot Carte, M.B., C.B., retired upon half-pay, to have the honorary rank of Inspector-General of Hospitals.

BIRTHS.

- FAUGHT.—On January 6, at Morar, Gwalior, India, the wife of J. G. Faught, Staff Surgeon, of a daughter.
- FURBER.—On February 14, at 7, Ashford-road, Maidstone, the wife of George Henry Furber, Surgeon, of a daughter.
- LEIGHTON.—On February 12, at The Danes, near Hertford, the wife of E. I. Leighton, M.B., of a daughter.
- ORD.—On February 16, at 16, Streatham-paragon, S.W., the wife of Dr. William M. Ord, of a daughter.
- SWALES.—On February 14, at Alexandra-terrace, Sheerness, the wife of Peter Swales, Surgeon, of a daughter.

MARRIAGES.

- BLIGH—WILLET.—On January 31, at the British Consulate, Pau, France, and subsequently by the Rev. George Brown, John Bligh, of Cavan, Ireland, to M. A. Alice, younger daughter of the late John Willett, M.D.
- CARTER—EMMOTT.—On January 25, at Allygurb, North-Western Provinces, India, Frederic Carter, Surgeon 1st Ghorka Regiment Light Infantry, to Agnes Jane, only daughter of the late Christopher Browning Emmott, M.D., of Egham, Surrey.
- HATCHELL—COPE.—On February 6, at St. Paul's Church, Burslem, Frederick Hore Hatchell, L.R.C.S. Ireland, youngest son of the late Captain C. H. Hatchell, 76th Regiment, to Clara Ellen, third daughter of the late W. S. Cope, Esq., of Port-vale House, Longport.
- MARRIS—SINCLAIR.—On February 15, at St. Giles's Church, Camberwell, Charles Marris, Esq., Freswick House, Sparkbrook, Warwickshire, son of the late Rev. George Marris, to Jessie Sophia Euphemia, only daughter of Donald Sinclair, M.D., Peckham, Surrey, niece of Sir John Sinclair, of Barrock, Bart.

DEATHS.

- BREAKEY, JANE KENNEDY, youngest child of Dr. Breakey, R.N., at the Royal Naval Hospital, Plymouth, of scarlatina, on February 16, aged 4 years.
- COCKBURN, JAMES BALFOUR, second son of the late Dr. Archibald William Cockburn, at 12, Darnaway-street, Edinburgh, on February 12, aged 20.
- GALEN, ALEXANDER, son of the late John Galen, M.D., of Aberdeen, at Kensington, on February 13.
- MAXWELL, ERNEST ARTHUR, third son of Peter Maxwell, M.D., at Stickney, near Boston, Lincolnshire, on February 15, aged 2 years and 9 months.
- PIERPOINT, NATHANIEL BRADFORD, M.D., M.R.C.S., and L.S.A., of 23, Little Pulteney-street, Golden-square, at Hastings, on February 11, aged 53.
- STRAKER, DR. ADOLPHUS WILLIAM, Professor University College, at 73, Offord-road, Barnsbury, on February 17, aged 45.

VACANCIES.

- In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
- BIRKENHEAD BOROUGH HOSPITAL.—Assistant House-Surgeon. Candidates must be registered Medical Practitioners. Applications to the Chairman of the Weekly Board, on or before February 26.
- BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Honorary Surgeon. Must be F. or M.R.C.S.E. Applications to Mr. James G. Gell, Secretary, on or before February 27. Election on March 19.
- BIRMINGHAM QUEEN'S HOSPITAL.—Resident Physician and Medical Tutor. Candidates must be Graduates in Medicine of a University of Great Britain or Ireland. Applications, with diplomas and testimonials, to Mr. H. C. Burdett, on or before March 22.
- BRISTOL LUNATIC ASYLUM, STAPLETON, NEAR BRISTOL.—Assistant Medical Superintendent. Must be duly qualified to practise. Applications to Mr. J. F. Williams, Clerk to the Visitors, Council House, Bristol, on or before March 5.
- CAXTON AND ARRINGTON UNION.—Medical Officer for the Caxton No. 1 District of this Union. Candidates will be required to possess the qualifications prescribed by the General Orders of the Local Government Board. Residence within the district required. Applications to Mr. H. Mortlock, Clerk to the Guardians, on or before March 11. Election the following day.

HOLBORN UNION.—Dispenser. Must be L.S.A., or be duly registered under the Pharmacy Act, 1868. Applications, with particulars of qualification and testimonials, to Mr. James W. Hill, Clerk's Office, Workhouse, Gray's-inn-road, W.C., on or before February 26.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant Medical Officer. Must be qualified in accordance with the Rules of the institution, which may be had on application to Mr. John Calder, Secretary, on or before March 6.

MARGATE ROYAL SEA-BATHING INFIRMARY.—Resident Surgeon. Must have some legal qualification to practise. Applications to the Secretary, on or before February 29.

ST. MARYLEBONE PROVIDENT DISPENSARY.—Medical Officer-in-Ordinary. Must possess a Physician's or Surgeon's diploma of one of the Colleges of London, Edinburgh, or Glasgow, and be a L.S.A. Applications to the Secretary, 16A, Duke-street, Portland-place, on or before March 2.

SALOP AND MONTGOMERY COUNTIES LUNATIC ASYLUM.—Medical Superintendent. Must be duly qualified to practise Medicine and Surgery. Applications and testimonials to the Clerk to the Visitors, on before March 1.

UXBRIDGE UNION.—Medical Officer for the Workhouse at Hillingdon. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications to Mr. C. Woodbridge, Clerk, on or before February 29. Election on March 1.

VICTORIA HOSPITAL FOR CHILDREN, GOUGH HOUSE, QUEEN'S-ROAD, CHELSEA.—Assistant-Surgeon. Must be F. or M.R.C.S.E., and not practising pharmacy. Applications to the Secretary, on or before February 28.

WALLASEY DISPENSARY.—House-Surgeon. Must be duly qualified and registered. Applications to Mr. W. D. Broome, Hon. Secretary, Withfield-terrace, Liscard, Cheshire.

WEST KENT GENERAL HOSPITAL, MAIDSTONE.—Physician. Must be duly qualified. Applications and testimonials to the Secretary, on or before February 19. Election on February 27.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Mr. M. Norris, on or before March 1. Election on the 7th.

WEST WARD UNION.—Medical Officer and Public Vaccinator for the District of Shap. Candidates must be duly qualified. Applications to Mr. J. P. Shepherd, on or before March 6. Election on the same day.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Blything Union.—Mr. H. B. Riordan has resigned the Fifth District area, 9791; population, 3681; salary £43 per annum.

APPOINTMENTS.

North Bierley Union.—James Field, M.R.C.S. Eng., L.S.A., to the Fourth District.

Norwich Union.—Wm. Summerhayes, M.R.C.S. Eng., L.S.A., to the Third District; Wm. Woodhouse, M.R.C.S. Eng., L.S.A., to the Fifth District.

St. Asaph Union.—John H. Wolstenholme, M.R.C.S. Eng., L.S.A., to the Rhuddlan District.

Scarborough Union.—John Carr, M.R.C.S. Eng., L.S.A., to the Sherburn District.

Thingoe Union.—Wm. E. S. Stanley, L.R.C.S. Edin., L.R.C.P. Edin., to the Eighth District.

THE QUEEN has been pleased to grant the office and place of Reader of Physic in the University of Cambridge to George Edward Paget, M.D., in the room of Henry John Hayles Bond, M.D., resigned.

DR. DAVID FERRIER has been appointed Professor of Forensic Medicine of King's College, London.

MR. W. A. BONNEY, of 320, King's-road, Chelsea, has been appointed Medical Officer of Health for the north-west district of Chelsea.

MR. JOHN ATKINSON, L.R.C.P. Ire., of Athboy, is a candidate for the Coronership of the County Meath, *vice* Mr. Matthew Marmion, deceased.

DR. GOUPIL, a Paris Physician of some celebrity, has just been tried by court-martial at Versailles for inciting to civil war on October 31, 1870, and sentenced to two years imprisonment.

THE Chelsea Vestry have fined their dust contractors £180 for neglect of duty. An amendment to reduce the fine to £50 was negatived by a large majority.

THE new wing at King's College Hospital has just been completed, and furnishes accommodation for upwards of 100 additional in-door patients, besides providing increased space and convenience for the Medical staff.

THE Chelsea Board of Guardians have resolved to appoint a public vaccinator. He must be a Medical Practitioner, not holding any parochial office.

THE Liverpool Corporation has resolved to appoint a public analyst at a salary of 200*l.* a year.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—On Thanksgiving-day, Tuesday, February 27, the Library will be closed, and the ordinary evening meeting will not be held.

DR. LANKESTER, at an inquest held a few days since on the body of a newly-born child which was found in a parcel in the Chester-road, Regents'-park, and whose death was caused by suffocation, remarked "that within the last few years over 100,000 children had been found which had met with a violent death. Such a state of things was a disgrace to the British nation." A verdict of "Wilful murder against some person or persons unknown" was returned.

It has been lately proposed to supply the town of Guildford with water from the new well in Millmead. The Guildford Local Board have issued analyses of the water by Messrs. Medlock and Wanklyn, from which it appears that the water is excellent from the chalk formation, containing a little carbonate of lime and small quantities of other salts, but no free ammonia, and merely an undeterminable quantity of nitric acid. It is, therefore, absolutely free from sewage contamination.

BELFAST MEDICAL BENEVOLENT SOCIETY.—The annual meeting of this useful and important Society was held last week in the Society's rooms in High-street. The accounts were audited and passed. Three deaths were announced. It was determined to select a committee of management to meet quarterly; and it was resolved that a deputation should visit several places enumerated, and solicit support therefrom for the future.

THE DIPLOMA MANUFACTURERS.—It is a source of sincere congratulation that the Senate Investigating Committee is after the diploma-dealers in real earnest. Philadelphia's high reputation as a seat of scientific learning, especially in the department of Medicine, has suffered long and severely enough at the hands of these gentry, and we trust that the present Legislature will wipe their disreputable trade out of existence. There is very strong evidence that a few men in this city have been growing rich in selling cunningly contrived diplomas to men who have disgraced themselves and imposed upon the public by buying them. The testimony already adduced is strong enough to warrant the extreme exercise of legislative power; and we look to see justice dealt out without the slightest mercy to those who have carried on this nefarious traffic to the most serious injury of the reputation of Philadelphia, and the cause of the Profession of Medicine everywhere.—*Philadelphia Evening Bulletin.*

BROMIDE OF SODIUM.—Whatever may be the real therapeutic value of the bromide of potassium in the treatment of epilepsy and other disorders of the nervous system, it has come to be generally acknowledged that its prolonged use is often attended with serious inconveniences, and even dangers—as dulness of the mental faculties, loss of memory, great muscular feebleness of the lower extremities, etc. I have heard many epileptics declare that they would rather suffer from their fits than from the condition brought on by the doses of bromide of potassium necessary to suspend their attacks, or lessen the number of them. It is, therefore, a matter of some moment to those who treat nervous disorders to find a remedy of that efficacy so largely claimed for the bromide of potassium in some affections. There is reason to believe that in the bromide of sodium a happy substitute has been found that will fully meet every indication for which the bromide of potassium has been given, while it is much better tolerated by the system, and free from the objections which are justly urged against the latter. For some time past I have habitually used the bromide of sodium in all disorders of the nervous system where before I prescribed the bromide of potassium, and, so far as my own experience goes, speak positively to this point. I have given it in a number of cases of epilepsy continuously for months without any of the unpleasant symptoms which so constantly follow the prolonged administration of the potassium salt, excepting the eruption, and with the best results in mitigating or suspending the paroxysms. Dr. Decaisne has given the bromide of sodium for a year without its producing the systemic saturation so frequent during the long and continuous exhibition of the bromide of potassium. According to Nimias, of Venice, this latter salt accumulates in the various organs, the brain, spinal cord, lungs, liver, etc., and is neither readily eliminated nor assimilated (see the *Medical World*, July, 1871, p. 31). Soda is the alkali found throughout the body, and in all the secretions, and would naturally be more readily absorbed and appropriated than the potassic salt. Another point in favour of the use of the sodic rather than the potassic salt, and which, so far as I know, has not yet been mentioned, is the fact of the depressing influence of the salts of potash on the heart when they are largely or long given.

No such effects are alleged to follow the continuous use of the salts of soda. The taste of the bromide of sodium is much less unpleasant than that of the bromide of potassium, being very like common salt, and it may be used to replace the latter, mixed with the food, as with bread-and-butter, eggs, in milk, etc. Hence it is of more easy administration than the bromide of potassium, to the taste of which some persons have invincible repugnance, and increasing with its use. It is of the first importance that bromide of sodium should be perfectly free from all impurities, particularly of iodine. Larger doses of the hydrated salt are required than of the anhydrous, for it crystallises with four equivalents of water. According to Dr. Morin (*Comptes-Rendus* of the Académie des Sciences, January and April, 1870), anhydrous bromide of sodium contains 11 per cent. more bromide than bromide of potassium. Dr. Morin and Dr. Balard—the discoverer of this salt (1826)—give the following table of the approximative amount of bromine in the corresponding quantities of bromide of sodium and bromide of potassium:—

Bromine. Grammes.	Bromide of Sodium. Grammes.	Bromide of Potassium. Grammes.
3.33	4.33	5.00
6.66	8.66	10.00
10.00	13.00	15.00
13.63	17.33	20.00
16.06	21.66	25.00
12.00	26.00	30.00

The doses of bromide of sodium are about the same as those of bromide of potassium. In epilepsy, I usually give twenty grains three times daily, and have rarely gone above that amount. It sometimes seems to cause or encourage constipation.—*Meredith Clymer, M.D.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Dr. Jordan.—Please send the lecture on approbation.

Charles Orton, Esq.—The paper came safely to hand.

Dr. Sawyer, Birmingham.—We shall be glad to receive the reports, and shall publish them as we can.

A. P.—The preparation is not to be found in the British Pharmacopœia. Most of the alterations are made under good chemical guidance. Nothing can be perfect; and if it were it would not please everybody.

Stafford.—Dr. Herbert Davies's work on the "Use of Blisters in Acute Rheumatism," was published by Churchills in 1862. He says that they eliminate acid and diminish the acidity of the urine, so as to render the giving of alkalies unnecessary or even useless.

CONTAGIOUS DISEASES ACT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me to suggest that the insertion of a clause in the above Act, treating the wilful communication of syphilis—like that of scarlet fever, etc.—as a misdemeanour, would make it much more efficient than the Acts proposed to be repealed. On information given upon oath, either to a magistrate or a sanitary inspector, power should be given to institute inquiries as to the mode of living of the person accused. Should the result prove unsatisfactory, the magistrate or sanitary inspector should be directed to order the examination of the suspected person, by a competent midwife if a woman, or by the Surgeon of the police if a man. If the person so examined should then be found affected by venereal disease, he or she should be confined, by a magistrate's order, in the syphilitic Hospital until cured, and should afterwards suffer a month's imprisonment. The proceedings to be private. Even Mr. Jacob Bright would not contend that a person commits no crime in wilfully communicating syphilitic disease.

I am, &c.,

H. R.

Newcomer.—Write to the oldest established Practitioner, tell him of your qualifications, and of the line of practice you propose to follow; that you hope for the honour of his acquaintance, and desire to be on good terms with your Professional brethren.

B.—Dover's powder was the invention of Thomas Dover, or Dovor, M.B. His "Ancient Physician's Legacy, 1733," may be seen in the library of the College of Surgeons, or of the Medico-Chirurgical Society. He used to treat gout by first actively purging, then smoothing things down with a dose of this opiate powder, which, as he made it, contained carbonate of potassium.

The *Philadelphia Evening Bulletin* mistakes the position of the English Medical journals in the Medical education of women. We never objected to the Medical education of women, nor to their obtaining any public recognition which that qualification may merit, nor to the exercise of their skill amongst those who think fit to employ them. What we object to is the intrusion of women into Hospitals and schools with male students, amidst scenes which no decent woman would choose to witness unless compelled by duty.

Nix.—The case was tried before the Lord Chief Baron Pollock, and resulted in a verdict for the plaintiff.

Is it True?—It is stated, on the authority of *Nature*, that the magistrates of Chelmsford have declined to grant the use of the shire hall for a lecture on the sun, illustrated by experiments in spectrum analysis, on the ground that the electric-light might endanger the safety of the building.

Not too Soon.—*Bogus Diplomas.*—This morning the Senatorial Investigating Committee reassembled at the Girard House for the purpose of further examining into the matter of the sale of bogus diplomas by disreputable Medical colleges.—*Philadelphia Bulletin*, February 5.

POISONING MADE EASY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You will agree with me that strychnine ought not to be publicly sold to anybody who chooses to apply for it; yet it is so sold by most chemists and druggists—not, indeed, under the name of strychnine, but in sixpenny packets, marked "Battle's Vermin Killer," and labelled, I am bound to add, "poison." The startling fact came to my knowledge in this wise:—Our house being infested with mice, a packet of the powder was procured by the servant, and mixed with some cheese. A bit happening to fall on the floor, was eaten by a little dog of mine, which soon became convulsed, and exhibited those spasmodic twitchings which strychnine always produces. Luckily I was at home at the time, and immediately forced down the poor animal's throat some castor oil and very strong tea. The beneficial results of this treatment were soon apparent, and I was shortly enabled to announce that Tiny was out of danger. But, Sir, I protest against strychnine being sold to the public, not merely for the sake of our dumb pets, but for the sake of our children and ourselves. At present, anyone possessed of sixpence may give or take a deadly dose with the greatest ease; and I would ask whether, in these days of "latent insanity," such facilities for poisoning should be allowed. We all know the carelessness of servants; is it safe to have in the house a compound containing strychnine, of which one-eighth of a grain is sufficient to kill a dog, and one-fourth of a grain to affect a healthy man?

I am, &c., THOMAS W. SALTER, F.C.S.

St. John's Cottage, New Wandsworth, S.W., Feb. 19.

Province of York.—*Convocation Report on Intemperance.*—The report just issued enters minutely and elaborately into the question of intemperance—the extent of the evil, the causes, consequences, and remedies. The document is free from the Utopian schemes and ideas which characterise the extreme partisans on either side of the question. It is true that it conveys no information not previously known; but it is a creditable, and we think will be a useful production.

Poor-law Medical Relief.—A very long report of the proceedings of the late meeting at Worcester is contained in the *Worcester Chronicle* of February 21. Dr. Rogers' speech is given in full. It is exhaustive and instructive; but it is too long to be more than referred to here. It will well repay perusal. The *Chronicle* can be obtained by order of Dawson and Co., newsagents, Warwick-square.

This Patient and That.—An old contributor writes thus:—"Within a few days I have had experience of two very different styles of reception. In the first instance, I was sent for to a great hotel to see lady A., a patient whom I had attended for many years when she came to town for the season. On entering her sitting-room, 'Ah! my dear Doctor,' said she, 'How do you do?—we are so glad to see you.' You ask what is the matter. 'Why, thank Heaven, little or nothing; but we could not pass through without seeing you, and it occurred to me that Fanny has been complaining of headache lately. So we made that an excuse for sending for you.' Now for the other picture. I received a hasty and urgent summons to see Mr. B., at another hotel. I went at once; and entering the room hastily, said, 'I am afraid you are not well, Mr. B.' 'Of course not,' he growled, 'else I should not have sent for you.' I will leave it to your readers to judge which of these patients one would feel most inclined to strain mind and body in order to serve at a pinch."

THE INFLUENCE OF CHASTITY ON HEALTH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your paper of February 10, p. 109, there is an extract from Dr. Dobell's "Reports on Progress of Medicine in various parts of the World" which ought not to pass unchallenged. The "English Physician" who there propounds a theory—revolting, I honestly believe, to the large majority of my Professional brethren—obtained his M.D. degree at Glasgow in 1867; he was in practice, or rather trying to get into practice, for a very short period in Java, and it may be doubted if he had opportunities sufficient to form a sound opinion upon so difficult a subject.

He speaks of resistance to the sexual passion as "attended with bad consequences to health," while in a preceding paragraph he says that "all the unmarried Europeans either keep mistresses or resort to the public women." So that he confesses he never saw the attempt made to resist, and even had he done so his stay in the island was far too short for him to judge of the results.

I was in active practice in Java from 1857 to 1865, and never met with a case where chastity was so punished, although happily I met with many who practised it; need I say that too many cases of unchastity suffered severely? It frequently happened that young lads, fresh from the restraints of home and religious training, tempted and almost persuaded by licentious companions, argued with me the necessity of sexual intercourse. My reply was twofold—1st. Look at your stables, and those of all around you, therein you will find hundreds, nay thousands, of stallions which have been years in bondage, and yet perfectly healthy. (Most stables contain from ten to twenty horses, which are caught wild in the neighbouring island, and readily broken into carriage work. These horses are never put to the mare; mares themselves are seldom used.) 2nd. What applies to you must also apply to your sisters: if necessary for the one, then for the other also. I seldom had to argue further. My first reply was suggested, I think, by an anecdote of the old drinking days. A gentleman who objected to hard

Drinking after dinner once asked his friends, on the removal of the cloth, whether they were to drink as men or as beasts. All, of course, indignantly exclaimed, "As men!" "Then," said the host, "we shall all get drunk, for nowadays it is beasts alone that drink to quench their thirst!" It does, indeed, appear that beasts can, when called upon to do so, better restrain their passions than men. I am, &c., M.D. LOND.

Melbourne.—Controversies in the newspapers on Medical or Surgical questions can have but one effect on the Profession—that of lowering it in the eyes of the public. The case of *Turner v. Van Hemert* is no exception to this rule. The evidence given at the trial was not calculated to settle the real question at issue; and we think if a new trial had been granted the defendant would have succeeded in reversing the verdict of the jury. We cannot commend the letters of Mr. Beane and Mr. Crooke in the *Argus* of December 18.

Q.—A letter from Dr. Letheby was read at a late meeting of the Health Officers' Association, and was taken down by our reporter; but how it escaped publication we cannot well say. It is to the effect that he had declined to sign a Medical memorial to the Home Secretary in favour of the Contagious Diseases Acts, which had been extensively circulated with a view of getting signatures. "I fear," he says, "that such a method of getting up what is no other than an *in terrorem* expression of opinion is likely to be misunderstood and to be abused. I regret, indeed, that I signed a similar sort of document on the subject of the Medical use of alcohol, notwithstanding that my opinions were in accordance with it."

THE LATE FREDERICK LEWIS, M.R.C.S.E.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the *Times* of last Wednesday appeared an announcement of the death of Frederick Lewis, M.R.C.S.E. The identity of both name and title with those of the Senior Surgeon of this Hospital has been the cause of much pain and annoyance.

May I beg the early insertion of this letter; for, besides allaying the anxiety of friends, it may, perhaps, limit the number of inquiries regarding a vacancy which has, happily, never occurred.

I am, &c., T. C. HEPWORTH, Secretary.

Western Ophthalmic Hospital, 155, Marylebone-rd., W., Feb. 21.

Alpha.—By 18 Geo. II., cap. 20, sec. 1, "No person shall be capable of being a justice or of acting as such for any county, riding, or division, who shall not have, either in law or equity, to and for his own use and benefit in possession, a freehold, copyhold, or customary estate for life, or for some greater estate, or an estate for some long term of years, determinable upon one or more life or lives, or for a certain term originally created for twenty-one years or more, in lands, tenements, or hereditaments in England or Wales of the clear yearly value of £100; or who shall not be seized of or entitled to the immediate reversion and remainder in lands, etc., in England or Wales which are leased for one, two, or three lives, upon reserved rents, and which are of the clear yearly value of £300."

"The Nation's Wave of Suspense."—There has been sent us a lithographed sheet bearing this title, and combining in a concise tabular form all the particulars of the illness from which H.R.H. the Prince of Wales has happily recovered. In one column are copies of every bulletin; in another a kind of diagrammatic representation of the amount of his danger from day to day; and in a third there are memoranda of the visits of his Physicians and of the prayers offered in the churches. Piety and loyalty may be gratified by ordering this sheet from Messrs. Houlston and Sons, Paternoster-row.

THE "MEDICAL DIRECTORY."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The gentlemen who have compiled so ably the "Medical Directory" seem to have created "a tempest in a teapot." Seldom has more virtuous indignation been manifested than by those who imagined themselves aggrieved by their titles not having been fully appended to their names. It is the verification of the old adage—"He who desires to please everyone pleases no one." The only criterion for the editors of the "Directory" was the registration by the Medical Council; as my case was exceptional, I will state it, in order to show that the registration has some real value.

On presenting my diploma at the office of the Registrar, even the clerks pronounced it as of that class commonly known as "Bogus," for such a document had never been seen or even heard of—this was in August, 1867. The Medical College of Pittsfield, incorporated in 1837 by an Act of the Legislature of Massachusetts, was as much unknown as if the diploma had been granted by Queen Pomare of Tahiti, or the King of Timbuctoo. Still this College has the same privileges and powers of granting diplomas as Harvard University. The pre-requisites for admission to examination for the degree of Doctor of Medicine are—1. Three full years' study of Medicine under a regular Practitioner. 2. Attendance on two full courses of lectures in Medical institutions regularly established, one of which course must be in the Pittsfield College. 3. A defensible thesis on some subject connected with Medicine. 4. An adequate knowledge of the Latin language and good moral character. 5. The examinations to be held in presence of the trustees, Faculty of Medicine, and overseers of the institution. 6. The thesis must be publicly read and defended.

The Registrar, Dr. Francis Hawkins, put himself in correspondence with the Dean of Faculty of Pittsfield College, who, in reply, confirmed the fact of my having graduated in 1839, but he omitted that I had undergone a regular examination. The Medical Council refused my registration until such particulars had been received. It was not until January 20, 1868, that I received the following from the Registrar:—

"Dear Sir,—I have had the pleasure of receiving a very satisfactory report of your examination for the degree of M.D. from the Dean of the Faculty of Berkshire Medical College. The document shall be submitted to the Medical Council at its next meeting."

My admission to be registered did not take place until June, 1868.

This case of itself has no intrinsic interest beyond showing that, without some positive proof of having received a regular Medical education, persons are not admitted by the Council of Medical Education for registration.

In my own case, I had previously attended three full courses of lectures at the then London University, and also attended the Hospital practice of the Middlesex and North London Hospitals for two years. The reason of my not graduating in England prior to returning to America was, that my age was not sufficient, though I petitioned the College of Surgeons to be allowed.

The only method to properly meet the case of foreign diplomas is, that the candidate should go through the ordeal of examination by a board of eminent men appointed by the State. In that case it would be of little consequence if the diploma was from Heidelberg or Kamschatka, for it is the Medical capacity which is demanded for the safety of the public, not the mere addenda of worthless titles. I am, &c.,

199, Brompton-road, January 29.

ROBERT H. COLLYER.

The College of Surgeons.—The Library and Muscum will be closed on Tuesday next, the General Thanksgiving-day.

Dr. Denman.—We understand that the Midwifery Board will not meet this month, owing to the dearth of candidates.

Argus.—You will find a biographical notice of Dermott in vol. xvi. of the *Medical Times and Gazette*, p. 618 *et seq.* He died September 12, 1847, aged 45.

A Hospital Surgeon.—The election will take place next week. Mr. Henry Spencer Smith, the senior candidate, is Surgeon to St. Mary's Hospital, received his Medical education at St. Bartholomew's Hospital, and was the able secretary to the Royal Commission on Contagious Diseases, etc.

THE YOUNG FAMILY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A correspondent of your journal of February 3, signing himself "X," has fallen into an error, in stating that "a Mr. Young, late a Surgeon of some eminence, in Sackville-street, was brother to Sir Charles Young, Garter King-at-Arms; and these were, he believes, sons of a Dr. Young, an eminent physician and Physician to St. George's Hospital." As an old pupil of the late James Forbes Young, M.D. Edin., I am in a position to inform "X." that my friend was brother to Sir Charles Young, as also Mr. Henry Young, an eminent solicitor, of Essex-street, Strand. These three were the only children of an old naval Surgeon, who settled in general practice in Lambeth, and who sent his sons to the Charterhouse School. At his death J. F. Young succeeded to his excellent connexion, and removed to a large house and grounds in Upper Kennington-lane, where he took the lead as one of the first general Practitioners on the Surrey side of the metropolitan Thames. For many years his receipts were upwards of £2000 per annum. He was a man of liberal and enlightened understanding, a most judicious and successful Practitioner, and was frequently called in consultation by his Medical confrères in the neighbourhood. For several years he was one of the J.P.s for the county of Surrey. He was never married. I am, &c., E. MAY, M.R.C.P., M.D.

Pau, Basses Pyrénées, February 15.

LEARNED MISTAKES.

Wise men are known by great mistakes;

In Medicine this a fact is—
Proving the influence of the
Profession on the practice.

In early times the lance was used
For bleeding—then the lancet;
And people killed themselves by
drugs
Just when and how they fancied.

Extracts expressed by older heads
Provoked their pill and pillage;
And "Death's Head" was the trade
mark of
The Doctor of the village.

So oft they bled, they seemed to earn
The title *leech* awarded—
The animal that sucks the blood—
And all for motives sordid.

Each Doctor talked "phlogiston"
then—
Cup-bearer for his squire;
Like him with brazen basin old
Unhorsed by Quixote's ire.

Torments were practised to relieve
Torments less hard to bear,
And men grew rich on others' wants,
And bright on others' care.

Oft, after long and tedious woes
Some patient's patience bore,
Death had the upshot; for his leg
The *issue* had before.

The Barber-Surgeons we became—
One art too small to harbour us—
Whence by transition easy rose
The Surgeons barbarous.

Such the defect of Medicine once—
No boards to weigh her son
Down by examinations when
Diplomacy was none.

Hippocrates, and Luke, and Chiron,
Ne'er had passed "the College";
Yet we adore Apollo yet,
And grant our greater knowledge.

As once our sires to *Mercury*
Their adoration gave;
They brought their science to the
light—
Their victims to the *grave*.

But we, to 'scape their errors, leap
Alike on faulty ground:
No doubt 'tis in the clock of time,
The "pendulum's rebound."

Dementia has e'en possessed
Those who essay its cure,
When to the drunkard drinks are
given,
And spirits scarce *impure*!

So steel pneumonia now would
save—
Of old her worst marauder;
And some give draughts of element
In dropsy's dire disorder!

I knew a man who, waterlogged,
Flooded the soaking floor,
That while he could not run or rise,
His legs *ran* daily more.

Such ones, when loaded to the fill,
Themselves are on the brink,
And 'midst their watertide, at last
Inevitably *sink*.

Those Doctors cure insanity
By ministering *iron*;
And these in hydrophobia
The simple *bark* rely on.

To close the one in rigid bounds—
To teach the proselyte of hounds
To growl and foam agast,
Bespeaks a leech who "passed his
First,"

And went beyond his *last*.
C. A. F.

COMMUNICATIONS have been received from—

Dr. JORDAN; Dr. E. MAY; Mr. C. ORTON; Dr. SAWYER; Mr. R. YOUNG; H. R.; Mr. RIGDEN; Dr. PHILLIPS; Mr. T. RUSSELL; Mr. BAGSHAW; Mr. T. W. SALTER; Mr. JAYAKAR; M.D. LOND.; ALPHA; Dr. PAGET; Dr. ALLBUTT; Rev. Canon BARDSLEY; Mr. HEPWORTH; Professor FLOWER; Mr. MAUNDER; Mr. H. HANCOCK; Mr. T. BRYANT; Mr. J. CHATTO; Mr. J. W. PROCTER; Mr. WILLIAMS; Mr. COLLET; Mr. F. SANDERS; Dr. G. C. FRANKLIN; Dr. R. H. COLLYER.

BOOKS RECEIVED—

Meadows on Pelvic Hæmatocœle—Roth on Hahnemann's Merits, Errors and Critics—De Warkor on the Detection of Criminal Abortion—Carlier's Darwinism Refuted—Prince on the Climate of Uckfield—Wunderlich's Medical Thermometry.

PERIODICALS AND NEWSPAPERS RECEIVED—

Leicester Journal—Chemist and Druggist—L'Union Médicale du Canada—Naturc—Pharmaceutical Journal—Lincolnshire Chronicle—Liverpool Daily Courier—Kilburn Times—Cincinnati Clinic—Philadelphia Evening Budget—Medical Press and Circular.

APPOINTMENTS FOR THE WEEK.

February 24. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Mr. Wm. B. Donne, "On the Theatre in Shakespeare's Time."

26. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Victor de Méric will exhibit Casts and Drawings in a Case of Congenitally Deformed Hands and Feet. Mr. Walter Coulson, "On Lithotomy after Lithotripsy."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

27. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY. No Meeting.

28. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Goulstonian Lectures—Dr. Hensley, "On the Mechanism of Respiration, Circulation, and Digestion."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

SOCIETY OF ARTS, 8 p.m. Meeting.

29. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

March 1. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Goulstonian Lectures—Dr. Hensley, "On the Mechanism of Respiration, Circulation, and Digestion."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

ROYAL INSTITUTION, 9 p.m. Mr. C. W. Siemens, "Measuring Temperatures by Electricity."

VITAL STATISTICS OF LONDON.

Week ending Saturday, February 17, 1872.

BIRTHS.

Births of Boys, 1255; Girls, 1108; Total, 2363.
Average of 10 corresponding weeks, 1862-71, 2212.5.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	685	635	1320
Average of the ten years 1862-71	754.5	719.2	1473.7
Average corrected to increased population	1821
Deaths of people aged 90 and upwards

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.57 in. The highest was 29.74 in. at the beginning of the week, and the lowest 29.44 in. on Monday morning.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

† Through an error which was discovered on the revision of the enumerated numbers at the Census Office, the correct population of Manchester at the middle of 1871 was 351,171, and not 356,099, as published in recent Weekly Returns. The number for the middle of 1872 (352,759) shows, therefore, an increase of 1271 upon the corrected number for 1871.

No. 12, Ward's Patent Albert
 Lounging Chair, the most simple and luxurious extant, is fitted for the Drawing Room, Boudoir, Cabin, or Camp; is made in Wood, Iron, or Brass, and folds into a small compass for shipment. From 4½ Guineas.

No. 17, a Four-wheel Victoria Pleasure-ground Chair, mounted in a very light Iron-framed Carriage upon C and patent India-rubber Springs, is either drawn by Hand or Animal, and is the most elegant and easiest Chair made.
 No. 16, a ditto, upon three wheels, mounted same as four wheels, on C and India-rubber Springs.
 No. 9, a Bath Chair, with Leather Head, and Folding German Shutter.

No. 18, a Sofa Britska Spinal Carriage with the inside Tray made to take out and in, on which an invalid may be taken from her room to the carriage.

No. 24, Ward's Improved Child's Perambulator, with Patent Parasol. A variety of level ground, the upper ones for ascending or descending a staircase: the sketch conveys the exact idea; it is also made portable for travelling. Several other kinds are always in stock, upon various principles.

N.B.—The largest assortment in the World of INVALID CHAIRS, CARRIAGES, and BEDS, always on hand, for Sale or Hire.

BY HER MAJESTY'S ROYAL LETTERS PATENT
 AND BY SPECIAL APPOINTMENT TO HER MAJESTY
 THE EMPRESS
 OF RUSSIA & FRANCE
 AND THE
ROYAL FAMILY
JOHN WARD
 5 & 6, LEICESTER-SQUARE, LONDON.

Nos. 10, 10, Sketch of Earl's
 General Invalid Couch or Bed, made with or without a Convenience; it adjusts the back seat and legs to any given position by means of machinery, and is recommended by the Faculty as being the most complete Bed ever made for confirmed Invalids, or for Fractured Limbs.
 No. 11 is Ward's Patent Reclining Chair, with Shifting Elbows for more easily getting on and off the Chair when the leg-rest is drawn out, as shown in the drawing.
 No. 7 is an elegant Patent Recumbent Chair.
 Nos. 13, 13 is a Couch-Chair or Bed invented by Dr. Hester, and may be placed in any position by the Invalid without the assistance of a second person.

Nos. 2, 3, 4, and 5 are all Self-Propelling Chairs, upon the best and most scientific principles; either may be used by a child eight years of age with perfect ease.

Established more than a century.

ORIGINAL LECTURES.

SKETCHES OF
SUCCESS AND FAILURE IN MEDICINE.BEING THE SUBSTANCE OF THE
LUMLEIAN LECTURES AT THE LONDON ROYAL COLLEGE OF PHYSICIANS
IN 1862.

By CHARLES J. B. WILLIAMS, M.D., F.R.S.

(Continued from page 184.)

PART V.

Gangrenous Abscess of the Lung: Causes: Peculiar Odour: Convulsive Cough: Deep Seat of the Abscess—Treatment—Recoveries—Deaths and Causes.

THIS affection was not noticed by Laennec, who describes only a few instances of gangrene of the lung, a much more rare and always fatal lesion. Gangrenous or fetid abscess of the lung is not so uncommon as is generally supposed. During the period of seven years I find notes of twelve cases; and I have been consulted in others, the issue of which is uncertain. Neither is the lesion so fatal as might have been anticipated from its nature and gravity—for of these twelve only three have died, and nine have more or less completely recovered. I believe that all but one are still living (1862).

The tendency of inflammation of the lung to terminate in abscess or gangrene does not seem to depend on the severity of the inflammation, but rather on the obstruction accidentally produced in the circulation and nutrition of a part of the lung. In several of the cases there has been a prolonged chill, when the body has been previously in an unhealthy state, or much exhausted. A young gentleman, in the summer of 1856, was bathing in the Thames, and, missing his boat, was obliged to swim a very long way. He was much exhausted, and severely chilled, and was afterwards attacked with inflammation of the right lung. In a few days he began to cough up fetid matter, and continued to do so from time to time for several weeks, sometimes with small sloughy shreds, in which filaments of lung tissue were detected by the microscope; yet this patient entirely recovered in a few months. (He is living and well in 1872.)

In October, 1857, I saw a young clergyman who, also after a severe chill in bathing, was attacked with pain in the right scapula, and in a few days began to cough up large quantities of very offensive matter, mixed with blood. There were signs of a cavity in the right scapular region. He was much reduced in flesh and strength; but, after going to the seaside, and taking tonics and cod-liver oil, he very much improved, still occasionally bringing up blood. A year after I heard that he had quite recovered, with the exception of occasional pain in the right shoulder, and slight recurrences of hæmoptysis.

Another patient had been suffering for some months previously with carbunculous boils. After long exposure to wet and cold, he had severe pain in the right side, and began to cough up fetid matter.

There are two points connected with gangrenous abscess of the lung to which I would call your attention. One is the peculiar fetor of the expectorated matter when first voided; this, as well as the breath in the act of coughing, is extremely offensive—in fact, the smell is that of putrid flesh, and quite different from the rotten-egg odour of fetid pus, which is obviously that of hydro-sulphuric acid. But after the matter of fetid abscess has remained some hours in the spittoon, the odour changes to one of a sweetish and rather fragrant character, very like that of cowslips; and this is so characteristic that I have, on several occasions, diagnosed fetid abscess on scenting this fragrant odour. It is well known that some of the sweetest perfumes are now manufactured by slight chemical changes in some very disgusting matters; and this seems to be an instance in which a similar change takes place spontaneously.

The other point which I would notice is the violently convulsive character of the cough, which is more like whooping-cough than any other. When we see a patient straining every muscle and shaking in every limb in the coughing fit, often until it ends in retching and vomiting, whilst the air is filled with the horrible stench, we cannot avoid the conclusion that these are efforts of the system to rid itself of the offensive matter. The same thing happens in whooping-cough. The matter to be expelled is not putrid, certainly, in this case; but

it is a highly irritating mucus, secreted by the tracheal glands under the influence of an animal poison; and the violent cough ceases as soon as it is expelled, until more is formed again, and excites a fresh paroxysm. An analogous process is witnessed in dysentery and cholera, in which violent muscular efforts are excited to rid the alimentary canal from offensive and irritating matters by vomiting and diarrhoea; and in catarrhal cystitis, in which the straining dysuria is equally urgent.

The common seat of these fetid abscesses is at the base of the right lung, and in some instances they are sufficiently near the surface to give audible signs of partial consolidation and excavation: in others the abscess is so deep-seated and central in its position, and so surrounded by healthy lung-tissue, as to give no acoustic indications of its presence. The depth of the abscess, at the very bottom of the lung, is one of the circumstances which increase the difficulty of expelling all its contents; and it sometimes happens that after a patient has apparently recovered, there are repeated recurrences of hæmoptysis, followed by fetid expectoration, from a residue of offensive matter being left, and gradually leading to the formation of morc.

The most important remedies in the treatment of fetid abscess of the lung are antiseptics, tonics, and nutrients, which tend to correct the putrescence of the matter formed in the diseased part, to promote its healing, and to keep up the strength of the system. I have found the diluted nitro-muriatic acid the most efficacious and agreeable antiseptic. It should be given in doses of from thirty to sixty minims several times a day; and these, and even larger doses, are well borne if combined with a drachm or two of pure glycerine, which has the effect of sheathing the acid, and is in itself both antiseptic and nutrient. Inhalations of carbolic acid, or creosote and chloroform, are also very useful, not only for their antiseptic influence, but also through the power of the latter to mitigate the violence of the cough (a). It is useful also to fumigate the patient's room with chloroform or carbolic acid in such diluted strength as shall not irritate the air-passages, and yet sufficient to remove the fetor of the air, which is sometimes very sickening. A linctus containing creosote, chloric ether, and a little morphia is also of service in mitigating the cough. When the fits of coughing are so frequent as much to disturb the rest, it is necessary to give opiates in larger doses; but it is desirable as much as possible to confine their operation to the night, so that it may not interfere with the appetite and digestion. To improve these, and to aid in maintaining the strength, bitters and stronger tonics are generally required; and they may be very well combined with the acid and glycerine mixture before recommended. And, as in all cases in which the blood is liable to be contaminated with offensive matter, it is important to take care that the natural excretories of its impurities—the intestinal and urinary excretions—are free and active.

In the matter of nourishment and sustenance, these are cases generally requiring as much high feeding and stimulants as the stomach will bear without disturbance; and it is often necessary to coax the palate and humour the taste with all the varieties and resources of culinary art in order to maintain a sufficient appetite for the purpose. One maxim is of great moment in these and all cases where feeding is required, and not mere stimulation—that the stimulants should be given with the food (solid or liquid), and not at intermediate times; as *adjuncts* to a meal, not *substitutes* for it.

In illustrating this subject by a few examples, I will cite first the cases of success. About sixteen years ago I went to see a patient of Mr. Bellis, of Maidenhead, aged upwards of 60, who, after a severe chill, began to expectorate large quantities of offensive matter of the character before described, and was becoming much exhausted by it and by the violent fits of cough. The signs of cavity were obvious in the lower lobe of the right lung. He was carefully watched and treated on the plan recommended, and entirely recovered in a few months, and has been a hale old man ever since. Singularly enough, this same gentleman's son-in-law was attacked in the same way, and I

(a) I take this opportunity of recommending chloroform as one of the best remedies for whooping-cough. From ten to thirty drops on a handkerchief held to the mouth and nose of a child at the commencement of the paroxysm, and repeated if necessary, will not only shorten the fits, but will diminish their frequency, and in several instances I have found the duration of the disease abridged in a remarkable manner. I believe that the chloroform, besides its composing influence, has a chemical operation on the tracheal membrane which secretes the specific poison of whooping-cough, and prevents its formation. A similar operation may be ascribed to nitrous acid fumes, to alum, and to nitric acid largely administered; and to cauterisation of the mucous membrane of the trachea by solution of nitrate of silver—all of which remedies have the reputation of shortening the duration of the disease.

went into Yorkshire to see him. He was an enormously stout man of 45, and it was awful to see his huge frame convulsed with the tremendous cough. The stench in the room gave me a sickening that I did not recover for some days. Yet this patient also made a quick recovery on the same plan.

The case of a lady near Staines (aged about 30), whom I saw on October 15, 1856, was still more formidable. Fetid matter was brought up for several months, to the extent of from half a pint to a pint and a half in the day, and there were abundant signs of a large squashy cavity in the lower lobe of the right lung. This was a stout woman too; and, fortunately, her stomach was stout also, and bore a prodigious quantity of food and stimulants, with a corresponding proportion of cod-liver oil and tonics. She entirely recovered; and I have heard of her continuing well within the last year or two.

A gentleman, aged 25, at the end of March, 1850, after depression from a bilious disease, was subjected to extreme exertion and chill in helping at a fire, and was attacked with inflammation of the right lung, followed in fourteen days by profuse expectoration of very offensive matter, with gurgling and other signs of large cavity at the base of the lung. On April 21 there came on sudden severe pain in the lower front of the right chest, with extreme oppression, and signs of collapse, requiring the free use of opium and stimulants. After twenty-four hours more horribly offensive matter was expectorated, and the enlargement of the cavity was made obvious by the sound of metallic tinkling. Yet, by aid of antiseptics, with nitric acid and bark in the day, morphia at night, and liberal nourishment, this patient improved so much that in June there were no more signs of cavity, only partial dulness and obstruction; and he afterwards made a complete recovery.

Another gentleman, aged 30 (November, 1850), after suffering six weeks from dyspnoea, frequent pulse, scanty secretions, and moderate cough, with dulness and defective breath at the base of both lungs, suddenly began to cough violently, and in two or three days brought up a pint and a half of extremely offensive pus. No signs of cavity could be detected. In a few days, under mineral acids and cod-liver oil, the expectoration diminished and lost its fetor; and by the end of February the patient was quite well.

In two or three cases fetid abscesses of the lung have seemed to have their origin in the liver, being preceded by marked tenderness and fulness of that organ.

A gentleman, aged 26 (October, 1850), after suffering for three weeks from nausea, fever, fulness and tenderness of the right side, was attacked with severe pain in the same part, soon relieved by leeches; but in a week's time, after several rigors and accessions of fever, he began to cough up quantities of greenish and drab-coloured matter, extremely fetid, and sometimes very bitter in taste. There were signs of consolidation and partial cavity at the front of the lower lobe of the right lung. These symptoms were attended with extreme emaciation and weakness; but, with the exception of some cough and expectoration (not fetid), they gradually subsided; the patient was recovering flesh and strength, when, in a few weeks, there was a return of the fetid expectoration, violent cough, and feverish disturbance, which, after a week or two, again gave place to a state of amendment. These attacks continued to recur at irregular intervals for eight years, gradually becoming less frequent and less severe, and ultimately ceased altogether. In this case there were signs of considerable disease of the lower lobe of the right lung, and it appeared that it was so placed that the whole of the offensive matter could not be completely evacuated; so that, although the lung healed above, the matter which remained gradually increased until it was sufficient to cause the local and general disturbance of a fresh attack of hæmoptysis, fetid expectoration, and constitutional disturbance. An attempt was made at one time to give vent to this matter by an incision through the integuments and intercostal space over the cavity, but without success. Eventually, the constitutional powers, invigorated by pure air, favourable climate, nourishing food, and the occasional use of tonics, gradually diminished the evil, and after some years succeeded in overcoming it.

Of the four fatal cases of fetid abscess of the lung, three are recorded within the period before mentioned; the fourth occurred more recently. But I will notice each, in order to point out the several circumstances which seemed to prevent the success of the treatment.

On November 16, 1850, Mr. Bateman, of Islington, requested me to see a gentleman, aged 56, who had been six weeks suffering from low inflammation of the right lung with expectoration, which sometimes had an extremely offensive character, and that which was now preserved had the characteristic

cowslip odour before mentioned. Four days before there had been severe pain of the right side. The signs were dulness and deficient motion in the lower two-thirds of the right side of the chest, obscure coarse crepitation below right scapula, loud bleating bronchophony above. Under the free use of nitro-muriatic acid, with creosote inhalations, the fetor of the expectoration diminished, and the pulse lowered from 110 to 85 on the 22nd, but there was increased pain and extreme tenderness of the right side, the integuments of which were swollen, and pitted on pressure. There were now also signs of air in the right pleura, proving that the pulmonary abscess had perforated that membrane. As may be supposed, therefore, the amendment was only transient, and the patient died on December 5. He was not temperate in habits, and the amount of lesion in the lung was obviously too extensive to admit of cure.

A lady, aged 50 (seen first with the late Mr. Nussey, and afterwards with Dr. Jenks, at Brighton), at the beginning of 1849 was attacked with cough and feverish symptoms, followed by severe pain in the right back. Leeches and blisters gave some relief, but the cough continued, and brought up sputa (first bloody, then purulent and viscid) in great quantities—sometimes fetid, more frequently inodorous. Unfortunately, this patient had a most fastidious stomach, and could bear neither strong acids, tonics, cod-liver oil, nor even much nutriment; and she was gradually worn down by the exhausting cough and expectoration, and died in the following summer. There had been signs of consolidation and partial excavation of the lower and middle lobes of the right lung, and after death these were found carnefied, with a narrow passage with sloughy walls reaching down to the diaphragm, and there spreading to four or five inches in diameter, and limited by the strongly adherent pleurae. There were no tubercles in either lung.

A little boy, aged 4, was brought to me on July 19, 1856. In the preceding August he had a feverish attack, with cough, and in September began to spit up very offensive matter. Relief and improvement followed; but at the end of October the violent cough, with fetid breath and expectoration, again returned; and these attacks had returned at intervals of from six to eight weeks ever since, causing extreme weakness at the time; and although there was improvement in the intervals, the poor child was obviously wasting away under the disease. The lower two-thirds of the right lung were dull and obstructed, a tympanitic-stroke sound in the lower front, and amphoric breathing at the scapula; crepitus above: some crepitus also at left apex. Temporary amendment took place under a tonic treatment, with cod-liver oil, etc.; but in the October following diarrhoea and sickness interrupted this, and the disease lapsed into fatal phthisis.

To these three fatal cases I will add a fourth, which will serve to exemplify another cause of failure. A gentleman, aged 52 (seen in consultation with Dr. Sharpe, of Norwood), had suffered during the summer of 1861 from a succession of boils. In the autumn, during a tour in Scotland, he was attacked with severe pain in both sides of the chest, and began to cough and expectorate very offensive matter. This, and the violence of the cough, coming on in paroxysms only when the matter had accumulated, were quite characteristic; yet I could never discover signs of cavity, nor even of marked consolidation in any part. I suppose it was deep-seated in the centre of the lung. I expected this patient to get well, as most of the others had done; but no treatment succeeded in permanently diminishing the quantity and fetor of the expectoration. At last it was discovered that the urine was saccharine, and this I believe to have been the cause of the intractability of the case. Sugar in the blood often causes boils and carbuncles to form, and it may well be supposed capable of preventing the healing of a gangrenous abscess. This patient was ultimately under the care of Dr. Blakiston, at St. Leonard's; and I went there to see him in consequence of a sudden aggravation of his symptoms. He was attacked with vomiting and severe pain and oppression at the sternum and epigastrium, with sudden failure of strength and great acceleration of the pulse. There was so much fulness and dulness on percussion, as well as extreme tenderness of the epigastrium and right hypochondrium, that I came to the conclusion that an abscess was forming in the liver, probably caused by extension of the lesion from the lung. The patient died two days after, and a post-mortem examination was not permitted.

It is a remarkable fact that in all the cases of fetid abscess of the lung that I have now noticed, the seat of disease has been the right lung, and I do not recollect in other instances which have occurred in my practice (not fewer than

twenty more) that I ever met with a case of abscess of the left lung. (b)

If, as is probable, gangrenous abscess has its origin in obstructed circulation in the great pulmonary plexus, this may reasonably be expected to occur most frequently in the part in which the largest quantity of blood is apt to stagnate—the central portions of the large lower lobe—where the respiratory movements are most impaired.

(To be continued.)

LECTURES ON THE PRINCIPLES OF THE TREATMENT OF FEVER.

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE III.

(Continued from page 152.)

THE ADMINISTRATION OF STIMULANTS.

Alcohol.—The mode of action of alcohol upon the organism during the febrile state is very complex, and before discussing the nature of the modifications in the pathological changes probably effected by it, it is necessary to refer to the great distinction between the two objects for which wine and other stimulants are given during illness. Alcohol is prescribed—1. For the purpose of promoting digestion, improving the appetite, and relieving unpleasant sensations about the stomach; and 2. With the view of directly influencing those most active and serious abnormal changes which are taking place in the blood and in the tissues in all bad forms of fever, which, if they progress beyond a certain degree, will certainly lead to a fatal result.

I propose to defer the consideration of this latter part of the subject until the action of alcohol in moderate doses in the healthy state and in cases of slight fever has been discussed. The forms in which this substance is taken are very numerous, and nothing is more remarkable than the capriciousness exhibited by different stomachs as regards the reception of alcohol. Some persons like, and can take without suffering, any form of alcohol. With others beer and malt liquors agree well—better than wine or spirits. A certain number can even take porter, but not ale, or *vice versa*. With some dry sherry is the only wine that will agree. Port wine suits others; while not a few prefer, or can only take without suffering from derangement of the digestive organs, certain hocks or clarets, or perry or cider. Brandy or whisky diluted will often agree when every other kind of alcoholic drink fails; but even pure rectified spirit properly diluted will not always be absorbed by the stomach without exciting discomfort and favouring the development of unpleasant gases, with certain organic acids, among which butyric, acetic, and valerianic are found.

No one has yet been able to give any satisfactory explanation of the fact that a little wine will occasion in some stomachs the greatest disturbance. Within a few minutes, not only is the process of digestion stopped, but there is pain, an unpleasant feeling of nausea, not unfrequently accompanied by an actual desire to vomit. In other persons a glass of wine will occasion no inconvenience at the time, but may lead, in the course of from twelve to twenty-four hours, to the development of that unpleasant collection of symptoms which constitutes what is often termed a "bilious attack." Vomiting, purgation, and free diuresis afford relief; but sometimes the disturbance lasts for days, and is not allayed until the stomach has had twenty-four hours' complete rest from work, or until free action of the alimentary canal and all the glands that pour their secretions into it has been promoted by a dose of mercury. It is, after all, not improbable that this most unpleasant action of alcohol indicates a highly sensitive but not unhealthy action of the nerves of the stomach, and that tolerance of wine and spirits is due to a change which has been induced in the finest nerve fibres—in consequence of which their sensitiveness has been impaired. The tolerance of opium, tobacco, and some other poisons is

(b) The following case may be an exception; but having been seen only once, and so many years after, must be considered doubtful:—Miss S., aged 56 (September 8, 1854), twenty-five years ago had fetid abscess of the lung, and for six or seven years continued to cough up offensive matter. No fever since, but short breath, wheezing, and occasional cough have persisted; lately with intermittent pulse and increasing weakness. Physical signs: Dulness and partial obstruction, with crepitus in lower two-thirds of left lung; sonorous rhonchus above on both sides.

probably to be explained in the same manner. Nor is tissue change limited to the nerves of the stomach; for it is an unquestionable fact that many of those persons who habitually subject their tissues to the influence of alcohol and tobacco, or both, at an early age, exhibit very distinctly signs of change in many tissues of the body. They look older; and, indeed, physiologically speaking, their tissues are considerably older, and have deteriorated in a much greater degree, than would have been the case if they had not been exposed to the action of alcohol.

It is very remarkable how great a difference, as regards the capacity for the assimilation of alcohol, is observed in the same person when in ordinary good health, and when suffering from even a slight cold. I have observed this many times myself. When in health a very small quantity of wine will disagree, and not unfrequently give rise to serious disturbance of digestion; but when one feels depressed and miserable from a feverish cold, three or four glasses of wine may be taken within a very short time with benefit, and with a feeling of immediate relief. Persons accustomed to alcohol in one form may take with advantage some other alcoholic fluid during illness.

If at the outset we have any reason to apprehend that an attack of fever is going to be severe, it is very desirable to administer small quantities of alcohol early in the disease. In this way the stomach may be accustomed to the remedy; whereas, if its use is postponed until the patient is very ill, and alcohol required in very large doses, the stomach is often in so highly irritable a state as to reject it. The patient's life may be in jeopardy from this circumstance, or fatal exhaustion alone may actually destroy him.

OF GIVING ALCOHOL TO YOUNG PERSONS.

My conclusions as regards giving alcohol to the young are in the main not at variance with the opinions of those who advocate extreme temperance. My own experience leads me to believe that the majority of young healthy people would do well without alcohol; and I believe the habitual daily consumption by young persons—even of a moderate quantity—of wine or beer, is quite unnecessary, and mere waste, while in some instances it is positively injurious to health. At the same time, there can be no doubt that in certain cases where the health fails in children, and even in infants, great benefit results from giving small quantities of wine daily for a short time. Hard-working people, students, professional men, and people actively engaged have been advised to take stimulants, as a general rule—and some, no doubt, require them; but I believe many would enjoy very good health without any alcohol at all, while the recommendation that they should take plenty of claret or other light wine is bad advice for several reasons. Not only is a bottle of light wine not required, but in many cases it is actually injurious. That people who can get it will often take a bottle of light wine, and more, is quite certain; but that they require it, or that it is good for their health, will not bear discussion.

Up to the age of 40 very little stimulant is, as a general rule, really desirable for healthy persons, and I expect most people of average health would get on better without any. My own personal experience is this:—I was never very strong, though always able to get through a very considerable amount of physical exertion without suffering from fatigue. Up to the age of 40 I hardly ever touched stimulants of any kind, and when I did take a little I not unfrequently experienced an attack of sick headache before my ordinary condition of health was restored. Lately, however, I have found the advantage of half a tumbler of ale daily; and I can bear half an ounce, and sometimes three or four ounces, of wine without suffering. I dare say, as I grow older, I may, like most persons, require a little more; but when in the country, and taking plenty of exercise, I feel very well and contented without any stimulants whatever. The experience of some members of my family who have lived to be old, and that of many persons of whom I have inquired, accords with my own. In old age, I believe, stimulants are really necessary, and sometimes are even more important than food itself. I feel sure the life of many old people is prolonged by the judicious use of alcohol, and I think that some, who have been very careful all through life, take far too little stimulant when they grow old.

OF THE PROBABLE ACTION OF ALCOHOL IN THE BODY.

But we may now very briefly consider the influence of alcohol upon the organism, and its probable operation as an article of diet. What becomes of alcohol when it is taken into the stomach? There is no doubt that if the spirit is strong when introduced, it is much diluted by the pouring out of fluid from the vessels and glands of the stomach, and that it is quickly absorbed, in its diluted state, into the blood. That this

is so is proved by the familiar fact that the smell of alcohol is often very perceptible in the breath. Moreover, as is well known, alcohol has been detected by chemical tests in the breath, in the sweat, in the urine, and in the other secretions by a number of observers. Alcohol has also been proved to exist in the blood. There is, therefore, no doubt that alcohol, as alcohol, may not only be taken up by the blood, but may circulate with the nutrient fluid, and eventually pass away from it unchanged. But it must not therefore be concluded that *all the alcohol every person takes* is thus absorbed as alcohol, caused to circulate through the body as alcohol, and at last excreted unchanged; for such a conclusion would be opposed to the facts of observation and experiment. The truth seems to be, that some of the alcohol taken is unchanged in the system, but that a considerable and very varying proportion of the total quantity introduced is caused to disappear altogether as alcohol, and to pass through most important changes, escaping at last from the organism probably as carbonic acid and water.

A certain quantity of alcohol is *digested* and *assimilated*; and it is quite certain that the capacity for the digestion of alcohol varies very remarkably in different individuals. It is most probable that the alcohol is taken up by, and carried with, the portal blood to the liver. It is then appropriated with other substances by the bioplasm of the hepatic cells, and completely changed. Its elements are rearranged, and added to the constituents which form the liver-cell, and which gradually break up to form the ingredients of bile, the liver-sugar, and the so-called amyloid matter.

It is the living matter of the yeast-cell that splits up to form alcohol and carbonic acid, water, and a form of cellulose. We shall not be surprised to find that another form of living matter—that of the liver-cell—has the power of appropriating alcohol, rearranging its elements, and causing them to combine with other elements to form compounds having properties very different from those of the materials out of which they were made. And it seems probable that under certain circumstances other forms of bioplasm of the body are able to take up and appropriate alcohol; for it is certain that in some prolonged cases of exhausting disease a large amount of alcohol is readily assimilated, while ordinary foods can only be taken in such infinitesimal amount that we cannot attribute to them much influence in the maintenance of life. In severe cases of fever, as I shall again have occasion to state, the greater proportion of the alcohol introduced is probably not oxidised, as used to be supposed, but appropriated. Its effect is to lower, not to elevate, the temperature; and, so far from increasing the dyspnoea in bad cases of bronchitis, pneumonia, etc., by throwing increased work upon the lungs, as used to be affirmed, it has a directly contrary effect.

Dr. Parkes has shown that diluted alcohol, given daily in such proportions that not more than two ounces of absolute alcohol are consumed in the twenty-four hours, in most cases improves the appetite, and slightly quickens the heart's action; but that larger amounts have an opposite effect as regards the appetite, and greatly increase the cardiac beats.

Anstie and Dupré showed that if doses of alcohol sufficiently large to produce narcotic effects are taken, alcohol escapes in the excretions, but when smaller quantities are taken it is not to be detected. This may be the true explanation of the fact that alcohol in certain cases cannot be detected in any of the secretions at all. It is certain that the quantity required to produce narcosis varies greatly in different individuals, and perhaps this may account for the different results obtained in the course of different experiments.

Dr. Dupré has quite recently proved that, of the alcohol taken in moderate doses (48 to 68 grammes of absolute alcohol), only a minute fraction is excreted as alcohol, while by far the larger proportion is disposed of in the system in some other manner.^(a) Dupré's observations show that this alcohol is not stored up in the system as alcohol, and slowly evolved in the form of alcohol. He remarks that the amount of alcohol eliminated per day does not increase with the continuance of the alcohol diet, and that, therefore, all the alcohol taken daily must be disposed of daily, and converted into some other substance in the system.^(b)

We must therefore conclude that, of the alcohol taken, only

(a) *Proceedings of the Royal Society*, January 25, 1872.

(b) Dr. Dupré has discovered in the urine and in the breath a substance, which, though not alcohol, gives the ordinary reactions relied upon for detecting that substance. It yields acetic acid by oxidation, and gives the emerald-green reaction with bichromate of potassium and strong sulphuric acid. It yields iodoform. This body was found after six weeks' total abstinence from alcohol, and was detected in the case of a teetotaler.

a small but very variable amount is excreted as alcohol, but that the larger proportion, at least in the case of most organisms, is changed in the system; not simply acted upon by other things in a state of change, as may be effected out of the body, but actually taken up by the living matter or bioplasm, appropriated and converted into other substances. Though probably not applied to the nutrition of tissues, its elements may perhaps assist to form some of the constituents of bile, sugar, fatty, and amyloid matter.

ORIGINAL COMMUNICATIONS.

THE CURVES OF THE DEVELOPED GENITAL PASSAGE.(a)

By J. MATTHEWS DUNCAN, M.D.

THE observer of the current literature of midwifery finds nothing more characteristic of it than the number of papers on the mechanism of natural parturition. These papers indicated, for the most part, an enlightened zeal, for they are engaged with a most important branch of this mechanism—namely, the mode of action of the force of labour upon the foetus and upon the passage, and the explanation thereby obtained of the changes which take place in these as natural labour advances.

For these inquiries great additional value would accrue were the amount of power exerted by the combined forces of parturition well known; but they can be carried on to a great degree of advancement even while the amount of power exerted by the machine is unknown or at least unsettled.

Some of these inquiries as to the action of the force of labour upon the foetus and passage are very easily solved, and have been long in this condition. But the most, and by far the most important, are questions only recently raised, and of which it may be said that few are familiar to the Profession even as questions, and still fewer can be regarded as settled. These inquiries form the natural sequel to the most recent developments of our knowledge of natural parturition. These have been chiefly engaged in describing *how* the foetus and the passage actually behave during the process, while the new inquiries are destined to explain *why* they so behave. These new inquiries will introduce us far more deeply into the subject of the mechanism of labour than those which have preceded them. They are specially difficult because of the varying conditions of the force of labour and of the correlated parts—the foetus and the passage. The former has the relations of its parts extensively changed while the process of labour proceeds, and the latter is only produced at the time by what is called the development of parts as the foetus advances.

The subject to which I wish at present to direct attention is the curves of the genital passage and their influence on the phenomena of parturition.

I.

The first curve to which I direct attention is said to be at the brim of the pelvis, and to have its convexity directed downwards and forwards. I do not admit that this curve exists; but it is of the utmost importance to decide the point, because, without doing so, we cannot possibly determine the primary direction of the driving force of labour. Hitherto and now the axis of the uterus has been and is generally regarded as coincident with the axis of the brim of the pelvis, and to indicate the direction of the resultant of the forces of parturition. But an elaborate attempt has been recently made by Schatz and Schultze—especially by the former of these authors—to demonstrate that the axis of the uterus at rest and in action is inclined to the axis of the brim of the pelvis at a small angle opening forwards and upwards and of about ten degrees. I have just said that the axis of the uterus has been generally considered to indicate the primary direction of the driving power; but it is evident that this can only be the case if a variety of conditions be satisfied. Of these the following are probably principal:—The assistant driving force, which is auxiliary to the proper uterine force, must be also directed in the axis of the brim of the pelvis, being supposed to be uniformly applied to the uterus by the circumjacent viscera and parts acting like a fluid, exerting pressure equally in all directions; the uterus must be distended with a fluid which is copious enough to prevent any part of the walls being specially pressed upon or indented by the foetus, or it must have its

(a) Read to the Royal Society of Edinburgh on February 19, 1872.

tendency to become spheroidal superiorly unrestrained. Now, Schatz, in addition to giving the proper uterine driving force an inclination to the axis of the brim by ascribing to the uterine axis such an inclination, still further increases the inclination of the whole driving force by describing the special direction of the auxiliary bearing-down driving force as still more inclined than the direction of the uterine axis. The resultant of the combined or whole driving forces will, of course, according to Schatz, have a direction somewhere intermediate between that of the uterine and that of the auxiliary driving forces.

Smellie's authority is much relied upon in support of the existence of this curve. In his plates he gives the uterus this inclination to the axis of the brim of the pelvis, both in natural cases and in cases of deformity; but this is not satisfactory evidence as to what he believed, for it is probable that in preparing his plates he did not pay particular attention to the point. Those of them to which reference is here made (as xii. and xiv.) are not, in the proper sense, drawings or pictures, but mere plans, and might very well have been arranged as they are, merely because in other respects the works looked well. Dr. Barnes, in his recent work on obstetric operations, while adhering to the generally entertained view as to the coincidence of the axis of the uterus and of the brim of the pelvis, implies, by his descriptions and drawings, a belief that in most, if not all, cases of antero-posterior contraction of the brim of the pelvis, the uterine axis is inclined to the axis of the contracted brim, as Schatz believes it to be in cases generally. This is not the place for any full criticism of what Barnes very aptly calls the curve of the false promontory, because I confine myself to ordinary or natural conditions. I shall merely say that this important and practically valuable doctrine of Barnes regarding the curve of the false promontory is made too general. It can be true and applicable only where the posterior uterine obliquity is present, and it is not demonstrated, nor is it probable, that this always is so in cases of deformity.

It is extremely desirable that means should be devised for ascertaining the direction of the resultant of the combined forces of parturition, and especially of the axis of the uterus in action. The means adopted by Schatz, with this object in view, are not satisfactory; they merely go the length of showing how carefully he entered upon the question. But it may be permitted me to state reasons which tend to establish the ordinary opinion, and to discountenance that of Schatz.

If the uterine axis is inclined to the brim of the pelvis posteriorly to its axis, we should expect to find the child's head at the commencement of labour, while yet above the brim, to be in a position which has never, so far as I know, been ascribed to it in natural cases. Smellie, in his Plate xii., gives this position consistently, but not truly. He could not avoid doing so unless he represented the child at rest as having a left lateral flexion of the head; which would be ridiculous. His mode of drawing the uterus with this posterior obliquity created an exigency for him, which he could get over only by what must be regarded as misplacement of the head. One error thus led him into another. The erroneous posterior uterine obliquity forced him to represent the left side as presenting in the very commencement of labour, in an ordinary case of first cranial position, with the occiput looking to the left. I do not see how the difficulty—Smellie's yielding to which gave rise to error—can be avoided, except by assuming that the ordinary view as to the axis of the pregnant uterus is correct.

At the same point where Smellie stumbled, Naegele also fell into error, but in an opposite direction. In his classical essay on the mechanism of birth, describing the first position of the foetal head, he represents it as presenting at the brim of the pelvis, which it has not yet fully entered, more obliquely than when it has entered it, or as having at the earliest stage its perpendicular axis more inclined anteriorly to the axis of the brim; and in this way he accounts for his allegation that the right ear can generally be felt at this time without difficulty behind the pubic bone.^(b) Here a remark may be made similar to that applied to Smellie's drawing: namely, that the head could not be so placed unless the uterus had an anterior obliquity—an obliquity opposite in direction to that figured by Smellie, and described by Schatz; an obliquity quite incompatible with Naegele's own descriptions in his work on the female pelvis,^(c)—or unless the child maintained an unnatural and undescribed left lateral flexion of its head.

The now generally entertained views, that the axis of the uterus coincides with the axis of the brim of the pelvis, and that the foetal head presents at the brim directly,^(d) have at least the merit of evading such obvious and adverse criticism as the figure of Smellie and the expressed opinions of Schultze, Schatz, and of Naegele are liable to be subjected to.

The great authority of Naegele was long sufficient to give currency to his statement that the head of the foetus, as it passed through the brim of the pelvis, had its vertical axis in a position of anterior obliquity to the plane of the brim—an obliquity which is appropriately designated the Naegele obliquity, in order to distinguish it from other obliquities at the same situation. The great argument against this view, and the only one having a final character, is that it is not an accurate description of what takes place; but, in addition, it has been argued against it that it is impossible to find a mechanism to account for it. Stoltz's attempt to explain its occurrence by mere lateral flexibility of the neck of the child is insufficient, because it affords no explanation why the lateral flexion is towards the posterior shoulder; but the now alleged posterior obliquity of the uterus, as regards the axis of the brim, affords a solution which Naegele did not foresee when he described this obliquity as present and increasing with the increasing height of the head in or above the true pelvis. If, adopting the kind of nomenclature introduced by Barnes, we describe a curve of the natural promontory produced at the brim of the pelvis by the posterior obliquity of the uterus, then this curve, representing a deflection of the axis to the extent of about ten degrees, can be easily made to account theoretically for the alleged Naegele obliquity during the first half of the passage of the child's head through the ligamentous pelvis. For if we suppose, with Schatz, that the whole power of labour acts in an obliquely nearly corresponding to that of the axis of the uterus, or inclined still more posteriorly, then there will always be a tendency of the anterior half of the head, or of that which is nearer the concavity of the curvature of the passage, to descend first, and so produce the Naegele obliquity, if there be uniform resistance to the advance of all parts of the head. But, as the occurrence of Naegele's obliquity is now very generally denied, any mechanism which accounts for it derives little or no support of its own accuracy from the circumstance of its doing so.

Still another difficulty in the way of admitting the presence of this curve of the natural promontory as the natural or ordinary condition is worthy of consideration. It is justly held that in natural labour the advance of the head through the brim of the pelvis is impeded only by friction and imperfect dilatation, or dilatability of the soft parts; but, if this curve of the natural promontory exists, a new and considerable difficulty is introduced—namely, the difference between driving a body through a curved and a straight passage—a new difficulty which it appears to me unreasonable to admit. And this is not all; for this addition of difficulty is not overcome and passed when the child's head has traversed the curve, but lasts during most of the process of the birth of the child. If this curve exists, the axis of the genital passage, regarded in the antero-posterior vertical plane, has the shape of a Roman S; its first or upper curve, the curve of the natural promontory, having its concavity looking backwards; its second, and universally recognised curve, having its concavity looking forwards. I believe we are nearer the truth when adopting the view at present generally entertained, that, in the antero-posterior vertical plane, the genital passage has ordinarily only one curve, having the concavity of its axis looking forwards.

Direct therapeutical bearings of this matter are evident and important, both in natural and morbid parturition. Certain attitudes of the body, by increasing or diminishing the flexion of the iliac beams upon the sacrum (a movement which I have elsewhere described as nutation of the sacrum),^(e) may alter not only the dimensions of certain parts of the genital passage, but also the relations of the axis of the pelvic brim to the axis of the uterus, or to the direction of the resultant of the forces of labour. In an elaborate paper^(f) Schultze has attempted to show that similar results may be produced by flexion and extension of the spine. This author assumes that the lower lumbar vertebræ govern the uterine axis, and that the latter is normally inclined posteriorly to the plane of the pelvic brim. He therefore recommends that, when difficulty arises at the brim, the spine should be flexed so as to bring the axes of the uterus and of the brim, if possible, into coincidence; and if

we admit his assumptions, there can be no doubt as to the justice of his conclusion. For practical application, however, the proper treatment may be stated in such a way as to offend no theory as to axes of brim or of uterus, or so as to stand good whatever view is held on these points. When, before labour, or while the foetal head is still mobile above the brim, it is placed with its sagittal suture not traversing the centre of the brim, but lying anterior to it (as Smellie figures), then it will, during early labour, be pressed with a loss of force against the pubes, not directly into the brim. It will then be worth while to try whether flexion of the spine, by putting the woman into the attitude assumed in stooping forward, will correct the direction of the head (which I consider an unnatural direction). If it corrects it, the sagittal suture will be observed to leave the neighbourhood of the pubes, and approach or reach the middle of the plane of the brim. Again, if the uterine axis, or the resultant of the forces of labour, has this posterior obliquity to the axis of the brim, then, in the first half of its course through the ligamentous pelvis, the foetal head may be expected to show the Naegele obliquity—that is, its half lying in the anterior half of the pelvis will be lower than that in the posterior as regards the plane of the pelvic brim, being pushed down with greater force; and it will be well worth while to try whether or not flexion of the spine will correct this direction of the head (which I consider an unnatural direction).

II.

The second curvature of the pelvis, which I proceed to describe, is, like the former, situated at the brim of the pelvis; but of its frequent existence there can be no doubt whatever. Its presence is indicated by the deflection of the uterus from the mesial line to the right or to the left, and it is well known to be observed at all times—that is, before, during, and after pregnancy; but as this paper is concerned only with dynamical matters, this deflection or deviation is interesting only as observed during labour. On the direction of this deflection to right or to left I have no remarks to make, but I may refer the student first to the recent paper on this subject by Winkler, (g) and then to the earlier observations of Spiegelberg (h) on this uterine position during labour. For my present purpose it is more important to have some idea of the amount of deflection which occurs. With a view to ascertain it, however imperfectly, I examined a series of cases which I found to present this condition. I did not in all of these cases make out whether or not the deflection persisted during uterine action, but I ascertained that it did so in some of them. I hope to make further observations on this point; but such an inquiry is not essential to my present purpose, it being sufficient to know that the deviation does generally persist during the so-called erection of the uterus in a pain.

I proceeded as follows:—Having the pregnant woman lying flat on her back, I made out the position of the uterus by feeling its outline with my hands. This manipulation shortly induced a pain which made the uterine form more distinct than previously; and then I could observe the outline, mark the projection of the direction of the axis on the skin, and notice its just incidence on the outline of the fundus. Then I measured off, as on a plane, the angle between the projection of the axis and the vertical line joining the ensiform cartilage and the symphysis pubis. I did not try to have guidance from feeling the uterine angles and the parts attached thereto, as Winkler has done in similar circumstances, because I thought that such guidance would not insure greater approach to accuracy in the measurements I wished to make with a view to purely dynamical considerations.

This angle I found in five cases to be 8°, 10°, 11°, 14°, and 15° respectively, or on an average about 10°. The problem now to be solved is to make out from this angle on the surface of the spheroid what is the corresponding deflection of the axis of the spheroid; and since the angle, as measured low down on the surface of the abdomen, lies in a plane nearly parallel to that in which the axis of the uterus is deflected from the antero-posterior mesial plane, the deflection of the axis may be regarded as nearly identical in amount with the angle measured on the surface.

It is probable that this angle of deviation of the axis of the uterus from the axis of the brim of the pelvis has important physiological and practical bearings; but as yet little has been made out regarding them. It has been looked upon as affording some explanation of the alleged comparative frequency of laceration of the cervix on the left side in ordinary labour. (i)

But the most interesting application of it is to assist in accounting for the production of face cases. (k) It has been shown how, under certain conditions, and supposing a right lateral deviation of the uterus, the part of the head on the left side of the brim—that is, the seat of the concavity of the curvature—will have a greater tendency to descend—that is, to be more powerfully pushed downwards than the part on the right side of the brim. Of this there can be no doubt; and the probability of this being a true theory or explanation of face cases is highly increased by remarking the apt manner in which other things known in regard to face-presentations adapt themselves to it.

Another ingenious dynamical theory of face-presentation has been started by Schatz. He states it as follows:—"When the uterus alone is in action, or when there is also acting uniform resistance around by the walls of the pelvis, a cranial presentation always occurs, if the occipital foramen of the foetal head at the time of the first more important shortening of the long axis of the uterus lies backwards from this towards the back of the foetus, but a face-presentation if it deviates forwards from this towards the breast side of the foetus. With the co-operation of non-uniform resistance by the walls of the pelvis, cranial presentation is produced if the occurring posture or negative distance of the great occipital foramen towards the back of the foetus from the long axis of the uterus, multiplied into the positive or negative difference of resistance by the walls of the pelvis, is greater on the posterior side of the foetus than the product of the same factors on the breast side. In the opposite circumstances face-presentation is produced." (l) To all this ingenious theorising there can be no objection, if the conditions are assumed. But the two chief premisses are merely assumed; they are not shown to occur; they are not shown to be more likely to occur in face-presentation cases than in others. Under these circumstances, I submit that there can be no hesitation in preferring the formerly described theory of face cases, where the corresponding assumptions or premisses are not mere assumptions, but well known facts. I refer to the occasional lateral deviation of the uterus, the occasional dolichocephalous condition of the head, and the greater liability of cases of the second or right occipital position to be transformed into face cases than of the first or left occipital position.

III.

The last curve of the developed genital passage which falls to be considered is the most extensive and the best known. It is the great curve in the antero-posterior vertical plane, which begins about the middle of the third bone of the sacrum, and extends through the outlet of the ligamentous pelvis to the outlet from the soft parts. Its length may be greatly diminished by rupture of the perineum, and still more if the sphincter ani is torn through. It forms a curve whose amount of bending varies from about 60° to about 150°.

In connexion with this curve, fall to be studied the synclitic and allied movements of the foetal head during its progress, to which Kueneke has recently directed attention, and which have been so carefully discussed at home and abroad (m) that it is unnecessary to re-enter upon them here.

In connexion with this curve have also to be studied the development of the lower part of the genital passage—the greater development posteriorly where the force is particularly or more strongly applied, than anteriorly where there is little more than counter-pressure, or pressure against a fixed wall, and that chiefly during the temporary abeyance of the power of parturition. There is to be noted, also, in connexion with this curve, the inevitable tendency of the force of labour, not merely to distend the perineum, but also to rupture it centrally, to force the presenting part through it—a tendency the study of which, apart from other considerations, leaves no possible doubt as to the expediency of the practice of supporting the perineum: a practice which can be demonstrated to favour the maintenance of its entirety.

A novel practice, founded upon what I regard as a misapprehension of the conditions of this curvature, has been recently much dwelt upon by Professor Schultze, of Jena. (n) The practice has for its object to facilitate and promote the advance of the child after its head has reached the floor of the pelvis. It is proposed to effect this by extension of the spine, with a view to which a hard pillow is placed beneath the loins as the

woman lies on her back. The extension of the spine he believes to increase the posterior obliquity of the axis of the uterus, and therefore of the force of labour as exerted in this part. By the change supposed to be thus effected in the direction of the axis of the uterus, the axis of the force of labour is brought more nearly to the direction of the axis of the outlet of the pelvis, whereby there is supposed to be produced a diminution of the otherwise necessary loss of power arising from the change of direction of the passage at this part. Schultze alleges that he has found this extension of the spine to be useful in practice. If this utility is confirmed and ascertained, nothing of course can be said against it. But for the enforcement of his recommendation of this practice it is evident that he trusts chiefly to theoretical arguments; and therefore I proceed to examine them, and believe I shall show that they are fallacious. Before doing so, it is worth while to point out that the attitude recommended by Schultze is a very unnatural one, and that a woman straining in labour, advanced to the stage at present under consideration, naturally assumes an attitude nearly opposite to that implied by extension of the spine—an attitude of some degree of flexion—an attitude which, in consequence of the relaxed state of the sacro-sciatic ligaments, may be accompanied by some degree of enlargement of the outlet by the posterior nutation of the apex of the sacrum.

To Schultze's theory of the facilitation of the latter part of the second stage of labour by extension of the spine several objections may be made. Firstly, it is inconsistent with his views as to the facilitation of the entry of the foetal head into the brim of the pelvis by flexion of the spine. That view is based upon the assumption that the child's head enters the brim of the pelvis so as pretty nearly to occupy it and have a nearly vertical axis in the axis of the brim. If this be true of the foetal head at the brim, it will be true of it during its course *mutatis mutandis*, and it will be true of that part of the body which occupies the brim when the child's head is pressing on the perineum. It will be impossible, therefore, by any change of the axis of the uterus to bring the line of the labour force to bear upon the perineum in the direction of a straight line, as Schultze represents it. Second, the upper cylindrical solid portion of the ligamentous pelvis, having a length of at least one inch and a half, has a well-determined axis, with which must correspond the axis of any body fully occupying it, if the body is of uniform consistence—conditions with which the foetus nearly complies. If this be the case, the direction of the force of labour will follow the same axis, and no change of its direction above the brim of the pelvis, however produced, can have any effect upon its direction in any part below the brim of the pelvis. Third, Schultze forgets that his practice is intended to produce or increase posterior obliquity of the axis of the uterus to the brim, to increase the supposed curve of the natural promontory; and that every additional degree of that curve necessarily produces additional loss of power. The more, then, he extends the spine, he will diminish the power of labour available at the outlet of the pelvis, instead of increasing it, as he expects. Fourth, if Schultze's views, as illustrated by his diagrams, are correct, (o) a dangerous amount and direction of force would be brought to bear upon the perineum—a structure whose integrity is already sufficiently imperilled by a force whose direction is gradually changed as the foetus passes through the lower half of the ligamentous pelvis.

Before concluding the consideration of the great curve of the genital passage in the antero-posterior vertical mesial plane, it is necessary to point out an important difficulty introduced into its study by the change in the condition of the ovum when passing through it, as compared with the ordinary condition of the ovum when passing the pelvic brim. Hitherto I have spoken on the assumption that the ordinary view of the action of the power of labour holds good at all points of the course of the child. This view is that the power is uniformly applied by the concave surface of the approximately spheroidal uterus to the uniform surface of the approximately spheroidal ovum, in a direction corresponding to the axis of the uterus and of the developed genital passage. Now, this view is probably nearly correct so long as the membranes are unruptured, or while no special part of the foetus impinges on the uterus so as to injure its approximately spheroidal form, and provided no part of the foetus impinges on the passage so as to cause special friction or obstruction at the part impinging. But, while the great antero-posterior vertical curvature of the genital passage is being permeated, this view is no longer tenable, although

even then it may, in a confessedly inexact way, be advantageously kept in mind, if other more exact conditions are not stated. While this curve is being described, the membranes are generally ruptured, and the waters more or less completely discharged, and consequently the foetus is in a variety of places impinging on and changing the form of the propelling uterus, and meeting with frictional obstruction in the passage at special points more than at others. These changes introduce an amount of complication of the problem which damages greatly the value of such considerations as I have above adduced, and I see no means at present of overcoming the difficulty of arriving at exactness, though there is probably no insuperable difficulty in the matter. Another element of confusion is introduced in the want of uniformity which exists in the composition of the foetus as a mechanical body. It is especially to be noted that it contains a longitudinally placed elastic beam of connected vertebrae, which lies nearer the surface of the mass at one side than at the other.

The ovum or foetus, in its passage through the developed genital canal, is subjected, in various circumstances, to various rotations on some more or less longitudinally directed axis. It is also subject, in various circumstances, to various revolutions or sinuous deflections, in which its long axis moves through portions of curves which are measured by corresponding angles. On these curves and their influence I have made a few remarks, while feeling deeply their imperfection and the need of much further observation and research.

The student who has followed the argument in this paper will have observed the resort to inferences when direct observations would have been preferable. This remark applies to every subject discussed in it; and, while it is to be greatly regretted that such is the case, it is at the same time not to be forgotten that no method of making direct and exact observations has hitherto been discovered. The adoption of the homolographic method is surrounded with difficulties, not only in the method itself, but also in the procuring of subjects on which to use it; and while results obtained by it would be of greatest interest and importance, it is evident that they would not be complete or sufficient, for they can never be other than observations on parts in the repose of death, not in the turgescence and action of life. Until very recently all our knowledge of the force of labour was on a like imperfect footing; but already ingenuity has suggested a means of basing this subject on exact observations, and Schatz has availed himself of these means, and greatly assisted us to arrive at results which we regard as probably the most important hitherto achieved in obstetric science. Till some ingenuity has succeeded in devising means of making like exact observations to settle the points discussed in this paper, we must be content to do our best to reach the truth by reasoning on what we do know more or less exactly. And it should be remembered that by this method we may reach the greatest assurance, if not certainty. A boy playing with his dissected puzzle-map may be certain that a county is rightly placed if it fits exactly into an entire hole formed of the conterminous boundaries of surrounding counties, especially if it also fits in nowhere else. So a theory which suits itself to all, or is in opposition to none, of numerous known conterminous conditions, may be, provisionally at least, assumed to be correct; and such assumption of correctness will vary with the number and testing character of the conditions so humoured by the theory.

CHLORAL IN TETANUS.—At a recent meeting of the Belgian Academy of Medicine, M. Rommelaire read a very favourable report on a case of traumatic tetanus successfully treated by chloral by M. Geens. After trying various heroic remedies in a very bad case of this, he obtained complete success with chloral, in doses of forty-five grains, administered by the rectum.—*Journal de Bruxelles*, December.

DEATH OF PROFESSOR LAUGIER.—Another of the celebrities of the Paris Medical Faculty has just passed away, in the person of Professor Laugier. Although he had attained his seventy-third year, he was still, until quite recently, most actively employed as Clinical Surgeon at the Hôtel-Dieu. During the siege of Paris, too, he took charge of an ambulance. At his funeral, which was attended by a large number of the members of the Faculty, the Institute, and the Academy of Medicine, of all of which bodies he was a member, the speakers laid great stress upon the importance of the projected revival of the *concours*, which had led to the election of so many eminent Professors between 1830 and 1850. Laugier only attained his Professorship after contesting four of these *concours*.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,
Student of Guy's Hospital.

No. III.

(Continued from page 222.)

It appears, from the results obtained upon the schema, that the degree of dicrotism depends especially on two conditions—first, the amount of capillary obstruction; secondly, the rapidity of the heart's action. The tracing represented in Fig 5 was obtained from the schema, the capillaries being dilated, and the contractions of normal rapidity. Under these conditions, the tension of the arterial walls being at its minimum, they are more easily distended by the various waves transmitted through the blood, which are accordingly all well marked. The tracing is not fully dicrotous, and the dicrotic wave or diastolic expansion is preceded by the slight secondary wave noticed above. Now, by making the contractions in quicker succession, the other conditions remaining the same, the arterial tension is increased. This is shown sphygmographically by the elevation of the mainspring to a higher plane in the artery, the writing-lever being raised above the level of the slide. The distance between the short intermediate lever and the mainspring requires to be diminished accordingly by the regulation of the long screw which traverses the former. A tracing obtained under these conditions, represented in Fig. 6, is seen to be hyper-dicrotous—that is, the lever reaches the lowest level. In other words, the artery is least distended, not at the termination of diastole, as is usually the case, but at the termination of systole. The arterial tension is greatly increased by the rapid contractions of the heart; more blood is received by the arteries than can be got rid of by the capillaries, and a certain amount of tension being reached, it continues till either the capillary obstruction is decreased or the contractions of the heart become slower. Meanwhile, each contraction of the heart sends a comparatively small amount of blood into the arterial system; the tension, already great, is rapidly raised and again rapidly falls; the aorta, like the rest of the system, previously distended, becomes much more so by the cardiac systole, on the cessation of which it contracts by virtue of its elasticity, thus supplementing the heart's action, and, by a beautiful physiological economy of force, assists to urge on the blood through the capillaries. A fresh ventricular contraction now ensues, and, owing to the increased rapidity of the heart's action (which shortens its time of rest, and thereby has a most injurious effect upon it, as we shall see hereafter in the study of acute disease), the new pulse-wave closely follows the aortic contraction, and completes the distension of the artery commenced by the diastolic expansion. When the contractions of the heart become so rapid as not to leave time for the aortic contraction, the pulse assumes the *monocrotous* and most dangerous form. Fig. 7 represents a tracing taken with the capillaries more contracted, and the contractions of the heart normal in rapidity. The whole wave is smaller, from the increased tension of the arterial walls, and the dicrotism is greater than in Fig. 5, the pulse being now fully dicrotous—that is, owing to the capillary resistance being greater, the ventricular contraction being able to force less blood through the arteries, the aorta becomes more distended, and the diastolic expansion comparatively greater. By increasing the rapidity of the contractions, the tracing becomes more hyper-dicrotic than in Fig. 6, as shown in Fig. 8; the reason we have already seen. By still further increasing the capillary obstruction, the pulse-wave is again diminished and the degree of dicrotism increased, as shown in Figs. 9 and 10. These deductions are the result of constantly repeated observations. The tracings have the same characters, both in the aorta and radials, though in the latter the waves are somewhat exaggerated, and do not bear so close a resemblance to the human pulse, probably from the great increase of pressure present in them, produced both by the height of the column of fluid above them and the gradual contraction of the size of the tubing.

In another series of experiments, made under much more simple conditions—namely, with an indiarubber tube ten feet in length and of an uniform diameter, the heart and the tube lying horizontally in the same plane, and the free end of the tube raised to a height of four feet, in order to produce a regulated and ascertained amount of pressure in the tubing—the results obtained by varying the rapidity of the contraction and the constriction of the orifice of exit, when the sphygmo-

graph was placed at the distance of six feet from the heart, so that there should be a sufficient length of tubing before the point of application to produce the effect of the elastic aorta, were exactly similar to those stated above, though when the sphygmograph was placed only two feet from the heart, by variation of the constriction of the outlet, opposite results were obtained.

I am aware that these conclusions are opposed to the theories usually taught, and especially to Dr. Sanderson's views, he having laid down the rule, that "Dicrotism is characteristic of that condition of the circulation in which the arterial pressure is diminished while the venous is increased." Still, both experimental results and clinical observations have compelled me to form the views stated above, notwithstanding my reluctance to differ from one who has studied the subject so thoroughly. Besides these two most important conditions, there are certain pathological states which increase dicrotism, such as deficient muscular tone in the arteries, or obstruction to the circulation in the veins or in the right side of the heart.

Increased capillary obstruction has been stated to be an important element in the production of dicrotism. A few words will be necessary in explanation of the occurrence of this condition of obstruction. Wherever in the living body tubes are surrounded by circular and longitudinal layers of organic muscular fibre, as in the arteries, we find peristaltic action taking place; the œsophagus, intestines, Fallopian tubes, ureters, probably the vasa deferentia, and other gland-ducts, may be mentioned as examples—in fact, peristaltic movement is one of the leading characteristics of organic muscular fibre. Why should it be absent in the arteries, where it would especially serve a most useful physiological purpose? The highly interesting and important observations recently made by Legros and Onimus go far towards proving its occurrence, and many of the leading physiologists now entertain similar views. Peristaltic action may be seen by careful observation, by the aid of the ophthalmoscope, to occur in the human eye; also in the rabbit's ear or bat's wing. If the sympathetic trunk be divided in the neck of a rabbit, as in Bernard's experiment, peristalsis is lost in the ear of the injured side, while present in the opposite one. By this phenomenon, and the control exercised over it by the vaso-motor nerves, I shall seek to explain many of the variations in dicrotism. According to the old theory, paralysis of the vaso-motor nerves produced dilatation of the vessels, and this is undoubtedly correct. Mere dilatation of the vessels would mean an accelerated and less restricted flow of blood through them, and would be the reverse of obstruction; but when we consider that paralysis means loss of peristalsis—that is, loss of an important aid to the circulation—it is evident that obstruction must be produced: the effect will be the same whether the vessels be dilated or contracted. The circulatory system having thus lost one aid, calls into active service another—namely, the elastic coat of the aorta. This, by its greater distension, and consequently more powerful contraction, causes the pulse to become dicrotic, and economises the force of the heart's action; for that part of it which was ineffectually employed against the capillary obstruction is stored up in the elastic coat of the aorta, and again applied to the capillaries, in the shape of the dicrotic wave, during the heart's diastole.

There still remains one other feature in a pulse-tracing to be mentioned—namely, the *respiratory line*; or, as it might be designated, the *line of arterial tension*. It is found in a normal pulse-tracing by a line drawn through the bases of the percussion upstrokes, as stated above; it indicates the lowest plane to which the sphygmographic lever reaches in the artery; it therefore denotes the period of greatest arterial collapse. It varies according to the amount of blood contained in the vessel at the termination of diastole, and in the normal pulse maintains the same level throughout the tracing. But, under certain conditions, to be noticed hereafter, it may be affected by the acts of respiration. When this is forcibly performed its effects are visible in the normal pulse. Fig. 15, Pl. i., shows the increased arterial tension produced by an expiratory effort, the larger vessels of the thorax being perhaps partially emptied by the pressure of the contracted parietes; but more especially I take it to be produced by the much smaller amount of blood contained in the compressed lung than in the expanded one. The blood in the pulmonary circulation is therefore decreased, while that in the systemic is increased. The opposite effect is seen in Fig. 16, Pl. i., produced by an inspiratory effort, the conditions being exactly reversed; for here the widely expanded lung draws blood to fill its capillaries from the systemic circulation, the tension of which is accordingly diminished. Each portion of a pulse-tracing has now been discussed, and

the physiological meaning assigned to every movement of the lever. From the conclusions arrived at, it will be seen that the analysis of a pulse-tracing will yield us information on the following points:—

1. The amount of pressure employed will measure the softness or hardness of the pulse. This depends chiefly on the force of the heart's action, and on the tension of the arterial walls.

2. The percussion-wave will indicate, by its verticality and the proportion it bears to the tidal wave, the mode of the heart's contraction, whether slow and feeble, or sharp and strong. It is diminished by very high arterial tension, increased by low.

3. The height of the tidal wave is a measure of the amount of blood expelled from the ventricle.

4. Convexity of the succeeding curve indicates obstruction to the arterial collapse. It is spoken of as "prolonged systolic expansion," and may arise from various causes.

5. The amount of dirotism in a normal pulse is dependent on the tone of the muscular coat of the arteries. As a pathological condition, it is increased by capillary obstruction, by interference with the venous circulation, or a want of relation between the rapidity and force of the heart's contraction and the arterial tension.

6. The relative duration of systole and diastole must be noticed. This was formerly measured in the following manner:— A horizontal line is drawn from the base of one percussion-stroke to that of the succeeding one; a vertical line, drawn through the lowest point in the aortic notch at right angles to the horizontal line, will divide the latter into two parts, the first part representing the time occupied by the systole, the second that by the diastole. The systolic portion nominally extends over about two-fifths; the diastolic about three-fifths. This division, however, Mr. A. H. Garrod, in his highly interesting communications to the Royal Society (Nos. 120, 1870, and 126, 1871), to which I would refer my readers, has shown to be incorrect. The length of the systole may be found from the radial pulse-tracing by adding what he terms the *first cardio-arterial interval* to the *first arterial interval*. The first cardio-arterial interval is that which elapses between the commencement of the cardiac systole, as indicated in a cardiographic tracing, and the commencement of the percussion upstroke in a pulse-tracing. Taking x to represent the rapidity of the pulse, and z the first cardio-arterial interval, Mr. Garrod shows that the number of times that this interval is contained in its component beat may be calculated by the formula $xz = 39 \sqrt{x}$. The first arterial interval is that composing the systolic part of a pulse-tracing, extending from the commencement of the percussion upstroke to the lowest part of the aortic notch. Mr. Garrod calculates its duration by the following equation, in which y' represents the number of times it is contained in its component beat, and x the rapidity of the pulse— $x y' = 47 \sqrt{x}$.

7. The effect of respiration on the pulse, whether causing a variation in the arterial tension, and producing an undulating respiratory line.

These points should be noticed in examining all tracings. They may be applied in the examination of the healthy-pulse tracings in Pl. i. In Fig. 17 there is a little senile change perceptible in the prolonged systolic expansion, from the deficient elasticity of the arterial coats. In Fig. 18 the tidal wave is absorbed by the percussion-wave; the verticality of the upstroke indicates its origin from percussion, while the tidal wave appears as a faintly perceptible interruption in the downstroke following it. In Fig. 20 the percussion-stroke is lost, and only the tidal wave remains, the upstroke being oblique, instead of vertical. The pulse is very soft, only requiring one ounce of pressure, and the heart's contraction somewhat deficient in power. In Figs. 22 and 23 the effect of exercise is even on the pulse; the rapidity is increased and the tidal wave diminished. In Figs. 22 and 24 the dirotism is hardly discernible, the arterial tone being good. The variable tonicities of an artery appears to be entirely due to the muscular coat, for the contraction of the elastic coat is merely mechanical—it is the same after death as during life, and it is not controlled by nervous influence; whereas dirotism is increased by paralysing or narcotising the vaso-motor nerves by alcohol, warmth, and some drugs, whilst it is diminished by stimulating them with digitalis, by cold affusion, or other means. In a perfectly healthy male-pulse tracing, the downstroke should be an almost straight line, and the pressure employed considerable—say, ten ounces, or even more; but such pulses as these are very rare.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

THE LONDON HOSPITAL.

MR. MAUNDER'S CLINIC.

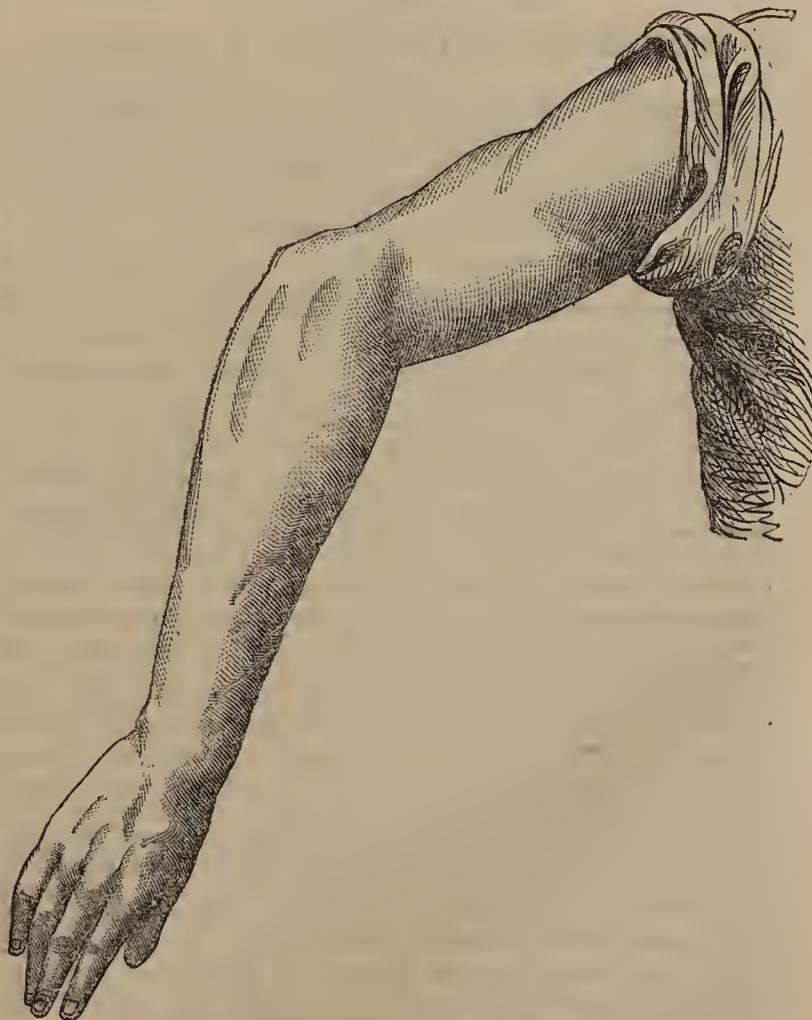

Case 1.—Excision of the Ankle-joint.

EIGHT years ago, G. H., then 14 years of age, was submitted to excision of the ankle-joint for strumous disease thereof. All the joint surfaces were removed, and in due time the wounds healed soundly. For some years this patient has been employed standing and walking many hours daily, and without the least discomfort. The limb is a most useful and shapely one, as seen in the drawing just taken (1872), and the young man walks with a scarcely perceptible halt.

Case 2.—Excision of Elbow-joint.

The drawing has been taken (1872) of the right arm of a male, about 34 years of age, who, three years ago, was sub-

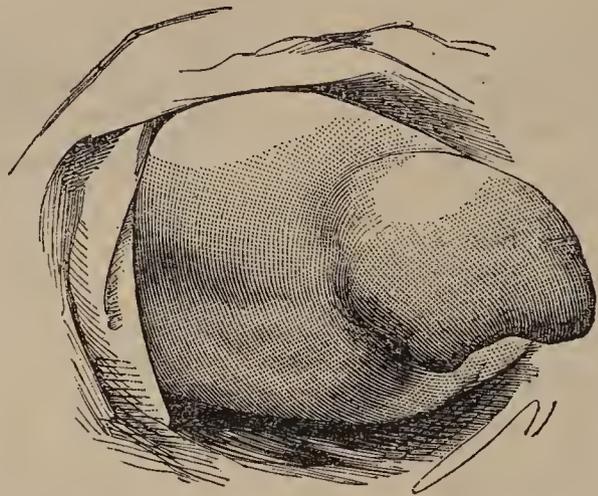

mitted to primary excision for compound comminuted fracture of the elbow-joint. The forearm is in a position of active

extension by the triceps muscle, a desideratum which Mr. Maunder has shown may be always secured to a patient who has undergone this operation, provided that a prolongation of the triceps tendon, which passes between the external condyle and the olecranon, to become continuous with the fascia of the forearm, be preserved. It is usually, but wrongfully, cut transversely, to facilitate exposure of the bone ends.

Case 3.—Amputation through Knee-joint.

The patient, a female, over 50 years of age, when in a very feeble state from want of food, and the subject of a large phagedænic sore on the leg, which got worse, was, at her own most urgent entreaty, submitted to amputation.

The operation was performed between two and three years ago, and the appearance of the stump (1872) is well shown. The articular cartilage and patella were left intact. The integument is non-adherent, and the patella, though somewhat retracted, is not immovable. The stump so formed is admirably adapted to bear pressure, and, indeed, we lately saw the patient sustain her whole weight upon it without the least discomfort. This operation requires in its performance great care and attention to details to prevent a very objectionable result—exposure of the condyles at the wound. The cicatrix lies altogether behind the condyles.

BIRMINGHAM GENERAL HOSPITAL.

PEMPHIGUS IN CONSTANTLY RECURRING PAROXYSMS THROUGH TWO YEARS—NEARLY SUSPENDED UNDER TREATMENT FOR EIGHT MONTHS—TEMPERATURE RECORD.

(Under the care of Dr. RUSSELL.)

I HAVE added to the notes of this case a brief record of a second, which occurred to me in private practice. Both cases are in agreement with a common type of this malady—viz., the continued recurrence of the eruption in periodic attacks; and they also illustrate the different modes in which this paroxysmal character may exhibit itself. In the former of the two, the subject being a young child, the paroxysms followed so close upon each other as to constitute almost a continuous disease; yet each paroxysm seemed to have been preceded by severe constitutional disturbance, together with a general erythematous rash. We witnessed one of these attacks in the Hospital, and, although it was at the distance of two years from the commencement of the illness, the intensity of the erythematous inflammation, and the height of the temperature, together with the vomiting, closely resembled the ordinary prodroma of an attack of erysipelas. The attack had all the characters of the "pemphigus acutus" of authors. On the other hand, in the second case the intervals between the three attacks were complete and prolonged, the reason being that in this case the exciting cause appeared to be pregnancy. The remarkable change, however, in the relation of the pregnancy to the eruption in the third outbreak will be noted. In one of several cases of pemphigus which I published in this journal in October, 1864, and 1865, the same paroxysmal character was exhibited in an equally characteristic shape, the outbreaks having continued over a period of ten years, sometimes lasting three months. It appeared that in this case, also, there was absence of the intense constitutional reaction noticed above in the child. This patient was 23 years of age. The acute febrile introduction appears to appertain chiefly to children. The cases formerly narrated, conjoined with my present ones, present this disease at ages

varying between 6 years and 70 years, and in very different states of constitution. In my former papers two cases of apparently local pemphigus were noted, and exhibited very remarkable nervous prodroma limited to the part affected by the bullæ. Nervous prodromata were again present in the other cases, and will also be noticed in the second of those which follow, accurately defining the site of the forthcoming eruption. To this I may add that in each of my present two cases symmetry in the arrangement of the erythematous spaces in the first and of the eruption of bullæ in the second is noted.

Of course, to refer to local nervous derangement as preceding the outbreak of the eruption in the case of pemphigus, as of many other maladies, is only to advance a step nearer in explaining the mechanism by which the condition in question is produced; it still leaves unaffected the differentiation of the primary cause in pemphigus as distinguished from other diseases. I may refer in this relation to a most interesting paper by Dr. Ballard, in the first volume of this journal for 1871, page 5, on a severe case of pemphigus contracted from an eruption on the teats of a cow, of which eruption he narrates very remarkable particulars derived from Mr. Ceely and from other authors. On the subject of the nervous derangements attending the disease, I may point to the general redness of the surface in one of my present patients after the bath as compared with the tendency to perspiration and flushing of the face observed in the subject of one of my former cases.

I think I am justified in believing that arsenic exerted a decidedly favourable influence in both of my present cases. In the former of the two an almost complete arrest of the paroxysms, which had been uninterrupted through two years, according to the mother's report, took place under this remedy, and a return was threatened when the arsenic was suspended for the experimental use of a hypophosphite. Nevertheless, I have no justification regarding the arsenic as having effected a cure; but the tolerance manifested by the young patient of even a full dose for nearly eight months may possibly afford means of keeping the eruption in check until some change in her constitution comes to her aid.

In the second case the benefit of the arsenic seemed equally direct. I make this remark because Hebra expressly states that "I even yet know of no *internal medicine* which has proved efficacious against pemphigus," and he specially includes arsenic in his condemnation.

Case 1.—E. B., aged 6 years. Her family history is perfectly free from all forms of nervous disease, from rheumatism, and, so far as I can ascertain, from syphilis. The mother, whom she very closely resembles, has never had any eruption. There are three children. The eldest, aged 13, has very good front teeth; he, like the patient, has light complexion, brown silky hair.

The patient passed through the process of dentition favourably, and was perfectly healthy till two years ago, when, after a very slight injury to the left leg, the mother found the limb next day much swollen, and "all on fire," and little blisters, never exceeding the size of a split pea, broke out over the entire surface of the leg. The attack did not much affect the child's health. It lasted ten days; but in three weeks after both legs and thighs became red and angry, and by the following morning were much swollen, and were covered, more or less, with small vesicles, gradually enlarging to the size of a fourpenny-piece. From this date the child has never been free from the disease, and the attacks have been getting gradually more severe. It was twelve months before the eruption spread to the trunk, and two months longer before the face and upper extremities were reached by it. Each time the bullæ were larger, and more generally distributed. The disease occurred in paroxysms, always commencing with a good deal of constitutional disturbance, followed by erythema; an interval of two or three days only separated the paroxysms.

The child looked plump and healthy; with a clear transparent skin, and clear corneæ. There was no glandular enlargement. She was admitted on April 10, and was sent to a convalescent institution in the middle of December.

When admitted she was just recovering from an attack of her disease, the crust of a general eruption of bullæ remaining.

Three days afterwards (on April 13) she was attacked with vomiting, but her temperature was not disturbed; on the evening of the next day erythema broke out on both legs, and extended to the arms by the following morning. On the 16th a deep red blush occupied a great part of the face and forehead, observing exact symmetry on the two sides, and also most part of the four limbs; it had also extended over the front of the neck, and over the right front of the chest. The old crust remained, and there were also a few recent bullæ.

The temperature, taken by our clinical assistant, Mr. E. Elkington, on the day following the appearance of the erythema (the 15th), was 104°, and in the evening 104·6°; pulse 150; the tongue coated; and there is some nocturnal delirium. The urine was 1032, loaded with urates. For five days (to April 19) the evening temperature remained at 104·6°, the morning remissions gradually increasing, till, from the evening of the fifth day, a sudden fall to normal occurred by the morning after, the temperature, however, of the succeeding evening running up to 102·5°. The evening pulse was 130 to 120; the tongue still coated. During the period of six days a few fresh bullæ appeared, but the erythema gradually subsided, leaving, however, extensive desquamation; but, during the next three days (to the 24th), the temperature gradually becoming normal, some scattered groups of vesicles showed themselves, especially around the mouth, which, indeed, throughout the entire period of the child's stay in the Hospital, was seldom free from a circle of vesicles. It was at this period (the 23rd) that administration of arsenic was commenced. But on April 24 the temperature suddenly ran up to 103·2° in the evening, and retained an evening marking of 102° for four days longer (until the 28th), when defervescence by lysis began, and was completed by May 2, thenceforward the temperature remaining normal through the remainder of the case. This last rise of temperature remained unexplained for three days, otherwise than by a few erythematous patches and by some bullæ; but, on the 27th, a general eruption of flat, rounded vesicles broke out, each one surrounded by an areola; and by May 2, the day on which the normal temperature was permanently regained, the front of the abdomen and the inside of the thighs presented a large crop of full-sized bullæ, which were also numerous on the other parts of the body and limbs, but more scanty on the face. This eruption ended without the contents of the bullæ becoming purulent; in the preceding attacks the fluid had always assumed a purulent character.

On May 11 the eruption had disappeared; the crusts were removed, their places being indicated by red patches, and the body was smooth. The mother affirmed that the child had not enjoyed so long an immunity from the disease for two years. This was the last batch of eruption which occurred to the child; though all through her residence one or two, or sometimes more, vesicles were apt to show themselves, and to the last they continued to encircle the mouth. The patches where the bullæ had rested became paler, and finally were indicated by their greater whiteness by comparison with surrounding skin, constituting, in fact, very superficial cicatrices. The skin was quite smooth and soft, and she was hearty and in good spirits. Nevertheless, two abortive attempts at a paroxysm took place (on June 13 and July 31), in the form of a brief eruption of small vesicles in considerable number—which, however, had no effect on the temperature of the body—and one single blister of very large size nearly covered the inside of one foot below the ankle, from friction of a boot. The sore it produced was open for a fortnight. A third attempt took place in September, when arsenic was temporarily replaced by phosphorus.

The treatment consisted simply in the daily use of a bran bath for half an hour, in the administration of the liquor potassæ arsenitis, and of cod-liver oil, and in a nutritious diet. The arsenic was commenced, as stated above, a fortnight after the patient's admission; a dose of two minims was raised to three, and by August 11 to five minims. It was borne without the least difficulty. On August 22 I purposely replaced the arsenite for the hypophosphite of soda, in doses of from seven to ten grains, but threatening of return of the disease compelled me to restore the arsenic, and to the present time she takes it in the dose of five minims. The nurse observed that each time she was taken out of the bath her body was remarkably red all over, the redness lasting for three-quarters of an hour.

Case 2.—Three attacks of pemphigus—the first two at precisely the same period, after successive labours; the third immediately after quickening, in the following pregnancy.

I have only a few particulars respecting this case. Mrs. H., aged 31, had passed through her first pregnancy and labour quite satisfactorily. Two days after her second labour (fifteen months from the first) she was attacked with pemphigus on the dorsum of each foot, and on the back of each hand and arm. The eruption was preceded by itching lasting an entire day. She was ill with her complaint for a month, and has not been well since.

The third child was born three years and a half subsequently; on the second day after, as before, the eruption again showed itself, preceded, as on the former occasion, by itching for a day;

and as the eruption extended, the premonitory itching was so precise that she could predict the spot to be occupied by the bullæ. I saw her in consultation about five weeks afterwards. At that time there were the remains of a broad belt of bullæ on the lower third of each leg; there were bullæ on the dorsum of both feet which were puffy, and others were scattered on the outside of each thigh, and on each gluteal region, the inner aspect of each thigh being free. There were also a tolerable number of bullæ on the back and front of each forearm, and a few chiefly on the posterior aspect of each upperarm, and some small ones on the throat. In the former attack the contents of the bullæ remained clear; on the present occasion I found them purulent in a large number.

I saw the patient but once. I am sure I prescribed arsenic, but I have omitted to note the medicine. I afterwards heard that she soon recovered.

Exactly seven months afterwards she again consulted me. She had just quickened, and a renewed eruption of bullæ intermixed with flat papules had appeared on the limbs and trunk. A broad patch existed at the lower part of each leg in front; other bullæ and papules were thickly scattered over the abdomen and arms, observing singularly accurate symmetry in their arrangement on either side. I at once prescribed Fowler's solution of arsenic. She did not return, but I heard that she recovered very rapidly.

Medical Times and Gazette.

SATURDAY, MARCH 2, 1872.

THE THANKSGIVING.

THE ceremonial of Tuesday last was one which must command a notice, even in the most professional of journals. The national demonstration which it elicited was an event which had the highest interest for all whose proper study is man. It would be easy to descant on such a simultaneous action of a large mass of the human species from the heights of philosophy, to read in it an illustration of the instincts and proclivities of race, an example of the influence of tradition, and of the contagious and epidemic character of national sentiment; or, to descend to a more purely professional standpoint, to make it the occasion for a clinical essay on the cases of accident which it sent into most of the London Hospitals, and which, unfortunately, are only too certain accessories of a great popular concourse. But the sights and recollections of Tuesday have left us for the time little taste for the freezing heights of philosophy; and we shall be forgiven, we hope, if we supplement our record of the casualties with a reminiscence of the bright scene and the august and impressive ceremony. For the Profession to which we belong, and for whom we write, the National Thanksgiving will ever be a memorable event. The *Te Deum* sung on the occasion was not for the slaughter

of a hostile army or the destruction of a threatening fleet. It was a nation's thanks to the Great Healer of sicknesses for the success which had crowned the efforts of those whose Profession and designation Himself has deigned to assume.

With some such reflection as this, we took our allotted place in the Cathedral of St. Paul's early on the bright morning of Tuesday last. Abler pens than ours have descanted upon the impressive sublimity of the scene; we therefore shall not attempt to describe it.

The hours fled rapidly, winged by the interest with which we watched, as one by one the representatives of English science, politics, wealth, art, commerce, industry, and last, not least, of refined and happy English womanhood, filled up the spaces under the vast dome and massive arches of Wren's perennial monument. As the sun, through the aisles of the Cathedral, glinted on masses of bright uniforms and gay colours, now lighting up faces which will be remembered in history, and now bringing into bold relief quaint garbs and antique guises which carry thought back to the Tudors and Plantagenets, the low hum of conversation (in which it was impossible, even in a church, not to indulge) is stopped, as a far-off sound, at first like the wind in a distant forest, becomes louder and louder, until as the voice of many waters it roars and surges round the Cathedral. Marshalled by heralds, and preceded by civic functionaries, the two dignified representatives of the two Chambers of Parliament, a long line of white-robed clergy, and officers of Royal State, whilst the organ peals out the National Anthem, the Queen, accompanied by the Princess of Wales, and leaning on the arm of the Prince of Wales, followed by her children and grandchildren, and by a brilliant Court, walked slowly up the nave. The Prince looks fairly stout, but pale, and a slight limp in his gait attests the severity of that local malady on which so much was written and read a few weeks ago. It is now well known that his Royal Highness was in some suffering during the whole time of the ceremony, and if the mere dictates of prudence had been listened to would not have been present. We will not attempt to criticise the solemn service of praise and thanksgiving which followed, although we should have nothing but favourable criticism to offer. It will suffice to say that the intoning by the officiating priest, the Rev. Mr. Cowan, was an example of the physiological perfection to which the human larynx can be trained, and that Mr. Goss's music (although a *Te Deum* of Handel or Sebastian Bach, and the unsurpassed, and perhaps unsurpassable, Hallelujah Chorus, would have been acceptable) was far above mediocrity, and was superlatively rendered by the choir.

And now for a word or two on the Medical aspect of the Cathedral. Male court dress is trying—it does not suit any but handsome people and good figures; still, our Professional brethren of the Royal Household stood the ordeal wonderfully, and may be congratulated generally on their appearance. We noticed Sir William Jenner, Sir William Fergusson, and Mr. Spencer Wells in friendly chat. Not far off was the venerable Sir Henry Holland, and Sir Charles Locock might have been taken for a general officer in his Deputy Lieutenant's uniform. It was rather late when Sir Wm. Gull arrived and was conducted to his seat. The part of the Cathedral where our brethren chiefly gathered was near that occupied by her Majesty's judges, and behind the seats for peers and peeresses. Dr. Burrows, the President of the Royal College of Physicians; Mr. Busk, the President of the Royal College of Surgeons; Dr. Risdon Bennett, the Senior Censor of the Royal College of Physicians; and Mr. Trimmer, the Secretary of the Royal College of Surgeons, were amongst the familiar faces which caught our eye. Not far off was Sir James Paget. Dr. Stokes, Physician-in-Ordinary to her Majesty in Ireland; Mr. Porter, Surgeon-in-Ordinary to her Majesty in Ireland; and Mr. Wharton, the President of the Royal College of Surgeons in Ireland, were also present. Amongst the other members of our Profession whom we

noticed in the Cathedral were—Dr. Acland, of Oxford, and Dr. Paget, of Cambridge, Dr. Wilson Fox, Dr. Andrew Clark, Dr. Tilbury Fox, and Dr. Lavies. But the space is so vast that no doubt many were undistinguishable. Dr. Lush, Dr. Brewer, and Sir Dominic Corrigan had seats amongst the Commons. The Medical Director-General of the Navy, Sir Alexander Armstrong; the Medical Director-General of the Army, Sir Galbraith Logan; and a long list of Medical officers, whose names we publish elsewhere, had seats on either side of the nave.

The interest of the day would have been heightened, we think, had the Medical attendants of his Royal Highness formed part of the Royal Procession. We suppose the rules of Court etiquette forbade. Still it was a proud day for Medicine. We believe that of the countless thousands who on Tuesday gave vent to that sentiment of loyalty, which, once awakened in England, is perhaps our strongest national passion, not one but would have given a share of the ovation to those whose skill, under the ruling of the Most High, has restored to the British empire the Heir Apparent.

THE GENERAL MEDICAL COUNCIL.

THE General Medical Council meets this session in the miserable room, hung with tenth-rate portraits of distinguished dentists, which they hire from the Dental Hospital. It appears that neither of the Royal Colleges can accommodate them, and Soho-square is the only alternative. We think that a body which possesses funded property to the amount of at least £23,000, which is in the receipt of a large income, and which represents in some sort the whole Medical Profession of the three kingdoms, should have a building of its own, and not rent a couple of rooms merely which have not the recommendations of comfort, cleanliness, or space. This, however, is a matter for their own consideration.

The main object of their session is to receive the reports of the Examining Bodies as to the result of their efforts to form Conjoint Examining Boards in the three divisions of the kingdom, and to proceed, if possible, thereon. It has, however, been long evident to well-informed observers, that no Conjoint Scheme which has any coherence or breadth to recommend it will, or probably can, be framed, or any which ought to receive the sanction of the Council. This opinion has been expressed in this journal for some months past, and events are bearing us out in our assertion. Not only does the Apothecaries' Society find insuperable legal difficulties in accepting the scheme of the Royal Colleges of Physicians and Surgeons, but now the University of London has been informed by her Majesty's Attorney and Solicitor-General, and by the Home Secretary, that they cannot in any way legally enter into the scheme. The English scheme, therefore, as a real attempt at the erection of one portal for the Medical Profession, is virtually at an end. On the side of Medicine it would only comprehend the Royal College of Physicians, with its comparatively small number of Licentiates, and the two Universities of Oxford and Cambridge, which between them grant perhaps a score of Medical degrees in a year. On the Surgical side is the Royal College of Surgeons, which, as we hear on adequate legal authority, can be compelled, by *mandamus* from the Court of Queen's Bench, to examine for its membership any person who has complied with reasonable, but not unreasonable, requirements as to course of study, and who shall prove himself on examination to be competent to practise as a Surgeon. The College of Surgeons can have no legal right to compel candidates for its membership to pay a sum of money to the Royal College of Physicians. Then, again, there is considerable doubt whether the General Medical Council has the power to sanction any scheme of the kind. The Act of 1858 gives it the right to sanction any scheme between two or more of the Examining Bodies for the combination of examinations only—not for the combination of licences to

practise or of diplomas. It is very amusing, after the talk there has been in some quarters of the antiquated bondage under which the Society of Apothecaries labours, and of the "happy despatch" which it has been performing on itself by refusing to break the law of the land, to find the most advanced and most liberal of the Universities obliged to bend to the same rule, and to acknowledge itself under the same antiquated trammels. The fact is, that neither public bodies nor public men can break or alter the laws of England in conformity with their particular views of what may be desirable or undesirable. We think the sooner some of the self-constituted leaders of the Medical Profession are convinced of this fact the better.

Then, again, as we stated last week, there is no hope of Conjoint Boards in Scotland or Ireland; especially not in the former kingdom, where the principle is regarded as mistaken and the idea is unpopular, and where at least one, and the most important, of the Universities finds that combination is impossible with due regard to its interests, and where other of the Universities and the Corporations are hopelessly at variance on the purposes which a Conjoint Board is to fulfil. We, therefore, can only surmise that the General Medical Council will exercise that policy of masterly inaction for which it is renowned, and on the present occasion will wisely let well alone. The fact is, Medical Reform is not so urgent a matter as to compel the Profession to put themselves under the heels of a Government department—the price they would be expected to pay for a new Medical Act—and we are obliged at last to confess that the legal difficulties which must be overcome before we can reach the long-talked-of "one portal" seem unsurmountable without fresh legislation.

The first business done on Thursday, we presume, will be the introduction of Mr. Bradford, the new representative of the Apothecaries' Society. Then will follow the appointment of Committees, then the reception of the Army Medical Return, and a letter from the Government on the subject of Death Registry. The resolutions of the Examining Bodies on the subject of Conjoint Examinations will then be received and discussed, and afterwards a communication from the Commissioners in Lunacy. It is rumoured that Dr. Acland will move for Committees on the Medical Education and Qualification of Women. We think that the Medical Council had better, for the present at least, leave that subject alone. We can assure them that they will satisfy nobody. If they attempt to settle it at all they must be prepared for a sitting protracted far beyond the usual limits, and out of doors the most unsparing criticism.

ACTION FOR ALLEGED MALPRACTICE IN VICTORIA.

CASES of action for malpractice would almost be unknown if it were not for meddling Surgeons and speculative lawyers. It is certain that in most of these cases the party proceeded against is more or less victimised. If the verdict be against him, it is usually on insufficient or *uncertain* evidence; and if for him, the plaintiff being usually a pauper, he is mulcted in his own costs, often to a very large amount. It is unnecessary to call the recollection of our readers to instances of both these kinds which have occurred in this country. A case is now occupying the attention of the Profession, and to some extent of the public, in Melbourne, which has some points of interest in it. It has been referred to occasionally by us, and we have strongly reprobated the evidence of the Surgical witnesses for the plaintiff as being opposed to sound Surgery, and subversive of the best interests of the Profession. The case may be told in a few words. An old woman, of doubtful age—say from 50 to 70—is tripped up by a dog in the street on October 11, at ten at night. She sends for Mr. Van Hemert, a Surgeon near to her, and he immediately attends. Pain in the groin being complained of, a careful examination was made, but no signs of fracture were detected. The limb was rotated, flexed, and extended; but then it was not shortened, nor was the foot

everted. There was no crepitus at the neck of the thigh-bone. The patient was a thin, spare woman, and, had fracture existed, there surely could have been no difficulty in detecting it. The chief seat of pain was at the knee, which was somewhat bruised. The treatment consisted in leeching, fomenting, rest, and position. To relieve the patient's anxiety, the limb was examined carefully on several occasions during five weeks, but no fracture could be detected. On making his visit on the morning of November 15, Mr. Van Hemert was informed by his patient "that, on turning in bed during the night, her thigh gave a sudden crack, which greatly alarmed her." The limb was examined, and found to be shortened; the foot was everted. On extension and rotation being made, crepitus was distinctly perceived at the neck of the thigh-bone. The limb was placed in a proper splint, but the patient was restless, and undid the bandage. Four days afterwards another Surgeon was called in, and Mr. Van Hemert summarily dismissed. This Surgeon, Mr. Crookes, called to his aid Mr. Beaney, and these gentlemen, on November 22, having placed the patient under chloroform, found (they say) crepitus distinctly at the neck of the bone, and that "the thigh could not be brought to its full length owing to ligamentous or other adventitious union." On this assumption—for it is merely an assumption, as we shall presently show—an action was brought against Mr. Van Hemert, and damages to a considerable amount awarded the plaintiff. On the trial the Medical evidence was, as usual, we regret to say, antagonistic, but the preponderance was in favour of the fracture having occurred at the time Mr. Van Hemert detected it on November 15. The Judge, however, summed up directly against the defendant, and in complete ignorance of the nature of the injury, and apparently ignoring the fact that there were no signs of fracture before November 15, and full proofs of it afterwards, assumed that Mr. Van Hemert had not exercised ordinary skill in his diagnosis, and consequently that his treatment was improper, and from that improper treatment the plaintiff had become a cripple for life. We contend that Mr. Van Hemert has been the subject of a great injustice. But what are we to say to the Surgeons who gave evidence against him? How are we to reconcile their evidence, which went to show that the fracture was produced on October 11, in opposition to the sworn testimony that at that time, and for five weeks after, no sign whatever of fracture existed? Under any circumstances they were certainly not justified in being so positive that the fracture had existed from the time of the accident. The very opinion they expressed at first is contradictory of this; for it is evident—as the *Australian Medical Gazette* says—"If there had been crepitation felt or heard, then was the fracture recent, and not of old standing. If there was adhesion in a false joint, there could have been no crepitation." We agree with our contemporary on the necessity of a judge in the trial of such cases having an assessor "to note the difference between Surgical facts and Surgeons' opinions." The judge was himself bewildered, and in his summing up must have sadly bewildered the jury. We regret that a motion for a new trial was refused, and that Mr. Van Hemert has met with "a denial of justice."

We have not gone into the minutiae of the case, as the main facts lie in a nutshell. We regret to state that Mr. Van Hemert had offended Mr. Crookes, in declining to meet him in consultation; and that Mr. Crookes (to use his own words) said that "he deserved to be well punished for his impudence and ignorance"—impudence in declining to meet Mr. Crookes, ignorance in the manner he had conducted the case. We are glad to perceive that the Medical Practitioners of Victoria have taken up the case with spirit and energy. A very influential meeting was held early in December, "not only," as the chairman said, "to express its disapproval of the proceedings at the trial, but also the refusal of a second trial, by which the injustice of the first might be remedied." Mr. Rudall, one of the speakers, said—

“Without going into details, he would say there were two reasons which prevented his understanding why the verdict had been given in this case. The fact was, that whatever the treatment, whether good, bad, or indifferent, it was distinctly proved that the patient had not chosen to follow it—what the Doctor had done being undone by her—which of itself ought to be a sufficient bar to damages. The second reason was, that however the case was treated, it was highly improbable that the result would have been in any way different.”

We append the following resolutions, which were carried unanimously :—

“1. That this meeting is of opinion that the verdict in the case of *Turner v. Van Hemert*, lately tried in the Supreme Court, was unjust, inasmuch as there was no evidence to prove the existence of fracture at the time of the accident, and was in contradiction to the scientific evidence given, which proves that an intracapsular fracture of the neck of the thigh-bone has remained undetected for weeks by the most skilful and careful Surgeons, and that it was highly improbable that under any treatment the case would have terminated less unfavourably for the patient.

“2. That the Medical Profession of Victoria herein expresses its sympathy with Mr. Van Hemert on account of the action lately brought against him by Mrs. Turner, and pledges itself to effect his reimbursement of the expenses to which he has been subjected in that action.”

A committee was formed for the purpose of carrying out this last resolution. We understand the costs, with damages, exceed £700.

THE ARMY ESTIMATES.

THE Army Estimates for the ensuing year do not at first glance contain much matter of interest to Medical officers. We observe, as the most important item, that, as mentioned by us a few weeks ago, an increase in the administrative staff at Aldershot by the appointment of a Deputy Inspector-General of Hospitals, is included among the detail of charges for the Medical Department at home. The number of Deputy Inspector-Generals at home is thus increased from thirteen to fourteen; the number for colonial service (seven) remains as for the preceding year. The numbers of Inspector-Generals for home and colonial service also remain unchanged, being five and one respectively. A Surgeon-Major or Surgeon is reduced from the strength of the Medical staff at Malta, and an Assistant-Surgeon is reduced from Gibraltar. In the changes for the Military Medical School at Netley the number of probationers provided for is thirty, being a decrease of thirty-six as compared with the previous year; and instead of a mess allowance of £300 to the Medical staff, and of £134 for wages and clothing of mess waiters, etc., the latter charge appears at £250, and the former is transformed into a mess allowance of £66 to Medical candidates, being a decrease of £118 for the mess establishment. A charge of £400 appears in this part of the estimates as allowance to the examiners of candidates for the Medical service. A Governor and Assistant-Commandant continue to appear among the charges for the Hospital at Netley, and the female nurses are increased from six to eight.

In his opening speech on the Army Estimates, Mr. Cardwell mentioned impending changes in the constitution of the Army Hospital Corps, according to a scheme which had been submitted to him. The only apparent indication of this in the present estimates is, that instead of only one officer, styled quartermaster and adjutant, being provided for this corps, an addition of eleven officers, styled deputy superintendents, is about to be made, and the allowances for quartermaster and adjutant are transformed into those for a superintendent. Besides this important increase of officers, we believe that the plan submitted to Mr. Cardwell includes the abolition of the rank of apothecaries to the forces, and the transference of the thirteen officers now employed in that grade, and of the two captains of orderlies (of whom one is now on the strength of the Hospital establishments at Netley and Woolwich respectively), to the commissioned ranks of the Army Hospital

Corps as deputy superintendents. The number of officers in the Army Hospital Corps will thus be 27, and of non-commissioned officers and men, including the 336 added in the present estimates, will be 1336. In the designations of the non-commissioned officers and rank and file, the following changes are observed:—Instead of sergeants-major, colour-sergeants, sergeants, corporals, second corporals, and privates, the respective ranks will be chief stewards, stewards, assistant-stewards, first, second, and third-class orderlies, the pay to each rank being the same as that given under the previous titles.

The duties of the newly organised Army Hospital Corps will include those formerly performed by the apothecaries and their subordinates, as also the care of the sick and the maintenance of cleanliness and discipline in the Hospitals, and will in all respects be performed under the directions of the Medical officers. In time of peace a corps of the number and nature described may naturally be expected to be sufficient for all ordinary duties, but would necessarily require considerable amplification during war, and should be considered only as the nucleus of skilled *personnel*, to be supplemented by a proportion of men from each regiment trained as bearers for the wounded and as ordinary Hospital orderlies.

Touching the prospects of promotion of Medical officers themselves, Mr. Cardwell's speech on the estimates appears to us to include indirectly an element of hope as to the probability of an impetus being given to that hitherto sluggishly moving stream. But to derive the full benefit for Medical officers which the new army scheme affords, it will be necessary that it should, as regards Medical officers, be manipulated in a special manner. The sixty-six head-quarter districts, which Mr. Cardwell mentioned as essential items in his scheme, should include on the staff of each a due proportion of Medical officers, of whom the senior, on account of the important duties of recruiting, invaliding, and general Medical care devolving on him, should be of some standing in the service. Now, it appears to us that if the Medical officers in charge of each of the new districts were to be Surgeons-Major, or Surgeons of twenty, or two- or three-and-twenty years' service, appointed for five years, on the understanding that at the expiration of that time they were to retire on even the present rate of £1 per diem after twenty-five years' service, numbers would be very glad of the chance. Thus would be introduced a continual removal of men—foregoing, indeed, further promotion to the higher ranks, but who, in compensation, would have attained in the districts in which they had served a “local habitation and a name,” which would be likely to procure a Professional position most useful to those who might desire, on retiring, to enter into private or consulting practice. If, in extension of Mr. Cardwell's scheme of localisation of corps, the Medical officers appointed to these head-quarter districts be selected for particular stations, other claims being equal, on the grounds of early connexion with that part of the country through family or educational ties, a strong additional inducement would be supplied for Medical officers to retire on the terms which we have sketched out.

We believe there is some foundation for the report that the unification scheme for the Army Medical Department is soon again likely to come to light. The chief feature of the plan will, of course, be the abolition of the regimental system. The title of Assistant-Surgeon will be discontinued; the two classes of executive officers will be Surgeons and Surgeons-Major. Of the latter there will be two classes—viz., those under twenty years' service ranking as Majors, and those of more than twenty years' service ranking as Lieutenant-Colonels. The grades in the inspecting ranks will be Surgeon-General and Deputy Surgeon-General, in lieu of the present term Inspector- and Deputy Inspector-General of Hospitals. We believe that in carrying out the details of the new system the present regimental Medical officers will find that all vested interests will be carefully protected.

THE WEEK.

TOPICS OF THE DAY.

SIR WILLIAM GULL has been gazetted Physician-in-Ordinary to His Royal Highness the Prince of Wales.

The President of the Medical Society, Dr. Andrew Clark, gives a *conversazione* at the Hanover-square Rooms on Tuesday, March 5.

The Adulteration of Food and Drugs Bill, brought in by Messrs. Muntz, Whitwell, and Dixon, proposes to inflict a penalty of not more than £50 on any person wilfully mixing, or causing to be admixed, "with any article of food or drink, any injurious or poisonous material to adulterate the same for sale;" and on any person wilfully mixing, or causing to be admixed, "any ingredient or material with any drug to adulterate the same for sale." This penalty is for the first offence. A second offence is to be regarded as a misdemeanour, and is punishable with six months' imprisonment and hard labour. The penalty for knowingly selling food or drink mixed with injurious material, or for selling as pure adulterated food, drink, or drugs, on conviction, is not to exceed £20, with costs. The justice will have the power of publishing the vendor's name, address, and offence. The Bill proposes that the Pharmacy Act of 1868, and the Adulteration of Food Act (23 and 24 Vic., cap. 84), shall be incorporated in the present measure. Power is given for the appointment of analysts, who shall possess competent Medical, chemical, and microscopical knowledge, in London and the counties. Inspectors of nuisances may submit to them suspected articles for analysis, and they are to report quarterly to the local authorities. Persons purchasing articles of food may require them to be analysed, on payment of a sum not less than one shilling nor more than five shillings.

A circular has been issued by the President of the Poor-law Medical Officers' Association, in which he calls attention to the fact that Mr. Stansfeld has adopted in his Sanitary Bill some of the main features of the Association programme. The Government scheme not being as yet entirely unfolded, the Association are wisely exhorted by the President not in any way to relax their efforts for a reform of the system of Poor-law Medical Relief.

ROYAL COLLEGE OF SURGEONS.

At a special meeting of the Council of this institution on the 29th ult., Mr. Henry Spencer Smith, F.R.C.S., of Queen Anne-street, was elected a member of the Court of Examiners in the vacancy occasioned by the retirement of Mr. Edward Cock, late President of the College. Mr. Smith, who is the Senior Surgeon to, and Lecturer on Clinical Surgery in, St. Mary's Hospital, received his Medical education at the St. Bartholomew's, Paris, and Berlin Hospitals. He is the translator of Schwann's "Microscopic Researches on the Structure and Growth of Animals and Plants," and other contributions on anatomical and physiological subjects published in the *Medical Gazette*. He was also Secretary to the Government Contagious Diseases Commission, of which Mr. F. C. Skey, C.B., F.R.S., was Chairman.

PROFESSORSHIP OF CHEMISTRY, QUEEN'S COLLEGE, CORK.

DR. MAXWELL SIMPSON, F.R.S., has been elected as successor to the late Dr. Blyth in the chair of Chemistry, Queen's College, Cork. Dr. Simpson has been for some time resident in London, and is well known in scientific circles for his attainments, particularly in the abstruse subject of organic chemistry. However numerous and eminent the competitors for the Professorship may have been, we are certain that the authorities of the Queen's University in Ireland could not have obtained a better man for the important post to which Dr. Simpson has been appointed.

BILL FOR THE SUPPRESSION OF ADULTERATION.

CONSIDERING the extent to which the adulteration of food, drink, and drugs is carried, it is clear that nothing but a most stringent Act of Parliament can effect a satisfactory remedy. Notwithstanding the agitation which has been going on for a long time past on the subject, we fear that the wholesome provisions of Mr. Muntz's Bill will not meet with the unqualified favour of the House of Commons. The interests involved are so vast, it is certain that in some quarters it will meet with strenuous opposition. It is, however, a step in the right direction, and the discussion upon it must be attended with beneficial consequences. It provides for the appointment of analysts in London by the City Commissioners of Sewers and the vestries and district boards; in the country by the courts of quarter-sessions and town councils. Inspectors of nuisances and other officers appointed by the local authorities may procure articles suspected to be adulterated, and submit them to the public analyst, and upon obtaining a certificate from him stating that the articles are adulterated, may obtain a summons against the seller or adulterator. The penalty for adulterating articles of food, drink, or drugs is to be for the first offence a fine not exceeding £50 and costs, and for a second offence imprisonment with hard labour for not more than six months. The penalty for selling adulterated articles is £20, with costs, and after a second offence the magistrates may cause the offender's name and address to be published at his own expense in such way as may appear to them desirable. The costs of executing the Act are to be paid out of the local rates.

ST. PANCRAS.—DR. HILL'S APPOINTMENT.

WHEN the Board of Guardians of St. Pancras appointed Dr. Hill as Medical Officer of the Infirmary, it was arranged by the contract that he should hand over to the guardians all fees which he should receive for post-mortem examinations and for giving evidence before the coroner. In noticing this arrangement a fortnight since we expressed our opinion that such a compact was illegal. That opinion, we believe, was not entertained by any of our contemporaries. It, however, appears that we were correct. At the meeting last week of the Board of Guardians a letter from the Local Government Board to the guardians was read, which stated—

"With respect to the proposal that the Medical Officer shall be required to account to the guardians for all fees for post-mortem examinations and coroners' inquests, I am directed to point out that the guardians cannot legally impose such a condition, as the law which enables coroners to summon Medical witnesses, and provides for the fees to be paid to them, depends on a statute totally different from that which provides for the salaries of officers of boards of guardians, and one over which neither this Board nor the guardians have any control." Hereupon it was remarked that Dr. Hill had expressed his willingness to hand over the inquest fees, provided he was paid the £225 per annum; and it was resolved that the salary of Dr. Hill be £225 per annum, on consideration that he provides an assistant, and places the fees received by him for post-mortem examinations and inquests in the hands of the treasurer to the guardians. The Board of Guardians of St. Pancras, true to their instincts and their antecedents, as might have been anticipated, ignore the authority of the Local Board; but will they be permitted, in opposition to an Act of Parliament, to carry out their resolution? It is to be hoped not. If carried out, it is easy to perceive that it would operate most injuriously on the office of coroner.

THE NAVAL SICK FUND.

THE Naval Sick Fund will be abolished on board her Majesty's ships on March 31 next. We are glad to learn that the abolition of the fund will not deprive our sick seamen of the eustomary extra comforts and necessaries, but that the Surgeons will still have the means of providing them, being by the new regulations provided with an allowance for "contingencies."

THE PLAGUE IN PERSIA.

DR. CASTALDI, the Ottoman sanitary delegate attached to the Turkish Embassy at Teheran, has recently, by order of the Ottoman Sanitary Department, inquired into the nature of a disease which had broken out in Persian Kurdistan, reported to be the plague. Dr. Castaldi has sent in his report, and in his opinion there cannot be any doubt as to the character of the disease. The malady is characterised by a strong fever, accompanied with typhus symptoms, with the appearance of buboes under the arms, in the groin, and in the neck, of carbuncles on various parts of the body, and of spots scattered over the whole surface of the skin. It carries the sufferer off quickly, attacking several houses in one place, and several persons in the same family, and transmits itself from an infected place to a healthy one. "Such a malady," says Dr. Castaldi, "cannot be anything but the Eastern plague of former times." According to the report, it was during the last winter that the plague appeared in the district of Mukry, in the Aderbidjau, in two villages situated at a short distance from each other, and called Djoumouchau and Arbauouz. These two small villages have been completely depopulated, only seven or eight persons having been spared by the scourge. Dr. Castaldi feels at a loss to point out the causes which have produced the epidemic, for the district is the healthiest in all Persia.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE following is the proposed balloting-list for the election of Officers and other Members of Council of the Royal Medical and Chirurgical Society of London, for the year 1872-73:—
President: Thomas Blizard Curling, F.R.S. *Vice-Presidents*: Alexander Patrick Stewart, M.D.; Andrew Whyte Barclay, M.D.; George Critchett; John Abernethy Kingdon. *Treasurers*: Thomas Graham Balfour, M.D., F.R.S.; John Birkett. *Secretaries*: Edmund Symes Thompson, M.D.; Thomas Smith. *Librarians*: Thomas King Chambers, M.D.; Charles Brooke, F.R.S. *Other Members of Council*: Edward Ballard, M.D.; Robert Greenhalgh, M.D.; George Harley, M.D., F.R.S.; Hugh James Sanderson, M.D.; Walter Hayle Walshe, M.D.; William Oliver Chalk; George Green Gascoyen; John Whitaker Hulke, F.R.S.; Edwin Saunders; William Scovell Savory, F.R.S. It is said that some of the leading general Practitioners have expressed dissatisfaction at the absence of any of their body from the above list; but it does not appear that any gentlemen who contribute to the transactions or the practical working of the Society are overlooked.

BILE-PIGMENTS AND JAUNDICE.

HEYNSIUS AND CAMPBELL have made an elaborate spectroscopic examination of bile, bile-pigments, the products of the oxidation of these latter, and of the urine in cases of diseased liver (Pflüger's "Arch. f. Physiol.," iv., p. 497). They fully described two pigments that have not been previously examined in detail—bilicyanin and choletelin. Bilicyanin was not detected in urine, either normal or pathological, though the authors appear to think that it is, perhaps, a constituent of normal urine, and that it has been confounded by previous observers with indican. Choletelin was found in specimens of dark urine from patients suffering from affections of the liver, though not in normal urine. As choletelin, though a derivative of ordinary bile-pigment by oxidation, does not give the well-known play of colours with strong nitric acid, the occasional failure of the nitric acid (Gmelin's) test when applied to the urine in cases of indubitable jaundice appears to be accounted for. Heynsius and Campbell's monograph is enriched by a copious account of everything of value that has been done with reference to the colouring matter of the bile by previous experimenters, and contains some terse and valuable notes on sources of error in spectroscopy.

THE NEW CONTAGIOUS DISEASES PREVENTION BILL.

THE Contagious Diseases Prevention Bill, prepared by Mr. Secretary Bruce and Mr. Winterbotham, is divided into four parts—1, Relating to Prostitutes and Contagious Diseases; 2, to the Protection of Women; 3, to Disorderly Houses; 4, Supplemental, relating to Legal Proceedings, Definitions, etc. Clause 2 of Part 1 provides that—

"Every common prostitute who in any public street, public highway, or place of public resort, solicits or importunes persons for the purpose of prostitution, shall be deemed to behave in an indecent manner within the meaning of the recited provision of the Vagrant Act, 1824."

Clause 3 enacts that when a common prostitute is in prison, "and is found, at the expiration of the term of her imprisonment, to be affected by contagious disease, she shall be liable to be detained in the infirmary of the prison, or to be removed to a certified Hospital, in manner provided by this Act. Where a woman so liable is found within seven days before the expiration of the term of her imprisonment to be affected with contagious disease, the fact of her being so affected shall be reported by the gaoler of the prison to a justice of the peace, and such justice, unless he is satisfied that she is not so affected, or that she intends to go to some asylum or other like institution, or otherwise to cease to be a common prostitute, shall order her to be detained in the infirmary of the prison for such period as is provided by this Act, and the woman shall be detained in such prison infirmary accordingly. Where a woman is ordered under this section to be detained in the infirmary of the prison, a justice of the peace may, by the same or any subsequent order, direct her to be removed to any certified Hospital the managers of which are willing to receive her; and any person authorised in this behalf by such order may remove such woman to the certified Hospital named in the order, and the woman may be detained in such Hospital for such period as is provided by this Act.

"Nothing in this section shall authorise an examination of a common prostitute in any prison further or other than may be made in the case of any other prisoner. Due notice of the said report shall be given to the woman, and she shall, if she so desire, be heard by the justice before any order is made."

We will not proceed with an analysis of the Act at present, but will observe that Clause 2 seems too feeble for its purpose, and some of the provisions of Clause 3 are feeble and illogical into the bargain—insufficient to protect the public and to insure the relief of the unhappy women.

THE LATE PROFESSOR DAY.

AT the last meeting of the Council of the St. Andrews Medical Graduates' Association, it was resolved to raise a fund for securing a life annuity for Mrs. Day, the widow of the late Emeritus Professor of St. Andrews, whose obituary has so recently appeared in our columns. Dr. Day did excellent work in promoting Medical education. By his writings he greatly advanced Medical literature and science, and in the cultivation of general science he was a successful labourer, some of the best papers in "Chambers' Encyclopædia" being from his hand. We feel sure, therefore, that the effort to secure an annuity to Mrs. Day will meet with support from the scientific public generally, as well as from the Profession.

CALCUTTA MEDICAL COLLEGE.

SURGEON H. C. CUTCLIFFE, F.R.C.S., now officiating as Professor of Anatomy in the Calcutta Medical College, and *ex officio* Second Surgeon of the College Hospital, has been appointed to officiate as Professor of Surgery in the Calcutta Medical College, and first Surgeon of the Hospital, during the absence of Dr. Fayer, C.S.I., who has obtained leave of absence to England on furlough for two years.

GRATUITY TO A MEDICAL OFFICER.

DR. LILLEY has been awarded, by the Kensington Board of Guardians, a gratuity of £21 for services rendered during the epidemic of small-pox.

SMALL-POX JOTTINGS.

Two cases of small-pox were reported last week in the Bromsgrove Workhouse Infirmary.—Small-pox has made its appearance in one of Mr. Muller's Orphan-houses in Ashley Down, Bristol. A teacher was first taken ill with suppressed small-pox, and she died, and since that time there have been about twenty cases amongst children in the same house, two of whom have died.—Small-pox has broken out again, and is making many victims, at Valparaiso.—Three fresh cases of small-pox were reported last week to the St. Martin's-in-the-Fields Vestry. Of two sent to the Hampstead Hospital, one had died.—Two deaths occurred in Bermondsey in the last fortnight from the disease.—Mr. Roberts, in his report to the Wakefield Board of Guardians last week, states—"During the past fortnight I have had to report two cases of small-pox—one, a woman aged 24, who, although never vaccinated, obstinately refused to be (she has since taken small-pox, and I understand that she is now dying in the Fever Hospital); the other, a woman aged 30, is an extremely mild case. She had been properly vaccinated. There is an unvaccinated adult in Hudson's-square. I have received a parish order for the child, who is feverish. The mother refuses to be vaccinated. There are several instances where such persons have taken small-pox and almost invariably died."—In Aberdeen small-pox remains in precisely the same condition as shown in our last report. The return issued last week is as follows:—Total number of cases admitted to the Hospital, 94; number of patients now in Hospital, 58; total discharged recovered, 22; total dead, 14.—The Medical Officer of Health for the Hackney District reports that small-pox was diminishing both in number of cases and intensity of the disease, the number of deaths occurring therefrom in the past fortnight being only 6, against 17 in the preceding month, and only 4 fresh cases having been brought under notice, against 13 in the previous fortnight.—Two new cases of small-pox were reported during the last fortnight in the Whitechapel district.—Three deaths occurred from small-pox in Halifax in the fortnight ending Tuesday last.—It was reported to the Sheffield Board of Guardians that there were last week twenty-eight small-pox cases in the workhouse.—Dr. Aldis reports only one case this week in St. George's, Hanover-square.

WATER-SUPPLY TO THE METROPOLIS.

THERE seem to be good grounds for believing that at length a supply of pure water will be given to the metropolis. It is, however, incumbent upon all those interested in the question not to be too sanguine in this expectation; still it is satisfactory to quote the following from the proceedings of Parliament:—

"The President of the Board of Trade, in reply to an inquiry whether it was intended to take any steps under the Metropolis Water Acts (1852-72), in consequence of the polluted state of the water recently supplied by some of the water companies, said a water commissioner had been appointed to examine, at least once a month, whether the water of the various companies is fit for use, and to make a report respecting it both before it undergoes the process of filtration and before it passes into distribution. He is also instructed to make a special report when there is any necessity for such a step. In the case to which the question refers he was asked to make a special report, which I have just received. After the consideration of that report I shall be able to decide whether there should be any further inquiry into the water-supply of the particular companies referred to."

WATER-SUPPLY OF GIBRALTAR.

WE regret to hear that the hopes of a plentiful and suitable water-supply for Gibraltar, based upon the late discovery of springs on the north front of the rock, are doomed to disappointment. A correspondent informs us that latterly, while the quantity of water continues abundant, it has become so impregnated with salts as to be quite unsuitable for drinking purposes.

MR. LIEBREICH AT THE ROYAL INSTITUTION.

ON Friday evening, March 8, Mr. Liebreich, the Ophthalmologist whom the siege of Paris sent to seek refuge in London, will deliver a discourse at the Royal Institution, in Albemarle-street. He will treat of the effect of certain faults of vision in painting, with especial reference to Turner and Mulready. In the one case, we believe, there was in the painter's eye some want of optical adjustment, in the other a yellow discoloration of the lens; and the speaker will show how certain peculiarities in their paintings will be lessened or removed if the spectator look through a lens which shall reproduce the defect in the eye of the painter.

THE CAPTURED MEDICAL STUDENTS AT HAVANA.

A CORRESPONDENT writes that—"The Medical students now undergoing imprisonment for the desecration of the tomb of Caslanon were removed about a fortnight ago from the city prison, La Punta (the scene of the November massacre), to the villa of the Captain-General, the Molivo del Rey, on the Pasco de Jacon. It is satisfactory to know that the students are in excellent health and spirits. Food and cigars are brought daily to them by their friends. They wear the ordinary prison dress, with their hair closely cut, and with their legs chained. The most melancholy sight was to see the fathers and mothers, brothers, and sisters of these boys, who were sitting on rough benches under the verandah, distracted with grief and anxiety, and whose minds must surely give way; in fact, some have already done so under their cruel infliction. It is considered in Havana that the removal of the students from the common prison is the first step towards their ultimate release."

A NECESSARY PRECAUTION.

COMPARISONS, it is said, are odious, but they may sometimes be made with advantage. The Paddington Sanitary Committee seem actuated by a different spirit from that of their brethren of St. Pancras. We are gratified to announce that at their last meeting they passed the following resolution:—"That no person suffering a contagious disease be removed from one private house to another in the vestry ambulance-car unless the Medical Officer or one of the inspectors of nuisances be consulted as to the propriety of such removal, and also as to the sanitary condition of the premises to which it is proposed to remove such person."

THE HEALTH OF PARIS.

THE sanitary state of Paris has much improved under the mild spring weather prevailing. The deaths of the week ending February 16 were only 747, against 821 the week before. The diminished numbers of fatal cases are chiefly small-pox, 2; chicken-pox or measles, 6; scarlatina, 3; typhus fever, 20, etc. The average number of deaths in Paris is 45,000. The numbers actually registered in 1870 were 73,581, while in 1871 they amounted to the startling total of 99,945—twice the ordinary death-rate.

CONSUMPTION IN LONDON.

THE quarterly report of the Hospital for Consumption and Diseases of the Chest, Brompton, presented to the meeting last week, states that the Committee had inspected several properties, but had not found any site suitable for the purpose of a convalescent Hospital. The number of patients admitted since November 23 was 242; discharged, many greatly benefited, 217; died, 25; new out-patient cases, 3105.

LAWS RELATING TO THE PUBLIC HEALTH.

THE Bill of Sir Selwyn-Ibbetson for the better execution of the above laws makes provisions for the appointment of a Health Committee in rural parishes. It is to consist of not less than two persons, and will be entrusted with certain power

and duties as to sewer and nuisance authorities. If the Committee fail to fulfil their duties the Bill provides for the Local Government Board appointing their successors.

FROM ABROAD.—THE NEW GERMAN UNIVERSITY AT STRASBURG—
EPIDEMIC VARIOLA AT GENEVA.

DR. HERGOTT, in a recent article in the *Gazette Médicale*, furnishes some account of the new German University about being established at Strasburg. Every attempt is being made, he says, to attract Professors of the highest eminence, it being given them to understand that Strasburg will prove their surest road to arrive at Berlin, while their payment is to be very large. It is just stated that Professor Gusserow, of Zurich, has accepted the chair of obstetrics at Strasburg, and that his salary is to be 15,000 fr. This, in comparison with the salaries of the Professors in Germany, is an enormous sum, their emoluments being derived from two sources—a moderate fixed amount contributed by the State, and the fees derived from the students. These last for some of the Professors reach a large sum, amounting to more than 25,000 fr. per annum, forming the recompense of their talent and industry, and for their zeal in the instruction of the students. This, says Dr. Hergott, is a just arrangement, for it seems to be contrary to all justice that a somnolent Professor without auditors and one who has the power of attracting crowds should receive the same remuneration. Positive Germany has long since utilised this stimulus for its Professorial body, rendering fixed payments very low, but leaving a wide scope for eventual emoluments. In France, on the contrary, the fixed payments constitute the main resource, while any eventual payments, in the shape of fees for examinations, are of little account. In Germany, again, the fixed payment varies at different universities, and for different Professors at the same university. In the case of an important Professor it sometimes undergoes increase in order to retain his services when he has received a call from another university where the payment is higher. This is a system of competition well calculated to maintain the ardour for work and zeal for instruction. In France the Professor is immobilised in the same university, and receives no assurance of competent remuneration for sustained labours; consequently, for him, the obtaining his chair constitutes his grand effort, and all serious work too often terminates with the successful *concours*. In Germany the future lies widely open to the Professor, while in France it is most limited, the obstinacy with which the Paris Faculty has always closed its doors to all provincial notabilities being well known.

The Professors to whom chairs at Strasburg have been offered have, before accepting these, repaired to that city in order to ascertain whether all the appliances for teaching were suitable, and some of these, it is said, have declined the appointments because they did not seem to them to be so. However, it is said that such will be amply provided, in the shape of laboratories, libraries, etc.; but some difficulty lies in the way with respect to clinical teaching. It seems that the Civil Hospital at Strasburg has been founded, and is maintained, by private benevolence, its income of about 750,000 francs not being derived in any degree from the State or municipality. By a voluntary arrangement it has allowed this Hospital, consisting of about 1000 beds, to be employed by the Faculty for clinical instruction; but not regarding this arrangement as a contract, the Committee in whose hands the management of the Hospital rests believes that it has full power to withdraw this concession should it consider it as injurious to the patients confided to its care. It does not question the ability of the new Professors to treat the patients, but looks to the great antipathy which the patients feel at being obliged to receive their services in place of those of Medical officers who have long enjoyed their confidence and esteem. The question remains at present in suspense, but in the event of the Committee persisting in their refusal, the

Germans will have to resort to the military Hospital which now belongs to them, or to establish a new clinical Hospital.

The chairs that have thus far been filled up are those of Anatomy, by Professor Waldeyer; Physiological Chemistry, by Hoppe-Seyler, from Tübingen; Pathological Anatomy, by Recklinghausen, from Wurzburg; Materia Medica, by Schmidberg; Surgery, by Lücke, from Bern; Gynæcology, by Gusserow, from Zurich; Internal Pathology, by Leyden, from Königsberg; Psychiatry, by Kraft-Ebing; and Ophthalmology, by Laqueur, from Lyons. The "rump" of the French Medical Faculty which remains at Strasburg will, it is stated, complete the education of their former students, but has entered into no definitive relations with the new University. The bulk of this Faculty, which has vacated its chairs, does not seem hitherto to have met with a very encouraging reception in France, beyond having received warm praise for the sacrifices which it has made.

In a recent treatise by Dr. Revilliod, Senior Physician to the Cantonal Hospital at Geneva, giving an account of the small-pox epidemic of 1870-71, as observed in that Hospital, he states that this has been the most intense epidemic observed at Geneva during the present century. It has furnished twice as many cases as that of 1850, although it lasted a shorter time. It especially affected persons who had resided in the canton for less than twelve years, the natives of the canton only supplying 23 per cent. of the cases. While a first vaccination has often proved insufficient, revaccination has proved its protective power in an absolute manner. This epidemic has presented as a special characteristic the frequency of anomalous forms—and especially the hæmorrhagic form—which have proved the principal cause of the mortality. Such anomalies have also characterised many other diseases during the prevalence of the epidemic. Many of the cases of hæmorrhagic variola pursued a benign course. In 1858 hæmorrhagic variola represented 7 per cent. of the cases of variola, and there were only 20 per cent. of recoveries; while in 1870-71 there were 17 per cent. of cases, and 16.40 per cent. of recoveries. The eruptions known as "rash" were only met with exceptionally. M. Revilliod calls for the enactment of a law for compulsory vaccination, such as prevails in England, Germany, and the Canton de Vaud.

PARLIAMENTARY.—VACCINATION—CONTAGIOUS DISEASES.

IN the House of Lords, on Thursday, February 22, Lord Buckhurst's motion for a Select Committee to inquire into the working of the Vaccination Acts was withdrawn.

IN the House of Commons, on Friday,

Sir J. Trelawney gave notice that on Thursday next he would move that there be a call of the House on March 21 when the Contagious Diseases Acts Bill is to be discussed.

THE St. Olave's Board of Guardians have resolved to erect a new Infirmary in their district.

NEW AND SAFE MODE OF ADMINISTERING CHLOROFORM.—Mr. Crooke states that all the advantages of chloroform are much more speedily obtained and its dangers avoided by causing the patient to "begin to inhale (from thirty to sixty drops of chloroform having been poured first on a handkerchief) very gently for about two seconds, and then to proceed to inhale with the utmost energy, forcing inspiration to the fullest extent of the chest's capacity.—*Australian Medical Gazette*, November.

VACCINATIONS IN MILAN DURING 1871.—The total number of these performed under the auspices of the Milan municipality ("animal" vaccine virus being employed) between January 1 and December 31, 1871, was 17,069. Of these 1504 were vaccinations of children, of which 1270 were successful in their results, 4 were spurious, 35 failed, and 195 were not verified. There were also 15,565 adults revaccinated, the results being successful in 5039, spurious in 435, and unsuccessful in 3814, while in 6277 they were not verified. Among these 15,655 revaccinations there were only 68 cases in which variola in a mild form or varioloid appeared.—*Gazetta Medica Lombardia*, February 17.

ACCIDENTS FROM THE ROYAL PROCESSION.

It was hardly possible that such a concourse of people as assembled to see the Royal Procession and illumination on Tuesday could come together and separate without accident. Even now, when the affair has passed over, and we reflect on the vast multitudes who were assembled, we are thankful that more serious results did not attend the tremendous crush along the Strand, Fleet-street, and Ludgate-hill. Only one death actually occurred in the streets, though many were severely injured, and some were almost given up who, nevertheless, have recovered, having been only stunned. The perils of our streets were on Tuesday at their acme. What with scaffoldings giving way and people falling from them, or small boys and other articles falling on the heads of people below, no little danger of a somewhat unusual kind attended the procession. Then there were kicks from horses, falls, blows, and the like, not unfrequently followed up by a cab passing over the unfortunate individual, so that if he escaped with his life he was fortunate. The most curious accident we have heard of, however, happened to a man in the crowd, who, getting weary of waiting, and almost hopeless of seeing anything worth seeing, was seized with a yawning fit and dislocated his jaw. He went to Charing-cross Hospital, and Mr. Slack, the House-Surgeon, replaced it by the help of his thumbs.

The accidents began almost as early as the procession. Some boys had climbed trees in the Park, and several had got on the branch of an elm. This tree is at all times a dangerous one to trust to. In warm weather its limbs will sometimes drop off without warning; and here, though in early spring, the branch gave way, and two boys were very badly hurt—one had his thigh fractured, the other was stunned and badly bruised about the head. Both were taken to the Westminster Hospital, and the one with fractured thigh still remains there doing well. A woman, who was injured by the fall of a scaffolding near Marlborough House, was also admitted with a fractured leg. A variety of other slight forms of accidents were treated during the day and evening, but none of great importance.

The brunt of the work fell on Charing-cross and King's College Hospitals, for the crowd was greater in that vicinity than elsewhere. At the former Hospital four patients were treated for accidents received by falls from scaffolds—such as sprained ankles; two at least for kicks from horses; six run over by cabs; and as many as eight-and-twenty for falls in the crowd, cut heads, bruises, etc. One patient had a fractured leg, another got fractured ribs, another fracture of a metatarsal bone. One elbow and one shoulder were dislocated, besides the jaw already mentioned. Two old women were admitted suffering from concussion, and one man, who was really very ill, was suffering from concussion and a severe scalp wound. Two had bruised backs and heads; but all now are fairly well and likely to recover. Those who were able to leave were removed to their homes; those too ill were taken into the Hospital, where, however, only one or two are now left.

At King's College Hospital, about four-and-twenty patients were treated for wounds, bruises, etc., who were afterwards well enough to go away. These had nothing greatly the matter with them. Two women were admitted—one with Pott's fracture of the leg, and another with numerous bruises, especially of the face. There is now unfortunately in the Hospital a policeman almost comatose and quite pulseless, who we fear will not survive; so far as can be made out he has no bones fractured. Two are dead; one a child, aged nine weeks, from Spitalfields, who was suffocated, and one a poor man who was crushed in the street. His age was 48. On these no doubt an inquest will be held at once.

MEETING OF THE GENERAL MEDICAL COUNCIL.

HELD AT 32, SOHO-SQUARE.

FIRST DAY—THURSDAY, FEBRUARY 29.

THE 1872 Session of our Medical Parliament commenced at two o'clock on Thursday last, the President, Dr. Paget, in the chair. The Members present were—Dr. Bennett, Mr. Quain, Dr. Humphry, Dr. Embleton, Dr. Storrar, Dr. Alexander Wood, Dr. Andrew Wood, Dr. Fleming, Dr. Macrobin, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Sir D. Corrigan, Dr. Quain, Dr. Sharpey, Sir W. Gull, Dr. Parkes, Dr. Stokes, and Dr. Francis Hawkins (Registrar).

On the introduction of Dr. PARKES, Edward Bradford, Esq., was received by the President into the Council as the representative of the Apothecaries' Society of London.

The PRESIDENT said he was sorry to announce that Dr. Christison had written to say he was unable to attend the meeting of the Council in consequence of the state of his health. His letter also referred to the business of the Society, and if the necessary permission (which had been telegraphed for) were given, he (the President) would read it.

The PRESIDENT'S opening address was as follows:—I need only say a word or two to you at this meeting, because there will be plenty of discussion upon the principal subjects which are about to be brought before us. In the first place, let me say that I am sorry we are called together at a season of the year which is very inconvenient to many of us—(hear, hear)—but you are aware you are called together to-day in accordance with your own order, made on July 10 last, that a meeting of the General Council should be held early in 1872 to receive the proposals of the Bodies for Conjoint Examination, and to consider whether any steps should be taken to carry out the resolutions of the Council in favour of such combinations. It has occurred to me—and only occurred to me this morning, a few hours ago—that it would be a matter of courtesy to our new member, who can scarcely be expected to be conversant with all the minutes of our Council, to give some idea of what has been, or attempted to be, done in the Council and by the Council on this, the principal subject which we have met to discuss at this meeting. I beg you will excuse me if I do this imperfectly, and I beg you will correct me if I do it inexactly, for the reason I have mentioned—that I have not had time to consider the matter to make quite sure of my perfect accuracy in what I am about to say. Of course I shall confine myself to a mere statement. The subject has been before the Council several times before. I need not go further back than the report of a committee that was appointed in 1868. That was an important committee in every sense, particularly in its number and in the authority of the members composing it. There were amongst them many persons to whose opinions we all attach the greatest weight and importance. Mr. Syme was the chairman, and the other members of the committee were Mr. Caesar Hawkins, Dr. Acland, Dr. Alexander Wood, Dr. Allen Thomson, Dr. Aquila Smith, Mr. Hargrave, Dr. Apjohn, Dr. Sharpey, Dr. Parkes, Dr. Christison, and Dr. Stokes. That committee worked hard, did a great deal, made numerous inquiries, and made a final report in the following year (1869). From that report, which is a very long one, I will quote only some of the concluding passages. In volume vii., page 92, of our Minutes, you will find what I am about to read from the report of this numerous and able committee:—"One of the greatest evils at the present moment is the inequality of these examinations for the licence. This inequality of the test of efficiency is the more unfortunate as every licence confirms in the right to practise everywhere. The ease of the examination of one licensing body tends to depress the standard of the examination in all the rest. Visitations of examinations, doubtless, partly remedy this state of things; but to completely remove it a bolder course is necessary. The time has now arrived when, leaving to the Universities and Corporations full liberty to deal as they please with their honorary distinctions and degrees, the Medical Council should endeavour to effect such combinations of the

Licensing Bodies included in Schedule (A) as may form a Conjoint Examining Board for each division of the kingdom, before which every person who desires a licence to practise should appear, and by which he should be examined on all subjects. Any higher degrees he may wish to take, which may come afterwards, should be optional. This plan is one which the Council has often approached and has recommended in principle. We feel sure that the examinations for licences will never be made satisfactory without it, and, therefore, that it is for the public good to enforce it without delay. Considering, also, the extent to which the Colleges of Surgeons and Physicians have already combined in England and Scotland, we cannot apprehend any insuperable difficulty in carrying out this object. To enter into the details of such an arrangement of Conjoint Examining Boards would lead us beyond the scope of the inquiry entrusted to us. The notice of the point has to a great extent grown out of the subject, and we trust the Council will appoint another committee to consider and report how the examinations for licences in the three kingdoms can be thus provided for, and then apply, if necessary, for Parliamentary powers to carry the recommendations into effect." Then, towards the close of the report (p. 94), after recommending that a fresh committee should be appointed, they add—"This committee should also have power to enter into the other matters noticed in the report, especially into the possibility of forming Conjoint Examining Boards before which every student shall appear to entitle him to receive a licence to practise." This report is signed by Dr. Andrew Wood, Chairman. Mr. Syme was the original chairman of the committee, but he ceased to be so when he left the Council.

Sir DOMINIC CORRIGAN: Would it not be well to notice that the report was not adopted?

The PRESIDENT: This report was a very long one, and Sir Dominic Corrigan is quite right (I am obliged to him for calling my attention to it) in saying it was not adopted; and I believe it was never proposed that it should be adopted. But I have been informed by a member of the committee that the report, including the words that I have now read, was adopted by this numerous and influential committee unanimously. I may also remark that this report was adopted by gentlemen who were perfectly well aware how much the Council had accomplished by means of the visitation of examinations of the nineteen Licensing Bodies, and how much more was likely to be accomplished. I will now refer to some resolutions with which all of you here, except, possibly, our new member, are quite familiar—the resolutions which were passed on February 26 and 28, 1870, by the Council itself, by a very large majority.

"That this Council is of opinion that a Joint Examining Board should be formed in each of the three divisions of the kingdom; and that every person who desires to be registered under any of the qualifications recognised in Schedule (A) to the Medical Act shall be required, previously to such registration, to appear before one of these Boards, and be examined on all the subjects which may be deemed advisable by the Medical Council; the rights and privileges of the Universities and Corporations being left, in all other respects, the same as at present."

That was followed two days later by another resolution—

"That in accordance with the foregoing resolution the Universities and Medical Corporations established in each division of the United Kingdom shall be requested to concert a scheme for the constitution and regulation of a Conjoint Examining Board for that part of the kingdom to which they belong, and shall, on or before June 1, 1870, transmit such scheme to the consideration of the General Medical Council."

You will see at once, therefore, that if those resolutions of February, 1870, had been carried out, we should in June, 1870, have had before us the very task that we have before us at this present meeting. The reason that that was not done you all know well. It was in 1870, subsequent to the February meeting, that the Government introduced its Bill for amending the Medical Act. In that Bill it was proposed to make compulsory upon the Universities and the Medical Corporations, in Schedule (A) of the Medical Act, a scheme for Conjoint Examinations, and that Bill gives to the Medical Council the power of drawing up a scheme itself if the "Medical authorities," as they are termed, in any one division of the kingdom failed to do so. If the Medical authorities failed in proposing a satisfactory scheme for a Conjoint Examination in any division of the kingdom, it was put in the power of the Medical Council, and, indeed, made incumbent on the Medical Council, to propose a scheme itself; and that scheme, if approved

by the Privy Council, would have become compulsory on the Medical authorities of that division of the kingdom. This Bill, as you will also remember, was very carefully considered and discussed by the Medical Council, and the Bill, including the provisions to which I have alluded, was adopted and approved by the Medical Council by a large majority. It did not, however, pass through Parliament, and did not become law, and therefore the Medical Council has no power whatever of compelling the Licensing Bodies to adopt, or imposing upon them, any course whatever. The only power under which Conjoint Examinations can be formed is the power given in the 19th clause of the Medical Act; and I will read this section, because it is, and must be, the basis of all that we do on this important matter during the present meeting. It is as follows:—"Any two or more of the Colleges and Bodies in the United Kingdom mentioned in Schedule (A) to this Act may, with the sanction and under the directions of the General Council, unite or co-operate in conducting the examinations required for the qualifications to be held under this Act." You see that that section of the Medical Act merely gives a permissive power to the Medical Corporations, and that the powers of the Medical Council in this matter are very limited indeed—as limited as they are generally in the other sections of that Act. Well, now we come to quite recent times—the last meeting of the Medical Council in July last. On that occasion the Medical Council came to an almost unanimous—I may call it a unanimous—resolution, because no member voted against it—

"That a letter be addressed to each Licensing Body, transmitting a copy of the resolution of the Council of February 26, 1870, and a copy of the resolution of February 28, 1870, on the formation of Conjoint Examining Boards, and urging that arrangements for the formation of such Boards should be undertaken without delay, and should be communicated to the President of this Council before the close of the present year."

In accordance with that a letter was addressed, as you know, by the Registrar to all the different Licensing Bodies. Answers have been received from nearly all of them, and yesterday the Executive Committee, before meeting, ordered that all that had been then received should be put into proof, so as to be as soon as possible in the hands of the members of the Council. Their great length has prevented their being in your hands sooner. They are printed in the programme of to-day. I do not think there is anything else to be said. I have purposely confined myself to a mere statement of facts, in the first place, and would avoid altogether expressing any opinion on the matter. Not that I do not hold any opinion—I hold a very strong one indeed upon this question—but I think opinions had better be reserved for discussion, and probably they will be expressed by other members of the Council far better than I can express them. You will observe that the power given under that 19th section is merely a power of combination of Licensing Bodies to make their examinations conjointly; but what is aimed at in these various resolutions which we have come to in the Medical Council is something more than that. It is not only that these examinations should be held conjointly, but that there should be no separate examinations—that we should, at all events, remove that blot from the existing Medical system; a blot which is almost perpetuated by the Act of 1858, because that Act, in one of its sections, required the Medical Council to put on its Register the name of any man who should bring up a diploma issued by any one of the nineteen Licensing Bodies. Now, such diploma may be one exclusively of Surgery, or it may be one exclusively of Medicine—granted, in the one case or in the other, after an examination exclusively Surgical, or after an examination exclusively Medical; and so, whether the Medical Council will it or not, the men can put their names on the Register, and become legally qualified Medical Practitioners, and practise (for there is no means of preventing them) both Medicine and Surgery, although they may have given a proof of their competency to practise only one or only the other. What the Medical Council has aimed at in these various resolutions is not merely to join examinations together, but finally and entirely to remove that blot from the existing system; and this we can only obtain either by an unaided Medical Act or by some such schemes as we shall have before us during this meeting of the Council.

The Business, Finance, and Registration of Medical Students Committees of last year were then unanimously re-elected.

[We shall continue the report of the day's proceedings in our next number.]

REVIEWS.

A Treatise on Hæmophilia (sometimes called the Hereditary Hæmorrhagic Diathesis). By J. WICKHAM LEGG, M.D., Casualty Physician to St. Bartholomew's Hospital. London: H. K. Lewis. Pp. 158.

THIS is a book which, in times not long gone by, would have been looked upon as of the highest type of excellence, and had bestowed on it the emphatic title of "learned"; but in these restless times, when authority is almost held in contempt, and every man seems inclined to judge for himself, we fear it is hardly likely to meet with a just appreciation. Nevertheless, we are of those who hold such books useful—nay, more, as highly honourable to their authors. We are constantly having the value and importance of original work thrust down our throats. Its value is incontestable, doubtless, when it is valuable; but it must be remembered that there is such a thing as good work and bad work. It is not everyone who can look down the tube of a microscope who has the gift of seeing, and interpreting what he sees aright. If we reflect on the enormous numbers of false facts floating about in our Medical knowledge, the result of imperfect or incorrect observation, we may well be thankful to a man who takes the trouble to use his brains in reducing incongruous observations to order—in short, to put pith and marrow into a spiritless collection of data.

It may seem that we are unnecessarily taking the author's part in thus apologising for his work, but we seek rather to assert for all such treatises a proper place—a place which is not now accorded them, especially by those critics whose own facts are about the most questionable things in their published and authenticated productions. The number of scholarly Physicians is none too large, and we, for our own part, are glad to see a work which plainly indicates scholarly acquirements in its author.

The subject of Dr. Legg's memoir is obscure, and the material available for its elucidation scanty. In point of fact, the condition has been more frequently accepted as an untoward circumstance in the history of the patient than been the subject of special inquiry. The cases recorded by Dr. Legg himself are not free from imperfection—for, indeed, to make them perfect is not possible. Nevertheless, Dr. Legg's memoir is an exceedingly interesting one. The author has been at great pains with his subject, and he may be pronounced both ingenious and ingenuous: of which the former characteristic is not always the most prominent in Medical writings. The subject is hardly likely to attract general attention; but should anyone be driven by the exigencies of practice to make a special study of the subject, we can cordially commend Dr. Legg's work for his perusal.

Cancerous and other Intra-thoracic Growths, their Natural History and Diagnosis. Being the Substance of the Lumleian Lectures delivered before the Royal College of Physicians of London. By J. RISDON BENNETT, M.D., Fellow, Senior Censor, and Representative of the College in the General Medical Council; Consulting Physician to St. Thomas's Hospital, etc. London J. and A. Churchill. Pp. 189.

THIS very unpretentious work is really a most valuable contribution to a most difficult and intricate subject. The University of London is justly believed to exact a very high qualifying standard from its M.D.s, and these men usually afterwards attain to eminence. At the last examination a short clear history of a mediastinal tumour was given for comment. Yet, such is the obscurity of the subject, only one man came to a right conclusion on the subject.

In this volume Dr. Bennett gives the history of certain very interesting cases, one of them as yet comparatively rare—viz., a case of lymphadenoma of the mediastinum. These semi-malignant growths have not yet been perfectly studied, but the account of the case given here, and of the pathological appearances, may be taken as typical. Dr. Bennett founds his observations mainly on cases which have occurred in his own practice, for he has had the fortune, good or bad, to encounter about thirty of them altogether. Certain of these, with others occurring in the practice of his colleagues, and some from the *Pathological Transactions*, he has tabulated—thirty-nine in all—and from them has deduced very valuable conclusions. For clinical purposes he classifies his cases into three divisions:

1. Those in which cancerous deposits, usually in masses varying in size, are disseminated through the lungs, having more or less analogy with disseminated tubercle, but without inducing any change in the intervening lung.

2. Those in which the cancerous growth is more localised, attains for the most part to a greater size, and leads to important ulterior changes—such as ulceration and gangrene.

3. Mediastinal or other tumours, inducing pressure on the tubes, vessels, and nerves, with all its important and very various consequences.

Though hardly a book to appeal to the bulk of the Profession, we cordially commend it to those who aim at a more correct knowledge of thoracic disease and pathology.

Worms: a Series of Lectures on Practical Helminthology. Delivered at the Medical College of the Middlesex Hospital. By T. SPENCER COBBOLD, M.D., F.R.S., etc. London: J. and A. Churchill. Pp. 178.

CERTAIN of these lectures appeared in our columns, and are now republished along with others for the first time laid before the public. Dr. Cobbold claims for himself, and claims most justly, that he has done something to advance a scientific knowledge of our unbidden internal guests. He is particularly, we think, entitled to claim credit for the general recognition of the *tænia mediocancellata* (as a frequent human parasite in this country, and its association with measly beef and mutton. We are most happy to acknowledge the services of Dr. Cobbold in furthering our knowledge of scientific as well as practical helminthology, but in the present treatise it is the latter aspect of the subject which mainly invites attention. In respect of the value of this short treatise to the Practitioner, we are most happy to say of it that it is good, reliable, and withal exceedingly interesting. The study of parasites is at first sight very repugnant; but the strange metamorphoses they undergo, and the very various effects to which they give rise, are more wonderful than an Eastern fable. These aspects of the study are mainly dwelt upon in the work of Küchenmeister, translated for the Old Sydenham Society, and in Dr. Cobbold's great work on "Entozoa," but to the Practitioner the main thing is to cure the patient and prevent a recurrence of the disease. As an aid in so doing he will find this little work by Dr. Cobbold much more valuable than other more pretentious teachers. As a successful Practitioner Dr. Cobbold has acquired quite a great reputation as for being a man of science, and the stores of his knowledge acquired by practice are here laid open to the public.

Lectures on the Clinical Uses of Electricity. Delivered in University College Hospital. By J. RUSSELL REYNOLDS, M.D., F.R.S., Professor of the Principles and Practice of Medicine in University College, Physician to University College Hospital, etc. London: J. and A. Churchill. Pp. 112.

THESE lectures, republished from the columns of a contemporary, may be safely recommended as a guide to those who wish to use electricity aright, and who are ignorant of the general principles requisite for their guidance. For this special and somewhat limited purpose it would be difficult to say too much in the book's favour. Undoubtedly something of the kind was wanted; for many men who desire to know more of the subject than is given in text-books on Medicine have no time to consult the large and valuable works available in our language. Hitherto, as far as we can remember, no small and handy treatise on the subject has been of a character such as to warrant us speaking of it in terms of commendation.

FOREIGN AND COLONIAL
CORRESPONDENCE.

WEST INDIES.

TRINIDAD, February 7, 1872.

THE SMALL-POX EPIDEMIC IN TRINIDAD.

THE epidemic has reached a most alarming height. In Port of Spain the number of new cases reported last week to the Health Department amounted to 425; this, it is well known, falls far short of the real number, as every effort is made by the bulk of the population to conceal cases, in order to avoid the measures of disinfection and cleansing ordered by the Board of Health. What makes the alarm greater is the occurrence of many cases among the wealthier people, and these, too, of the worst kind—that, is petechial and hæmorrhagic cases. The number of these is very large; at the Small-pox Hospital the proportion of them to the total number admitted has been 17 per cent. Every one, so far, has proved fatal. The Hospital admissions do not fairly represent the disease as it is seen outside, as we

rarely have slight cases; but there is no doubt that the proportion of petechial and hæmorrhagic cases far exceeds that of any former epidemic. This is not to be wondered at. Port of Spain has increased in population from 18,880 in 1861 to 23,561 in 1871, with hardly any increase in the area built upon. The town is shut in by a range of steep hills on the east, by the sea on the south and part of the west, by a large park called the Queen's Park on the north, and it can only enlarge, and that to a very limited extent, on the north-west. Every scrap of land that can be built on is built on, and now the constant influx of people from the neighbouring islands is provided for by cramming them into little wooden huts, already overcrowded. In a tropical climate the inconvenience of an overcrowded house is not felt in the day, especially by the negroes, who live almost entirely out of doors; and at night they shrink so from the slightest cold, that the more closely they are packed the better they like it. Add to this overcrowding the grossest neglect on the part of the municipal body of the cleansing of streets and yards, so that the street-gutters are full of festering, stinking black mud almost continually, and an easy explanation is to be found of the prevalence of the worst forms of small-pox. But there are other causes than these at work. Fresh meat is very dear—none can be had at less than 1s. a pound; mutton is 1s. 3d. a pound—the consequence is, that the great mass of the population live on fish, fresh or salt. Unfortunately, salt fish is even cheaper than fresh, and is relished better. A dish of rice or plantain and salt fish is, therefore, the mainstay of a large proportion of the inhabitants. Even respectable people who have lived a long time in the colonies take to eating salt fish at least once a day. Now, salt fish is always slightly putrid—there is no such thing as salt fish perfectly free from taint; and the water in which it is boiled is a most disgusting liquid. There is no doubt that the daily use of a salted and tainted food like this predisposes the blood to that malignant form of small-pox which prevails now so extensively.

The registered deaths in Port of Spain during the month of January amounted to 564, which is at the rate of 287 per 1000 of the population annually. There is no doubt, however, that the actual number of deaths much exceeds this figure, as it is the practice of many persons to bury children, and even adults, occasionally out in the "bush."

Among the more intelligent classes a universal gloom prevails, and, indeed, there is a sort of panic-terror upon them. The slightest illness alarms them, and there is no doubt that many cases of mild small-pox have been fatal from nothing but fright. I had one such case in the Small-pox Hospital. A man died from mere fright on the fifth day of a comparatively slight eruption. Rum was given constantly, but it never roused his pulse or his spirits. During the last week the depression of spirits among the newly admitted patients has been remarkable. For the first time since the commencement of the epidemic I have had to give alcoholic stimulants at the earliest stage of the eruption. One man had a pulse of 50; another, admitted the same day, had one of 60; another 72. All were suffering from fear.

Business is almost at a standstill; the only thing thought about or talked about is the epidemic. The worst of it is that no one can get away; all the steamers refuse to take passengers, and there are, as yet, but very few sailing vessels for Europe.

The conduct of the Government in not taking effectual measures at first to isolate the cases and stamp out the epidemic is most severely criticised. It is very easy to cast blame after the event, but the Governor followed the advice of the majority of the Medical members of the Board of Health. The only one who urged vigorous measures was the late Medical Officer of Health, your correspondent, and as he was not supported by the other members of the Board, his plans were not adopted.

The number of new cases reported in Port of Spain last week was 425. There have been reported about 2500 in all, but this is much below the real number. The disease is spreading fast in the country districts.

GENERAL CORRESPONDENCE.

PENSIONS FOR POOR-LAW OFFICERS.

LETTER FROM MR. W. ELLIOTT PORTER.

[To the Editor of the Medical Times and Gazette.]

SIR,—I endorse all Mr. J. Colville, in your issue of the 17th, said on the subject of pensions for Poor-law Medical Officers; and permit me to add I think it would be for the good of the

service and the public, particularly in rural districts, if the Medical officers retiring on Government pensions were retained for ten years as referees for their successors. A Medical staff would thus be given to the service and the public that would be both efficient and complete. Of this I am certain, if the duties of Poor-law Medical Officers are to be properly performed, they must be entrusted to men under, and not over, fifty years of age.

I am, &c.,

W. ELLIOTT PORTER.

(Fifteen years in the Poor-law Medical Service.)

Lindfield, February.

THE SMALL-POX ANALOGIES OF CHOLERA.

LETTER FROM DR. E. FULHAM TURNER.

[To the Editor of the Medical Times and Gazette.]

SIR,—It would have been vastly more edifying to the Professional public if Dr. George Johnson had addressed himself to the question raised in my last letter as well as poked fun at my pugnacious propensities and bad logic. The question raised was, Whether the eruption of small-pox is essentially curative? I ventured to say No! and argued that if Dr. Johnson's position were true, it would follow that the bowel discharges of typhoid, the mulberry rash of typhus, the eruption and sorethroat of scarlet fever, and the pharyngeal infiltrations of diphtheria were also essentially curative; and, therefore, to be encouraged and promoted. I hardly thought it would have been necessary to explain to Dr. Johnson the reason why the good people of the fourteenth century—John of Gaddesden and others—used these red-hot remedies in the treatment of their variolous patients. They did not do it for the purpose (though that was one unfortunate result) of compelling them to rebreathe an atmosphere loaded with their own poisonous emanations, but in order to force out through the skin the morbid matter existing in the blood. Now, Dr. Johnson virtually says that their theory of elimination was correct, but that their mode of carrying it out was bad and induced worse evils, as no doubt it did.

But, I repeat that the majority of us do not believe in the elimination theory at all, and I for one am curious to know how it is applied by Dr. Johnson in the treatment of small-pox and kindred diseases produced by the introduction into the system of a specific poison. We know his practice in the case of cholera, and are anxious to know whether he tries to sweat out, or purge out, or pump out, the poison of small-pox, scarlet fever, etc., or *what* he tries to do with it.

As the revelation of my name is a matter of perfect indifference to me, I beg to subscribe myself,

Yours, &c., E. FULHAM TURNER, M.B. Lond.

Upper Clapton, February 26.

ON THE ASPECTS OF LAW AND MEDICINE IN RELATION TO OUR CRIMINAL JURISPRUDENCE, WITH SPECIAL REFERENCE TO CASES OF INSANITY.

LETTER FROM MR. FRAS. WORKMAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am directed to forward to you for publication, should you think fit, the enclosed paper, which was read by Mr. May, Sen., our Surgical President, before the Reading Pathological Society on February 21.

A petition to the House of Commons, advocating the views dwelt upon in Mr. May's paper, has been since drawn up and signed on behalf of the Society, and I enclose a copy of it.

I am, &c., FRAS. WORKMAN,

Reading. Hon. Sec. Reading Pathological Society.

Public attention has been drawn to this important subject by the late trials of the Rev. Mr. Watson and Christiana Edmunds, the results of which I cannot but regard as a reproach to our legislation too intolerable to be longer sustained. The only plea of insanity accepted by the judges in criminal cases is the inability of the prisoner to distinguish right from wrong at the time when the crime was committed. The opinions of many learned psychologists are in direct antagonism to this legal dictum, and they declare it to be erroneous and inconsistent with our knowledge of the manifestations of unsound mind. This conflict of opinion has been so painfully developed in the trial, conviction, and subsequent reprieve of Miss Edmunds that public feeling has been shocked, and our laws have been brought into general disrespect, if not contempt. It is believed that many persons of unsound mind

retain the abstract knowledge of right and wrong, although the judgment and the power of controlling the will may be diminished or perverted, though not entirely lost. If this be true, it must result that every alleged criminal act should be held responsible to the law, extenuating circumstances being admitted under the plea of insanity, and punishment awarded according to the degree of proved mental aberration. To admit the contrary would be a direct encouragement to crime and dangerous to the public weal. Both law and Medicine are concerned in the solution of this important problem. Law deals with the applicability of the penal statutes, and Medicine, personified in the experienced Physician, must be the best exponent of psychological phenomena, since the structure and functions of man, and the physical and mental derangements to which he is subject, are the objects of the study and practice of his Professional life. When skilled in forensic investigations, who can be found better qualified to detect the crafty malingerer and to elucidate the truth?—now proving the offence to be the act of an unfortunate aberrate, and now only the culminating crime of a life of hardened villany. But to give due weight to the judgment of such a man, he must take an official position in the judicial inquiry. Trial by jury, so dearly cherished by Englishmen as the Palladium of our civil rights, is sorely taxed in cases of disputed insanity. If to define sanity and insanity be a puzzle to the most acute metaphysician, if to fix the boundary in many cases be simply impossible, is it reasonable to expect a jury composed of men of ordinary intelligence satisfactorily to dispose of cases involving subtle distinctions, and replete with doubts and difficulties even to the most accomplished Medical jurist? We need not wonder that Medical evidence is not always complimentary to our Profession, since all legally qualified Practitioners are not psychological experts; and from the nature of their Professional engagements and the absence of special training they cannot be, and yet they are called to give evidence and to express opinions for the guidance of juries on the issues of which hang life or death! At the trial of Miss Edmunds important Medical evidence in favour of her insanity was adduced, but it was overruled; the unhappy prisoner was convicted and condemned, and then submitted again to Medical inquiry, and ultimately reprieved. Surely this reproach to our jurisprudence cannot endure. I venture to ask the members of this Society to concur with me in asserting the time to have arrived when, in the name of justice and humanity, and for the honour and dignity of our Profession, we are called to urge the Legislature to investigate and revise our laws in relation to criminal jurisprudence, and specially with regard to cases of questionable sanity.

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The humble Petition of the Presidents, Vice-Presidents, and Members of the Reading Pathological Society sheweth—

That your petitioners are legally qualified Medical Practitioners, associated for the discussion of subjects relating to the Medical Profession.

That your petitioners are deeply impressed with the importance of the subject of insanity in relation to criminal jurisprudence, and are not satisfied with the present state of the laws in relation thereto.

That your petitioners are of opinion that, with a view to the elucidation of cases involving the plea of insanity, it is essential for the ends of justice that one or more Medical experts be appointed, who shall exercise *official functions* in judicial inquiries.

That your petitioners earnestly implore your Honourable House to take this subject into your serious consideration, with a view to the early revision of the law. And your petitioners, as in duty bound, will ever pray.

RICHARD WOODHOUSE, M.D., President of the Reading Pathological Society;

GEORGE MAY, F.R.C.S. Eng., President of the Reading Pathological Society;

and signed by both at the request and on behalf of the Society.

THE CURATIVE EFFECTS OF THE SMALL-POX ERUPTION.(?)

[To the Editor of the Medical Times and Gazette.]

SIR,—I was sorry to see the tone of annoyance in which Dr. George Johnson answered the letter of your correspondent "M.B." It really seems a pity that men so identify themselves with their opinions that it is as displeasing to them to have their

opinions criticised as it might be if their personal character or private affairs were commented on. For my own part, I think that an opinion put forward publicly is public property, and open to comment from all quarters; and, as a friend of free discussion, I shall venture some comments on the doctrines of Dr. George Johnson, while expressing my sincere respect for his personal character.

The dictum for consideration is this—

"In the *treatment* of cholera and choleraic diarrhoea (which is, in fact, cholera in a mild form), the main principle to bear in mind is, that the discharges are as essentially curative as is the cutaneous eruption in small-pox."—(Dr. G. Johnson, *Medical Times and Gazette*, February 3, 1872, p. 126.)

This is the "main principle." It lies in small compass; and if this be annihilated, of course its value as a guide to treatment is also annihilated.

And annihilated it certainly is in the mind of anyone who watches by the bedside a case of *varioid* or modified small-pox, or *variola sine eruptione*, or who reads an account of it in any impartial author; for here we have violent fever, heat ranging above 103°, intense cerebral and spinal irritation, with something like opisthotonos—all vanishing suddenly on the morning of the fifth day, with the occurrence of an eruption so insignificant that it has to be felt for in the hair: half a dozen tiny vesicles, some drying up, and becoming horny or chaffy.

As "M.B." justly observes, it is absurd to suppose that this is a cure by elimination; it is, on the contrary, an example of a disease cut short and aborted in the course of its phenomena. The eruption is not curative, but the disease is cut short—eruption and all.

If the eruption were curative, our "main principle" should be to bring it out, as our forefathers did. Sydenham, by his cooling treatment, abolished the old doctrine, which one is astonished to see revived two hundred years later, and applied to an utterly distinct disease.

I take down at hazard Aitken's "Science and Practice of Medicine," vol. i., p. 359. Respecting the treatment of small-pox, he says—"The main object, in the first instance, is to prevent, if possible, a copious eruption; for the severity and danger of the disorder may be measured in some degree by this. The vulgar belief that 'better out than in' does not apply in the case of small-pox."

February 27.

I am, &c., S.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 13.

T. B. CURLING, F.R.S., President, in the Chair.

DR. W. H. BROADBENT read a paper "On the Cerebral Mechanism of Thought and Speech." The objects of the paper were stated to be, by means of the light thrown upon cerebral physiology by cases of loss and derangement of speech, to construct a theory of the mechanism of thought and language, and to connect this with the facts of cerebral structure so far as known. Ten cases were related in the first place, of which the most interesting were—1. A case of right hemiplegia with loss of speech and writing. The hemiplegia temporary; the loss of speech permanent, except as to a few words mostly used in the expression of feeling; loss of writing absolute. She was, however, able to read; and displayed great energy and resource in recovering the control of her property, of which she had been deprived under the idea that she was imbecile. On post-mortem examination three years after the attack, two apoplectic cysts were found in the upper margin of the fissure of Sylvius of the left hemisphere: one in the posterior part of the third frontal convolution; another further back, the latter involving also some convolutions of the island of Reil. 2. A case of abscess in the left frontal lobe, not affecting the surface of the third convolution or the island of Reil, but involving the white substance of the third frontal gyrus deeply. The order in which the symptoms appeared was—slight paralysis of right face; then incipient loss of speech and writing; a few days later total loss of speech and writing, with right hemiplegia; subsequently partial recovery of speech. 7. A case of congenital aphasia without idiocy in a boy, aged 12, who understood all that was said, could be sent on errands, etc., could write his name, and could copy from printed into written

characters, but could not speak except to say "yes," "no," "father," and "mother"; indistinctly answered "kreiger kruger" to all questions; could not write the simplest word, such as "no," from dictation, or understand the simplest written question, but could write and understand figures. 8. A case in which an intelligent man, after head symptoms, completely lost the power of reading either printed or written characters, while he could write readily and correctly from dictation or spontaneously. His conversation was good and his vocabulary extensive, but at times he was at a loss for a name, and he was quite unable, when asked, to name the simplest and most familiar object presented to his notice. The loss of power to read was of course a part of this more general loss of power to name. He died from hæmorrhage into the left temporo-sphenoidal lobe, which penetrated into the ventricle. Two old hæmorrhages were discovered: one in the substance of the infra-marginal convolution of this lobe; another larger, which had apparently caused softening of the adjacent brain-substance, between the extremity of the fissure of Sylvius and the ventricle where the descending cornu is given off. The latter would involve most important fibres. The extent of softening could not be ascertained on account of the recent hæmorrhage into the same part. The 9th and 10th were cases in which, with derangement of speech in the 9th and absolute loss in the 10th, there was loss of comprehension of words, with ready interpretation of signs. The cases related, so far as they bear on the question, are all corroborative of the view which assigns a close functional relation with language to the left third frontal gyrus; and, as the result of his own observation and of examination of many cases published as exceptions, the author considers this relation to be absolutely established, not, however, in the sense of its being the seat of a faculty of language, but as an important link in the cell and fibre mechanism for speech, which mechanism may be interrupted at other points above or below, as well as at this particular node. The distinction established by Sanders, W. Ogle, Bastian, and others between amnesia and aphasia proper or ataxic aphasia implies lesion at different parts; and a further subdivision of amnesic cases may be made, Case 8 being used as an illustration. Here an object seen no longer evoked the appropriate name; the channel between the visual centre and the intellectual centre was interrupted. And if a similar interruption occur in the channel from the auditory centre to the intellectual centre, so that articulate sounds no longer revive the accustomed intellectual associations, the patient will, on the one hand, be incapable of understanding what is said to him, and, on the other, will have no check on his own utterances. The lesion will in a case of this kind be at a different spot from that which destroys the memory for words (amnesia) or the memory for the utterance of words (aphasia). The results of the author's careful examination into the course and distribution of the fibres in the cerebral hemispheres are, that the fibres radiating from the crus and central ganglia and the fibres of the corpus callosum are distributed almost exclusively to the convolutions of the longitudinal and Sylvian margins of the hemispheres, the intervening convolutions receiving no radiating or callosal fibres. These latter convolutions, which are thus withdrawn from immediate relation with the outer world, which are also those that are latest in order of development, and which make the difference between the human and quadrumanous brain, he considers will be those engaged in intellectual operations, receiving the raw material of thought from marginal convolutions at the summit of the sensory tract and employing in the expression of the volitional product of thought the marginal convolutions which are in fibrous connexion with the motor ganglia and tract. The theory of the mechanism of speech and thought is a modification of that of Dr. Bastian, (a) agreeing with it that the materials of thought are remembered impressions, and not remembered movements, and that there are definite cell-areas in the hemispherical cortex in which impressions are translated into perceptions, which may be called "perceptive centres," but differing from it in relegating to these perceptive centres, which will be situated in the marginal convolutions, only the rudimentary perceptive act, and in making the higher intellectual elaboration by which an idea is evolved the function of a new cell-area in some of the super-added convolutions upon which perceptions from various senses are converged, and in which they are combined or fused into a conception of which a word is made the symbol. A part of the general theory is an hypothesis as to the nervous change which is the concomitant of sensation, which is taken to be absorption of the force of the impinging impression and

integration of matter in the cells concerned, which may be compared to the fixing of luminous vibrations by the green cells of plants. On this view, the seat of sensation would vary in different classes of animals, and at different periods in the development of the human intellect, gradually shifting upwards from the thalami to the marginal and super-added convolutions. Considering first the mechanism of speech, words may be regarded from two different aspects—firstly, as motor processes; and, secondly, as intellectual symbols. As movements, they will be represented by groups of cells in the corpora striata; and the grouping of the cells taking place under the guidance of the auditory sense, which is bilateral, will also be bilateral—that is, motor cell-groups representing articulate sounds will be formed in both corpora striata. As the left third frontal gyrus, however, is the outlet for intellectual expression, the sound groups in the left corpus striatum will take the lead in speech, and thus, though speech is not lost in lesion of this corpus striatum, the temporary embarrassment is greater and lasts longer than in lesion of this ganglion on the right side, till the way round is opened from the left third frontal gyrus to the right corpus striatum, which will probably be by the corpus callosum and right third frontal. As intellectual symbols, words are primarily revived auditory impressions, and are probably represented in the auditory perceptive centre by receptive cell-groups. The auditory perception of a given name will be associated with other perceptions, to which the object indicated gives origin, in the cell-area which constitutes the higher centre, and will come to stand for the resultant of these impressions generally. The way out from this higher centre is seen from pathological evidence to be the left third frontal gyrus. Words other than names are intellectual agents rather than intellectual symbols; are employed in mental action, not impressed upon the mind in association with visual and other perceptions. We can thus approximately understand how names may be forgotten while the framework of a sentence is readily uttered, or even a periphrasis invented. The action of the hemispheres is apparently necessarily bilateral as far as the formation of rudimentary perceptions, the marginal convolutions being symmetrically associated by the corpus callosum. The unilateral employment of the left hemisphere only becomes possible in the super-added convolutions, and the unilateral education of Broca and Moxon is a motor, or rather efferent, education only. The mechanism of thought is so far prefigured in that of language that a detailed exposition of it need not be recapitulated.

Mr. POWER said that he wished to ask Dr. Broadbent one question, and that in order to make his meaning clear he would illustrate it by a diagram. An object, say a cube, was presented to a child; and the visual impression excited was communicated to the optic ganglia, by which it might be at once reflected downwards; but more commonly it was not reflected, but ascended to a higher centre. At the same time the name of the object was pronounced in the child's hearing, and the resulting auditory impression reached the auditory ganglion. If not there reflected, it likewise ascended to the higher centre. At the same time the child touched the object, and the tactile impression followed a course similar to that of the others. The three impressions, meeting in and combined by the higher centre, occasioned the formation of the complex idea of a cube, and this, operating downwards upon the muscles of articulation, led the child to say "cube." An arrest of this process on the sensory side of the combining centre produced amnesia; an arrest on the motor side of the combining centre produced aphasia. Where, in the whole, did Dr. Broadbent place the corpus striatum?

Dr. BROADBENT replied that he placed the corpus striatum between the combining centre and the muscles of articulation, as the organ by which the former acted upon the latter.

Mr. JOHN WOOD inquired how far the method of teaching the deaf to speak by watching the lips of others would harmonise with Dr. Broadbent's views.

Mr. SAVORY accepted the distinction drawn by the author between language and words; but objected that, on the view propounded, the mechanical act of speech was seated in centres which were comparatively more developed in the lower animals than in man. If that were so, he should expect the faculty of speech to be widely diffused among the lower animals, instead of being limited to a few birds.

Dr. WILKS expressed his general assent to the views of the author. The acquirement of language was a complex process, and might be imperfect in the sense that some of its ordinary factors might be omitted. Thus it was quite possible to learn a foreign language by sight only, so as to read it by the eye with perfect comprehension, while yet ignorant of its sounds, and unable either to speak it or to understand it when spoken.

Dr. BROADBENT, in reply, said that he had located the mechanical art of speech in the corpora striata, because he regarded those bodies as the centres of muscular movement generally. Mr. Savory was mistaken in supposing that they were comparatively more developed in the lower animals than in man. Their development, throughout the animal kingdom, followed very closely that of the cerebral hemispheres, and reached its highest point in the human species.

The meeting then adjourned, the President first announcing that the ordinary meeting for the 27th, the day of thanksgiving for the recovery of the Prince of Wales, would not be held.

THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 20.

Mr. HILTON, F.R.C.S., President, in the Chair.

THE PRESIDENT announced that the Council had come to the conclusion that the Society had now reached a period in its history when some generalisation might be deduced from its doings in the past. They would therefore now be at liberty to take up the discussion of any particular subject, or even an abstract discussion, provided some specimens or drawings were submitted to the Society. Any member might give notice of his intention to bring forward a subject, and the secretaries would set apart a portion of the time of the Society for the purpose.

The Morbid Growth Committee reported on Mr. Hutchinson's Tumour from the Leg. Although it had entered the substance of the muscles, it had not, strictly speaking, invaded these. It belonged to the division of round-celled sarcomata.

Dr. C. T. WILLIAMS brought before the Society a young man with a very marked Depression of the Lower Portion of the Sternum, so that at this point the antero-posterior measurement was only four inches and a half. The grandfather had been apparently in the same condition. The boy had weak lungs.

Dr. C. J. B. WILLIAMS said this malformation did not greatly interfere with the respiratory organs, provided it was not excessive. He alluded to the case of a captain in the navy who had such a malformation. After a time the heart and lungs became affected, and he died dropsical. He thought that chest affections aggravated the condition. Certain forms of gymnastics were the best remedy.

Dr. MURCHISON, alluding to a statement by Dr. C. T. Williams, that the liver was drawn up, said he would have thought it more likely to be displaced downwards; but Dr. Williams said it was drawn up.

Mr. W. ADAMS next exhibited a specimen of Mollitus Ossium for Dr. Dowse. It consisted of the upper half of the humerus. There the compact tissue was reduced in density and thickness, and the cancellous tissue was gelatinous. The thigh-bone was in an early stage of the same condition. They were removed from an old woman, aged 61, who had died eight days after fracturing a limb. The condition was only discovered after death. There was no history obtainable. (Referred to Dr. Duffin and Mr. Adams.)

Dr. MOXON exhibited a specimen of Miliary Tubercle, softening to Vomicæ, in a case of Acute Tuberculosis. Dr. Moxon said he believed this was the first specimen deliberately exhibited to the Society as tubercle of the lung. This, he supposed, must have one of two reasons—either that long ago everybody knew enough about tubercle, or that even now no one feels sure enough concerning it. He had looked back through the writings of many authorities to learn those proper characters of tubercle which appeared so long to have satisfied the members of the Society, but always he found there was the same supposition that tubercle was a matter of course; and thus far it appeared clear that everyone did know all about tubercle long ago. From this point of view the neglect of the subject by the Society was another proof of its pathological completeness, and yet there were some facts not quite in concord with so satisfactory an account of the matter. He specially alluded to three of these facts. Dr. Cayley had shown microscopic specimens of tubercle in the liver, etc.; Dr. Bastian had shown specimens to prove the histological identity of tubercle and early fibroid disease; and a committee, which had decided in favour of the tuberculous nature of some disease consequent on inoculation in the lower animals, had stated the histological grounds of their opinion. Now, he had found, on comparison of the characters described by these gentlemen, that they were very far from corresponding in the three cases.

The characters relied on by the committee were a good deal fresh and unusual, and differed much from the descriptions by Dr. Cayley, and these from Dr. Bastian's; who, whilst saying on the one part that a tubercle had the same structure as early fibroid tissue, on the other part said he agreed with Virchow's description of tubercle as identical with lymph-gland tissue. From all this it would appear that there is yet a great deal that is very unsatisfactory in our knowledge of tubercle, and especially in its histology. In his examinations of tubercle he had found what Dr. Cayley described, and also he had seen the early fibroid-like appearances that Dr. Bastian represented; but he had never been able to make out anything like lymphatic gland. Of course, if by lymphatic gland you only mean cells with filamentous intercellular matter, then other cells with filamentous intercellular matter would be the same. But when we have regard to the characters of the cells and the consistence of the intercellular matter, or the distinctness of its filaments, then the thing becomes different. Everyone knew that a lymphatic gland is very complex, and that in the follicular tissue of the gland there are not merely cells and filaments, but that the filaments are themselves connected with stellate cells, from which the cells among the filaments appear to arise; further, these free cells are indistinguishable from pus corpuscles, and therefore cannot be very like tubercle corpuscles. If you brush out under water a section of gland and a section of tubercle, the first becomes a beautiful plexus of fine fibrils, whose meshes have been brushed empty; but the other all brushes away, and no filaments remain—neither, indeed, can any filaments be seen before brushing. Hence he thought Virchow's comparison with lymphatic gland most unsatisfactory, and thought that at present the naked-eye appearances, taken altogether, were of infinitely more consequence than the microscopic appearances. By "taken altogether," he meant that the position, arrangement, and distribution of the tubercles in question, along with their physical characters, are of important weight in settling the tuberculous nature of any case. In the case which he exhibited, it was specially to the naked-eye appearances that he would draw attention. The case was that of an industrious, steady young shoemaker, who, after suffering for five months with urinary troubles, which shortly were, in their order, hæmaturia, hydruria, dysuria, and pyuria, got chest symptoms and hectic, and sank within a few weeks of the appearance of these. Dr. Moxon found at post-mortem extensive scrofulous disease of the left kidney, bladder, and prostate, which were dreadfully ulcerated; but besides this there was general tuberculosis—minute tubercles crowding the liver, spleen, kidneys, and lungs. The state of the lung deserved settled attention, because its tubercles showed very beautifully a gradation from the condition of minute grains at the base of the lung up to little vomicæ of the size of peas in the apex, the intermediate gradations of enlargement and central softening, conclusively showing that the tubercles—large, intermediate, and small—were all of one nature, while the small ones and the scattered distribution of all showed their identity with the miliary tubercles so generally distributed in the body; thus the case offered an example of genuine miliary universal tubercle, running in the lung through the common course of softening into vomicæ. He would shortly state what he conceived to be the significance of the case, which had a very special point in opposition to the views now known as those of Niemeyer, which views are just now meeting with an extent of favourable acceptance which he thought they were not entitled to, but rather obtained through our natural kindness toward foreign notions when they visit us. He understood that Niemeyer's views had no such weight in their own country. The view proper to Niemeyer is this, that the process which produces vomicæ in the lung is from the first inflammatory, and that tubercles in the form of little grey knots were apt to supervene secondarily. The point of the present case lies here, that the softening to vomicæ present in it was evidently a secondary process in, of, or about the tubercles. The chief ground for accepting Niemeyer's view lies in the fact that secondary miliary tuberculosis, or general tubercle, as it is called, almost invariably kills while the tubercles are small, so as to allow of Niemeyer's school regarding them as distinct from the softening deposits which produce vomicæ. In this case, however, life was prolonged until tubercles, which were unquestionably true tubercles in Niemeyer's sense, and secondary to scrofulous inflammation in another part, went on themselves to soften into vomicæ; thus proving that the subsequent history of Niemeyer's secondary tubercles is to go on and form those same cavities which his view assumes to be of a distinct nature when found in common phthisis. The case affords proof that the same vomicæ, which Niemeyer calls primary

catarrhal pneumonia (which he holds to be distinct in kind from tubercle, but liable to cause tubercle, as one thing causes another different thing), do arise from changes in or about secondary tubercle. Here we have a strong ground for holding to Laennec's belief—namely, that the vomices of common phthisis arise through the natural changes of tubercles. Of the essential truth of that view, Dr. Moxon entertained no doubt whatever. The specimen was accompanied by a full-sized painting of the lung, and charts of the microscopic appearances with high and low powers.

Dr. GREEN said, as to the grey granulation, it was not comparable to the whole lymph gland, but only to its follicular structure. He had found lymphoid corpuscles and a stroma in tubercle, but he was not certain but that the latter might be the result of the hardening process. He asked if the excavations at the apex were not due to the pneumonic process.

Dr. POWELL said in this instance the disease was most advanced in the kidney. He took that to mean that the kidney was in a cheesy condition, to which the miliary tubercles were a subsequent development. He was disposed to think the breaking-down process pneumonic. One might often see a lung stuck full of grey granulations with no ulceration. He had often seen a stroma in tubercle.

Dr. CAYLEY considered that Dr. Moxon had overstated Dr. Niemeyer's views. He did not think the stroma of tubercle the same as that of lymphoid structures.

Dr. MOXON said he wanted to show the specimen simply as one of miliary phthisis.

Dr. C. J. B. WILLIAMS said Dr. Moxon's views corresponded with his own. The tubercle was often surrounded by a ring of inflamed tissue. Degeneration of tubercle and pneumonia went, he thought, hand in hand. The degeneration was fatty, going on to calcification. He thought the stroma accidental.

The specimen and subject were then referred to a committee consisting of Drs. Moxon, Sanderson, Powell, and Cayley, and Messrs. Hulke and Arnott, with a view to a report and discussion.

Dr. PEACOCK related a case of Intra-thoracic Tumour involving the Heart and Right Lung, and leading to Obliteration of the Descending Cava, as follows:—W. H. S., aged 27, was admitted into the Victoria-park Hospital, under the care of Dr. Peacock, on February 12, 1869. He ascribed the illness for which he was admitted to having taken cold from getting wet five weeks before. He then had severe cough and difficulty of breathing—increased on exertion—and after three weeks became incapable of following his employment. After resting for a week he returned to his engagement; but in another week he became worse, and applied for admission into the Hospital. On admission, his face was tumid and suffused, and the right side of the head and neck, and the corresponding portion of the chest and the right arm, were much swollen, and on the chest and neck there were large distended veins. There were also enlarged glands in each axilla, and a sinus discharging matter in the right axilla. The glands in the neck were also enlarged, and the right radial artery was less than the left. There was also evidence of effusion into the right side of the chest, and the lung was displaced towards the sternum in front. It was evident that there was a tumour pressing on the large veins in the neck, and on the parts within the right side of the chest, and, as there were suspicious cicatrices on the leg and he acknowledged having had syphilis, it was thought that the enlargement might be of a specific nature, and iodide of potassium was prescribed. There was, however, no improvement from the treatment, and as it produced depression it was discontinued. On March 18 the effusion in the pleural cavity had increased, and he had urgent dyspnoea. The chest was therefore tapped, and thirty ounces of fluid removed, with immediate relief. After a short time, however, he again became worse; his voice became quite abortive, and the fluid reaccumulated, so as to displace the heart towards the left axilla. On April 10, the dyspnoea being again very urgent, he was again tapped, but this time with little advantage, and he died shortly after. On examination, the cervical and mediastinal glands were found very much enlarged, and converted into a yellowish homogeneous-looking material. The right pleural cavity still contained some fluid, but the heart had returned to its natural position. The surface of the costal pleura was studded with small masses similar in appearance to the diseased glands, which varied in size from a pea or bean to a pigeon's egg. The lung was much compressed, but contained some small masses of the same kind in its substance. At the base of the heart, and extending from that situation up the bodies of the vertebrae behind the trachea, there was a large tumour, which had compressed and entirely obliterated the descending cava shortly

above its entrance into the right auricle, and protruded forwards into the trachea, destroying the cartilages, but not penetrating the mucous membrane. The left recurrent vein entered into this mass, but could not be traced further. The masses also projected below into the cavity of the pericardium, and the surface of the heart was covered with small separate growths in the recent state, entirely resembling the other growths. The notes of the microscopic examination of the tumours at the time they were first removed from the body had been misplaced; but Dr. Payne, who had examined portions from the perforation, stated that they had entirely the character of lymphadenoma.

Dr. PEACOCK then related a case of very great Distension of the Colon from Habitual Constipation. The subject of this disease was a man, aged 30, admitted into St. Thomas's Hospital, under the care of Dr. Peacock, on May 11, 1871. Mr. J. P. Purvis, of Greenwich, by whom he was sent to the Hospital, stated that he had suffered from constipation and flatulence all his life, but especially since 1860, when he had an attack of obstruction of the bowels, which was only relieved after a large quantity of hardened faeces had been removed from the rectum. About six weeks before his death a similar attack occurred, and was again partially relieved by emptying the rectum and by enemata, but he continued to suffer at intervals in the same way, and the abdomen was at times enormously distended. When admitted into St. Thomas's Hospital the abdomen was very greatly enlarged, and was obscurely tympanitic on percussion everywhere except in the left iliac region, where there was entire dulness. The integuments in that situation, and also the scrotum and penis, were oedematous, and he was much prostrated. An attempt was made to afford him relief by aperients and enemata, but he died somewhat unexpectedly on the 14th, or three days after his admission. On examination, all the organs of the body were found healthy, except the lower part of the intestinal canal, which was excessively distended—indeed, the colon had in places a diameter of six or eight inches, and contained fifteen quarts of soft, greenish-coloured, faeculent matter. The lining membrane was in places ulcerated, but no source of obstruction existed anywhere. Dr. Peacock remarked that the case very closely resembled one of carcinomatous stricture of the sigmoid flexure, and it would almost necessarily have been supposed to be of that character had it not been that Mr. Purvis, in sending the patient into the Hospital, stated that when the bowels were freely relieved the distension almost entirely disappeared.

Dr. MOXON asked what was the degree of probability of the existence of stricture in an intestinal obstruction. He had never seen a fatal case without.

Mr. T. SMITH had relieved a case in a child by lumbar colotomy where there was no obstruction beyond dilatation and a sudden turn of the gut.

In reply to Dr. C. T. Williams, Mr. PURVIS said the man had from infancy been accustomed to use enemata for the relief of his bowels.

Mr. HOLTHOUSE said Abercrombie mentioned several cases of obstruction where there was no mechanical obstacle.

Mr. ARNOTT asked if colotomy would have been of any use here.

Mr. CROFT referred to the case of a woman with umbilical hernia and symptoms supposed to be due to strangulation. She died of exhaustion, and the gut was found much distended below.

Mr. HULKE asked as to the condition of the muscular coat.

Mr. WEEDEN COOKE referred to Mr. Gay's case; and

Mr. GAY, mentioning the case of a boy who for three months never had his bowels moved, but who nevertheless ate heartily till he grew to an enormous size, also referred to another where the engorgement was confined to the sigmoid flexure.

Dr. THOROWGOOD referred to the case of a young man who suffered from obstinate constipation who was cured by a meat diet.

The PRESIDENT remarked that in rabbits the peristaltic action ceased at a distended portion of gut.

Dr. NUNNELEY exhibited a specimen of Congenital Occlusion of the Hepatic Ducts; and Mr. W. ADAMS the Skull of a Child showing Depressed Fracture.

The meeting then adjourned.

THE military authorities at Strasburg have bought the Contades Beer Gardens, which are to be converted into a military Hospital.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, FEBRUARY 7.

Dr. J. BRAXTON HICKS, F.R.S., President, in the Chair.

The following gentlemen were elected Fellows of the Society :—Dr. J. N. Agnew (Toronto), Dr. Bethune (Toronto), Dr. C. H. Carter, Dr. W. Hope, Mr. Albert Hunt, Dr. Kennedy (Toronto), Dr. Konrad (Pesth), Dr. J. G. Lock (Tenby), Mr. George Parr, Dr. W. L. Richardson (Boston), Mr. J. D. Shapland (Croydon), Dr. J. A. Temple (Toronto), and Dr. N. Toltschinoff (Kieff).

Dr. MEADOWS exhibited a specimen of Cystic Disease of the Ovary, which illustrated, he thought, one of the possible modes of origin of the disease. The ovary was situated on one side of the cyst, and appeared to be almost, but not quite entire. It contained several Graafian follicles upon its free surface, and there were one or two of larger size at the attached border of the ovary, in close juxtaposition with the one large cyst; and Dr. Meadows expressed his belief that this cyst had resulted from an abortive attempt of a Graafian follicle to escape from the ovary at its attached border. Not being able to effect this, it had gone on developing into the cyst exhibited.

Dr. WILTSHIRE asked whether the possibility of the cyst having arisen from the parovarium had been entertained.

Dr. BANTOCK believed it to be a cyst of the parovarium. He believed that, when the disease originated in the ovary, multilocular disease is always found to a greater or less extent; while, in those cases where the disease begins in the parovarium, a single cyst with the ovary at the base is the most frequent, if not the invariable condition.

The PRESIDENT suggested that cysts originating in the parovarium would probably always be simple, and yet the Fallopian tube is found passing round the half of the tumour both in compound and single cysts. He thought the explanation given by Dr. Meadows the most probable one, at any rate in the compound cysts.

Dr. FRANCIS R. HOGG exhibited some photographs of Military Female Hospitals, and gave an interesting account of their internal arrangements. They are chiefly intended for cases of parturition. The Hospital at Woolwich is a building one storey high, consisting of two large wards with a smaller ward attached. In the parturition ward, adapted for ten patients, each patient has 1483 cubic feet of air. The average temperature in July was 69° Fahr., and in December 47° Fahr. Dr. Hogg believed the low temperature prevented the spread of scarlet fever and other fevers. Out of the last 278 cases, only one patient died.

Dr. J. J. PHILLIPS exhibited a cedar pencil, four inches long, one end of which was covered with a phosphatic calculus, extracted from the bladder of a girl, aged 18. The pencil had been passed into the vagina six months previously, and for four months gave rise to no inconvenience. Irritability of the bladder then supervened, and for six weeks there had been incontinence of urine. One end of the pencil was found in the vagina, the other in the bladder. It could not be extracted by the vagina, but was readily pushed into the bladder. The urethra was then rapidly dilated under chloroform, and the pencil extracted. The vesico-vaginal fistula closed, and on the fourth day there was no incontinence of urine. The patient made a good recovery.

Mr. JALLAND, of Horncastle, related a case of Vaginal Thrombus. There was no increase in size of the tumour during labour, and it offered no hindrance to the birth of the child. After expulsion of the placenta there was rapid enlargement of it, and spontaneous rupture. The patient became pulseless and unconscious. The hæmorrhage was controlled by pressure firmly applied with the fingers; and this was continued for half an hour. The patient gradually rallied, and got quite well.

Dr. J. J. PHILLIPS read a paper "On Retroflexion of the Uterus as a frequent Cause of Abortion." The paper commenced by a reference to the subject of retroversion of the gravid uterus so familiar to all obstetrical Practitioners, and associated with retention of urine about the third or fourth month of utero-gestation. This complication of pregnancy was well recognised in all the text-books on midwifery, and the influence of this displacement, if persistent, in inducing abortion was noticed by many writers. Dr. Tyler Smith, in a valuable paper on the etiology of retroversion of the gravid womb, had incidentally referred to the great tendency to abortion which existed in such cases. The object of the present paper, however, was to show that in a large number of cases repeated

early abortions resulted from a *retroflexed* state of the uterus, and that their true nature was very apt to be overlooked, as they were not necessarily accompanied by any severe or well-marked bladder symptoms. The author had made it a practice to ascertain whether any marked disorder of structure or of position of the uterus could be found to exist in cases of repeated abortions, and the result of this had been such as to convince him that, after making due allowance for various constitutional causes, a most important factor in the production of the abortions in many cases was retroflexion of the uterus; and that this should occupy a leading position in an enumeration of the local disorders tending to the premature expulsion of the ovum. He excluded from consideration those cases in which, in addition to the displacement, the uterus was bound down by perimetric adhesions. Various points in the clinical history of these cases were then noticed. Difficult micturition, present in many cases in a greater or less degree, was not a constant symptom. Frequently the uterus was excited to the expulsion of its contents before it had attained such a size as of necessity to interfere mechanically with the passage of the urine. The increased susceptibility of the retroflexed pregnant uterus to concussion from sudden movements, the mechanical irritation to which it might be subjected, the straining in micturition and defæcation, and the irritation which the abnormal position of the uterus set up, seemed all to be very efficient exciters of uterine action. Further, the interference with the circulation in cases of retroflexion tended to the effusion of blood between the placenta and uterus, and this in its turn excited uterine action, or led to the death of the ovum. Two apparently characteristic cases were then detailed, in which repeated abortions (in one case six successive ones in the third month) had occurred, but in which the recurrence of this accident was prevented in a subsequent pregnancy by simply introducing a Hodge's pessary, and thus maintaining the uterus in a position favourable for its ascent during its growth. The treatment applicable in such cases, both before and after the supervention of pregnancy, was then noticed, and the paper concluded by referring to the influence of retroflexion in causing imperfect deliverance in cases of abortion. Some of the cases which the author had seen of long retention of a portion of the ovum had been cases complicated with retroflexion of the uterus.

Dr. TILT admitted that any considerable amount of uterine displacement was a cause of abortion; but were the cases referred to cases of uncomplicated displacement? Dr. Tilt had frequently seen chronic inflammation of the womb cause successive abortions, the liability to which ceased on the uterus becoming healthy.

Dr. BANTOCK could not agree with Dr. Tilt, for he had always believed that inflammation of the uterus was a decided bar against impregnation; but he entirely agreed with the accuracy of Dr. Phillips's observations as to the frequent occurrence of abortion as a result of displacement of the uterus either backwards or forwards. He had notes of several cases of abortion from displacement. Dr. Bantock briefly referred to some of these.

Dr. ROUTH thought the remarks made by Dr. Tilt more in accordance with his experience than those of Dr. Bantock. Flexions of the uterus, whether anteflexions or retroflexions, were, he considered, much more frequently the cause of sterility than of abortion. He could not then recall a single case in which he knew that pure uncomplicated flexion had existed before pregnancy, and in which afterwards pregnancy occurred, where abortion followed; but he was quite aware of cases where the flexion was complicated with ulcerations in which this had occurred. Again, ulcerations of themselves would not necessarily cause abortion. Many such cases got well. Dr. Routh thought that the author of the paper had not sufficiently insisted that no syphilitic taint existed in the cases, syphilis being, he believed, a very common disease among patients attending at Guy's Hospital.

Dr. RASCH said it would decrease the value of the discussion if certain well-known constitutional causes of abortion, like syphilis, were introduced into it. The subject of the paper was a certain well-defined mechanical cause of abortion which must be familiar to those engaged in obstetric practice, and he could fully subscribe to the author's views. In one point the paper might have been more distinct—namely, as it affected therapeutics. In cases of retroflexion produced, he believed, by some external violence during pregnancy, catheterism and one reposition of the uterus were often enough; but where the retroflexion was due to alterations in the texture of the uterus the proper treatment was to insert a Hodge's pessary, and keep it in till the fifth month. He also strongly advocated

The prone position. Dr. Rasch's experience of retained placenta after abortion made him concur in the closing remarks of the paper.

Dr. WYNN WILLIAMS said that ulceration and inflammation of the cervix uteri, and also displacements of the uterus, were occasionally the cause of sterility, at other times of abortion. Syphilis, although frequently, was not invariably, followed by abortion, or we should have no congenital syphilis. He could relate cases of abortion due to displacements; and he, like the author of the paper, had been in the habit of using a Hodge's pessary in the early months of pregnancy.

Dr. BARNES said his own experience entirely confirmed the author's conclusion that retroflexion was a frequent cause of abortion. It was necessary to remember that there were two different forms of retroflexion. The first form he believed to be congenital; it was often associated with a narrow os externum uteri, and dysmenorrhœa and sterility were the consequences. The other form might be called "acquired" retroflexion; it generally arose after a labour, the heavy uterus falling back while the parts were in a state of relaxation. In this case pregnancy would often occur, and end in abortion. With reference to Dr. Tilt's suggestion, he would observe that it was hardly possible to find a pure case of retroflexion. This displacement necessarily induced morbid conditions, especially engorgement of the body of the uterus and dilatation of its cavity. These secondary conditions might be concerned in producing the abortion, but still the retroflexion was the essential cause. Nor could Dr. Barnes assent to Dr. Bantock's observation that inflammation of the cervix uteri was a constant cause of sterility. Women frequently conceived while under treatment for this affection. He thought Dr. Phillips's paper would be useful in drawing attention to an important clinical fact.

The PRESIDENT said that, from the position of the retroflexed uterus, a tendency to abortion might be *a priori* anticipated; for not only was the organ exposed to concussion from movements of the body, coitus, etc., but, in consequence of the dependent position, there was three inches addition to the column of blood, the gravitation of which would retard the return into the veins, and thus assist in extravasation and death of the ovum. With regard to the increased difficulty in the discharge of the ovum referred to, he could say that in eight cases out of ten of abortion to which he was called in consultation there was a retroflexed uterus.

Dr. PHILLIPS then replied.

Some interesting cases which had occurred in the practice of Mr. Bassett, of Birmingham, were then read. The first was a case of concealed accidental uterine hæmorrhage, fatal before delivery could be accomplished; the second, one of placenta prævia without hæmorrhage at the time of delivery; the third, a case of rupture of a varix in the genital organs during pregnancy; and the fourth was a case of destruction of the uterus by a severe labour.

Dr. WILTSHIRE thought the use of Barnes's dilating bags would have been useful in the first case.

Dr. BARNES, in answer to the President's question whether others had observed cases of placenta prævia without hæmorrhage, said he had seen such cases. They illustrated his theory of the physiology of placenta prævia. Hæmorrhage was not an absolute necessity in such cases. In Mr. Bassett's case probably that part of the placenta which came within the lower zone of the uterus had undergone such alteration of structure that it had ceased to be in vascular relation with the uterus. In reference to the first case just read, it was an illustration of what he had long ago pointed out, that fatty degeneration of the placenta was a cause of "accidental hæmorrhage."

OBITUARY.

THOMAS LEIGH BLUNDELL, M.D.,

DIED last week at an advanced age, at St. Leonard's-on-Sea. Thirty years ago Dr. Blundell had an extensive obstetric practice in the City of London. He was Consulting Physician to the Royal Maternity Charity, Senior Physician to the London Dispensary, and formerly lectured on Midwifery and the Diseases of Women and Children to the Aldersgate-street School of Medicine. We believe that he made few or no contributions to the literature of the Profession.

It has been decided to open a nurses' training institution in Bradford.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, February 22:—

Kingcombe, Alfred Partridge, Ivy-bridge, Devonshire.
Ticchurst, Charles Sage, Hastings.

As an Assistant in Compounding and Dispensing Medicines—
Pearson, John Johnson, Whitehaven.

The following gentlemen also on the same day passed their first Professional examination:—

Ayling, Arthur Henry Williams, Middlesex Hospital.
Corbin, Edward Kinnersly, St. Thomas's Hospital.
Hiels, Edward John William, Guy's Hospital.
May, William Allan, Guy's Hospital.
Payne, Henry Peter, King's College.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ANDREWS, GEORGE, L.R.C.P.L., M.R.C.S.E., L.S.A.—Medical Officer for the Walton District of the West Derby Union.

BURROUGHS, E. F. H., M.R.C.S., L.S.A., etc.—Medical Officer to the Barnstaple and Ilfracombe Railway Company, and to the Provincial Assurance Society.

CARTER, EDWARD HUNT, M.R.C.S.E., L.S.A., Medical Officer to the Guardians of Chelmsford Union for the Chelmsford District—To be Medical Officer of Health to the Chelmsford Local Board of Health.

EDWARDS, J. ELLIS, M.R.C.S.E., L.S.A.—Assistant Medical Officer at the North Wales Counties Lunatic Asylum, Denbigh.

FOLY, CHARLES JAMES, M.D., L.R.C.S., and L.M.—Medical Officer for the Stratford District of the West Ham Union.

FURLONG, NICHOLAS, L.K. & Q.C.P. Irel., L.R.C.S. Irel.—Medical Officer, Public Vaccinator, and Registrar of Births, Deaths, etc., for the Ennis-morthy Dispensary District of this Union, *vice* Thomas G. Cranfield, M.D., deceased.

HAWTHORNE, JOHN, M.D., L.R.C.S. Edin.—Medical Officer for the Workhouse and Fever Hospital, Banbridge Union, co. Down.

JOHNSTON, RICH., M.R.C.P. and L.R.C.S.I., and L.M. (late Assistant House-Surgeon to the General Hospital, Notts)—House-Surgeon to the Dispensary, Nottingham, *vice* J. Rein, M.R.C.S.E. and L.S.A., resigned.

McMASTER, ANDREW, L.R.C.S.I., L.R.C.P. Edin.—Medical Officer for the Omagh Union.

SANDERSON, ROBERT, M.C.Q.U.I., L.R.C.S.I., etc.—Medical Officer, etc., for the Clonelly Dispensary District of the Irvinestown Union.

WILLIAMS, D. W., M.D., M.R.C.P.—Physician to Dorset County Hospital, *vice* C. Cowdell, M.D., deceased.

WOOD, WILLIAM, M.R.C.S.E., L.S.A.—Medical Officer for District No. 5 of the Beverley Union.

MARRIAGES.

BROWNING—KENDALL.—On February 22, at St. Margaret's Church, King's Lynn, George A. Browning, Navigating Lieutenant R.N., to Mary Elizabeth, second daughter of the late Thomas M. Kendall.

COPLAND—SPENCE.—On February 22, at St. Andrew's, Islington, Henry S. Copland, C.E., Hertford House, Brondesbury-road, Kilburn, son of the late Dr. James Copland, F.R.S., to Maria Louisa, daughter of John Spence, F.R.C.S., Bedale, Yorkshire.

HUGHES—GILLAN.—On January 25, at the Church of the Holy Trinity, Allahabad, David Erskine Hughes, M.D., F.R.C.S.E., Bombay Medical Service, to Mary Jane, elder daughter of the Rev. Robert Gillan, D.D., Inchinan, Renfrewshire, Scotland.

LEES—LAWRENCE.—On February 20, at Meanwood Church, Meanwood, near Leeds, F. Arnold Lees, L.R.C.P. Lond., M.R.C.S. Eng., to Mary, second daughter of John St. Lawrence, Esq., Dalton-in-Furness.

TARDREW—PAGE.—On February 21, at St. Paul's Church, Deptford, Philip Tardew, elder son of Edwin Tardew, Esq., of Bristol, to Annic, second daughter of the late J. P. Page, Surgeon 19th Hussars.

WITT—COOPER.—On February 21, at St. Mark's Church, Hamilton-terrace Gerard Ranelagh, youngest son of Dr. Witt, M.R.C.P., of Spring-gardens, St. James's-park, to Cecilia Jane Seymour, youngest daughter of William Bush Cooper, Esq., of the Temple, and Llwyndcofr, Carmarthenshire.

DEATHS.

ANDERSON, CHARLES ABERCROMBY, C.B. M.D., Inspector-General of Hospitals and Fleets, in London, on February 25.

ANDREWS, ELIZABETH, the wife of Onslow Andrews, Esq., and mother of Onslow Andrews, M.D., Alfred B. Andrews, Esq., M.R.C.S., and Henry Charles Andrews, M.D., at Brabourne, near Ashford, Kent, on Feb. 28.

BLUNDELL, THOMAS LEIGH, M.D., of London, Consulting Physician to the Royal Maternity Charity, at St. Leonard's-on-Sea, on February 22, aged 84.

CHAPMAN, LILLIAN HATTON, youngest daughter of the late Dr. E. C. Chapman, of Biarritz, at Barnes, S.W., on February 16, aged 3½ years.

EASTWOOD, CHARLES SEPTIMUS, M.D., Oshawa, Ontario, Canada, at Lytham, Lancashire, on February 18, aged 42.

FIRTH, Dr. JOSEPH THOMAS FORBES, at 45, Union-road, Rotherhithe, on February 24, aged 46.

JERVIS, MARY JANE, wife of Thos. Jervis, M.D., at 32, Connaught-square, W., on February 24.

LORIMER, JOHN, M.D., L.R.C.S. Edin., L.S.A., Medical Practitioner of Batavia, of dysentery, on the evening of February 8.
 MOSSMAN, CHARLES STUART, only surviving son of the late Dr. Mossman, of Bradford, Yorkshire, in New Zealand, on December 9, in his 50th year.
 PALMER, WILLIAM GRIMES, M.R.C.S. and L.S.A., at Loughborough, Leicestershire, on February 16, in the 65th year of his age.
 THURSFIELD, WILLIAM, Surgeon, at St. Leonard's-churchyard, Bridgworth, on February 20, in the 73rd year of his age.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM QUEEN'S HOSPITAL.—Resident Physician and Medical Tutor. Candidates must be Graduates in Medicine of a University of Great Britain or Ireland. Applications, with diplomas and testimonials, to Mr. H. C. Burdett, on or before March 22.

BRISTOL LUNATIC ASYLUM, STAPLETON, NEAR BRISTOL.—Assistant Medical Superintendent. Must be duly qualified to practise. Applications to Mr. J. F. Williams, Clerk to the Visitors, Council House, Bristol, on or before March 5.

CAXTON AND ARRINGTON UNION.—Medical Officer for the Caxton No. 1 District of this Union. Candidates will be required to possess the qualifications prescribed by the General Orders of the Local Government Board. Residence within the district required. Applications to Mr. H. Mortlock, Clerk to the Guardians, on or before March 11. Election the following day.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Clinical Assistant. Must possess at least one qualification. Applications to the Secretary, on or before March 2.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant Medical Officer. Must be qualified in accordance with the Rules of the institution, which may be had on application to Mr. John Calder, Secretary, on or before March 6.

LOCHMABEN, DUMFRIESSHIRE.—Medical Officer wanted for this Parish. Good scope for private practice. Applications to the Inspector of the Poor, on or before March 22.

ST. MARYLEBONE PROVIDENT DISPENSARY.—Medical Officer-in-Ordinary. Must possess a Physician's or Surgeon's diploma of one of the Colleges of London, Edinburgh, or Glasgow, and be a L.S.A. Applications to the Secretary, 16A, Duke-street, Portland-place, on or before March 2.

STOCKTON-ON-TEES DISPENSARY.—Registered Practitioner, to visit and dispense. Testimonials, etc., to Mr. E. E. Clapham, on or before March 9. The duties will commence early in April.

WALLASEY DISPENSARY.—House-Surgeon. Must be duly qualified and registered. Applications to Mr. W. D. Broome, Hon. Secretary, Withenfield-terrace, Liscard, Cheshire, on or before March 3.

WEST HAM, STRATFORD, AND SOUTH ESSEX DISPENSARY.—Dispenser. Applications to Mr. Thomas G. Tonge, 2, St. John's-terrace, Stratford, E., on or before March 6.

WEST WARD UNION.—Medical Officer and Public Vaccinator for the District of Shap. Candidates must be duly qualified. Applications to Mr. J. P. Shepherd, on or before March 6. Election on the same day.

UNION AND PAROCHIAL MEDICAL SERVICE.

•• The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Barrow-upon-Soar Union.—Mr. Samuel Wright has resigned the Workhouse (salary £40 per annum) and the Rothley District; area 4505; population 3140; salary £35 per annum.
Burton-upon-Trent Union.—Mr. Thomas H. Creswell has resigned the Lullington District; area 2907; population 625; salary £10 per annum.

APPOINTMENTS.

Calne Union.—Charles A. Brigstocke, M.R.C.S. Eng., L.S.A., to the Union and Workhouse.
Christchurch Union.—John S. Morrill, F.R.C.S. Eng., L.R.C.P. Lond., L.S.A., to the Eastern District.
Holsworthy Union.—Francis C. Fitzgerald, L.R.C.S. Ire., L.K. & Q. College of Physicians, Ireland, to the Fourth District.
St. George's-in-the-East Parish.—Henry B. Courtenay, L.S.A., L.F.P. & S. Glas., to the South District; George G. A. Sutcliffe, M.R.C.S.E., L.R.C.P. Edin., to the North District.
Tonbridge Union.—Henry M. Lawrence, L.R.C.P. Edin., L.R.C.S. Edin., to the Fourth District.

SIR JAMES PAGET, BART., AND DR. MATTHEWS DUNCAN have been elected Honorary Members of the Royal Medical Society of Edinburgh.

MR. WINTER has been appointed by the Bethnal-green Guardians their officer for enforcing compliance with the requirements of the Vaccination Laws.

ALEXANDER M'KELLAR, M.D., of the Queen's University of Ireland, M.R.C.S.E., and lately attached to the Prussian army during the war, has been appointed Resident Medical Officer to the Royal Free Hospital.

WILLIAM PATRICK, a potted meat manufacturer at Birmingham, was fined 20*l.* and costs last week for having meat which was proved to have been that of an animal suffering from inflammation, and at the time it was seized it was in the process of being made into potted meat.

THE state of health in Syria is most excellent. Quarantines have been entirely removed from the Turkish, Syrian, and Egyptian coasts.

SCARLATINA is now raging in the higher parts of Heptonstall. Three deaths from the disease have already occurred in one family.

THE following is the list of gentlemen who competed successfully for appointments as Assistant-Surgeons in her Majesty's British Medical Service at the examination held at the London University on February 12:—

Order of merit.	Names.	Marks.	Order of merit.	Names.	Marks.
1.	Magill, J.	2239	7.	Bushe, C. J. L.	1727
2.	O'Donnell, R. W.	1956	8.	Quill, R. H.	1725
3.	Donovan, W.	1885	9.	Slaughter, W. B.	1686
4.	Swayne, C. H.	1795	10.	Brown D. B.	1675
5.	Tindler, B. M.	1785	11.	Keys, C. W. M.	1675
6.	Browne, A. L.	1775	12.	Stokes, H. H.	1530

THE THANKSGIVING SERVICE.—Fifteen cards of admission to the Thanksgiving ceremony at St. Paul's Cathedral were placed at the disposal of the Director-General of the Army Medical Department, and were distributed as follows:—The Director-General, Dr. Balfour, F.R.S., Head of the Statistical Branch; Dr. Rutherford, C.B., Head of the Medical Branch; Staff Surgeon Dr. Marston, acting as Head of the Sanitary Branch; Inspector-General F. W. Innes, M.D., C.B., Principal Medical Officer at Netley; Professors Parker, Longmore, Maclean, and Aitken, of the Army Medical School at Netley, Principal Medical Officers; Inspector-General J. D. McIlree, Portsmouth; Deputy Inspectors-General J. Fraser, M.D., C.B., Manchester; C. A. Gordon, M.D., C.B., Dover; N. Hefferman, M.B., Colchester; Surgeon-Major J. M. S. Fogo, R.A., Acting Principal Medical Officer at Woolwich; and Staff Surgeon-Major A. Leith Adams, on the Recruiting Staff in London. The following were the representatives of the Medical Service:—Medical Director-General Sir Alexander Armstrong, K.C.B.; Inspectors-General of Hospitals and Fleets Sir E. Hilditch, M.D., Sir David Deas, K.C.B., and Charles A. Anderson, M.D., C.B.; Deputy Inspectors-General of Hospitals and Fleets Henry J. Domville, M.D., Alexander E. Mackay, M.D., W. T. Domville, M.D., William Macleod, M.D., and William Henry Hoggett; Staff Surgeon S. Wade; Surgeon Thomas Jameson, M.D.; Assistant-Surgeons W. B. Fletcher, F. Buckle, and R. G. M'Calmar.

NOTES, QUERIES, AND REPLIES.

Be that questionedly much shall learn much.—Bacon.

Ishmael.—Address, Dr. Joseph Rogers, Dean-street, Soho, London, W.C.
Wallingford.—The remedy was prompt and serviceable, but pretty well known. Ammonia might have done as well.
White-Celled Blood.—We are sorry that the article with this title does not suit our columns.
Homo Vagus.—The motto of the Royal College of Physicians is the Hippocratic aphorism, "Ο βίος βραχυς η δε τέχνη μακρη"—"Life is short and art is long." The Royal College of Surgeons takes *Que prosunt omnibus artes*—"Arts that serve all men"; the Society of Apothecaries, Apollo's boast, *Opifereque per orbem dicor*—"Over all the world I am called the help-bearer." The Pharmaceutical Society has the motto, *Habenda ratio valetudinis*—"Regard must be had to the state of health." We know not the motto of the Obstetrical Society—perhaps *Diva quæ ter vocata audis*, or *Juno Lucina fer opem*. The General Medical Council also, we believe, are destitute as yet of a motto; perhaps *ἀναρχάιον και ἀτελευτήδιον το πᾶν*, or *In nova fert animus mutatas dicere formas corpora*. The Medical Department of the Local Government Board might adopt the motto, *Et si nullus erit pulvis, tamen excute nullum*.

FEVER HOSPITALS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
 SIR,—I should be much obliged if any of your readers could give me information on the subject of existing Fever Hospitals in England, Scotland, or Ireland. Reports, copies of rules, description of building, or even intimation of the existence of such an institution, will be thankfully received.
 I am, &c.,
 EDWARD T. WILSON, M.B. Oxon., F.R.C.P.
 6, Montpellier-terrace, Cheltenham, Feb. 26.

COMMUNICATIONS have been received from—

MR. T. HARVEY; ISHMAEL; DR. BROADBENT; MR. WORKMAN; MR. SWIFT; MR. GRAHAM; MR. CUTCLIFFE; MR. KENNEY; DR. NFIELD; MR. W. E. PORTER; HOMO VAGUS; MR. W. W. REEVES; DR. J. MATTHEWS DUNCAN; MR. F. A. MAHOMED; MR. H. MORRIS; MR. C. F. MAUNDER; DR. C. J. B. WILLIAMS; DR. LIONEL S. BEALE; MR. J. CHATTO; MR. TERRY; MR. BURROUGHS; DR. ALDIS; MR. JOHNSTON; DR. E. F. TURNER; MR. THURSFIELD; DR. PLAYFAIR; DR. ROGERS; MR. A. O'MKELLAR; DR. E. T. WILSON; MR. J. B. WALKER; MR. G. LAWSON; DR. H. C. ANDREWS; DR. MACEVERS.

BOOKS RECEIVED—

Dr. Dunglison on the Public Medical Libraries of Philadelphia—Transactions of the Obstetrical Society, vol. xiii.—Hunt on the Cause of Death in Fever—Smith's Mental Capacity—Historie de nos Relations avec l'Académie de Médecine, 1827-1871.

PERIODICALS AND NEWSPAPERS RECEIVED—

Melbourne Age—Australian Medical Journal—Australian Medical Gazette—Pharmaceutical Journal—Morning Mail—Philadelphia Medical Times—Canada Lancet—Birmingham Post—American Journal of the Medical Sciences—Birmingham Morning News—Irish Daily Telegraph—Western Daily News.

APPOINTMENTS FOR THE WEEK.

March 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Mr. Moncure Conway, "Demonology."

4. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Teevan, "On Impotence." Prof. Erasmus Wilson, F.R.S., "On Neuropathic Excoriations of the Skin: a peculiar form of Cutaneous Affection associated with General Derangement of the Nervous System." Also a Paper by Dr. Sansom, "Inflammation of the Lungs as a Cause of Consumption."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

5. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

OBSTETRICAL SOCIETY, 8 p.m. Dr. Granville Bantock, "On the Use of the Sponge Tent in Menorrhagia." Mr. Bryant, "On a Case of Fibrocystic Disease of the Uterus successfully Extirpated." Dr. Martin (Berlin), "On some forms of Distorted Pelves."

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Croonian Lectures—Dr. Bristowe, "On Disease and its Remedial Treatment."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

ROYAL MICROSCOPICAL SOCIETY, 8 p.m. Dr. Klein, "On the Earliest Stages of Development of *Salmo fario*," and "On the Nerves of the Cornea."

SOCIETY OF ARTS, 8 p.m. Meeting.

7. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Mr. J. L. Milton, "On the Pathology and Treatment of Eczema."

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

8. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. H. Weber, "On a Case of Hyperpyrexia in Rheumatic Fever treated by Cool Baths and Affusions." Dr. R. Southey, "On Two Cases of persistent Omphalo-mesenteric Duct leading to Fatal Intestinal Obstruction." Mr. Teevan, "The Treatment adopted for the Relief of Four Cases of Impassable Stricture."

QUEKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Objects only.

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Croonian Lectures—Dr. Bristowe, "On Disease and its Remedial Treatment."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

ROYAL INSTITUTION, 9 p.m. Mr. R. Liebreich, M.R.C.S., M.R.I., "On the Effect of certain Faults of Vision on Painting, with especial reference to Turner and Mulready."

EXPECTED OPERATIONS.

ROYAL FREE HOSPITAL.—The following Operation will be performed on Saturday (this day), at 2¼ p.m.:—
By Mr. Gant—Excision of Knee-joint.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.67 in. The highest was 29.98 in. on Wednesday evening, and the lowest 29.36 in. on Saturday afternoon.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

MEETING OF THE GENERAL MEDICAL COUNCIL.

HELD AT 32, SOHO-SQUARE.

FIRST DAY—THURSDAY, FEBRUARY 29—Continued.

The next business was the reception of the Returns from the Army Medical Department, sent with the following communication from the Director-General:—

Army Medical Department, October 5, 1871.

Sir,—I am desired by the Director-General to acknowledge the receipt of your letter of July 19 last, and agreeably with the request therein contained, beg leave to enclose a statement, with alterations suggested, showing the Degrees, Diplomas, and Licences of the Candidates for Commissions in the Medical Department of the Army, who in August last presented themselves for examination.

I have the honour to be, Sir,
Your obedient Servant,
(Signed) THOS. CRAWFORD, M.D.
Dr. F. Hawkins, Head of Medical Branch.
Registrar, General Council of Medical Education,
32, Soho-square, London, W.

Statement of the Degrees, Diplomas, and Licences of the Candidates for Commissions in the Medical Department of the Army who, in August, 1871, presented themselves for Examination, showing the number that passed, and did not pass, distinguishing the Qualifications, both Medical and Surgical, under the heads of the several Licensing Bodies.

REMARKS.—Total number of candidates, 34; Succeeded in obtaining appointments, 14; succeeded in examination, but not in obtaining appointments, there being only fourteen vacancies, 19; failed in examination, 1.

Dr. ALEXANDER WOOD said that, having regard to their experience of these returns last year, he should move the following resolution:—"That the returns of the Army Medical Department be received and remitted to a committee for consideration."

The motion was seconded by Mr. HARGRAVE and unanimously adopted.

The REGISTRAR read the correspondence with the Home Office respecting a resolution passed by the General Medical Council at their last meeting on the subject of death registry.

CONJOINT EXAMINING BOARDS.

The replies of the following Examining Bodies were read by the REGISTRAR:—The Royal Colleges of Physicians and Surgeons of London, the University of Oxford, the University of Cambridge, the University of Durham, the University of London, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons, Glasgow, the University of Edinburgh, the University of Aberdeen, the University of Glasgow, the University of St. Andrews. The scheme proposed by the Royal College of Physicians of London and the Royal College of Surgeons of England was as follows:—

SCHEME FOR AN EXAMINING BOARD FOR ENGLAND, ADOPTED BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

In view of the legal difficulties which have been stated by the Society of Apothecaries to prevent that Society taking part in the formation of an Examining Board in this division of the United Kingdom:

Resolved,—

I.—That a Board of Examiners be appointed in this division of the United Kingdom by the co-operation of the Royal College of Physicians of London, the Royal College of Surgeons of England, and of such other of

the Medical authorities in England, mentioned in Schedule (A) to the Medical Act, as may take part in its formation, it being understood that, liberty being left to such co-operating Medical authorities to confer as they think proper, their honorary distinctions and degrees, each of them will abstain from the exercise of its independent privilege of giving admission to the Medical Register.

II.—That the Board be constituted of Examiners, or of Examiners and Assessors appointed by the several co-operating Medical authorities.

III.—That Examiners be appointed on the following subjects:—Anatomy and Physiology; Chemistry; Materia Medica, Medical Botany, and Pharmacy; Forensic Medicine; Medicine; Surgery; Midwifery; or on such subjects as may be hereafter required.

IV.—That no Examiner hold office for more than five successive years, and that no Examiner who has continued in office for that period be eligible for re-election until after the expiration of one year.

V.—That the Examiners be appointed annually by the several co-operating Medical authorities, on the nomination of a committee called herein "The Committee of Reference," but no member of the Committee of Reference shall be eligible for nomination as an Examiner.

VI.—That a Committee of Reference, to consist of an equal number of representatives of Medicine and of Surgery, be appointed, as follows:—One representative of Medicine, and one representative of Surgery, to be appointed by each of the Universities in England. Four representatives of Medicine to be appointed by the Royal College of Physicians of London. Four representatives of Surgery to be appointed by the Royal College of Surgeons of England.

VII.—That one-fourth of the Committee of Reference go out of office annually, and that after the first four years no retiring member be re-eligible until after the expiration of one year.

VIII.—That the duties of the Committee of Reference be generally as follows:—1. To determine the number of Examiners to be assigned to each subject of examination. 2. To nominate the Examiners for appointment by the several co-operating Medical authorities. 3. To arrange and superintend all matters relating to the examinations, in accordance with regulations approved by the co-operating Medical authorities. 4. To consider such questions in relation to the Examinations as they may think fit, or such as shall be referred to them by any of the co-operating Medical authorities, and to report their proceedings to all the said authorities.

IX.—That there be two or more examinations on Professional subjects, and that the fees of candidates be not less than thirty guineas, to be paid in two or more payments.

X.—That every matriculated student of an English university who shall have completed the curriculum of study required by his university, and shall have passed such an examination or examinations, at his university, as shall comprise the subjects of the primary examination or examinations conducted by the Board, be eligible for admission to the final examination; and that every candidate so admissible to examination be required to pay a fee of five guineas, but he shall not be thereby entitled to the licence of the Royal College of Physicians of London, nor to the diploma of Member of the Royal College of Surgeons of England, without the payment of an additional fee of not less than twenty-five guineas.

XI.—That every candidate who shall have passed the final examination conducted by the Board shall, subject to the By-laws of each Licensing Body, be entitled to receive—The Licence of the Royal College of Physicians of London, and the diploma of Member of the Royal College of Surgeons of England.

(Signed)
GEORGE BURROWS, President of the Royal College of Physicians.
GEORGE BUSK, President of the Royal College of Surgeons.

The remaining correspondence having been read by the REGISTRAR,

Mr. BRADFORD, the representative of the Apothecaries' Society, presented a statement, which, after some discussion, was read. The effect of the statement was that the Apothecaries' Society had been advised that restrictions were attempted to be imposed by the scheme of the Colleges of Physicians and Surgeons, which were unreasonable and illegal; and the Apothecaries' Society therefore protested against the adoption of that scheme.

LETTER FROM THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON.

Apothecaries' Hall, February 29, 1872.

Sir,—The Society of Apothecaries have reason to believe that a draft scheme for an Examining Board for England, prepared by a Committee of the Royal College of Physicians of London and a Committee of the Royal College of Surgeons of England, and approved by the Governing Bodies of those Colleges, will be submitted for the sanction of the General Medical Council.

The Society of Apothecaries having been advised that the conditions and restrictions attempted to be imposed by this scheme are unreasonable and illegal, I am desired to acquaint you, for the information of the General Medical Council, that the Society of Apothecaries, as one of the Examining Bodies of England mentioned in Schedule (A) of the Medical Act, protest against the adoption of such scheme, and respectfully invite the General Medical Council to refuse their sanction to it.

The 15th section of the Medical Act provides that every person then possessed, and every person thereafter becoming possessed, of any one of the qualifications described in Schedule (A) to the Act, shall be entitled to be registered on producing to the Registrar of the Branch Council for England, Scotland, or Ireland the document confirming or evidencing the qualification in respect whereof he seeks to be registered.

By the proposed scheme each of the Colleges pledges itself to abstain from the exercise of its independent privilege of giving admission to the Medical Register—that is to say, the College of Physicians engages to refuse its licence to any candidate who does not pass the examination proposed by the Joint Board, and thereby entitle himself to the diploma of the College of Surgeons as well as the licence of the College of Physicians; and, in like manner, the College of Surgeons engages to refuse its diploma to any candidate who does not pass the examination of the Joint Board, and thereby entitle himself to the licence of the College of Physicians, as well as the diploma of the College of Surgeons.

The Society of Apothecaries are advised that, having regard to the 15th section of the Medical Act, entitling every person to be registered in respect of any one of the qualifications described in Schedule (A), it is contrary to the policy and the expressed intention of the Act for the Colleges

of Physicians and Surgeons to bind each other to abstain from the independent privilege of giving admission to the Medical Register, or to require, as a condition or consequence of examination by a Joint Examining Board, that a candidate shall obtain and pay for both the licence of the College of Physicians and the diploma of the College of Surgeons.

The Society of Apothecaries therefore formally protest against the proposed scheme, on the ground that it would violate the express provisions of the Medical Act, and they respectfully submit that the General Medical Council are bound to withhold their sanction from it.

The draft scheme is prefaced by an allusion to legal difficulties, which it alleges the Society of Apothecaries have stated to prevent that Society taking part in the formation of an Examining Board in this division of the United Kingdom.

This assumption is purely gratuitous. The Society of Apothecaries have never stated the existence of legal difficulties which would prevent their taking part in the formation of an Examining Board.

The opinion which the Society had received from their counsel was frankly read to the Committee of the two Royal Colleges, and this very opinion, while it pointed out the difficulties in the way of the Society's taking part in the particular scheme to which the opinion had reference, suggested means by which those difficulties might, to a great extent, be obviated.

The Society deem it respectful to the General Medical Council to state that, acting upon the invitation of the Council to the Medical Authorities to concert a scheme for the constitution and regulation of a Conjoint Examining Board, the Society cordially co-operated with the Colleges of Physicians and Surgeons for the establishment of such a Board in this division of the kingdom, and so far with success that a draft scheme for an Examining Board, prepared by the Committees of the two Royal Colleges and this Society, received the signatures of the Presidents of the two Colleges and the Master of this Society, and was recommended for the adoption of the Governing Bodies of the three Medical Corporations; but the Council of the Royal College of Surgeons having declined to sanction this scheme, other proposals were made, which have resulted in the present scheme of the College of Physicians and the College of Surgeons.

The Society of Apothecaries desire to add that this latter scheme was decided upon by the two Colleges without communication with the Society, and without any opportunity being afforded to the Society of expressing an opinion upon it.

I have the honour to be, Sir, your most obedient servant,
(Signed) GEORGE KELSON, Master of the Society.

To the President of the General Medical Council.

Letters from the University of Oxford, Pembroke College, Cambridge University College, Durham, and other English Examining Bodies, were read by the Registrar.

A resolution was proposed by Mr. HARGRAVE—"That the documents received from the English Licensing Bodies, as now read, be entered on the Minutes."

Dr. QUAIN seconded the resolution, which was carried.

Sir WILLIAM GULL was desirous of knowing why the Apothecaries' Society could not join in the joint scheme. He also would ask Dr. Storrar if there was not some way by which the University of London might escape from the difficulties they felt in joining the scheme.

Dr. BENNETT moved—"That the Council now proceed to take into consideration the scheme submitted to them by the Conjoint Colleges of London, the Colleges of Physicians and Surgeons commencing the discussion of that by the consideration of the scheme as it is printed in the programme."

Dr. ACLAND seconded the resolution, but suggested that the Council should state its approval or disapproval of the Conjoint Scheme before it proceeded to the consideration of the remaining replies. Clause 9 really empowered any two bodies to unite, as had already been done in Scotland; and it was entirely competent to the Colleges of Physicians and Surgeons to present a Conjoint Scheme for England without consulting any other body. As regards the London University, it appeared that the Secretary of State and law officers of the Crown could not consent to the scheme, although the London University desired to give their consent. He cordially assented to Dr. Bennett's proposal that the Council should express their approval of that which was before them—namely, the scheme of the Colleges of Physicians and Surgeons. The adherence to the scheme of other bodies was no concern of the Council. He should advise that the protest of the Apothecaries' Society be referred to the solicitor of the Council, inasmuch as it was a protest against the legality of their procedure.

The resolution, altered in accordance with Dr. Acland's suggestion, was put as follows:—"That the Council, having considered the Conjoint Scheme of the Royal College of Physicians of London and the Royal College of Surgeons of England, do approve of and give its consent to the same."

Dr. THOMSON was not prepared to enter upon the discussion of the sections until the whole replies were before the Council, and moved as an amendment—"That before proceeding to the consideration of the English scheme the remaining documents which had been laid before the Council be read."

Sir DOMINIC CORRIGAN having seconded the amendment,

Dr. BENNETT withdrew the resolution, and

The remaining communications having been read by the Registrar,

Dr. BENNETT, in moving the original resolution, said he felt it incumbent upon him to allude in the first place to the

amount of time and labour which had been bestowed upon the subject by the two Colleges, who had endeavoured to carry out in the most loyal way the suggestions of the Council. The scheme had been prepared in the face of very great difficulties. A communication having been received from the legal adviser of the Apothecaries' Society that there were difficulties in the way of their joining in the scheme, the Colleges had proceeded to carry out their scheme independent of the Apothecaries' Society, the object being the formation of such a board as should give a thoroughly efficient examination, and prevent anyone coming upon the Registry by means of the simple licence of either College. It was felt that if a satisfactory scheme could be drawn up there was a prospect of other bodies joining in it. The scheme was submitted to the highest legal authority. The opinions of Sir Roundell Palmer, Mr. Denman, and others were taken upon it—among other things upon the subject of the possible difficulty with the Apothecaries' Company—and their opinion was that it was perfectly competent to the Colleges to do what the scheme professed to do irrespective of the Apothecaries' Society altogether. Dr. Bennett then proceeded to illustrate the working of the proposed scheme. The Colleges asked the sanction of the Council to the scheme, in order at once to prepare the necessary details for bringing the Conjoint Boards into immediate action. They were anxious, if possible, to do so before the commencement of the next session. Any suggestions which the Council had to offer would be entertained; but at the same time it must be remembered that this complete scheme came before them after enormous difficulties had been overcome, and that any suggestions involving material alterations would in all probability involve the throwing it back for an indefinite period, and possibly of defeating it altogether. He did not see how the Apothecaries' Society could possibly be brought to concur in the scheme, there being so many difficulties in the way.

Dr. ACLAND seconded the resolution.

Dr. ANDREW WOOD gave his distinct approval to the scheme as a scheme for the co-operation of the two Colleges, but he demurred to its being called a scheme for an Examining Board for England. There had been an endeavour to form a Conjoint Board for England, which should include everybody. The way in which the proposed scheme got over the difficulty was by leaving out a most important body—the Society of Apothecaries. The present scheme, therefore, was not a complete scheme for England. If the Council agreed to sanction the proposed scheme, he thought no slur should be thrown upon the Irish and Scotch Boards if they did not succeed in forming a satisfactory scheme, seeing that in England the difficulty had been got rid of by leaving out the Society of Apothecaries of London. Now, what were the legal difficulties referred to? They seemed to be that the Colleges of Physicians and Surgeons had been unwilling to consent to some arrangements proposed by the Apothecaries' Society. He would call their attention to what had been done in Ireland, which would show that the difficulties were not insurmountable. It seemed to him that in Ireland the subject had been grappled with in the most manly way. He must confess that, notwithstanding all his sanguine expectations that the scheme might be carried out by mutual concession, he had come to the conclusion that it could not be carried out in that degree which would give it any effect, or would benefit the Profession and the public, unless it was done by Medical legislation.

Sir DOMINIC CORRIGAN gave his hearty co-operation to the scheme. The objection had been made that all the bodies had not joined; but it had not been the fault of the Colleges of Physicians and Surgeons. He, however, did not think the resolution grappled with the great question before them—namely, that the various bodies should unite and form a Conjoint Examining Board.

Dr. ALEXANDER WOOD called the attention of the Council to the resolution passed at the meeting of July 10, 1871—"That in case the arrangements for Conjoint Examining Boards are not completed in each division of the kingdom by the close of the year, in accordance with the recommendations of the Council on the subject, the Executive Committee should be authorised to seek an interview with the Lord President of the Privy Council, and to urge upon him the desirability of Medical legislation on the subject of Conjoint Examining Boards in the session of 1872;" and to the amendment which he himself had moved—"That a meeting of the Medical Council be held early in 1872 to receive the proposals of the Bodies for Conjoint Examinations, and to consider whether any and what steps should be taken to carry out the resolutions of the Council." He submitted that there was not before them the shadow of a scheme for three Conjoint Examining Boards for each division

of the kingdom. It was little more than the scheme which the College of Surgeons of Edinburgh and the Faculty of Surgeons and Physicians of Glasgow had submitted in the second year of the existence of the Council which received its sanction. If the Council passed the resolution of Dr. Bennett, they were scarcely a single step nearer the desired consummation than they were at this time last year. He did not suppose the Apothecaries' Society would suffer itself to be extinguished quietly, but anticipated that they would continue to give licences. He hoped there would be no opposition to Dr. Bennett's motion; but it should be distinctly understood that no such scheme was submitted to the Council as had been intended.

Dr. PARKES would also support Dr. Bennett's motion. He thought that it was a very small portion of what the Council had proposed. It was of very great importance that the Council should make it a truly Conjoint Board for the whole of England, and that could only be done by taking in the Apothecaries' Society. He would ask the representative whether there was any really insuperable objection to their joining in the scheme, and if not, he would propose to add this clause to the resolution—"In approving of this Conjoint Scheme, the Council desires to express its opinion that if the legal difficulties could be overcome, the Society of Apothecaries in London should be admitted to a share of the examination."

Mr. BRADFORD thought it right that it should not go forth that the Society of Apothecaries had been the means of defeating the Conjoint Scheme. He utterly denied that such was the fact. To the scheme as originally proposed the Society saw little objection, but a new scheme was suggested to which they were constrained to object. The Society of Apothecaries did not break off the negotiations, but there were certain difficulties pointed out by their legal adviser which were necessary to be considered. No opportunity of discussing these difficulties was afforded by the Royal Colleges. The conference was adjourned *sine die*, and from that day to the present the Society has received no official communication except a printed draft copy of the scheme now before the Council. They had not been invited to co-operate or to take any part in it. Their difficulties had been these: In the first place, they were bound by the stringent conditions of an Act of Parliament. The difficulty arising from the condition of apprenticeship imposed by the Act of 1815 was, they were advised, very grave. The next difficulty was the question of the fee; the Act restricted the fee for the licence to practise as an apothecary (in the country) to six guineas, and they were advised that a larger fee could not be exacted from a candidate who sought their licence *alone*, and who could pass the necessary examination. Mr. Bradford disputed that the two Colleges had power to bind themselves to refuse an examination in Surgery alone to one of the Society's licentiates unless he were willing to undergo the examination of the proposed Conjoint Board, and to pay the fee of thirty guineas. The 15th section of the Act of 1858 distinctly enacted that every person who possessed one of the qualifications set forth in Schedule (A) was entitled to be registered. The Society of Apothecaries were quite willing to co-operate with the other Medical authorities in forming a Conjoint Scheme for this division of the kingdom. Was there a better qualified Practitioner than one who held the licence of the Society of Apothecaries, together with the diploma of the Royal College of Surgeons. During a great number of years, those students who obtained the certificate of the Society had to the extent of 85 per cent. become Fellows or Members of the Royal College of Surgeons. What reason could be shown, or how was it consistent with public feeling, that this connexion should cease?

Dr. QUAIN, having been engaged a great deal in endeavouring to form a Conjoint Scheme, thought he ought to say that their endeavour had been as far as possible loyally and conscientiously to carry out the resolution of the Council, and they had succeeded so far that they had got the entire co-operation of all the bodies in England but one. It was not the fact that the Colleges had thrown over the Society of Apothecaries. The scheme which was agreed to originally was simply a scheme for the examination of general Practitioners. It was not a Conjoint Scheme, and it was a scheme which the College of Surgeons were not favourable to. The scheme was then put into the present form. The Apothecaries' Society raised several difficulties; they said it was a thing they could not join in; they withdrew, and of course afterwards no communication was made to them. It was for them to remove the difficulties.

Mr. BRADFORD was understood to dissent from Dr. Quain's statement.

Dr. QUAIN repeated that that was the true position of matters. The possibility of the carrying out of the scheme had been assailed on the ground of its illegality, but Dr. Bennett had told them that the most eminent legal advisers had distinctly stated it could be carried out. If the Apothecaries' Society were willing to co-operate, the College of Physicians would be only too glad.

Dr. ANDREW WOOD suggested that another effort should be made to include the Society of Apothecaries.

Dr. HUMPHRY thought justice had scarcely been done to the completeness of the scheme. It was a complete scheme as far as English Corporate Bodies could produce; and he thought if the Corporate Bodies beyond the border and on the other side of the Channel had done as much, the difficulty would have been very much reduced. He bore testimony to the general correctness of what Dr. Quain had said with reference to the Apothecaries' Society.

Mr. BRADFORD regretted very much that there should be a misunderstanding as to the cause of their retiring from the conference. The President of the College of Physicians declared the meeting closed, much to the surprise of the Apothecaries' Society, who expected that a discussion would have arisen as to the nature of the legal objections. The legal adviser of the Society had drawn up a formal opinion, and had raised the objections which had been stated; but there was nothing insuperable in those objections, nor did he (Mr. Bradford) ever suppose it was impossible to form a Conjoint Board.

Dr. STORRAR, as representing the University of London, felt he could hardly give a silent vote. He reminded the Council of the active part the University of London had taken in promoting this combination. He most heartily congratulated the Colleges of Physicians and Surgeons on the attitude they had taken, and desired to assist them in any way he could in making their Conjoint Scheme workable. The legal difficulties of the University of London had nothing to do with their approval of the scheme. It would, no doubt, be the fact that every single Medical graduate of the University of London would appear before the Conjoint Board. At any rate, whether the University of London was included or not, he felt they had public spirit enough amongst them to recognise the principle as a sound one, and to support it. He held the Apothecaries' Society in very great respect for the work they had done. They occupied an important place in the Medical education of the country, and he confessed it was with a pang that he saw the probability of their being extinguished. He did not think that the legal difficulties should stand in the way to what was proposed to be done; but most unquestionably the University of London, with all its respect for the Apothecaries' Society, could not refuse to come into the scheme upon the ground that the Apothecaries' Society was excluded.

Dr. THOMSON wished to move an amendment, with the view of conciliation—"That the Council approves generally of the Scheme for a Conjoint Examining Board for England proposed by the Royal College of Physicians of London and the Royal College of Surgeons of England, so far as it goes, but that the Council is of opinion that further exertion should be made to include all the Licensing Bodies in the scheme."

It being now six o'clock, the consideration of the resolution was postponed to the following day.

SECOND DAY.—FRIDAY, MARCH 1.

Dr. PAGET, President, in the Chair.

At the commencement of business the standing orders were suspended, to enable the Council to give priority to the consideration of the case of a student accused of forging a certificate. During the discussion on this subject the representatives of the press were excluded. On their readmission,

Dr. BENNETT proposed—"That the Registrar be directed to write to the solicitor, authorising him to take the necessary steps to prosecute the student alleged to be guilty of forging a certificate of having passed his preliminary examination at the Society of Apothecaries, by which he obtained admission on the Students' Register."

The motion was seconded by Dr. A. SMITH, and agreed to.

The adjourned debate on Dr. Bennett's motion was then resumed.

Dr. THOMSON, in moving his amendment, said he was far from wishing to delay the scheme proposed, or to modify the general expression of approval which the great majority of the Council seemed disposed to give to it. On the contrary, he was prepared to give it his approbation in no stinted terms, so far as it went. Still, under the circumstances in which they had been brought together, he thought it was not right that at this stage of the proceedings any expression of opinion

should go forth from the Council which would be an unqualified approval of a scheme which was defective in that it did not include the whole of the Bodies belonging to the English section. He had no wish to diminish by anything he said the approval which many would give to the scheme, but rather desired that the Council should look at it as part of a whole, and not merely at the benefits which this scheme undoubtedly would confer upon the Profession and the public if faithfully carried out. The Council was about to consider in what manner Joint Examining Boards might be constituted for each division of the country, for it was this question which was remitted to the different sections to consider. The Council was not yet sufficiently informed upon all the circumstances which had prevented the Apothecaries' Company from being included in the scheme, and the London University had not yet given its adhesion. He therefore desiderated much fuller information upon the reasons for expecting that the London University would join in the scheme. He made his amendment in no adverse spirit, but simply because he thought it essential to a right and just expression of the opinion of the Council that it should consider the scheme proposed only as part of a general scheme. At the same time he was quite prepared to modify the expressions in his amendment in any way that might gain the general approval of the Council. For instance, he had used the word "generally," because he conceived that, good as the scheme was, it might before long be subject to some changes; but he did not care whether the word was retained or not. In communication with several members of the Council, he found that it would be possible to alter the form of his amendment, so as to secure for it a much more general approval and remove the objections that some had felt to it. If, therefore, the Council would permit him, he would withdraw his amendment and substitute for it the following:—"That the Council approve of the Conjoint Scheme of Examination submitted by the Royal College of Physicians of London and the Royal College of Surgeons of England, to which the Universities of Oxford, Cambridge, and Durham have given their adhesion; the Council has at the same time to express the desire that means may be found by which the University of London and the Apothecaries' Society may be enabled to join in the scheme so as to render it a complete scheme for a Conjoint Board for England."

This substitution was permitted by the Council, and the new amendment was seconded by Dr. PARKES.

The PRESIDENT said he did not quite see what Dr. Thomson intended to convey by his amendment. Did he mean to give the formal sanction of the Council to the scheme, or merely to express approval of it and wait till the next meeting of the Council to confirm it?

Dr. THOMSON said he saw the force of the President's objection, and would be willing to insert the words "and sanction" after the words "approve of."

Mr. QUAIN drew attention to the following paragraph in the letter of the Apothecaries' Society to the Council:—"The Society of Apothecaries are advised that, having regard to the 15th section of the Medical Act, entitling every person to be registered in respect of any *one* of the qualifications described in Schedule (A), it is contrary to the policy and the expressed intention of the Act, for the Colleges of Physicians and Surgeons to bind each other to abstain from the independent privilege of giving admission to the Medical Register. If this were correct he apprehended that all the Council had been doing, in trying to form a single board for each division of the Kingdom, would be useless, as contrary to the spirit of the Act. In another part of the letter it was said that it was a "purely gratuitous assumption" to allege that the Society of Apothecaries had stated legal difficulties "to prevent that Society taking part in the formation of an Examining Board in this division of the United Kingdom." He would in reply to this read a memorandum which had been made of what took place in October last when the Society of Apothecaries seceded from the other two Corporations:—"At a meeting at the College of Physicians, Mr. Upton (the legal adviser of the Society of Apothecaries) read an opinion by Mr. Archibald in reference to the legal powers of the Society of Apothecaries to take part in the Conjoint Scheme, and the result of that opinion was that there were three objections to the scheme, which rendered it legally impossible for the Society to join in it. These objections were as follows: 1. That the apprenticeship required by the Apothecaries' Act could not be set aside. 2. That the Society could not enforce an examination in Surgery in the case of candidates for its licence. 3. That the Society could not compel the payment of the proposed increased fee. As regards the first of these three objections, Mr.

Upton stated that means might be devised to get over it, but not so in the case of the other two. After this statement the President of the College of Physicians, who was in the chair at the meeting, suggested, that as the legal difficulties of the Society of Apothecaries were insuperable, it was useless to try to continue the negotiations with that body. The representatives of the Society of Apothecaries agreeing with the President's remark, retired from the meeting, and the committee of the two Colleges then continued their negotiations for the scheme." This was a fair explanation of the retirement of the Apothecaries' Society. In another part of their letter the Society stated—"The Society deem it respectful to the General Medical Council to state that, acting upon the invitation of the Council to the Medical Authorities to concert a scheme for the constitution and regulation of a Conjoint Examining Board, the Society cordially co-operated with the Colleges of Physicians and Surgeons for the establishment of such a Board in this division of the kingdom, and so far with success that a draft scheme for an Examining Board, prepared by the committees of the two Royal Colleges and this Society, received the signatures of the Presidents of the two Colleges and the Master of this Society, and was recommended for the adoption of the governing bodies of the three Medical Corporations; but the Council of the Royal College of Surgeons having declined to sanction this scheme, other proposals were made, which have resulted in the present scheme of the College of Physicians and the College of Surgeons." It would be interesting to know what the actual facts were in regard to this. A draft scheme was agreed upon by committees of the three bodies, but it had reference only to the formation of a board for the examination of general Practitioners, and in it the Universities were wholly excluded. In the College of Surgeons, therefore, a resolution was come to that it was not expedient to agree to a scheme which omitted altogether the Universities. That was the reason why that draft scheme came to an end. There was also a difficulty about the constitution of the Examining Board. It was proposed that the three Corporations should appoint the examiners, but the Society of Apothecaries continually referred to what they must do in appointing examiners. The Committee of Reference in its present form was not then decided upon. It was, however, under discussion long before, when the Syndicates of the Society were present; and Mr. Upton, on their behalf, stated that the Society could not legally agree to such a committee, and, as a matter of feeling, would not do so if no legal difficulties stood in the way. There was a clause in the Apothecaries' Act of 1815 which required that every member of the Board of Examiners should be a member of the Society of not less than ten years' standing, and that was always a difficulty in the way of the Society of Apothecaries. They felt bound by this clause to require that the examiners in Medicine should be persons who had been members of the Society for at least ten years. Of course it could not be expected that the Universities would agree that their graduates should be examined in Medicine by any Examining Board when the selection was confined to certain persons—not because they were the best men in the country, but because they had been Members of the Apothecaries' Society ten years. Objections had been taken to the scheme by some members of the Council, on the ground that it was simply a union of two Corporations. If they could show in Scotland a union of two Corporations with all the Universities but one, and that one to come in as soon as the law would permit, he should be delighted to see it. In conclusion he expressed a hope that they would not go to the Government or to Parliament, but would have energy and firmness enough to carry the matter themselves. (Hear, hear.) When the Act of 1845 was passed there was then a strong Ministry (Sir Robert Peel's), and the Minister for the Home Department, who had charge of the scheme, was a strong man, in a Parliamentary sense (Sir James Graham). It was that Government which created the nineteen competing bodies, and placed the Profession in the difficulty in which they now found themselves. He would not, therefore, go back to the Government if he could help it to get rid of the difficulties which they had created. He would rather attempt to do it among themselves. They understood the subject, and the Government certainly did not. Neither would it be expedient just now to go to the noble lord at the head of the Privy Council. They would be very bad patriots indeed if they did anything to divert that nobleman's attention to Medical politics and away from the *Alabama* claims. (Laughter.)

Dr. ALEXANDER WOOD: I did not propose that.

Mr. QUAIN: But you read a paper to that effect.

Dr. ALEXANDER WOOD: That resolution was moved at the last meeting of the Council, and I moved an amendment upon

it, which was carried, and under which we have met here to-day.

Dr. BENNETT said he could quite confirm what Mr. Quain had said with reference to the Apothecaries' Company. He had the highest opinion of the gentleman who legally advised the Society; but he was at a loss to understand how they could have inserted in their letter the statements to which Mr. Quain had drawn attention. The objections raised by the Apothecaries' Company to the revised draft scheme necessarily obtained to the scheme now before the Council. With reference to that revised draft scheme, Mr. Upton pulled from his pocket the written opinion of counsel applied to by them with reference to the possibility of the Apothecaries' Society joining in that scheme, and the opinion was to the effect that there were legal difficulties in the way. These difficulties appeared to them to be insuperable. The President thereupon said, "It is quite clear that we need not discuss this matter further," and the conference broke up. The College of Physicians and the College of Surgeons then took up the scheme on their own account, and completed it in the form in which it was now brought before the Council. When Dr. Alexander Wood spoke somewhat contemptuously of the scheme as a small matter, he really could not have understood it. For the first time they had a junction of two bodies who agreed to give up their power of conferring a right to be placed on the Register; for the first time they had a scheme in which the Universities were capable of joining, and to which they had already received the adhesion of several Universities. Had anything at all proportionate to this been done in Scotland or in Ireland? There had not even been an approach to it. For the first time they had a scheme which rendered it imperative on every man whose name was placed on the register of the agreeing bodies to have been examined on all subjects; and for the first time they had a scheme in which the Board of Examiners was constituted, not necessarily of the Fellows or Members of the Colleges that were united. The Colleges and Universities united in this scheme had unanimously manifested a spirit of self-sacrifice which he had not yet seen on the other side of the border. They had voluntarily agreed to give up their rights as far as regards the Register and the Board of Examination, and they appointed a Committee who were to nominate the examiners, and through whom all the details of the examinations would be carried out. He therefore held that if the scheme should end in nothing but the amalgamation of the two bodies they would still have gone an enormous step in advance in the way in which the Medical Council were desirous they should go towards securing a uniformity of examination. Even in the event of none of the Universities nor the Apothecaries' Society joining, they would have a scheme which would certainly deal with a very large majority of the Practitioners in England. Ninety-eight or ninety-nine per cent. of the candidates would come before the Conjoint Board; therefore, however much in appearance they might seem to have failed to carry out a conjoint scheme for England, in reality they had gone a great way towards it. For these reasons he hoped that the Council would not hesitate to give their sanction to the scheme, quite apart from the question of introducing others, simply on the basis of its being a step in advance, and not a short or trifling step, but a great and important one. He was of opinion that the only way in which their friends, either in Scotland or Ireland, would eventually succeed, would be by doing something of the same sort. They would have to be contented with making gradual advances, and then by-and-bye they would be able to extend their basis and bring in body after body as facilities for doing so offered themselves. Thus ultimately complete schemes for the three kingdoms would be formed. No doubt the difficulties in Ireland and Scotland were very great, and he did not blame them for not having succeeded, but he did blame some of them for not having sent in notice of what they had done in a more formal manner. In the English scheme, if carefully looked at, it would be seen that there were all the elements of such a Board as the Council had long been looking for. The Committee of Reference, it was true, was not appointed by Government, but they would be appointed irrespective of the peculiar prejudices or proclivities of one or the other Board. The examiners would, no doubt, be selected from the best men that could be found in the kingdom, and the licences would be granted simply from the result of the examination. This scheme, then, ought rightly to come before the Council as a Joint Scheme for England, although at present it would not be said that they were prepared to put it in operation as a complete scheme for the whole of England. If the general feeling of the Council was that he should facilitate their proceedings by withdrawing his resolution, and allowing Dr.

Thomson's amendment to stand as a substantive resolution, he was disposed to do so. Still he did not approve of tacking on to the end of the resolution the reference to the Apothecaries' Society and the University of London.

The PRESIDENT stated that he had received a letter from Sir R. Christison, the only absent member of the Council, dealing with the whole subject of Conjoint Boards.

Dr. Thomson's amendment was carried by 14 against 3. On its being put as a substantive motion,

Sir D. CORRIGAN moved, as an amendment—"That the Council, under the powers conferred upon it by Clause 19 of the Medical Act, approve the Conjoint Scheme of the Royal College of Physicians of London, and the Royal College of Surgeons of England, for an Examining Board."

Dr. A. SMITH seconded the amendment.

Dr. PARKES objected that the amendment was the same in effect as the original resolution.

The PRESIDENT: It is a competent amendment on what is now the motion before the chair.

Dr. ARJOHN: I wish to ask Dr. Bennett to explain how far the Universities are co-operating in this scheme.

Dr. BENNETT: You have the replies of the Universities.

Dr. ARJOHN said he had read the whole scheme from beginning to end, and found nothing of co-operation on the part of the Universities.

Sir D. CORRIGAN said in the resolution now before the Council there was a statement that the Universities had given their adhesion to the scheme, but the fact really was that they had not given their adhesion to it. The words they used were that they approved the scheme. He might approve of the formation of a joint-stock company, but it did not follow that he would join it and take shares. There was not a single word from the Universities stating that they would unite and become parties to the scheme, and give up their privileges as the College of Physicians and the College of Surgeons had done. The College of Physicians and the College of Surgeons gave up their privileges of conferring separate diplomas without a separate examination; was there a single word about the Universities doing so? He regretted in the beginning, and he still regretted, that the Apothecary question should have been introduced at all. It had no connexion with the subject on the paper. A private squabble between two Licensing Bodies had been brought before the Council, and had occupied their time the greater portion of two days. If three or four Bodies met in accordance with the suggestion of the Council last year, but did not agree upon a joint scheme, it was no business of the Council to go into the private squabbles of the disagreeing Bodies. Clause 19 of the Medical Act was perfectly clear and distinct: "Any two or more of the Colleges and Bodies in the United Kingdom mentioned in Schedule (A) to this Act may, with the sanction and under the directions of the General Council, unite or co-operate in conducting the examinations required for qualifications to be registered under this Act." It authorised any two or more Bodies to unite; but when two Bodies came before the Council and said, "We have taken a step in a right direction," while another Body came and said, "We are badly treated—we have been kept out," the Council ought never to have listened to the squabble, and never have allowed recriminating explanations. Suppose that the College of Surgeons of Ireland and the Apothecaries' Hall of Dublin united to issue joint certificates, what right would the College of Physicians have to interfere? None whatever. It was the concern of the two Bodies under Clause 19. Suppose, on the other hand, the College of Surgeons and the College of Physicians of Ireland were to choose to unite for the purpose of issuing a joint certificate, and the Apothecaries' Hall and Dublin University were to come forward and say—"We were badly treated; we had a right to come in," the Council would have no business to meddle with them. On turning to Scotland, when the case was before the Council of the College of Physicians and the College of Surgeons for a joint scheme, suppose the Faculty of Physicians and Surgeons of Glasgow had come before us and said—"We were badly treated;" suppose the University of Aberdeen had said the same, and the University of St. Andrews as well; if the Council departed from what was laid down in Clause 19, they would simply become umpires in private squabbles, the end of which no one could see. They had seen yesterday that representatives of the two Bodies might differ as to the meaning of papers.

The PRESIDENT: Don't you think you are making the matter much worse by dwelling longer upon it?

Dr. QUAIN: We were answering the request of the Medical Council to co-operate together, and an explanation was given

why we did not all co-operate, and that was the reason of this discussion.

Sir D. CORRIGAN said his point was that the Council ought not to have devoted a moment of time to that explanation. One phrase in the resolution was very vague. The Council was asked to express its desire "that means may be found" by which the Apothecaries' Society and the University of London might be enabled to join. By whom were these means to be found? Were they to be found by the Council? Were they to send the matter back for those Bodies to squabble over again? What they ought to do was to put aside the Apothecaries' Society and the London University, and simply ask themselves—"Is the application of those two Bodies, the College of Physicians and the College of Surgeons, in accordance with the Act of Parliament?" The application was within that Act, and the Council had no right to go into any extraneous subject, but simply to deal with it as an independent matter before them.

Dr. THOMSON said he could see that there was an inaccuracy in the resolution, and as it was important that motions put before the Council should be accurate as to matters of fact, he wished to substitute the word "approval" for the word "adhesion." (No, no.)

Dr. A. SMITH, in seconding the amendment, said it had been clearly shown that but a very slight approach had been made towards establishing a Conjoint Board such as had been contemplated by the Council, and Sir D. Corrigan's amendment expressed exactly what had been done, and no more.

Dr. ACLAND thought it would be hardly right for the Council to come to a decision without hearing something from the representatives of the Universities. It had been stated that some of the Universities had given their adhesion to the scheme, and, in fact, were about to join in it. He absolutely repudiated any interpretation of that kind; such an idea never entered into the heads of his University, at all events; and no person in the least conversant with the way in which public business was transacted at Oxford would entertain the idea. No one could be responsible for the votes of a great body like the convocation of a University consisting of hundreds and thousands of persons, any more than the Government could be responsible for the votes of the House of Commons. It was a question of numbers. He could not prophesy what would be carried, but as to the way in which they came to their conclusions there was no question at all. When a proposition was submitted to them there was one thing perfectly certain—that they would vote *bonâ fide* upon a *bonâ fide* proposition; and any proposition would be certain to be lost about which there was the slightest supposition of any undercurrent or *arrière pensée*. What had happened at Oxford was this—they had voted that they entirely approved of, and consented to, this scheme; but, in order to make it possible for them to act upon that scheme, they must alter their statute. At the present time their examinations took place under certain laws, and next November the examination would proceed just as it did last year, unless the statute was altered; and if the Council voted the resolution to-day, the Oxford University would begin at once—in fact, they began long ago—to consider what would be their duty to the nation in the then altered condition of the University. Those who were not familiar with the conduct of the English Universities might not perhaps observe what would follow this Conjoint Scheme, and the discussion which had taken place had not yet reached the real, essential merits of the case. It was quite a misapprehension if any member supposed for a moment that this scheme was simply a scheme of the College of Surgeons and the College of Physicians. It was the scheme of all the English Bodies, except the Apothecaries' Hall. What would happen if the scheme was carried out? The University of Oxford would cease to confer degrees upon a pass examination, and would leave to the Medical Council the pass examination of all those who had an Oxford education. That was the way in which the University had always looked upon it, and in a certain sense the change would be enormous. Directly they bound themselves to this change they would have to consider what should be the nature of the University honours in respect to Medicine. It seemed to him that considerations of this kind were of much more significance than any of the arguments that had been addressed to the Council with regard to the amount of allegiance given to the scheme. The London University, he believed, had virtually in a certain sense acted on this principle from the time of its foundation. It had always taken the view that the University degree was a kind of honours degree, and to a certain extent that was the view which had been taken at Oxford for the past ten years. It was only because it was seen that it had been impossible for the

College of Physicians and the College of Surgeons to draw out the scheme before that the Oxford University had not refused to approve of it, on the ground that they had not had sufficient time to consider it.

Dr. HUMPHREY said it was clear from the reports sent to the Council that the Universities were co-operating in the scheme, and it was perfectly certain that the University of Cambridge was acting *bonâ fide* in the matter. The authorities at that University had considered the question in all its various stages, entered most carefully into every point, and made several suggestions which had been adopted. It was therefore not a scheme emanating simply from the College of Physicians and College of Surgeons, but it had emanated from the various Universities in connexion with the Colleges. The University of Cambridge was quite aware that in assenting to it, it would give up its privilege of admitting to the Medical Register. This had not only been the subject of consideration in the Syndicate, but it had been discussed openly in the Senate, and it was quite clear that if the scheme was carried out the University would henceforth not give its degree except to those who passed the Joint Board.

Dr. EMBLETON said the adhesion of the University of Durham to the scheme was complete and *bonâ fide*, and in every respect the same as the adhesion of the Universities of Oxford and Cambridge. It was not a mere approval, but an adhesion.

Sir W. GULL, on behalf of the University of London, said that for the last twenty years they had had before them the question as to how far the University could confer degrees that might be useful for practice in the country. They had set before them this great object—to show how Medicine should be studied, and to advance the study of Medicine in every possible direction. They had all felt that the object of the University was not at all contrary to the universal scheme of registration, but as a part of it, and as going before it; and they had been most desirous on all points to give their sanction to this scheme for one Examining Board. He therefore trusted that without any delay the Council would give their adhesion to the scheme brought before them. It was a very much larger scheme than those not acquainted with the practice of Medicine in England were at all alive to. It was the very largest scheme that could be brought forward as affecting the Profession, whether in England, Scotland, or Ireland, and he therefore hoped that they would at once approve of it.

Dr. ALEXANDER WOOD said Sir Dominic Corrigan had artfully (not using the word in a bad sense) directed the attention of the Council away from the main question before them, and if they were to agree to his proposal they would place themselves in a very awkward position; for they would be simply giving their consent to a scheme of junction proposed by two Colleges in London. No such question ought to be brought before them, for as far as he knew there was no request on the part of those Colleges to have the sanction of the Council to any contemplated union whatever. They would therefore be going beyond their functions to exercise the powers given them by Clause 19 of the Medical Act. The Council had requested certain Bodies to do certain things. In compliance with that request, certain answers had been laid on the table by the various Bodies in England, Scotland, and Ireland; and they were now required to express an opinion upon those answers—not to sanction the propositions which they contained under Clause 19, but to say how far they had fulfilled the request which was sent to them at the close of the session of last year. Taking this view of the matter, he was disposed to think that Dr. Thomson's motion was a perfectly legitimate one. They were entitled to say in what respects they thought the Bodies to whom they applied had succeeded, and in what respects they thought they had failed. He did not undervalue in the least the scheme which had been submitted to them. No one could do so who had watched the progress of the different Medical Bodies in England and knew the difficulties that had been overcome. He had the fullest sense of what had been done, and felt grateful to those by whose exertions it had been accomplished; but at the same time he thought it was right that they should express their regret that the scheme did not go still further. Of actual fact accomplished, there was nothing beyond the union of the College of Surgeons and the College of Physicians, with the adhesion of the Universities when they should get the law altered. It had been thrown out as an objection against the Scotch Bodies that their union made it optional with a man either to come before the united board or the separate board. He wished to tell his friends in London that they had yet to know whether the law would enable them to dispense with the power conferred upon their Colleges by Royal charter. He believed at the present moment, if the

College of Physicians of Edinburgh or the College of Surgeons of Edinburgh were to refuse to take a man upon trial who demanded to be taken upon trial, that there were legal forms which could be used for their compulsion, and that they could be made to follow out their charter, and take the man upon trial by their separate Colleges. Therefore, having a wholesome horror of law, they had avoided doing that which might expose them to the pains and penalties of law. Still they had done their utmost to discourage the separate system and to make the joint system the general one. Ten years hence he should like to hear whether the London Bodies had not found out that they had made a mistake in attempting to make that compulsory which the law in its present state would not allow to be made compulsory.

Mr. BRADFORD: We understand from our legal advisers that these Bodies will not be competent to refuse to examine separately.

Dr. QUAIN: The College of Physicians and the College of Surgeons have taken the utmost pains to ascertain the legality of their proceedings, and they will refuse nobody, but the examination will be before such a Board as they appoint, and that will be the Conjoint Board.

Sir Dominic Corrigan's amendment was put to the Council and negatived, 7 voting in its favour, and 14 against.

Dr. Thomson's motion was then agreed to *nem. con.*

The following communication was then read from the Commissioners in Lunacy:—

Office of Commissioners in Lunacy, 19, Whitehall-place, S.W.
August 2, 1871.

Sir,—The Commissioners in Lunacy have recently had occasion to make inquiry respecting the validity of a Medical certificate for the admission of a patient into a licensed house in the county of Sussex, which was signed by a Dr. J. D. Blake, of Taunton.

In reply to the inquiries made by the Board, Dr. Blake had stated that he is not duly registered as required by the 16th section of the 21 and 22, cap. 90, and the Board now submit the matter for the consideration of the Medical Council, with a view to their considering what proceedings, if any, they may feel it their duty to take in the case.

The Board beg to point out that, by means of the certificate signed by Dr. Blake, a private female patient has been for several days illegally placed under confinement.

After a short discussion, the following motion was moved by Sir D. CORRIGAN, seconded by Dr. A. SMITH, and agreed to—
“That in reply to the letter of the Secretary to the Commissioners in Lunacy, dated August 2, 1871, the attention of the Commissioners be drawn to Clause 38 and Clause 40 of the Medical Act (1858), under which it is declared that no certificate required by any Act now in force shall be valid unless the person signing the same be registered under that Act, and that any person who shall wilfully and falsely pretend to be, take, or use the name and title of a Physician, etc., shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds.”

Dr. GULL, referring to the letter received from Sir R. Christison, proposed that it should be put on the programme for the next day.

Sir D. CORRIGAN said it would be setting a very dangerous precedent to print a letter from a member of the Council on the programme.

The PRESIDENT suggested that it might be printed in a separate form and sent round with the programme.

This suggestion was agreed to, and the Council adjourned.

THIRD DAY.—SATURDAY, MARCH 2.

The following communication from the King and Queen's College of Physicians in Ireland was taken as read, and ordered to be entered on the Minutes:—

King and Queen's College of Physicians in Ireland,
Dublin, February 28, 1872.

Sir,—I am directed by the President of the College of Physicians to inform you that this College, after a very careful consideration of the Report of the Conference, recently convened by the Royal College of Surgeons on the question of the advisability of forming a Conjoint Examining Board in Ireland, has arrived at the conclusion entertained in the resolution, thirty copies of which I have the honour of forwarding to you for the use of the General Medical Council.

I have the honour to be, Sir,
Your obedient Servant,
(Signed) J. MAGEE FINNY,
Fellow and Registrar.

The Registrar, General Medical Council.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Resolution of the College of Physicians of February 24, 1872.

“The College, having considered the report on the subject of a Conjoint Examining Board, prepared at a conference of representatives of the several Medical Corporations of Ireland, is of opinion that there should be established an Examining Board or Boards, before which all candidates should present themselves who desire to be placed on the ‘Medical Register’ as qualified to hold public appointments, or as being legally entitled to practise Medicine or Surgery.

“The College is, however, not prepared at present to say in what manner

such Examining Board or Boards should be appointed, or what should be the extent of the powers of such Board or Boards; whether confined to Professional subjects, or embracing examination in Arts and Sciences.

“The College has, however, no hesitation in expressing its opinion that any Central or Conjoint Board or Boards should have no concern whatever with the details of education, which should be left, as at present, to the several Licensing Bodies to arrange as they see fit, according to their own requirements and local adaptations.”

A communication from Medical Professors in Scotland regarding Conjoint Examinations was also taken as read, and ordered to be entered on the Minutes.

225, St. Vincent-street, Glasgow,
February 29, 1872.

Dear Sir,—I send you herewith a document for presentation to the Medical Council at whatever you may consider the proper time, and to facilitate the reading of it I send thirty copies, which may be used for distribution among the members of Council.

It is likely that a similar document may reach you from Edinburgh, and perhaps one or two from other places, which may be considered identical for practical purposes, although we have not had time to send them together.

I am, yours truly,
(Signed) W. T. GAIRDNER.

Dr. F. Hawkins.

The undersigned having been informed of the recent proceedings on the part of the Universities and Corporations in Scotland, with a view to the formation of a Conjoint Board of Examination at the instance of the Medical Council, feel bound to indicate their dissent from these proceedings on the following grounds:—

1. The reason alleged for such proceedings in the first instance—viz., the attainment of “uniformity of qualification” (i.e., a fixed minimum of Medical knowledge and skill on the part of candidates, secured through examinations conducted upon a precisely similar plan by examiners making precisely similar requirements)—appears to the undersigned an object neither desirable nor attainable.

2. Even were the object in question a desirable one, it evidently cannot be secured by the measures proposed. It is inconceivable that one Board sitting in England, another in Scotland, and a third in Ireland, each Board being of very complex constitution, and holding examinations in different places, without any concert or intercommunication, could possibly secure “uniformity” in any real sense of the word.

3. The immense number of candidates which would have to be examined in each division of the kingdom by the Conjoint Boards, would make it absolutely necessary either greatly to enlarge the number of examiners and to subdivide them into companies (of course with a still further loss of “uniformity” as regards results), or to work one set of examiners continuously day after day for long periods, with the practical effect of reducing their operations to a wearisome routine, incompatible with other Professional pursuits on the part of the examiners, and entailing great hardship upon candidates by want of accommodation with the sessional arrangements of the principal Medical schools.

4. The expense of examinations so conducted would be, if thrown upon the candidates, a very serious addition to the cost of Medical education and qualification, without any commensurate results as regards the security of the public.

5. The undersigned are decidedly of opinion that if, for the public security, an additional examination requires to be introduced, over and above the nineteen at present in operation, the cost of such additional examination should, in any case, not be thrown upon the candidates, nor yet on the existing Examining Bodies, but should be defrayed by the State, as representing the public.

6. The true object to be aimed at, whether in view of the public interest or that of the Medical Profession, is (in the opinion of the undersigned) not uniformity, nor yet a fixed maximum of qualification, but the watching and stimulating the existing Examining Boards, through a systematic inspection, conducted under the auspices either of Government or of the Medical Council.

7. The undersigned profess themselves willing and anxious to facilitate to the utmost a thoroughly efficient system of examination in the Universities and Corporations with which they are severally connected, and would gladly welcome the visits of any inspectors appointed on the part of the public to secure, as far as may be, efficiency on the part of all such Examining Bodies in the performance of their important duties. In the case of the Universities, such a system of inspection would be quite in accordance with the system already introduced by the Universities Act of Non-Professional Examiners. The undersigned are thoroughly satisfied with this system, and believe that an extension of it would do good.

8. The details of such inspection should, in the opinion of the undersigned, be arranged between the State, as representing the public, and the Medical Council as representing the Medical Profession.

9. The undersigned desire it to be understood that, so far from objecting to a “conjoint” system of examination, they would cordially welcome any voluntary joint action of different boards, with the view of diminishing the labour and responsibility of examination, and the expense and trouble of it to the candidates. The objection that they entertain to the proposed system is, that it would not diminish either the expense or the trouble to the candidates, but would, on the contrary, increase both; while, by removing the responsibility of the practical part of the examination in some measure from the existing Boards, it would tend very much to reduce all Medical examinations to a low dead level, and would render it nearly impossible to improve them in accordance with the demands of advancing Medical knowledge.

February, 1872.

ROBERT PERRY, M.D., Physician and Clinical Lecturer in Glasgow Royal Infirmary; Examiner on Chemistry and Clinical Medicine for the Faculty of Physicians and Surgeons, Glasgow.

HARRY RAINY, M.D., Professor of Forensic Medicine, Glasgow.

ANDREW BUCHANAN, Professor of Institutes of Medicine.

W. T. GAIRDNER, M.D., F.R.C.P. Edin., Professor of Practice of Medicine, University of Glasgow.

GEO. H. A. MACLEOD, M.D., F.R.S.E., Professor of Surgery, University of Glasgow.

JOHN YOUNG, M.D., L.R.C.S. Edin., Professor of Natural History, University of Glasgow.

JOHN B. COWAN, M.D., F.F.P.S.G., Professor of Materia Medica, University of Glasgow.

A short discussion occurred on a suggestion from Dr. Bennett

that the following letter from Sir R. Christison should be read. It was finally agreed that it should be regarded in the light of a speech delivered.

Edinburgh, February 29, 1872.

My Dear Sir,—I do not know whether an absent Member of the General Medical Council has any claim to submit his views to the Council on any question; but in case the cause of my absence on the present occasion, and the radical importance of the principle and scheme of Conjoint Examining Boards, in place of the existing independent Boards, may be considered as constituting any such claim, I beg to be allowed to address through you the following observations to the Council:—

I had from the first misgivings as to the expected advantages from the scheme of a Conjoint Examining Board, with the powers and for the purposes contemplated for such a Board by the English Universities and the two Royal Colleges of England. These misgivings have been gradually growing until now, when I have come to dread that the Council has been upon a wrong course altogether in attempting to carry out a measure which will unnecessarily and vexatiously multiply the examinations of candidates, will destroy the stimulus derived from the individuality of the present system of Examining Boards, and will detract from the useful influence, and even endanger the prosperity, of the present flourishing Royal Colleges.

It must be acknowledged that the Medical Council, without resorting to any great pressure upon the several Licensing Authorities, has gradually accomplished improvements in Medical education, and has effected a near approach to uniformity, as well as to sufficiency in the examinations of the several Examining Boards, so far as regards the minimum standard of qualification for Medical practice. What remained for the General Medical Council to accomplish in respect of examinations were—1. To persuade the several Royal Colleges to combine their Examining Boards in each division of the kingdom, so that no man should be licensed who had not undergone a complete examination both in Medicine proper and in Surgery; 2. To induce the Universities to receive from without an adequate number of examiners, not only to attain the same object, an examination "in omnibus," but likewise to put an end to the outcry against candidates being examined only by their own teachers; and 3. To establish a proper inspection of examinations, under the powers conferred by the Medical Act upon the Council.

Had these measures been carried through, and had the practical instructions of candidates been rendered more thorough by insisting that all students should be brought, during at least the final year of their studies, in more close contact with diseases in clinical observation, we should never have heard of this new Conjoint Board or Boards, the beginning of which is to be the destruction of the principal existing Examining Boards of the United Kingdom. Nor is there now, so far as I can see, any obstacle which should prevent all these important details being carried out promptly under the advice of the General Medical Council, if it be allowed to exercise as formerly the powers which it possesses under the Medical Act.

But, instead of continuing to follow out its mission with independence, the Council, and also, I fear, the Government of the country, have yielded to what was at first perhaps not an unreasonable clamour from without, and have consented to give the weight of their opinion in favour of a system of examination, which in this country was hitherto a theoretical system, and in other countries has proved to be either mischievous or a failure—a system, namely, whose essence is uniformity and centralisation. The clamour in favour of that system may have been not unreasonable when first it was raised, because those who raised and joined in it could not see at that time any other way to correct existing faults. But it would be an unreasonable and foolish clamour now, when experience shows how much more easily the faults in question may be mended, without disturbing the existing order of things, and when it may be shown that the proposed radical remedy is a dangerous revolution.

For, in the first place, uniformity of examination by a single Examining Board is a mere delusion. No one, I presume, would dream of effecting a uniformity of examination in Medicine by imitating the very doubtful plan in regard to elementary education, as followed in some countries, distributing the same written questions for written answers from all candidates all the same day—in all schools, and in all parts of the kingdom—to the disregard alike of convenient seasons of the several schools, and of the varying methods of teaching and varying doctrines taught at each. There must be oral as well as written examinations for Medical candidates; both must vary at the different schools; and the time for them must vary, to suit the seasonal periods of the schools. One board for each division of the kingdom is therefore an impossibility. In Scotland there must be three, in Ireland as many, in England probably twice that number. It follows that, whether these Boards meet in one city or in several, their examinations must be different, and any approximation to equality, which may be effected under the proposed new scheme for Conjoint Boards, may be also brought about as well through the influence of the Medical Council, by a proper understanding between the existing Boards of the country, as amended, or even as they now stand.

If, in the second place, it be insisted on that in each of the three divisions of the country the examinations shall be conducted really by only one Board, that Board will require such an enormous consumption of time for the purpose, even in Scotland and Ireland, but still more in England, as would be incompatible with the examiners following either Professional or Professorial pursuits. Examiners of the high position, in Professional and University life, of the present Examining Boards would not undertake such arduous and protracted duty. I leave the Council to infer what would be the class of men who would very soon come to constitute the examiners of a single Examining Board.

In the third place, a system of examination by such a Board as the New Conjoint one contemplates, conjoined as it is to be with the payment of a large fee to one or other of the Royal Colleges, will be very costly, as the amalgamating bodies evidently understand what they propose, that the fee shall be at least thirty guineas. This surely is an unreasonable proposition, if it be within the province of the Medical Council to effect equal improvement by simply improving the present system of examination by existing Boards. Medical education is costly enough already, considering the Professional emoluments to which it leads for nine-tenths of the members of our Profession.

In the fourth place, it is most unlikely that the Medical Profession, or the country at large, will long submit to the Royal Colleges thus drawing a large fee from every candidate, for whom they do nothing but give a title, which imparts to the generality of them no privilege. We have all had occasion to remark that our restless Profession is prompt to discover grievances, and energetic in demanding redress of them. Ten or twelve years

will hardly pass under the new system without the question arising everywhere,—What do we or our sons get in return from the Royal Colleges for the large fee drawn by them, without doing any work for it? I confess I cannot answer that question, unless in the case of that limited proportion of Medical men who, living in the capitals, can make use of the museums and libraries of the Colleges. It will not be long, then, before we shall hear a renewed clamour against the Medical Corporations—the most formidable of all clamours, a monetary one.

But, in the fifth place, I have a greater objection than all to this new scheme. It will tend to take away from our existing Universities and Corporations that self-reliance, emulation, and enterprise which are the result of such being allowed to teach, and to examine according to its own constitution, and the "genius loci," and which are of precious value to the interests of education. The world is now awaking to the evils arising from the government of a country centralising, and reducing to one standard, either education or, above all, examinations. It is now acknowledged by philosophers that the intellect of France has been thus damaged. Germany, after trial, is giving it up. The very "Staats Examen" of Prussia, of which the contemplated scheme is an imitation, has been recently given up. It is no longer held at Berlin, but at each University where the candidate obtains his degree; and thus it becomes little else than a mere form. The evils of over-examining, of uniform examinations, and of centralised Examining Boards have been so convincingly demonstrated in Dr. Lion Playfair's address here on January 31 last, of which I understand that a copy was sent by him to every member of the Medical Council, that I can scarcely imagine anyone, who has diligently perused that address, without acquiring serious doubts as to the course which pressure from without the Council has induced us to try. But it is not too late to recede; and I would earnestly entreat the Council to consider whether it be not its wisest course to pause at the present stage, to beg from the Government two years' respite at most, and to set about diligently to so far combine, or rather to complete, the present Boards, that no candidate shall obtain such a qualification as will entitle him to registration without having been examined both in Surgery and in Medicine,—and also to perfect clinical instruction, by urging that every candidate shall have an opportunity of having a certain responsible charge of patients before he is allowed to appear for his final examination.

With these objects attained, I am satisfied that under a due system of inspection of examinations, the complex, costly, vexatious, and doubtfully expedient check, by the scheme of Conjoint Examining Boards, would become superfluous, and would be proved to be so.

I am, yours most truly,

To Dr. Paget,

(Signed)

R. CHRISTISON.

President of the General Medical Council.

Dr. PARKES said, as it appeared that Scotland had not succeeded in forming a Conjoint Board of Examination, he wished to ask the Scotch Members of the Council whether they had any hope whatever of such a Board, satisfactory to the Council, being formed in Scotland.

Dr. MACROBIN said the Universities and Licensing Bodies were all at one with regard to the propriety of forming a Conjoint Board.

Dr. ANDREW WOOD said the Scotch Bodies had been very unjustly spoken of, as though they had not applied themselves in the best way they could to endeavour to conform to the wishes of the Medical Council. Last year the Medical Council met in July, and it was at the end of that month that the Registrar's letter reached the Scotch Bodies. As during August and September and the first part of October nothing whatever could be done in the schools, it was not till the middle of October that the Bodies had any opportunity of considering the question individually, and much later before they were enabled to come together in conference in regard to it. He believed, however, that every Body in Scotland did take it up in perfect *bona fides*. It was in vain to deny that there were a great many men in Scotland who did not approve of such a scheme; but, on the whole, the majority of all the Corporations and all the Universities did come to a resolution that it was desirable, if possible, to form a Conjoint Board. The circumstances in Scotland were very different from those in England. It was a comparatively easy matter to work out a Conjoint Examining Board in England, but even there, with their facilities, they had utterly failed; because at the present moment, instead of one Conjoint Board for England, there were actually three Licensing Boards left. England had had her difficulties, and had failed: Scotland had had her difficulties, but it could not be said that she had failed. She had merely not succeeded as yet. (Laughter.) England had produced an incomplete scheme, which was not a scheme for a Conjoint Board; but Scotland, with more honesty and frankness, had said: "We have been endeavouring to form a Conjoint Board; we have not yet succeeded, but we assure the Council we shall do our utmost in order to make a real Conjoint Board for Scotland." What were the difficulties in Scotland? In the first place, they had two Colleges of Surgeons—the College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow. In the second place, the Scotch Universities were in a very different state from the English. (Hear, hear.) The degrees of the Universities in England were pitched very high. They were only attainable by men who were able to go to a considerable expense and undergo a very high test. The consequence was that Oxford, he supposed, did not give a dozen degrees in a year.

Dr. ACLAND: Not six.

Dr. ANDREW WOOD: In Cambridge I suppose you do not give many more.

The PRESIDENT: About twelve.

Dr. ANDREW WOOD said he did not know how many Durham conferred.

Dr. EMBLETON: About the same as Oxford.

Dr. ANDREW WOOD said there would then be twenty-four in all, which, with thirty or forty given by the University of London—

Dr. STORRAR: Not quite so many.

Dr. QUAIN: How many would they give if it were possible to pass the examinations on easier terms?

Dr. ANDREW WOOD said the degrees given by the Universities of England formed but a small drop in the bucket as compared with the College of Surgeons and the College of Physicians.

Sir D. CORRIGAN rose to order. The discussion was irregular, as there was no resolution before the chair.

Sir W. GULL moved—"That this Council expresses its regret that no scheme had been framed and submitted to the Council by the Medical Authorities in Scotland, for establishing a Conjoint Examining Board."

Dr. ALEXANDER WOOD thought it was the practice of the Council to allow a member to answer a question. Dr. Andrew Wood was answering a question, and it was not right to interrupt him with a motion.

The PRESIDENT said Dr. Alexander Wood was right in theory, but it was not worth while to waste the time of the Council by a long speech when time was so valuable.

Sir W. GULL said the object of the Council in meeting together was to get a better standard of education for the Medical men of the country. They had it before them that Sir R. Christison was of opinion that a Conjoint Board would not be advantageous in Scotland, his argument being that it would centralise and reduce to one low standard the education of the different divisions of the kingdom. For his own part, he believed the result would be the exact opposite of that. There must be a certain number of Medical men, and the standard by which they were measured must necessarily be somewhat low; still it should be a real one, and the object of the Council was to fix a practical standard of Medical tests in the different divisions of the United Kingdom. By the establishment of Conjoint Boards, Universities and those different bodies which took an interest in intellectual and especially Medical education would be relieved from mere technical details, and set free to develop, in a much higher degree, the intellect and the Medical knowledge of the students, according to the genius of the different bodies. They would thus not be compelled to make their teaching correspond to any necessity of Medical practice. He believed, therefore, that Sir R. Christison had taken a somewhat wrong view of the matter, and that it was desirable that in Scotland, as in England and in Ireland, they should strive to get a fixed, plain, practical, useful standard, whereby every man could be judged before he was permitted to practise at all. The Universities should then be encouraged to form foci of scientific learning. It was a matter of regret that the Council had not received a scheme for a Conjoint Board in Scotland. It was quite true the English Bodies had in some degree failed, but only in a very limited degree, and not at all to the extent which some seemed to think. The University of London went heart and soul in this matter, and would in a short time get rid of the technical difficulties. He had no doubt, also, that the Apothecaries' Society would feel themselves obliged to join in the scheme; for, if not, they would be left alone—they would have done their work. A higher organisation would come, and they would have to go. The Conjoint Board was for the Medical necessities of the age, because the Universities wanted to be free to advance, while the public must have a comparatively low standard. Fifteen years ago he besought the graduates of the University of London not to ask for a licence to practise. He said the University had nothing to do with pounds, shillings, and pence, or with the wants of the public. It should confine itself entirely to the instruction of the intellect. (Hear, hear.) He hoped, therefore, that Sir R. Christison would see that the functions of the Universities would be elevated by a Conjoint Scheme for passing men into the Profession. He did not wish to imply blame or censure, but his motion was an expression of regret. It had been said that it was a delusion to think there could be anything like uniformity, but there might be a great uniformity of pass examinations. They did not want uniformity in the Colleges or the different

Universities, but they did want more or less uniformity in the pass examinations.

Dr. A. SMITH seconded the motion. The Council, he said, had abundant evidence already before them that there were many differences of opinion among the authorities in Scotland in reference to the Conjoint Board. There was no scheme from Scotland before the Council, and it would be much better to take the opinion of the Council on the motion at once.

Dr. ANDREW WOOD said it was the most extraordinary proposition he had ever heard, that the opinion of the Council should be taken on this matter before Scotland had had an opportunity of speaking in its own defence. The Scotch authorities had been twitted, and challenged, and blamed, as if they had not been doing their best to produce a conjoint scheme, and the Council could not, therefore, refuse to hear what was to be said on the other side. He was glad that he had been interrupted when previously addressing the Council, for Sir W. Gull's speech had completely confirmed his idea that the groove in which the Scotch Bodies were moving was exactly that which the Council would approve of when it was carried out. When the numbers of those who pass the English Universities were counted, it would be found there were only some forty or fifty in the course of a year; but how was it with Scotland? There were about seventy graduates annually from the Edinburgh University, about fifty from the Glasgow University, and about thirty-six from the Aberdeen University. In consequence of the decision given by the Privy Council, all these Universities were not only instructors for degrees and conferrers of degrees, but conferrers of licences which were in competition with the licences of the Corporations. Now, if there were to be a Conjoint Board in Scotland in which all the Universities and all the Corporations were to come together and be examined at one common examination, such as that proposed for England, the result, instead of tending to raise the level of the University education, would depress it down to the minimum. On the other hand, if the ideas which prevailed in Scotland were carried out, that the Conjoint Board should only hold a practical pass examination, while the various Corporations and Universities should be left to examine on the whole of the subjects according to their respective charters, but not giving a licence, or a degree, or a diploma to any man who had not passed the Conjoint Board, then the wishes of Sir W. Gull would be realised, because each Corporation would be left according to its own genius to raise the level of its scientific attainments. This was what they had been aiming at in Scotland, and it would be a very serious matter indeed if they were to be told that they were to have a pass examination, every part of which candidates should have to pass. There were other difficulties to contend with in Scotland besides these. The ruling powers in the College of Surgeons, and the College of Physicians, and the Glasgow Faculty were not selected Councils consisting of a few men. Everything had to be decided by a meeting of the Fellows of the Colleges, and the consequence not unfrequently was, that the delegates sent to the Council were outvoted in the College. Notwithstanding these difficulties, he believed that in the course of another year it was very probable that an agreement would be come to by the Scotch Bodies. Whether the scheme agreed to would satisfy the Council or not he did not know, but he presumed the Council did not intend to lay it on a bed of Procrustes and cut it down to the proportions of the incomplete English scheme. There were some very good hints which the English Bodies might take from the Scotch propositions. By whom would the Conjoint Examination in England be regulated? By a committee of reference. Who were to constitute that committee? Would it consist of members from Scotland, Ireland, and England? Would it be an imperial committee or merely a local one? It would be a local committee for England. If this system were imposed upon Scotland and Ireland, and local committees were constituted in those countries, where would be the guarantee for the one standard that they were aiming at?

Dr. ACLAND: Clause 19.

Dr. ANDREW WOOD said the *raison d'être* of Clause 19 was this. When the Medical Act was passed there were, as there still continued to be, certain Bodies which conferred only one qualification, and the object of that clause was to enable such Bodies to give complete qualifications. If the Conjoint scheme had not secured that no man should be registered who had not a complete qualification, what would be gained? The English scheme had not secured this, for the Apothecaries' Hall would still be entitled to put men on the Register in spite of the Conjoint Examination. If a little more time were allowed, the Scotch Bodies would be able to concoct a scheme which would tend more to uniformity, and would be

more in consonance with the object at which the Council were aiming than the scheme proposed for England. To say to the Colleges and Universities "At once abnegate your functions, give up your power of examining in Surgery or in Medicine," would lower the position of the Colleges and Universities. The Colleges of Surgeons and Physicians were a part of the British Constitution; they were Bodies in consonance with the genius of the Constitution for the self-government of the Profession, and any measure that would destroy them would be hostile to the interests of the Profession. He therefore trusted the Council would pause before taking any steps which would have such an effect. His idea of a scheme for Scotland was—first, a Conjoint Board formed by the co-operation of all the Licensing Bodies in Scotland, whose examination every student should be required to pass before he should be entitled to be registered; secondly, an examination by this Board to test the candidate's knowledge of Medicine and Surgery, and his ability to practise them (of course, the extent of that examination would be a matter for consideration afterwards); thirdly, a committee of management, supplemented by members from England and Ireland, to decide on the principles and method of conducting the examination, none of the members of the committee being examiners; fourthly, the examiners to be appointed in equal numbers by the Universities and Corporations. By the English scheme the examiners were to be appointed by the Colleges on the nomination of the committee. What did that mean?

Dr. QUAIN: The College of Surgeons are required by their Act to appoint their own examiners; but they have given that power up, holding it merely as a nominal thing.

Dr. ANDREW WOOD said the fifth point in his scheme would be that the fee to be paid for this examination should not be more than was sufficient to cover the expense. In Scotland there was a very strong opinion that the student should as much as possible be relieved from the burden of excessive fees. They could not afford thirty-guinea fees, for Scotland was a poor country. (Laughter.) Besides, one reason for having thirty-guinea fees in England was that ten guineas should go to the keeping-up of the Hunterian Museum. Any measure which would largely increase the fees would be a movement in the wrong direction; but if the mere expense of the Pass Examination were required from the student, it might be so managed, by diminishing the sum drawn by the Colleges and Universities for diplomas and degrees, that the student should not be burdened more than at present. He hoped he had vindicated Scotland from the charge of being in any way recalcitrant to the wishes of the Council or indisposed to make the best endeavours they could to form such a Conjoint Examining Board as would be approved of by the Council.

Dr. HUMPHRY thought Sir W. Gull's motion ought not to pass in its present form. It was right that they should express their regret that no scheme had been agreed to; but after what they had heard from Dr. Andrew Wood, and what they had read of the resolutions of the Corporate Bodies in Scotland, they ought to add their hope that a scheme would shortly be agreed to. He therefore proposed as an amendment—"That this Council, while regretting that no scheme for a Conjoint Examination has been framed in Scotland, yet, having considered the resolutions of the several Medical authorities in Scotland, sees reason to hope that in the course of a few months a scheme for a Conjoint Examining Board for Scotland may be matured to which this Council may be able to give its sanction, and urges the authorities to persevere in their efforts to effect the same." It was evident that all the Medical authorities in Scotland were agreed that a Conjoint Board should be formed, and the Council might fairly express its hope that ere long it would be formed. It was quite possible that the genius and character of the Scotch people might require somewhat different arrangements from those in England. The English authorities were not desirous that their plan should be taken as a model for Scotland; neither should Scotland think England had failed because the English scheme was not, according to Scotch ideas, perfect. The object the Council had in view was to reduce the number of examinations in the United Kingdom, so as to insure that every man who entered the Profession had passed a good and satisfactory examination, but they did not at present state what the precise nature of that examination was to be. They wished to strengthen the Medical bodies rather than to weaken them, and to maintain the independence of the Profession as exercised through the various Corporations, and he believed this would be secured by the Conjoint Examination. The examiners at Cambridge were at present always fettered in their questions by the knowledge that they must set a pass paper, and when released from the pass examination they

would be able to attend more to the development of the intellect than they had been hitherto. The same would be the case, no doubt, with the other Corporations. He dissented most strongly from the views expressed by Sir R. Christison, for he believed the individuality and independence of the several Corporate Bodies would be increased instead of diminished by the proposed scheme. It was, therefore, most desirable that they should still hold open the door to Scotland and to Ireland, and still urge them to propose a scheme in order that they might not fall into the hands of the Legislature. It was most important for the individuality of the Profession that they should as far as possible govern themselves. Any profession which relinquished self-government would relinquish one of its highest privileges and greatest duties, and that was one reason why he would urge the Scotch authorities to persevere with earnestness and energy to secure such an examination as would be recognised and sanctioned by the Council.

Dr. THOMSON seconded the amendment. He was extremely hopeful that the Scotch Bodies would ere long be able to come to an agreement by which a scheme acceptable to the Council would be framed. It was apparent, by what had fallen from Dr. Andrew Wood, that there was no essential difference of opinion among them upon the chief points of such a scheme, but the Profession at large had not in Scotland had the same means of forming an opinion as that which the Profession in England had had. He had always felt that they were committed to the formation of Conjoint Boards by the resolutions of the Council—(hear, hear)—and it was with that view that he had moved the resolution of February 26, 1870, upon which the whole matter rested. The Scotch Bodies, however, did not suppose it possible that any scheme would be acceptable to the Council which left out a single Body. If they had held the same view as the English Bodies, no doubt a scheme might have been already prepared. No one could regret more than he that the Scotch scheme was not actually before the Council, for up to the very last he had entertained the hope that, considering the essential agreement upon cardinal points, a scheme would have been arranged for the sanction of the Council.

Dr. ALEXANDER WOOD said he could vote neither for the motion nor the amendment. He stood in a somewhat enviable position, because he had never expressed any concurrence in the scheme as likely to prove beneficial to the Council, the Profession, or the student. When in 1870 Dr. Parkes brought forward his motion, he (Dr. Alexander Wood) stated that he thought there were several fundamental mistakes in the proposal, and he divided the Council upon the motion, asking time to consider it before it was pressed upon them. His amendment being lost, he declined to vote in the second division, and therefore he considered himself perfectly free from any pledge in regard to the Conjoint Examining Boards. From the documents sent in by the Scotch Bodies, it appeared that not a single one of them cordially assented to the proposal. The University of Edinburgh distinctly stated that it was almost under the compulsion of the strong desire expressed by the Council that they considered the question at all. The College of Physicians also distinctly said that they had no love for it, and it was only because a certain section of the Profession had expressed a strong opinion on the subject that they entertained it. The College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow took very much the same view. Then, again, after the Conference had met and honestly agreed upon a scheme, both Dr. Andrew Wood and Dr. Fleming were outvoted in their separate Bodies. These facts showed that there was no cordial feeling on the part of the Profession in Scotland in favour of the scheme. If the Council had done its duty years ago, such a scheme would have been unnecessary, and the present was an attempt on their part to make the Medical authorities discharge the duties of the Council. By the Act of 1858, powers were given to the Council to visit the examinations, and so to secure that none but those who were competent to practise should pass them. They allowed years to pass before they exercised that authority, and when they did begin to supervise the examinations they did it only in a half-hearted way. Had they used those powers effectually, the Profession would have been placed in a very different position long ago. A very great doubt existed, too, in the minds of some who had directed their attention seriously to the matter, as to whether it was really a good and advisable thing to have only one admission to the Profession. From the time when the Privy Council undertook to put the teachers of general education in Scotland on a Procrustean bed, and deal with them all after the same method, education began to decline, and the fear had been expressed

1 est the same result should follow in the case of Medical education. The great evil was, not that there was any want of Medical appliances, but that the students came to their Medical studies utterly unprepared to profit by them. (Hear, hear.) If the Council really desired to raise the character of Medical education, they must take more interest in the preliminary examination, and be careful that the soil of the student's mind was so prepared that he could receive the seeds of Medical knowledge to some profit, and that those seeds might germinate and make him a scientific professor of Medicine. It was deeply to be deplored that there were in Scotland four Universities all issuing Medical and other degrees. There was nothing in the population or the condition of Scotland to require such an immense amount of degree-conferring power, and it would be for the interest of Scotland that the four Universities should be allowed to continue as teaching Bodies, but that there should be only one central University having the power of conferring degrees. The English Universities stood in a different position with regard to the Medical Bodies from that in which the Universities of Scotland stood. The Scotch Universities met the Corporations as rivals, as men who were striving to get rich by degrees. (Laughter.) How was this difficulty to be overcome? An idea was prevalent that there was an attempt on the part of many Licensing Bodies to undersell one another in the character of their examinations. He did not believe that this was true. He had seen a great many examinations, but had never witnessed the slightest attempt of this kind; rather he had noticed a sort of *esprit de corps*, which led the various Bodies to push their examinations as high as possible. His idea of the best course to be adopted was this. He would first separate altogether that amount of protection which the State was entitled to give its subjects from the rush into the Profession of unqualified persons, from the giving a degree or distinction by any Body whatever. The admission into the Profession should be entirely separated from the admission into the University or Corporation; and the scheme suggested in Scotland would do this, for the Conjoint Board would restrict itself exclusively to such an examination as would determine that the candidate possessed that minimum of knowledge which would qualify him to deal with the lives and health of her Majesty's subjects. There its powers should end. True, by these means one more examination would be added to the many already existing, but he could not see how this could be avoided. He had himself not much faith in examinations; but if examination was to be the test, then it seemed to him that what he suggested was the only proper mode. Let there be an entrance into the Profession by an examination which should be conducted by representatives of all the Boards; but at the same time let the different Bodies retain their own individual examinations, which would keep them free and independent. These views were of a much higher character than those on which the imperfect English scheme was founded, and he trusted before many months were over the Scotch Bodies would be in a condition to bring forward a scheme embodying these principles.

Dr. QUAIN said he could assure Dr. Alexander Wood that he had not the slightest conception of the English scheme—(laughter)—not the least in the world. The difficulties of Scotland would be entirely met by adopting the English scheme, which did not aim at uniformity, but competence. It did not add a new examination to those already in existence, but reduced them to one. It would not interfere with the proceedings of the other Bodies, but left them quite free, while, for the convenience and advantage of the young men entering the Profession, it said, "When you have passed a competent examination, you are sure of being able to join two Bodies if you wish." The Universities were equally free.

Dr. PARKES said the statements made by Dr. Alexander Wood had convinced him that Scotland was as far from forming a Conjoint Board as Ireland, and that was going as far as any human event could be. (Laughter.) The returns from the Scotch Bodies showed what an imperfect Board was shadowed out. Even the plan proposed by the University of Aberdeen, which was far the best, fell below what the Council would wish to see. In the University of Edinburgh the proposition for a Conjoint Board was most coldly received. From the letter received from Sir R. Christison it was evident that most formidable obstacles existed in Scotland. The Council must, therefore, be prepared to take some decisive steps in the matter, and positively insist on the formation of such a Board; otherwise, what would be the use of expressing regret. For three years the Council had been considering the question, and where had they got to? (Hear, hear.) He did not see that they

were any nearer the formation of a Conjoint Board for Scotland than last year. Would they be any nearer next year?

Dr. ANDREW WOOD: You have not got it in England.

Dr. PARKES said at all events they had in England a substitute for it for the time. He hoped the Council would do something more than merely express regret. It appeared to him that they had done all they could do, and there was nothing left but to proceed by the aid of the Legislature.

Dr. ANDREW WOOD: You are going to threaten us?

Dr. PARKES said he did not call it a threat. The letter sent by Sir R. Christison did not really apply to the case before them. Their object was to prevent improper men from entering the Profession, but Sir R. Christison had always doubted whether improper men did enter the Profession, and had never thoroughly realised the fact that men who ought never to be admitted were stepping into the Profession, owing to the negligence of the various Licensing Bodies.

Dr. STORRAR said, at a former meeting of the Council Dr. Alexander Wood had moved "That a meeting of the General Medical Council be held, early in 1872, to receive the proposals of the Bodies for Conjoint Examinations, and to consider whether any or what steps should be taken to carry out the resolution of the Council in favour of such examinations. Judge, then, of his (Dr. Storrar's) astonishment when he found Dr. Alexander Wood coming forward as a free lance, stating that he never had any sympathy with these proposals. He, however, thought with Dr. Wood, that there was in Scotland too much degree-conferring. In England the degrees of the Universities were conferred with a sparing hand, for Medical degrees were considered honours raising the holders above the merc rank and file of the Profession. (Hear, hear.) In Scotland, however, the case was different, and Dr. Andrew Wood seemed to look upon it as a merit that so many degrees were conferred.

Dr. ANDREW WOOD: Never. I look upon it as a blot.

Dr. STORRAR said the system pursued in Scotland was very like a Dutch auction.

Dr. THOMSON: I believe there is no truth whatever in the statement that the University of Glasgow is trying to make money by degrees. I object to these remarks.

Dr. MACROBIN: So do I.

Dr. ALEXANDER WOOD: I rise to a point of order. A gentleman has said there is no truth whatever in the statement I have made. Do you allow that expression to pass?

Dr. THOMSON: I deny it. I say they are not; but I am ready to substitute other words.

Sir D. CORRIGAN: Dr. Allen Thomson said there was no truth whatever in the statement made by Dr. Alexander Wood.

Dr. THOMSON: If it is agreeable to the Council I am ready to substitute the words that I deny that the Scotch Universities are doing so.

Dr. ALEXANDER WOOD: What I said was this, that they were striving to get rich by degrees; and I insist that the language used by Dr. Thomson be withdrawn. I may be mistaken, but certainly Dr. Thomson has no right to use the words he did use. When the case of the Edinburgh Universities was argued before the Privy Council, the great argument used was that they could not afford not to become Licensing Bodies, because their money interest would suffer; and it was in reference to that argument that I used the expression that they were striving or endeavouring to get rich by degrees. Under these circumstances I think you can scarcely expect me to retract the expression; but if you think there is anything unbecoming the character of this Council in the expression, I am ready at your request to withdraw it, not otherwise. Still, I must say, in all the debates at which I have been present I have never heard such an expression used as Dr. Thomson used.

Dr. THOMSON: I have so far withdrawn it that I simply deny that the Scotch Universities are striving to get rich by degrees.

The PRESIDENT: After Dr. Wood's explanation, and Dr. Thomson's withdrawal of the offensive expression, nothing more need be said about it.

Dr. STORRAR said Dr. Alexander Wood had commented in rather strong terms upon the indisposition of the Council to promote preliminary education. Was he the only gentleman who had taken an interest in preliminary education in the Council? Were the representatives of Scotland, even, the only gentlemen who had taken an interest in it? Did Scotland stand conspicuous for her zeal in the cause of preliminary education? At the last preliminary examination at the College of Surgeons, somewhere about 50 per cent. of the candidates were rejected. That was the way in which England dealt with the preliminary examination. Dr. Alexander Wood, again, said that the Council had gone into the inspections in a half-

hearted manner. That might have been the case in Scotland, but on the part of Dr. Sharpey, Mr. Cæsar Hawkins, and himself, he could assert that they had entered on their work in a whole-hearted manner. By all means let the independence of the several Bodies be maintained—and the Council did not for a moment desire to interfere with it—but, leaving out the higher developments of Medical study and Medical competency, there was a certain requirement which should be imposed upon the rank and file of the Profession, and steps should be taken to secure that the competency, as far as it went, was thorough. Any proposal from Scotland which did not contemplate a complete examination from the commencement would not receive his consent.

Dr. ANDREW WOOD: Then you will never get it.

Dr. STORRAR said it was, then, well to know it. It had been admitted by members of the Council that the difficulty was a money one.

Dr. ANDREW WOOD: I never admitted that. Money was never mentioned.

Dr. FLEMING: Never, never, never.

Dr. STORRAR said he was glad to hear it repudiated. As to the objection that Scotland was a poor country, why that was quite a farce. There was no richer district in these islands than the great centres of population in the Lowlands.

Dr. ANDREW WOOD: Look at the students in Scotland.

Dr. STORRAR said they were poor, because there was no temptation offered for a higher class of men to come into the Profession. At all events, he should be utterly dissatisfied with a mere union of the Scotch Bodies for the purpose of clinical examination.

Dr. FLEMING said it was evident that, however much the representatives of the Corporations desired to be loyal to the Council, there was no cordial feeling in favour of the scheme on the part of the Profession generally. If it was the opinion of the Council that in Scotland a competition downwards was being carried on, it was their duty to send out competent inspectors to supervise and report on the manner in which the examinations were conducted. The feeling in Scotland against the change would rather be strengthened by what had taken place at the Council; but for his own part he should loyally use his best endeavours to effect the object which the Council had at heart. Dr. Quain had said that there would be no difficulty in adapting the English scheme to Scotland, but he must have forgotten the peculiar position of the Scotch Universities. It was to be regretted that the privilege of licensing was conferred on the Scotch Universities, but, as they had a hard struggle to obtain it, they would not give it up.

Dr. MACROBIN said the University of Aberdeen had entered very cordially into the matter, and all his colleagues were at one in reference to an examination almost identical with that proposed in the English scheme. (Hear, hear.)

Sir D. CORRIGAN said he had paid great attention to the debate, and the conclusion he had arrived at was that he could vote neither for the motion or the amendment. He could not vote for the amendment, because he could not see that there was a reasonable hope that the Conjoint Scheme would be carried out in Scotland. Dr. Humphry had talked about opening the door to the Irish and Scotch Bodies, but Ireland did not want a door opened. (Laughter.) Dr. Parkes had insisted on decisive steps being taken. He had proposed decisive steps once before in the case of the Queen's University, but the Queen's University quietly held up its hands, and said to Dr. Parkes, in the words of Shakespeare, "Come on." (Laughter.) Did he ever come on? (Renewed laughter.) He did not. Let him, then, take decisive steps—such as those he took against the Queen's University. (Laughter.)

Dr. Humphry's amendment was negatived by a majority of 1, and the original motion was carried by 16 against 1.

The Council then adjourned.

FOURTH DAY.—MONDAY, MARCH 4.

The Council re-assembled at two o'clock.

The following letter from Dr. Sanders, of Edinburgh, was read:—

11, Walker-street, Edinburgh, March 1, 1872.

Sir,—I have the honour to request that you will present to the General Medical Council the enclosed memorial drawn up by Professor W. T. Gairdner, of Glasgow, with reference to the proposed scheme of National Conjoint Examining Boards.

The enclosed paper has been signed in Edinburgh only; and it is proper I should state that no general or extensive application for signatures has been made. I had neither time nor opportunity for doing so, even if it had been necessary. The names appended are those of persons whose

opinions I had previous reason to believe were in accordance with the views expressed in the memorial.

I have the honour to be, Sir,

Your obedient Servant,

(Signed)

WILLIAM R. SANDERS.

To the Registrar of the General Medical Council.

The following signatures were attached to the copy of the memorial sent from Edinburgh:—J. H. Balfour, M.D., F.R.S., Professor of Medicine and Botany and Dean of the Medical Faculty, University of Edinburgh; Alexander Crum-Brown, M.D., D.Sc., F.R.C.P. Ed., F.R.S.E., Professor of Chemistry in the University of Edinburgh; William Turner, M.B. Lond., Professor of Anatomy, University of Edinburgh; T. Laycock, M.D., Professor of Practice of Medicine, University of Edinburgh; Alexander R. Simpson, Professor of Midwifery and the Diseases of Women and Children in the University of Edinburgh; William R. Sanders, M.D., Professor of General Pathology and Clinical Medicine, University of Edinburgh; C. Wyville Thomson, LL.D., D.Sc., F.R.S., Professor of Natural History in the University of Edinburgh; Douglas Maclagan, M.D., F.R.S.E., Professor of Medical Jurisprudence and Medical Police, University of Edinburgh; Robert Bowes Malcolm, M.D., F.R.C.P., F.R.S.E.; D. Argyll Robertson, M.D., F.R.C.S.E.

It was agreed that the letter should be printed on the Minutes.

CONJOINT BOARD FOR SCOTLAND.

Dr. PARKES moved—"That in case the Medical Authorities in Scotland have not succeeded in forming a proper scheme for the formation of a Conjoint Board for Scotland by January 1, 1873, the Council will endeavour to obtain a legislative enactment under which a Conjoint Board for Scotland may be constituted." He said that, first of all, he would ask the Council why they should hesitate about going to the Legislature? Five or six years ago there were endless meetings of the Council on the subject of fresh legislation. A committee was appointed, and eventually the President was requested to see the Home Secretary to ask him to bring in a Bill, and the members of the Council often complained that the Home Secretary had not stirred with sufficient alacrity in the matter. Therefore, it would be extraordinary if the Council, after having endeavoured to force on legislation in this matter, should now take an opposite view and endeavour to avoid it. But he would ask the Council to remember the exceedingly pertinent question put by the Government with regard to registering half-qualifications. With reference to Lord De Grey's Bill, the Council had passed resolutions affirming its principle, and promising to aid the President of the Council. Therefore, was it likely that the Government would drop this matter? Was it not more likely that if the Council took no action, the Government would by-and-by urge forward measures which the Council would not be able to control? Surely it was the part of wise men to take the initiative, and try to control the conduct of the Government in this matter. The next question that he would ask the Council was, whether there was now any hope of a Conjoint Board being formed in Scotland without the aid of legislation? He thought no member of the Council could answer that question except in the negative. (Oh, oh.) He said so on account of the opposition which had arisen in Scotland against the scheme. Two members of the Council had endeavoured to carry out the system of consolidated examinations, but were actually outvoted in their own Colleges.

Dr. ANDREW WOOD: Not on that point.

Dr. PARKES said, if that were not so, he would withdraw the observation; but he still contended it would be impossible to form a Conjoint Board in Scotland without the aid of legislation. (No, no.) Then could anyone point out the way? Sir William Gull's motion gave a little more time to Scotch Bodies; but what was the use of that? It was now eight years since facts were brought before the Council proving that some of the Licensing Bodies were admitting perfectly unqualified men to the Profession. The returns from the Army and Navy Medical Service showed that year after year the same thing was going on. Six years ago the Council instituted the visitation of examinations, and he did not mean to deny that the examinations were really improved; but no one who knew anything about these examinations would contend that they were an efficient remedy for the evil—in fact, they had failed in their particular object. (No, no.) They had failed partially, at all events. Four years had now passed since this scheme of Conjoint Boards was brought before the Council, and, with the honourable exception of England, nothing had been done; and even in England, though the scheme was a very admirable one, it was far from being so perfect as the Council would

desire. Sir Dominic Corrigan had reproached him with saying that he was always wanting the Council to be doing something vigorous, and he accepted that reproach. He thought the Council should speak out firmly and boldly what it desired, and not go on year after year entreating and yet finding their remonstrances unattended to. Sir Dominic had also alluded to the case of the Queen's University. He (Dr. Parkes) would only say that that was a case in which the Council had been entirely set at defiance. The Queen's University being asked as to its having offended against one of the points most earnestly insisted upon by the Council with regard to the preliminary examinations, returned first only an evasive answer, and finally no answer at all. The reason why they did not go to the Privy Council with a complaint against the Queen's University was, because it was probable that on the letter of the law, though not according to its spirit, the Council would lose the day, and it certainly did not seem desirable that, upon the first occasion of the Council appealing to the Privy Council, it should not be able to carry its point. After all its attempts to form a Conjoint Board, it was impossible to say that the Council would be doing its duty to itself, to the Profession, and to the public at large, if it did not seek the best method of cutting this Gordian knot, which certainly would never be untied.

Mr. HARGRAVE seconded the motion.

Dr. ANDREW WOOD said that he wished Dr. Parkes to understand that Scotland would not be dragooned into taking action. Scotland would judge for itself what was right, and, whilst it would be convinced by reason and argument, it would never yield to a pistol presented at its head. (Laughter.) A great deal had been done during the last eight or ten years in improving the status of the Profession; and although Dr. Parkes said that the visitation of examinations had proved a failure, it was not the case in Scotland, where a very great improvement had taken place. As to the Army and Medical Board (which seemed to be constituted as the infallible test in England of what is good), Mr. Busk, one of the examiners of that Board, had told him that during the last few years a vast improvement had taken place in the qualifications of those who came before the Army Board. If they were to have legislation, let legislation come; the Scotch did not fear it, nor did they oppose the last Bill that was brought into Parliament, upon which they were almost all agreed. Therefore, if Dr. Parkes thought that they were to be forced into this scheme by the threat of legislation, he would find himself grievously mistaken. Why was Scotland to be the *bête noir* with regard to this matter? Had they formed a Conjoint Board for England that was worthy of imitation? As to the great evil of diplomas being registered which only had regard to one part of Medicine or Surgery, the Conjoint Board for England perpetuated that by leaving out the Apothecaries' Society, which would still continue to give diplomas for Medicine only. The efforts in Scotland to form a Conjoint Board had been sincere and earnest; and were they to be told that, if they exercised the abilities and judgment they had in considering what kind of Conjoint Board ought to be formed, they were running counter to the Medical Council? English members might think that their plan was the best, but they ought to give the Scotch members credit for the same conscientiousness and desire to do what was right when they brought forward a plan which left the Licensing Bodies certain powers with regard to their examinations, their diplomas, and degrees—a plan which did not degrade them from their previous functions—a plan by which they gave up the power of registering the degrees and diplomas until a man was subjected to a practical examination. What was it that it was necessary to find out by examination? Surely it was that a man should be competent to practise; and by their examinations the Scotch members contended that they had a sufficient guarantee that men were tested as to their competence to practise. The motion of Dr. Parkes was a very invidious one to begin with, and, moreover, it would have just the opposite effect aimed at by its mover, because it would only tend to prevent the Scotch Bodies from continuing to take an interest in forming a Conjoint Board. Therefore he was of opinion, after what had passed on Saturday, that if the motion of regret that they had not been able to succeed was followed up by the mild and courteous motion of Sir William Gull, it would be the natural corollary of what was done on Saturday. The Scotch members would all be prepared, he believed, to vote for Sir William Gull's motion, and they would endeavour to prepare a scheme for such a Conjoint Board as might be presented to the Council. Whether it would be approved by Dr. Storrar he did not know; but it did not matter one pin—for if a good honest scheme were presented and refused, then let the Council

bring in a legislative enactment, but do not let them at this stage bring forward motions by which a slur was thrown on Scotland. Ireland could speak for itself, and Scotland could speak for itself. Let them recollect its emblem and its motto—*Nemo me impune lacessit*. No more loyal men to the Council were to be found than the Medical authorities in Scotland, but they must not be degraded into mere endorsers of what was proposed in England. (Cheers.)

Dr. BENNETT regretted that Dr. Andrew Wood had not spoken in a more conciliatory tone. He was quite satisfied that the Scotch members were anxious to carry out the views of the Council, and that their difficulties were very much greater than those experienced in England. At the same time he thought there was some foundation for the dissatisfaction felt on the part of some members of the Council that Scotland had not proceeded further, and had not yet fully grappled the whole scheme; but they were beginning to understand it more fully than they did at the commencement of the session; and he believed that in the course of a few months they would be able to bring up something with which the Council would be satisfied. It would be well not to be continually throwing in the teeth of the Council the perfection of the English scheme. It was not expected that the Scotch scheme would be a perfect scheme; but if they would only bring forward one as nearly perfect as the English, it would be carried as unanimously. He hoped that Dr. Parkes would see it his duty to withdraw his motion, and to allow Sir William Gull's to take its place as a substantive motion, for he felt sure that it would meet with the general concurrence of the Council. With reference to what was said about the one qualification of the Apothecaries' Company, it was perfectly true that such qualification was registered. But what would it be worth by-and-by? Men must go for a double qualification, and to get that they must come to the Conjoint Board; so that in that respect the scheme would be a complete scheme for England.

Dr. STORRAR said that Dr. Parkes could not be more earnest than himself in his desire to secure these Conjoint Examinations. At the same time, he felt persuaded that it was no use entertaining the idea of proceeding by Bill in Parliament, because the Parliamentary list of business was so crowded that there was very little chance of Medical legislation. Certainly no Bill could succeed in Parliament which had not the support of the Government, and he did not think from past experience that the Government would give its support to any measure of Medical reform which had not received a considerable amount of Professional unanimity. If a Bill were introduced this year or next year to which the Scotch Bodies were opposed, the influence of the Scotch Corporations and Universities would certainly prevail against the passing of that measure by the House of Commons. He would therefore urge upon the Council to do what they could by persuasion, by influencing public opinion, by enabling the Professional Bodies in Scotland, Ireland, and England to see what was the great object to be accomplished in the interest of the Profession; and if they went on hammering in this legitimate way upon the convictions of the public their success was certain. It had been asked, What was the good of having a Conjoint Board in England, if there was not one in Scotland and Ireland? The reply was, That there was a great advantage if, in a country which embraced twenty or twenty-two millions, and which furnished by far the widest field for practice in these realms, they could set up an effective pattern of Conjoint Examinations. Another objection was, that if the standard was very high men would go off to other Bodies; but he was not afraid of that. Good men would always prefer the best examinations within their reach; and if it should happen that the scum of English schools found their way to other schools—

Sir DOMINIC CORRIGAN: Scotland or Ireland?

Dr. STORRAR would not venture to say whither; but if such turned out to be the fact, then he would say that England would be the gainer, and there would be such a prestige given to English qualifications that the public would make a still broader distinction than they do now between English qualifications and qualifications derived from other sources. Having a little Scotch blood in him, he occasionally expressed himself in impetuous terms; but, at the same time, he was free to acknowledge that, although improvement had been slow, yet it was real. The Profession was in a much better condition than in 1858. No one who was aware how necessary it was in all affairs to carry the full swing of public opinion with them would doubt that they must act in the spirit of the old proverb—*Festina lente*. Whilst, therefore, he was most eager to promote the object Dr. Parkes had in view, he could not vote for the motion, but would support Sir William Gull's,

which he thought applied just that amount of courteous pressure on the Bodies in Scotland which would accomplish the object.

Sir WILLIAM GULL thought it would save the time of the Council if he proposed his motion as an amendment. He sympathised with Dr. Parkes very much as to the desirability of moving in the direction of a conjoint scheme; in fact, the time had passed for any argument as to its desirability. The point now before the Council was the difficulties peculiar to Scotch and Irish Bodies. Some Professors spoke of an additional expense being entailed on the students without any commensurate result with regard to the security of the public. In answer to that, he would say that the conjoint scheme was not for the sake of the Profession at all, but for the public, and that where an examination was for the safety of the public, the public should pay for it. Those who opposed the scheme did not seem to be quite alive to the idea of the Council as to a Conjoint Board, which idea was to set Corporations and schools free to teach many things which they cannot teach until they are released from the trammels of elementary things. This had been the guiding thought in the proceedings of the London University. Years ago, when the students of the London University were anxious to get the licence to practise with the degree, he objected to it, and thought that that should come in another way, because Universities had nothing to do with the mere practice of Medicine so called, but they had to do more with propagating a knowledge of the science of Medicine in its true sense. Another objection, which came from Edinburgh, had regard to the immense number of candidates. He had inquired from two of the members as to the number that would be likely to pass yearly in Scotland, and found that the maximum would not be above 250. Surely 250 candidates might be examined in a year without very great difficulty. In all departments of knowledge Scotland had taken a very leading part, both in Medicine and general science; therefore England could not put itself forward as leading the way at all. He had been much struck with the high position which men coming up from Ireland and Scotland took in the Civil Service examinations of the country, and he had no doubt that their Medical training was even superior to that of average English Medical students. His amendment, therefore, could not by any possibility be understood as any slur upon Scotland. He would now move—"That a notice of the resolution of March 2 be sent to the Medical authorities of Scotland, together with a statement that the Council still urges upon them the desirability of a Conjoint Scheme of Examination, and expresses the hope that such a scheme as the Council can sanction may be submitted to the Council by January 1, 1873."

Dr. HUMPHRY seconded this. He said that he was quite of opinion that they were more likely to attain their object by a courteous pressure upon the several Licensing Bodies than by going to Parliament, and he thought that the Council would show not only firmness but dignity by passing a resolution of that kind quite as much as by going to Parliament for a compulsory measure. To what extent the Conjoint Examination should go—whether it should be supplemental to other examinations, or whether, as was proposed in England, it should take the place of them—should not at the present time be discussed. The hope was that the Scotch Bodies would endeavour to frame such a scheme of examination as they thought best for Scotland. He regretted that Dr. Andrew Wood reproached England for the imperfection of its scheme. That very imperfection might assist Scotland in carrying out the same project; and, notwithstanding all the objections urged by various individuals, he would hope that the scheme would prove a success.

Dr. ALEXANDER WOOD drew attention to the different constitution of the Medical Bodies in Scotland, compared with those of England, every member of the Bodies in Scotland taking a part in the deliberations and having a vote, whereas in England the great bulk of the members had merely a nominal connexion with the Bodies to which they belonged; and he said that the members of the Profession in Scotland would naturally feel all the more alarmed on that account, for the interest of the Bodies with which they were so closely identified. He had listened with pleasure to some of the speeches which had been made, but a speech made even with Sir William Gull's well-known ability would never have equal weight with the report of a committee of the Council, to which he proposed that this matter should be submitted for careful consideration. Such a committee might meet with members of the Scotch Bodies, and endeavour to persuade them to come to the point at which they had arrived in England, and even to go a little further, and have a scheme which might

be even more thoroughly satisfactory to the Council than the English scheme.

Sir D. CORRIGAN characterised Dr. Parkes's resolution as exceedingly ill-judged, and the language used in introducing it as still more ill-judged. With respect to the Queen's University, in the first place, he would give as distinct a denial as courtesy would permit him to the statement that that University had evaded giving an answer to the Council's letter in the first instance; but he fully admitted that finally it gave no reply, simply because it scorned the attack. Two years had passed over, and now Dr. Parkes had got himself into the same scrape with the Scotch Bodies. Dr. Bennett seemed to think that he had got Apothecaries' Hall into a trap, but the fact was that a man who had got his licence from that Society had simply to go up to Scotland and present himself to the College of Surgeons. They had been informed that whatever took place the College of Physicians and the College of Surgeons in Edinburgh must continue to give their separate licences; therefore, what became of the whole idea of a Conjoint Scheme under such circumstances? It was clear that Dr. Storrar had not much practical experience with regard to Professional appointments, because he had fallen into a good-natured, romantic error—namely, that by acting upon the motto, *Festina lente*, the public would at length find out that the wonderful Conjoint Scheme of England would be valued so much that the people who had the giving of appointments would not give those appointments to men coming from any other part of the United Kingdom—that is to say, from Scotland or Ireland. With regard to that, all he could say was, after a very extensive experience, that in Ireland, at least, boards of guardians did not care one penny about the superior qualifications of a man who went before them as a candidate, with the single exception of a case when a board of guardians happened to be in such a distant part of the country that they could not get any Medical man unconnected with the board to attend themselves when they were sick, in which case they looked very sharply after the qualifications of the man; but where it was in a large district, or a populous city, boards of guardians never cared a penny about the qualifications. Some years ago he gave evidence before a committee of the House of Commons, and he would repeat it now, that if he wished to be successful in seeking such an appointment, he would rather have the qualification of a bank discounter than the qualification of Hippocrates. (Laughter.)

Dr. QUAIN reviewed the points contained in Sir Robert Christison's letter, and contended that the arguments in the letter were based upon an entire misconception of the English scheme.

Dr. FLEMING thought that the energy and common sense of the Scotch would carry them through the difficulties.

After some remarks from Drs. THOMSON, MACROBIN, and ACLAND, Sir William Gull's amendment was put and carried.

Upon being put as a substantive motion, Dr. BENNETT moved, and Dr. ACLAND seconded—"That the date of July 1, 1872, be substituted for January 1, 1873." This was agreed to.

COMMUNICATIONS FROM IRELAND.

The following communications from the Apothecaries' Hall and the Royal College of Surgeons of Ireland were read:—

The Apothecaries' Hall of Ireland, Dublin, March 1, 1872.

Dear Sir,—I have the honour to enclose copy of resolutions passed at a meeting of the General Council of Apothecaries' Hall, on February 14, 1872, and would respectfully ask you to lay it before the President and Medical Council at your earliest convenience.

I am, dear Sir, yours, &c.,

Dr. Hawkins.

(Signed) ROBERT MONTGOMERY, GOVERNOR.

The Apothecaries' Hall of Dublin, February 14, 1872.

Resolutions adopted by the General Council of the Apothecaries' Hall of Ireland, February 14, 1872:—

"That the proposed 'Scheme' for the formation of a Conjoint Examining Board for Ireland (see Minutes for February 29, 1872) commends itself to the approval of the Company for the following reasons:—

1. "That it provides ample means for securing a sound preliminary and Professional examination for Medical students.

2. "That it holds out marked encouragement to University education and training.

3. "That the constitution of the Conjoint Examining Board is such as to insure for the public a class of Medical Practitioners who shall be thoroughly tested in every department of the Profession.

4. "That it proposes having three Professional examinations in number, thereby tending to lessen the evil of the existing practice of cramming the student.

5. "That the fees for the examination or examinations of the Conjoint Scheme shall be only such as will cover the expenses of these examinations.

6. "That the right of the Medical authorities to carry out their respective regulations for their several degrees and licences is left intact.

7. "That by consolidating the Medical institutions of the country it will infuse strength and harmony into the whole Body Corporate of the Medical Profession in Ireland. The Company, however, are decided in the opinion that there ought not to be less than three examiners to form the Board for conducting the examination in each group of subjects specified in the table of the report, as a lesser number can hardly give a sufficient

or satisfactory examination owing to the great extent of these subjects, and especially as the larger number will have the effect of correcting any tendency that might exist to onesidedness on the part of an examiner."

(Signed, on behalf of the Governor and Company
of the Apothecaries' Hall of Ireland)
C. H. LEET, M.D., Secretary.

Royal College of Surgeons in Ireland, Dublin, March 2, 1872.

At a meeting of the Council of this College, held on February 17, 1872, the following resolution was passed, viz. :—

"That the Council, believing that the tendency of the scheme would be to supersede all existing degrees and diplomas by substituting the Conjoint Examination for them, is of opinion that no candidate (except in the case of graduates in Arts hereafter specified) shall be admitted to the final examination under the Conjoint Scheme unless he shall have paid to the 'Conjoint Fund' a fee of not less than thirty guineas, which shall be apportioned among the Co-operating Medical Authorities upon some equitable principle.

"That graduates in Arts of any British University shall be admitted to the final examination under the Conjoint Scheme upon payment of such fees as shall cover the expenses of this examination, but such graduate shall not be thereby entitled to the licence or diploma of the Colleges of Physicians or Surgeons or that of the Apothecaries' Hall without payment of an additional fee."

Dr. HUMPHRY moved—"That this Council expresses its regret that no scheme has been framed and submitted to the Council by the Medical Authorities in Ireland for establishing a Conjoint Examination. The Council has considered the resolutions of the Conference of Representatives on this question, and hopes that a scheme for a Conjoint Examination which the Council will be able to sanction may be submitted to the Council by July 1, 1872." He drew attention to the resolutions passed at a conference consisting of representatives of the Medical Authorities in Ireland, to the effect that the Conference agreed that it was expedient to have a joint examination in Medicine, Pharmacy, and Midwifery; and that the Irish Medical Authorities should not give their qualification to any candidate who had not passed such examination. The fact that those resolutions had been passed warranted them in expressing, with regard to Ireland, the same hope as had been expressed with regard to Scotland—that there would be forthcoming from that country a scheme for examination which would receive the sanction of the Council. The various remarks which had been made with respect to Scotland rendered it unnecessary to repeat the same line of argument now they were dealing with Ireland, because the two nations stood very much in the same position.

Dr. STOKES, in seconding this, said that he wished to remind Dr. Parkes that the Council had been constituted without any mandatory power, either direct or indirect; and such old institutions of the country as Universities and Medical Corporations were not to be dictated to on the *sic jubeo* system. Edmund Burke said that in all human transactions there must be an element of mutual confidence to bring them to a successful termination. There had been several attempts made by the different Irish Bodies to accomplish the scheme now under discussion; and a late conference between the College of Surgeons and the College of Physicians failed simply on the money question. There was an earnest desire to fulfil the wishes of the Council, but the difficulties were greater than those in England. They had in Ireland two Universities giving the higher degrees in Medicine under totally different arrangements; and they had to co-opt the Apothecaries' Company into the scheme. The University of Dublin, the Queen's University, the College of Physicians, the College of Surgeons, and the Apothecaries' Company, had all acted loyally towards the Council by sending some of their best men as their representatives to the Conference. The report of the delegates did not propose to interfere with any of the Bodies as to Professional education; it carried out the views of the Council as to preliminary education, and determined to entrust the preliminary examinations to the Universities of Ireland, thus taking the onus off the hands of the Corporations. It also encouraged University education, which was a great desideratum, assisting to place the members of the Medical Profession in the same social position as those of the Church and the Bar. He had voted against one resolution of the Conference—namely, that which recommended that candidates for the Conjoint Examination should pass three Professional examinations—because he thought there was great danger in a multiplicity of examinations. As long as they were tutorial they could not be too many. Examinations were good when they were educational, when they were applied to clinical Medicine or clinical Surgery, and when applied to the *art* of Surgery and the *art* of Medicine; but a long acquaintance with examinations had led him to the conclusion that when examiners took their candidates into the more recondite parts of the theory of Surgery and Medicine, there was a great danger of their falling into the mistake of seeking to find out what a man did *not* know.

(Cheers.) The report had been sufficiently adopted by the Licensing Bodies to justify him in saying to the Council that an enormous advance had taken place in the right direction among the Medical Bodies of Ireland. He could trace a sensible improvement from the second year of the existence of the Council. Young men had wonderfully improved in habits of industry, gentlemanly conduct, and literary attainments—in fact, they were not like the same individuals that they were. He quite agreed with the opinion that the result of the joint scheme would be to promote higher education, by relieving the Universities from the drudgery of teaching the A B C of Medical science.

Dr. A. SMITH reminded the Council that the report of the Conference was not intended to bind any one. It was only a report of delegates, and in no way did it issue from the Licensing Bodies; but it proved that the Irish Bodies had made a nearer approach to a complete Joint Examining Board than had been made by any other Body. Upon the subject of examination, he had long been of opinion that the test of an examination was of very little value when compared with the great importance of a *bonâ fide* preliminary examination; and the Council, he thought, had not devoted the attention it ought to insure that. One paragraph in the report he considered to be very valuable—viz., that in which they suggested that the constitution of the Preliminary Examining Boards should be dealt with by the Universities. No one thing would so much raise the educational standard of Medical men as the institution of *bonâ fide* boards to superintend preliminary education.

After a few remarks from Dr. APJOHN,

Dr. LEET said that the Apothecaries' Company of Dublin were prepared to admit such modifications in the scheme as would bring in the outstanding bodies, which he hoped would be accomplished.

The PRESIDENT: I shall vote for this motion with great satisfaction, particularly on account of the reference which has been made to the resolutions of the Conference of Representatives. When we consider what we know to be the fact—that there were fifteen of these gentlemen—three representatives of each of the five Medical Authorities of Ireland—that they met sixteen or seventeen times; that they were busy men, whose time was valuable to them—men of ability (as is shown by the scheme which they have produced, if by nothing else)—I think that this Council is bound to acknowledge the labours of these gentlemen. This scheme is actually more complete than the English scheme, because, in fact, it will include all the five Bodies in Ireland; and more comprehensive, because it includes proposals with regard to preliminary education as well as Professional education. At the same time, this Council, I think, must regret that the Bodies they represented were not of the same opinion as their representatives. But we have some hopes that they will soon come into the scheme, because three of the five Bodies, including the very distinguished University of Dublin (which assents to the general principle of this scheme, though objecting to one of the details), the College of Surgeons, and the Apothecaries' Hall, have given a general assent to it. With those facts before us, the prospect with regard to Ireland is not a hopeless one.

The motion was unanimously passed.

It was then agreed, on the motion of Dr. HUMPHRY, seconded by Mr. HARGRAVE—"That a copy of the foregoing resolution be forwarded to each of the Medical Authorities in Ireland."

SPECIAL EDUCATION OF WOMEN.

Dr. ACLAND moved—"That a committee be appointed to consider and report whether the General Medical Council has power to make rules for the special education of women, such as may entitle them to obtain a qualification to be certified by the Council. And that the committee do further report for what purpose such qualifications, if any, should be granted, what are the most desirable means for educating, examining, and certifying in respect of them, with especial reference to midwifery, the management of Medical institutions, dispensing, and nursing." He wished it to be distinctly understood that his motion had nothing to do with the question so much discussed of late, and which had been the source of a great deal of discomfort in Scotland—viz., whether or no women were entitled to be entered upon the Medical Register as ordinary Medical Practitioners. He avoided this by not using the words "Medical qualification." All that he asked was that a committee of inquiry should be appointed. Anyone at all conversant with the condition of the poor, especially in great towns, or with the condition of the labouring poor in agricultural districts, knew

perfectly well that there was a great want of well-trained women as nurses and midwives. Proof of such want was furnished by the fact that various institutions were endeavouring to supply it by furnishing women with certificates for various qualifications. The question, therefore, was (the want being admitted), was it the duty of the Medical Council to provide a licensed, and therefore a properly qualified, class of women for ministering to the sickness and sufferings of the poor? It was not necessary that the Council should examine such persons, but it would be desirable to have a general supervision of the institutions which granted the licences or certificates to trained and experienced women. Something of the sort was in operation at St. Thomas's Hospital; and, whether the idea was good or bad, no possible harm could result from an inquiry. It was very certain that there was an increasing demand in all departments of work for the service of women, and they were doing their work remarkably well in the post-offices and other places. (Cheers.) Was it not fitting, therefore, that the Medical Council should exercise some control over the qualifications and certificates that were being given to women as nurses and midwives?

Dr. STOKES seconded this.

Sir DOMINIC CORRIGAN spoke strongly against the motion.

The discussion was adjourned at six o'clock till the next day.

FIFTH DAY.—TUESDAY, MARCH 5.

The adjourned debate on Dr. Acland's motion was resumed by

Dr. ANDREW WOOD, who said when he first received notice of the motion, his impression was that Dr. Acland was anxious to bring into the Council some portion of the troubles by which Edinburgh had been vexed for the last three years; and he had some little hopes that it might act as a *diverticulum*, and quit Edinburgh of the matter to some extent. He was somewhat confirmed in this view, because he saw that the newspaper in Edinburgh which had all along advocated the "woman's rights" opinions had got hold of this motion in some way or other, and had inserted it with a chuckle. He had not the slightest doubt that the hearts of Miss Jex Blake and her compatriots were strongly agitated with hope that the question was being removed to a higher sphere than before. It was now a great relief, though it would be a monstrous disappointment to the ladies in Edinburgh, to find that the motion was really a much smaller affair; and now that it had been explained by Dr. Acland, he was utterly at a loss to understand why the Council had been called upon to interfere in the education of midwives. If the question had been the education of women, it would have been something worthy of Dr. Acland's lance, but for the Council to appoint a committee to draw up a curriculum of study and to endeavour to obtain a qualification for nurses, and midwives, and managers of Medical institutions, even if it was within their power, would be unworthy of them. No doubt it was of great consequence that midwives should be properly trained, but who were the proper persons to give that training? Why, it was done in every maternity institution in the kingdom, and the question of the training of nurses was drawing attention in many influential quarters. There were registers for midwives, and registers for nurses, but Dr. Acland ought to have thought twice before bringing a motion before the Council which sought to make an addition to the Medical Register for the benefit of nurses and midwives. The motion was completely *ultra vires*. The Council had no power to institute a new qualification; and even if they had the power he doubted whether it would add to the dignity of the Profession, or be in their proper sphere to institute it. Let Dr. Acland apply the same energy to this great subject out of doors which he had shown in the Council, and he would be applying it in its proper place. No doubt great results might accrue, but the Council had quite enough to do in registering and taking charge of the Medical Practitioners of the country, without bothering themselves with women. (Laughter.) Woman now, as in former days, was the *teterrima causa bella*—(laughter)—and it would not add to the cause of peace to introduce the woman question into the Council.

Dr. A. SMITH said he concurred in all the objections which had been made to the motion. Even if the Committee were appointed, and did report in accordance with what Dr. Acland had so well advocated, the Council would not be able to take any action upon it. The very title and preamble of the Medical Act precluded them from acting upon it. They had no power except to register and superintend the education of qualified Practitioners. The best course for Dr. Acland to pursue would be to withdraw the motion, for it would expose the Council to a good deal of censure out of doors if it appeared that time

had been occupied in discussing a proposition the result of which must be that they could take no action upon it.

Dr. ACLAND, in reply, said if he had to argue against the motion, he thought he could do so with much more force than he had yet listened to. Notwithstanding the care which he had taken to separate entirely the question of the Medical education of women from this subject, Dr. Andrew Wood seemed to have fallen into the same mistake as Sir D. Corrigan, and had begged the Council not to be dragged into the same dilemma as the Edinburgh University had been dragged into. The motion, however, had nothing to do with that subject. It simply raised the question whether, there being already a number of persons trained and said to be qualified, they were to remain outside the province of the Council on account of their sex. Dr. Andrew Wood had recommended him to go and do what he wished outside the Council; but, after fifteen years' experience, his colleagues knew him better than to think that, in a matter which, in his judgment, essentially concerned the Medical Profession, he should leave the Council alone and get up an agitation outside. His motion pledged the Council to nothing except an inquiry. Even Sir R. Christison had told him that, had he been present and able to do so, he would have consented to serve on the Committee.

Dr. ANDREW WOOD: But he is not in favour of your motion.

Dr. ACLAND said he should not wish to have a committee of members all of one way of thinking. It had been said that the Council had nothing to do with the licensing of midwives, but in the list of qualifications on the Register he found no less than three distinct licences in midwifery. At present these were confined to one sex, but he wished the Committee to say whether there was anything in the nature of those licences which justified them in discouraging persons of the other sex. He would ask Mr. Quain to say if he knew of anything in the by-laws or charter of the College of Surgeons which prevented the grant of the licences in midwifery to the other sex.

Mr. QUAIN said he did not know enough to answer the question one way or the other.

Dr. ACLAND said he had taken great pains to ascertain whether the subject was a proper one to bring before the Council, and he had met with only one opinion on it—namely, that it was a most desirable one for the Council to consider. When the report of the Committee was brought forward, he for one should be most unquestionably against doing anything if it appeared from the evidence undesirable or inexpedient.

The motion was carried by a majority of 1, 11 voting in its favour and 10 against.

The following members were then proposed for the Committee:—Sir W. Gull, Dr. Quain, Mr. Quain, Dr. Stokes, Mr. Hargrave, Dr. Thomson, Dr. Macrobin, and Dr. Acland.

Dr. QUAIN said no one could have a stronger conviction than he that the Council had not the power to make rules for the special education of women such as might entitle them to obtain a qualification to be certified by the Council; but he thought it was due to Dr. Acland to consent to the Committee.

Dr. ALEXANDER WOOD said, if the question had been the wider one which was discussed in Edinburgh, in regard to the admission of ladies to the Medical Register, that would have been quite within the sphere of the Council; but Dr. Acland, in moving the motion, so expressly limited it to the mere question of sick nurses that it was placed altogether outside the province of the Council, and if any of the money which by Act of Parliament was raised for special purposes was devoted to this inquiry, legal questions might arise upon it. Under these circumstances, he should decline to have anything to do with the consultations or deliberations of a Committee whose first duty should be to look at the Medical Act and point out by which clause they were entitled to supervise the education of sick nurses.

The Committee was then agreed to.

THE ENGLISH CONJOINT BOARD.

Dr. HUMPHRY moved, as a rider to the motion that had been passed with regard to the English Conjoint Board—"That this Council trusts that arrangements for carrying out the scheme for a Conjoint Examination by certain of the English Medical Authorities, which has received the sanction of the Council, will be so matured that the contemplated examination may commence early in 1873. The Council direct that a copy of this resolution be forwarded to each of the Medical Authorities co-operating under the above scheme." It appeared to him desirable that the Council should be able to look forward to some time when the examination should commence, so that the students and the Profession at large might not expect it to take place sooner than it really would. Certain of the Medical Authorities of London had already begun to consider the mode

in which the examination should be conducted, and he had learnt that it was scarcely possible that the arrangements could be matured before 1873, for some of the Authorities would have to alter their by-laws, which could not be done except in a regular or rather slow manner.

Dr. BENNETT seconded the motion.

Mr. QUAIN thought it would probably be better to ask the different Bodies to communicate with the Council in July, as to when their arrangements would be completed.

Dr. ACLAND asked if Dr. Humphry meant that the Conjoint Examination should begin early in 1873, and that all others should cease.

Dr. HUMPHRY: When this begins others will cease.

Dr. ACLAND said, in that case, it ought not to pass without further explanation.

Mr. QUAIN said the motion had been brought forward without notice, or any opportunity being given of consulting those who were engaged in the business of the institutions.

Dr. A. SMITH supported the view taken by Mr. Quain.

Dr. PARKES said, if the motion were agreed to, it would not enable them to inform the students when the Conjoint Examination would commence.

Dr. HUMPHRY said the object of the motion was to express a courteous intimation that the examination ought to commence at that time.

Mr. QUAIN said it was usually the rule that a young man was examined according to the laws in existence at the time he began his studies.

Dr. EMBLETON thought it would be better to delay the matter until the Conjoint Board for England were really formed. It was quite possible that by July the Apothecaries' Society might find means to join in the scheme. The students would require considerable notice before presenting themselves to the new Board.

The PRESIDENT thought the motion had answered the purpose for which it was brought forward, and therefore it might be withdrawn. The students would now know, at all events, that they would not be examined by the Conjoint Board this year.

Mr. BRADFORD expressed an ardent hope that means might be found to render the scheme for a Conjoint Board for England perfect. His individual opinion was that means might be found to enable the Society of Apothecaries to join the scheme. (Hear, hear.) He knew the sentiments of the governing body of that Society, and was quite sure that the feeling among them was in favour of co-operating in the formation of the Conjoint Board. Great misapprehension had prevailed on this point, and he should be sorry for the Council to separate without removing the misapprehension that it was a wilful act on the part of the Society to secede last year. He believed the other Bodies did not really know what the difficulties were which the Society had to contend with, but in another part of the counsel's opinion which was read at the meeting, means were suggested by which the difficulties might be got over. Unfortunately, it was imagined that the Society had wilfully seceded from the conference. If the Conjoint Board were established with the assistance of the Society, it would undoubtedly flourish like a tree planted by the river-side—(laughter)—but if the Society did not co-operate, nothing but difficulties would ensue. They had been told that if they did not join in the scheme they would, like certain foetal organs, cease to exist. He did not apprehend any such result, for he believed the Court of Examiners of the Society of Apothecaries was one of the vital organs of the Profession. He assured the Council that every means should be taken to overcome the difficulties which had arisen. (Hear, hear.)

The motion was then withdrawn.

Dr. ACLAND moved—"That a Committee be appointed to draw up a scheme of regulations, common to all the Conjoint Boards, having reference to the time and mode of the commencement of the examinations of the Conjoint Boards, and the cessation of the examinations of the other Examining Boards."

Dr. ANDREW WOOD: First catch your hare.

It was then objected by several members that the motion was too important to be brought forward without notice, and it was accordingly withdrawn.

The consideration of the report of the Committee on the Visitation of Examinations was again postponed.

The report of the Committee on the Registration of Medical Students and on Returns of Professional Examinations was as follows:—"Your Committee, owing to the time necessary for the complete correction and verification of the above-named returns being longer than the present short sessions of the

Council allow, and the recommendation of the President of the Council to this effect, beg leave to suggest that in future the returns hitherto compiled by this Committee be confided to the care of the Executive Committee."

The report was received and adopted on the motion of Dr. EMBLETON, seconded by Mr. HARGRAVE.

The report of the Committee on Army Medical Returns was approved, and the thanks of the Council were voted to the Director-General of the Army:—"Your Committee have carefully examined the returns supplied at the request of the Council by the Director-General of the Army Medical Service. They are of opinion that the best thanks of the Council are due to the Director-General for kindly acceding to their request, and altering the form of the returns from that adopted in former years. They recommend the Council to direct that the returns be printed on the Minutes."

The PRESIDENT said that of thirty-four gentlemen examined, only one entirely failed in the examination. The percentage of failures had decreased enormously in the course of the last few years. There was a time when it was 40 per cent.; now it was only about 3 per cent.

The following recommendations of the Executive Committee with reference to penal measures were also adopted:—

(From Minutes of Executive Committee for February 28, 1872, p. 4.)

Read—The following resolution, passed by the General Medical Council on July 8, 1871 (p. 32, sect. 4):—"That it be referred to the Executive Committee to report on the most desirable mode of procedure in the case of motions having reference to any penal measures."

Resolved—1. That the deliberations of the Council between the completion of the evidence and the decision of the case be held in private. 2. That the question as to the person charged being guilty or not guilty be put from the chair, and not in the form of resolution by mover and seconder.

The PRESIDENT said he had received two letters which referred to matters that ought to come under the cognisance of the Council—one was from a gentleman at Shrewsbury, acting on behalf of an association which had been recently engaged in prosecuting unqualified Practitioners; and the other was with reference to foreign degrees which could not be entered on the Register.

The first letter was referred to the Branch Council; the second related to a matter which the Council had no power to deal with.

The Executive and Pharmacopœia Committees were reappointed.

The following letter from the office of the Commissioners in Lunacy was read:—

19, Whitehall-place, S.W., March 2, 1872.

Sir,—I am directed by the Commissioners in Lunacy to call the attention of the Medical Council to the fact that Mr. William Dobson, a Member of the College of Surgeons, England, and Licentiate of Apothecaries' Hall, not being registered under the Medical Act, appears to have been practising at Malvern-road, Beeston-hill, Leeds, and so practising he recently signed a certificate under the Lunacy Acts. He has promised forthwith to register, and upon that understanding only do the Commissioners refrain from proceeding against him criminally.

I am, Sir, your obedient Servant,

(Signed)

CHARLES PALMER PHILLIPS, Secretary.

Dr. F. Hawkins, General Council of Medical Education, etc.

The Registrar was directed to acknowledge with thanks the receipt of the letter.

The Finance Committee's report was agreed to on the motion of Dr. QUAIN.

The Finance Committee beg leave to submit to the Council in the annexed table a statement of the income and of the expenditure of the Council during each of the years 1870 and 1871, and of the estimated income and expenditure for the year 1872.

It will be seen that the income of the year 1871 is less than that of the year 1870 by the sum of £510 5s. This diminution is due chiefly to a decrease in the amount of registration fees. This decrease appears in the returns from each of the several Branch Councils—the amount received by the English Branch Council being less during the year 1871 than that of the preceding year by £178 10s.; that of the Scottish Branch Council, by £111 15s.; whilst that of the Irish Branch Council is less by £117 5s. There is also a decrease in the amount credited to sales of Pharmacopœia and balance of account. This decrease, however, is not due to a diminished sale of the Pharmacopœia, but to the fact that the balance of £337 0s. 6d. to the credit of the Pharmacopœia account in 1870, which had been previously kept separate, has since then been paid over to the general account.

The expenditure for the year 1871 being less than that of 1870 by £1128 18s. 8½d., there is a balance in favour of income for the year 1871 of £878 19s. 6½d.

The reduced expenditure for 1871 is due to the fact of there having been but one meeting of the Council during that year 1871, whilst the Council assembled twice in the preceding year.

A communication addressed to the Chairman by Mr. Bell and Mr. Roope, applying for remuneration for extra work in connexion with the investigation into the accuracy of the Register, being laid before the Committee,

It was resolved to refer the application to the Executive Committee, who have charge of the publication of the Register.

March 2, 1872.

(Signed) RICHARD QUAIN, M.D., Chairman.

ORIGINAL LECTURES.

LECTURES ON THE
COMPARATIVE ANATOMY OF THE ORGANS
OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE II.

THE subject which will come next under our consideration is the general position of the alimentary canal within the abdominal cavity, and especially the mode in which it is retained in that position by the various layers or folds of the peritoneal membrane which pass around it. I propose now to treat only of the most ordinary, or what may be called typical, conditions of these parts in mammals, with which we should be well acquainted before we are able to appreciate the extent and the characters of the various deviations from these conditions so frequently met with.

To understand this somewhat complicated subject clearly, we must begin at the period when the alimentary canal is nothing more than a simple straight tube, suspended in the mesial line by a fold of peritoneum attached along the posterior or vertebral side of the abdominal cavity. (a) When the various portions of the canal become differentiated, the upper part of this fold will be the *mesogaster*, the next part the *mesentery*, the next the *mesocolon*, and the lowest the *mesorectum*. The changes which first take place in the canal are a widening of the calibre of the upper part to constitute the stomach (see Fig. 1, *g*), and an immense elongation of the part succeeding this, into the middle of which passes the vitelline duct, a structure which soon disappears, and is of no further consequence. The elongation at this particular spot, the two ends being comparatively fixed, causes the intestine to assume the form of a large loop, which for a time projects out of the body of the fœtus at the umbilicus, and which carries with it the corresponding portion of its peritoneal attachment or mesentery (Fig. 1, *me*). This loop has a narrow neck, formed by the

FIG. 1.

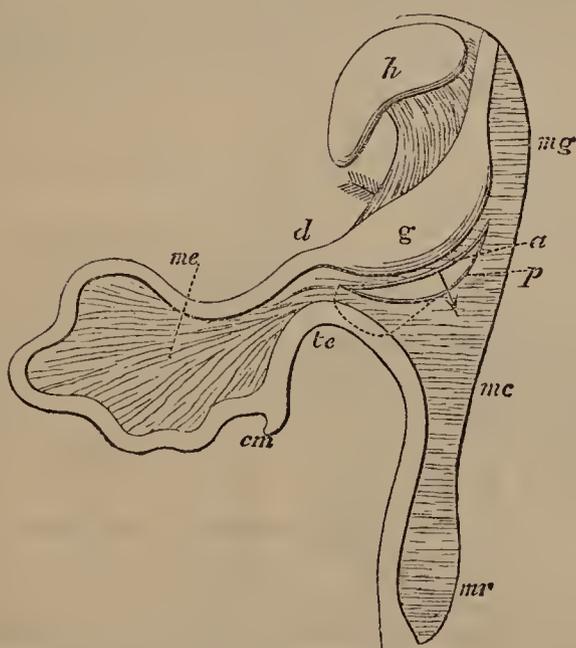

FIG. 1.—Diagrammatic representation of intestinal canal and its peritoneal attachments:—*h* the liver, *g* the stomach, *d* the duodenum, *cm* the cæcum, *te* the transverse colon, *mg* the mesogaster, *me* the mesentery, *mc* the mesocolon, *mr* the mesorectum. The peritoneal fold between *h* and *g* is the gastro-hepatic omentum; *a* and *p* are respectively the anterior and posterior layers of the great omentum or epiploon (which is supposed to be projected towards the observer) when in its simplest condition in mammals, being formed only of the mesogaster. The arrow is passed behind the gastro-hepatic omentum (through the foramen of Winslow) and the stomach, into the cavity or sac of the great omentum. The dotted line represents the position of the posterior layer of the great omentum, when the mesocolon is implicated in it as well as the mesogaster, as in man and some other forms.

(a) The descriptions and figures apply to the body in the upright position.

duodenum (*d*) above, and by what afterwards becomes the transverse colon (*te*) below, so that it includes the whole of the small intestine, together with the cæcum (when developed) and ascending colon. The remainder of the colon does not enter the loop, and retains more or less of its primitive condition and connexions, except that it may lengthen so as to be thrown into folds. As the part of the intestine forming the loop continues to elongate, the mesentery which supports it and conveys its vascular supply (from the superior mesenteric artery) increases in breadth at its peripheral part in a corresponding ratio with the intestine, but does not grow materially at the neck of the loop; hence the commencement of the duodenum and the right end of the transverse colon never lose their primitive relation, whatever changes take place in the position and growth of the viscera; and all the intestine between these points is slung on a continuous fold of mesentery, the root of which (containing the superior mesenteric artery) passes between them.

The loop in its early stages projects anteriorly and mesially, but after it is withdrawn into the abdominal cavity it becomes twisted upon itself to the left, and ultimately assumes somewhat of the form represented in Fig. 2. The duodenum is turned beneath the right end of the transverse colon; but they still form the boundaries of the narrow neck of the mesentery, the former being posterior and the latter anterior, instead of being above and below, as in the primitive position, and they continue the most fixed points of the whole abdominal part of the canal between the two extremities. The colon retains much of its original position and mode of attachment.

The rule that the whole of the intestinal canal is surrounded by, and suspended to, a continuous peritoneal fold is departed from in the adult condition in man and some of the higher Primates, in which at certain regions the intestine, appearing to grow faster than the corresponding portion of mesentery, gets more or less behind or outside its peritoneal covering. These parts are the duodenum and the ascending and descending colons; but this condition is perfectly exceptional among mammals.

The stomach changes very much from its early simple fusiform shape, suspended between two layers of mesentery, which pass in front (from the future lesser curvature) to the liver, and behind (the future great curvature) to the middle line of the abdominal wall. It gradually gets placed more transversely, with the lower or pyloric end to the right, and turns round, so that what was the left side comes to be anterior; and this same side grows rapidly at the end opposite the pylorus, producing the fundus, so that, at the upper or oesophageal end, the mesogaster comes to be placed altogether on the posterior surface, but passes along the lower border as it approaches the pylorus. Between the layers of the mesogaster the spleen is developed; and it is in this part that a very remarkable change takes place, which results in the formation of the great omentum. This is a bulging forwards (see Fig. 1) of a limited portion of the mesogaster close to its attachment to the stomach, usually extending as far as the pylorus on the right and the middle of the fundus on the left. This continues to push onwards until it forms a large descending flap of peritoneum, which passes in front of the transverse colon, and usually over the coil of small intestines, but being quite unconnected with either, merely lying movably upon them. From the mode of its growth, it will be readily seen that it forms a kind of bag open only above, its interior being continuous with the peritoneal cavity, which passes up behind the stomach to join the general cavity at the so-called foramen of Winslow, behind the gastro-splenic omentum. It is possible that the two contiguous serous layers may occasionally adhere so as to obliterate the cavity; but this must be regarded as an abnormal or pathological condition, and does not invalidate the fact that the great omentum, being formed by the folding of a double-layer of peritoneum, must by the nature of its construction always contain four layers of peritoneum: the two outer ones with their serous surfaces outwards, and the two inner ones with their serous surfaces inwards; notwithstanding statements

FIG. 2.

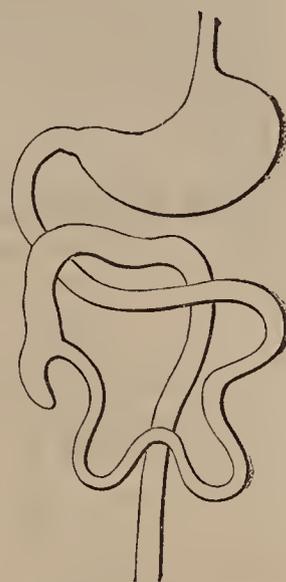

FIG. 2.—Diagrammatic plan of the general arrangement of the abdominal alimentary canal (seen from in front). The small intestine is greatly abbreviated.

that have been made to a contrary effect, to which I shall have to refer in future lectures.

In the majority of mammals, the great omentum is as above described, a process or doubling of the mesogaster only (Fig. 3, B); but in man and some other species a different arrangement occurs, by which the transverse mesocolon is more or less involved in it. This arises from the close connexion to which I have before referred between the right end of the transverse colon and the pyloric end of the stomach. At this spot, if the pushing forward (as it were) of the peritoneum takes place over a larger area than before described (as in the dotted line, Fig. 1), it will necessarily involve part of the mesocolon as well as the mesogaster, so that while the anterior layer of the omentum depends from the stomach, the posterior layer will return to the colon, and thus becomes continuous with the mesocolon (Fig. 3, C). In adult man this condition usually extends throughout the greater part of the length of the transverse colon, but in the lower Primates and in the foetal condition of man, and sometimes permanently, it only applies to the right extremity; in the middle and left part the mesocolon lying behind and independently of the omentum, as in ordinary mammals; and it must be noted that the transition from one condition to the other, which may be traced gradually in passing from left to right, is not due to any adhesion of serous surfaces as has been supposed, but simply to the extent of membrane involved in the forward growth of the great omentum. At least, this appears to me to be the true explanation of the different conditions of the great omentum met with in different animals and in different stages of human development. (b)

FIG. 3.

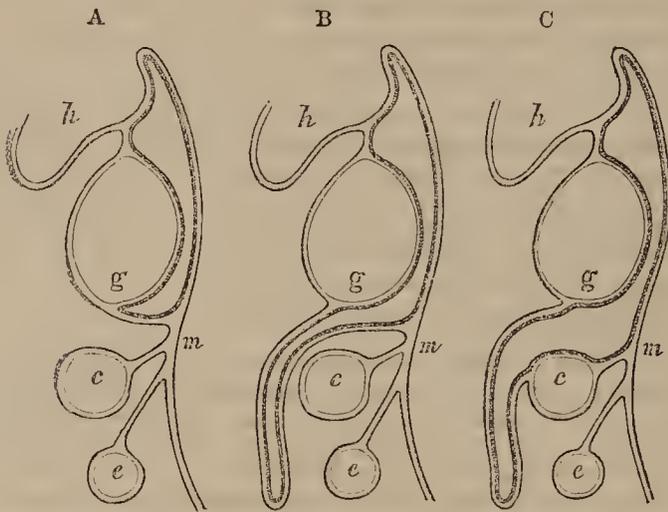

FIG. 3.—Diagrammatic plan of the different conditions of the great omentum, being imaginary vertical antero-posterior sections of the abdominal viscera. *h*, the liver; *g*, the stomach; *c*, the colon; *e*, the small intestine; *mg*, the mesogaster; *mc*, the mesocolon; *me*, the mesentery. Just as *g*, *c*, and *e* are sections of one continuous tube, winding backwards and forwards in a serpentine manner, so *mg*, *mc*, and *me* are sections of one continuous fold, following at its free edge the winding of the tube it suspends and incloses. The dark line is the layer of peritoneum bounding the lesser peritoneal cavity, or cavity of the great omentum. A represents the simple or primitive condition of these parts when no great omentum is formed. In B a great omentum is formed by the bulging forward of the upper part of the mesogaster only. In C a great omentum is formed at the expense of both mesogaster and mesocolon. Various intermediate conditions between the two last can easily be imagined, as where (as frequently is the case) the posterior layer of the great omentum joins the middle of the mesocolon.

The most important of the glands which pour their secretion into the alimentary canal, on account of its size, if not on account of the direct action of its secretion on the digestive process, is the *liver*. That it is present and largely developed in all mammals, and that it is always connected by its excretory duct with the same portion of the canal—viz., that which immediately succeeds the stomach—I need scarcely mention. It would be superfluous, also, to speak to the audience here assembled of its intimate structure or of its various and complex functions, for all the facts ascertained beyond dispute on these subjects are fully described in the courses of physiological lectures in every Medical school in the country, and minutely detailed in every text-book of physiology, while the results of the numerous recent researches made in various parts of the world, in the hope of elucidating the still numerous obscurities and difficulties that remain in connexion with it, are faithfully chronicled in several journals for the convenience

of those who wish to keep themselves *au courant* with the latest phases of discovery.

It is, however, within the province of these lectures to treat fully another part of the subject, on which it is at present impossible to turn to any existing work for a connected and systematic exposition. I mean the modifications of the external form of this organ throughout the entire series of animals composing the class.

It is true that the form of the liver has been described with tolerable detail in many monographs of different animals, and that brief notices, as those in Cuvier and Meckel, have been given of its shape and subdivisions in the larger number of families; but the fault of nearly all these descriptions is—and I here include all those I have had myself occasion to make—that they have not been drawn upon any distinct plan or with any definite system of nomenclature, and are, therefore, either unintelligible, or at least of little value, in drawing comparisons between the condition of the organ of one animal with that of another. Of course, there are exceptions to this remark, and, especially where figures have been given, it is possible to understand the construction of the organ; but even these, from being drawn from various points of view, or with the respective parts in various and different positions with regard to each other, are often difficult to comprehend.

The most general, and at the same time rudimentary method of describing the liver, is to say that it is divided into so many lobes; but as few anatomists are agreed as to what amount of severance from the adjoining tissue, or what magnitude in the severed part should render it worthy to be designated a lobe, the number of these parts observed in the same organ is often differently stated by different naturalists, or even by the same naturalist at different epochs of observation.

Duvernoy, when engaged in editing the second edition of Cuvier's great work, and with ample materials at his hands, undertook an entire revision of the question, and put forth a new system of nomenclature. (c) His views are that the lobes of a multifid liver are not the result of divisions of the organ, but of additions to a central part, which he calls the "*principal lobe*," and which constitutes almost the entire liver of man and such animals as have this organ undivided. That to this principal lobe may be added a *right lobe* and a *left lobe*, as well as a *right lobule* and a *left lobule*, and that thus the organ, when complete, is of very symmetrical composition. That one or other of these may be wanting, but no further ones are ever added, although additional subdivision may occasionally take place by partial fission of some of these; thus the principal lobe may be further divided into right, middle, and left portions. It is the principal lobe, he says, which essentially constitutes the liver; the gall-bladder is always adherent to it, and the triangular, the coronary, and the suspensory umbilical ligaments are also exclusively in relation with it, and not at all with the accessory lobes.

Criticising this classification, (d) Professor Owen remarks that "fissures rather than lobes are added to the liver of quadrupeds."

With this view I entirely coincide, more especially as one of the arguments upon which Duvernoy relied—the attachment of the coronary and triangular ligaments—does not in the least bear him out. I do not know to what animals his observations on these ligaments relate, but directly we pass to the examination of any of the forms with deeply fissured livers, we shall see that the lateral borders of the coronary (the so-called triangular or lateral ligaments) are not inserted into the principal lobe, but extend upon Duvernoy's supposed additional or super-added right and left lobes.

The difficulty which other anatomists have met with arises from the liver being divided sometimes—as in man, ruminants, cetacea, etc.—into two main lobes, which have always been called respectively right and left; and in other cases—as in the lower monkeys, carnivora, rodentia, etc.—into a larger number of lobes. Among the latter the primary division usually appears at first sight to be tripartite, the whole organ consisting of a middle, called "*cystic*" (Owen) or "*suspensory*" (Rolleston), (e) and two lateral lobes, called respectively right and left lobes. This introduces a confusion in de-

(c) "Etudes sur le Foie," *Ann. Sc. Nat.*, second series, vol. iv. (1835), p. 269; also Cuvier, "*Leçons Anat. Comp.*," second edition (1835), vol. iv., part 2, p. 431, *et seq.*

(d) "Anatomy of Vertebrates," vol. iii. (1868), p. 483.

(e) "On the Homologies of the Lobes of the Liver in Mammalia" (*British Association Report*, 1861, p. 274). In this paper the importance of the caudate lobe—called by the author "*right kidney lobule*," from its constant relation to that organ—was, I believe, for the first time indicated. It had been confounded with the Spigelian lobe of man by many anatomists.

(b) Two papers by Professor Cleland, in the *Journal of Anatomy and Physiology*, May, 1868, and May, 1870, contain some valuable remarks upon this subject.

scribing livers by the same terms throughout the whole series of mammals, as the right and the left lobes of the monkey or the dog, for instance, do not correspond with the part designated by the same name in man and the sheep. There are, moreover, intermediate conditions in which neither the bipartite nor the tripartite system of nomenclature will answer, which we should have considerable difficulties in describing, unless we can introduce a new system such as I shall now attempt, or use much circumlocution.

The liver is generally described and figured after it is removed from the body of the animal and extended upon a flat surface; the various parts are then distinctly displayed, but some violence is done to their natural relations. In this position it usually assumes a more or less quadrate or oval form, with the long diameter placed transversely. One of the long edges or "borders" is thicker than the other, also shorter, and commonly more or less excavated in the middle. From the position of this border in man, it is commonly called the *posterior* border; or because it is the part by which the organ is mainly connected to the walls of the abdominal cavity, it may be called the *attached* border. The opposite border is thinner, generally more extended in length, and is called the *anterior* or *free* border. As regards quadrupeds, *superior* and *inferior* would be more correct terms for these borders; but the first-mentioned designations are so extensively used in describing the human liver, that it would not be worth while to supersede them for others, also of partial application. To the terms *attached* and *free* I believe no objection can be made. The two ends are universally called *right* and *left*, from their respective positions in the body. The surfaces are commonly called *superior* and *inferior*, from their general relation in man, or *diaphragmatic* and *visceral*. As there is little risk of misunderstanding the former terms, I shall generally employ them. Although, as just stated, the most usual shape of the entire organ when spread out is a somewhat transversely elongated oval, it may be of reverse form, the distance from the attached to the free border being greater than from right to left side.

When *in situ* the whole organ is more or less rolled round, in a cylindrical manner, upon a central axis, so that the two extremities approach each other, the superior surface becoming convex and the inferior surface concave. The attached border being generally less extended than the free, there is more or less tendency, when the liver is largely developed, to form a short hollow cone, the apex of which is at the attached, and the base at the free border, usually incomplete for a considerable space behind, in consequence of the right and left extremities not coming in actual contact. The liver is so yielding in texture, and changes its position so readily, that this natural form can only be satisfactorily ascertained in animals in which the abdominal viscera have been hardened with spirit *in situ*.

attached than the free border, and about midway between the right or left extremities. It is a transversely elongated depression, into which the portal vein and hepatic artery enter, and from which the biliary or hepatic ducts emerge. Next to be noted among the great landmarks provided by the blood-vessels in intimate relation with the organ is the notch in the middle of the attached border, whence the great hepatic veins come out to join the vena cava inferior, which always lies in the closest relation with this part of the liver. For a short portion of its course the vena cava lies in an oblique fossa-excavated in the under surface of the attached border, passing from below upwards, from before backwards, and from the right to the left in relation to the regions of the liver itself, when removed from the body; but in reality it is rather the liver that is obliquely placed on the vein than the vein on the liver. It is not unfrequently so deeply embedded that the hepatic substance of either side of its channel meets above it, and it runs in a tunnel instead of a groove.

The third important point to note in connexion with the vessels of the liver is the position of the umbilical vein in foetal life, indicated afterwards only by its more or less persistent remnant—the round ligament (*u*). This vessel, passing from the umbilicus, approaches the liver at its free border, and runs either in a groove on its under surface, or in a channel through its substance directly to the left end of the portal fissure, whence, after giving off its branch to that vessel, it continues its course, under the name of *ductus venosus* (*dv*), to the posterior border to join the vena cava.

The relation of these vessels to one another is absolutely constant, whatever may be the external form of the organ itself. They form a kind of frame, as it were, around which the substance of the liver is encrusted, and they must be taken as the starting-point in all attempts at partitioning the organ into regions for descriptive purposes.

The umbilical vein divides the liver into two segments, one to the right and one to the left of it. These probably correspond with the two primitive bud-like projections from the intestinal wall, of which the liver is first constituted. In the early human foetus, and permanently in many animals, they are equal and symmetrically arranged, or very nearly so; and that they are natural divisions, notwithstanding the asymmetry that so often arises in the organ, and that they are corresponding or homologous parts throughout the series, can hardly be doubted.

When the two main parts into which the liver is thus divided are entire, they may be spoken of as the *right* and *left lobes*; when fissured, as the *right* and *left segments* of the liver, reserving the term *lobe* for the subdivision. This will involve no ambiguity, for the terms *right* and *left lobes* will no longer be used for divisions of the more complex forms of liver.

The fissure in which the umbilical vein runs is termed the *umbilical fissure*. It is not apparent on the upper surface, but its place is shown by the process of peritoneum which the vein carries out with it, constituting the suspensory ligament. Sometimes it is a deep and continuous fissure on the under surface, extending from the free border to the left end of the portal fissure, but often it is bridged over for a longer or shorter part of its course, and sometimes it is entirely obliterated, the vein running the whole of its course in the interior of the hepatic substance.

It frequently happens that each segment is further divided by a fissure running from the free, nearly, or even quite, to the attached border, and which I propose to call the *right* and *left lateral fissures*. When they are (as is usually the case) more deeply cut than the umbilical fissure, they give the organ that tripartite or trefoil-like form before spoken of, but which must not cause us to lose sight of its essentially bilobate character. The two lateral and the umbilical fissures thus divide the main portion of the whole organ into four principal lobes, which may conveniently be designated in order from the left to the right side by the following names:—*Left lateral*, *left central*, *right central*, and *right lateral*. (See Fig. 4.)

The left segment of the liver is rarely complicated to any further extent, except in some cases by minor or secondary fissures marking off small lobules, generally inconstant and irregular, and never worthy of any special designation. The principal differences to be noted depend on the degree of completeness of the lateral fissure and relative size of the two lobes.

On the other hand, the right segment offers several additional features which require attention. The right lateral fissure when complete passes into the right extremity of the portal fissure. The right central lobe, therefore, on its under surface, does not reach to the attached border of the liver, but is always bounded in that direction by the portal fissure. Moreover, when (as is

FIG. 4.

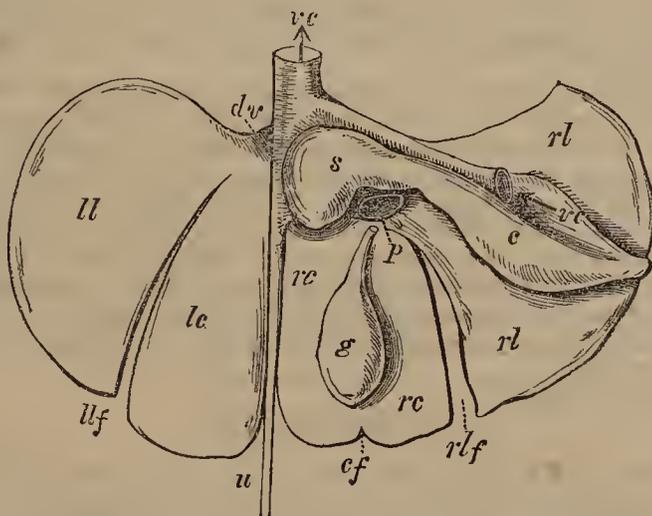

FIG. 4.—Diagrammatic view of the inferior or visceral surface of a multilobed liver of a mammal extended transversely. The posterior or attached border is uppermost. *vc*, the inferior vena cava; *p*, the vena portae entering at the hilus or transverse fissure; *u*, the umbilical vein of the foetus, represented by the round ligament in the adult, lying in the umbilical fissure; *dv*, the ductus venosus of the foetus, degenerating into a fibrous cord or quite disappearing in the adult; *llf*, the left lateral fissure; *rlf*, the right lateral fissure; *cf*, the cystic fissure; *ll*, the left lateral lobe; *lc*, the left central lobe; *rc*, the right central lobe; *rl*, the right lateral lobe; *s*, the Spigelian lobe; *c*, the caudate lobe; *g*, gall-bladder.

The most important and characteristic part of the liver is the *hilus*, more commonly called *transverse* or *portal* fissure (Fig. 4, *p*). This is always placed on the inferior surface, and nearer the

usually the case) a gall-bladder is present, it is always attached to the under surface of this lobe. The position of the gall-bladder with respect to the lobe may vary—sometimes it is merely applied to its surface, loosely connected by connective tissue; in other cases it is deeply embedded in a fossa, so much so sometimes as to appear on the upper surface of the lobe. Very often it is placed near the middle of the lobe—sometimes close to one or other of its lateral boundaries. In many cases the fossa in which the gall-bladder is sunk is continued to the free margin of the liver as an indent, or even a tolerably deep fissure. This is called the *cystic fissure*; but in consequence of its irregularity of position and frequent absence it is not of the same importance as the other fissures I have named, and does not mark off any distinct divisions of hepatic substance.

The right lateral lobe is of more complex form, and usually more subdivided than any of the others. It always has the great vena cava either grooving its surface or tunnelling through its substance, near the inner or left end of its attached border, and a peculiar prolongation of the lobe to the left between this vein and the portal fissure has long been known under the name of the *Spigelian lobe*. This is always a distinct hepatic region—sometimes a mere narrow, flat tract, but more often a prominent tongue-shaped process. Whatever may be its form, it is bounded in front or towards the free surface of the liver by the portal fissure; on the left by the fissure of the ductus venosus (sometimes, however, completely and smoothly bridged over, the surface boundary being then imaginary); posteriorly, and partially to the right, by the vena cava (unless this also is bridged over); but between this vessel and the right end of the portal fissure it has nothing to sever it from the adjoining part of the right lateral lobe. As the gastro-hepatic omentum covers the vessels passing into the portal fissure, the Spigelian lobe always lies upon it, and in direct relation to the pyloric end of the stomach.

The main body of the right lateral lobe is most commonly divided into two parts—not by a fissure such as the lateral ones, passing from the upper to the lower surface of the liver, but one which severs a part off from the under surface.

FIG. 5.

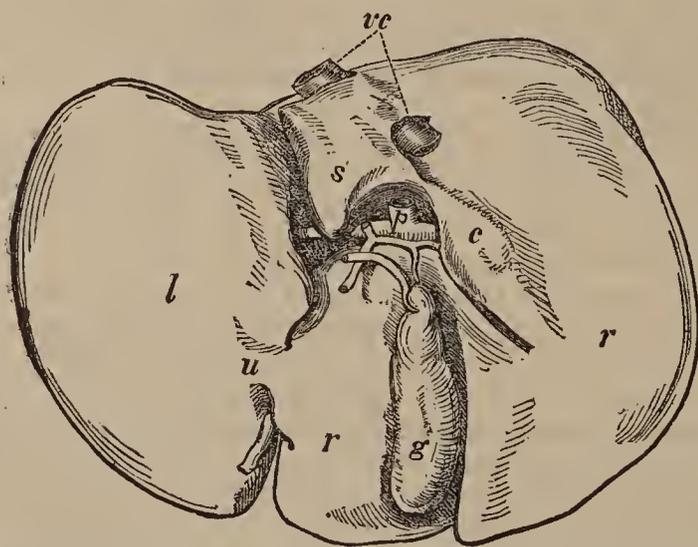

FIG. 5.—Under surface of human liver. *v c*, vena cava; *p*, vena portæ; *u*, umbilical fissure; *l*, left lobe; *v*, right lobe; *c*, Spigelian lobe; *g*, gall-bladder.

On looking attentively at the under surface of the human liver (Fig. 5), a ridge, *c*, is seen, much more distinctly marked in some than in others, running from the Spigelian lobe to the middle of the right lobe, and bounding in front the fossa in which the upper part of the right kidney is lodged. This ridge has received the name of "*caudate lobe*." If our observations were confined to human livers, we might wonder why this very insignificant-looking eminence ever attracted any attention, much more received a distinct name, and was classed as one of the five lobes of the liver. But a very small acquaintance with comparative anatomy will reveal the reason. This part, which in man is almost obsolete, or rather, for want of the development of fissures, completely fused with other parts, in most animals attains a considerable magnitude and a very characteristic form and relations, sometimes being actually the largest of all the lobes of the liver.

When of average form and size, it may be defined as a piece severed from the under surface of the right lateral lobe, connected, by an isthmus at the left, narrowest, or attached end, to the Spigelian, behind which isthmus the vena cava is always in relation to it, channelling through or grooving its surface.

It generally has a pointed apex, and its surface is deeply hollowed to receive the right kidney. Usually between this great hollow and the vena cava is a smaller impression, which fits upon the supra-renal capsule. Although essentially a portion of the right lateral lobe, and often more or less fused with it, a special designation is needed for it, and we cannot do better than retain the anthropotomist's "*caudate lobe*," keeping the name of "*right lateral*" for the remaining part of the lobe when divided; and the fissure which separates them may be called the *fissure of the caudate lobe*.

This completes the survey of the mammalian liver in its generalised form. It will be seen that six lobes have been recognised—two central, two lateral, and two accessory to one of the latter. No mention has been made of the so-called *lobulus quadratus* of human anatomy. This is simply the region of the under surface of the right central lobe, situated between the umbilical and the cystic fissures, and depends entirely upon the position of the latter for its size and form, or even its existence.

Locally associated with the liver, especially in the situation of its excretory duct, but very different in size, form, structure, and function, is the *pancreas*, which offers but comparatively few modifications throughout the mammalian series. It is more purely an organ of digestion than the liver, for no other function has been assigned to it than the effect that its secretion, poured into the duodenum by one or more ducts, has upon alimentary substances in preparing them for absorption by the lacteals and veins of the intestinal walls. Though many physiologists still have doubts about the particular effect the pancreatic fluid has on digestion, the prevailing opinion is that it emulsifies fatty substances, aids the saliva in converting starches into sugar, and to a certain extent acts upon nitrogenous substances, converting them into peptones.

ORIGINAL COMMUNICATIONS.

ON TINTING (TATTOOING) OPACITIES IN THE CORNEA.

By ARTHUR R. DUNNAGE, M.R.C.S.,
Dresser in the Eye Wards, Guy's Hospital.

ABOUT six years ago experiments were made at the Eye Department of Guy's Hospital in tattooing the cornea, which did not succeed. On the suggestion of Dr. Pagenstecher, the experiments were resumed in the beginning of last month (February) with a grooved needle recommended by him for this purpose.

The experiments have been uniformly successful. I propose to give an account of the operation and of its results. The grooved needle used in tattooing is made by Messrs. Weiss and Co., 62, Strand. The substances that have been used are indian ink, indigo, and burnt sienna, rubbed as thickly as possible.

The needle charged with the colour is pricked into the cornea as far required to leave a coloured point. The punctures must be made close together on the surface intended to be coloured, as the colour does not run, and the effect of each puncture is a coloured point. These points must be close together to get the effect of a black or coloured spot. To get a dead black spot the operation has to be repeated three or four times. It is as well not to tie up the eye after the operation, as the free colour seems to irritate a little if confined. In those cases where the eye was not tied there has been absolutely no inflammation.

Guy's Hospital.

PUBLIC HEALTH AND LOCAL GOVERNMENT BILL.—Sir C. Adderley's Bill for consolidating and amending all the laws on public health and local government for England and Wales, exclusive of the metropolis, contains 437 clauses, and fills 179 folio pages. The Bill distinguishes by special marks clauses taken from the Acts proposed to be repealed, without any substantial alteration, except such as are in accordance with the recommendations of the Commission; also the clauses taken from the dropped Government Bill of last Session on rating and local government; also a few clauses taken from Local Consolidation Acts, or from the Telegraphs or other public Acts. The remaining clauses with no special mark against them are new, and, like other clauses, carry out the recommendations of the Sanitary Commission. The clauses on rates re-enact existing law.

at present to recommend to our readers a careful perusal of Sir Robert Christison's vigorous and lucid letter against what he terms "the complex, costly, vexatious, and doubtfully expedient check by the scheme of Conjoint Examining Boards," and of the important memorial drawn up by Professor W. Gairdner, of Glasgow, and signed by many of the most eminent Teachers and Practitioners in Edinburgh and Glasgow. But some, at least, of the immediate results of the resolution passed by the Council must be evil. So long as the charter of the Society of Apothecaries remains in force and unaltered, that body must be ready to examine all candidates for its licence who have duly complied with its regulations, and the Medical Council cannot refuse to register the licences so obtained; thus, men with only one qualification, and having passed no examination in Surgery, will be on the Register of Legally qualified Practitioners. Then, should the College of Surgeons refuse to examine for a Surgical diploma men possessing this licence, except by means of the Conjoint Board, and at the charge of the thirty-guinea fee, one or both of two things may happen. The Society of Apothecaries may seek to compel the College to examine such candidates without subjecting them to the new double examination and the increased expense, as the Society is advised by high legal authority that the new combination is illegal; and then we shall see a costly and scandalous struggle between these Bodies, or the Society's licentiates may obtain, at a comparatively small cost, a Surgical diploma from beyond the Tweed; for it can scarcely be doubted that some one or more of the Scottish Licensing Bodies will be canny enough to recognise that by a cordial and hospitable reception of English candidates, or by some form of co-operation with the Society of Apothecaries, they may be able to help worthy and deserving men to a Surgical diploma, and to put money in their own coffers. Such a state of things, though it might not last long, would be deplorable, and it is to be earnestly desired that some means may yet be found to bring the Society of Apothecaries into the new scheme. Looking at the number of their licentiates, they are by far the most important Licensing Body after the College of Surgeons, and we cannot but believe that their adhesion to the new scheme might have been obtained had the alleged difficulties been discussed with a hearty desire to overcome them. The statements of the way in which, and the reasons why, the negotiations were broken off differ, and we cannot pretend to judge whether the account given by the Society or that given by the Colleges is most exact, but it seems not improbable that some hastiness has been shown on both sides, and we must confess to thinking that at the last the Society was treated with scant courtesy and consideration. The address of the President of the Council at the opening of the present session seems rather wanting in respect to the Society. He, no doubt, meant to be courteous, but assuredly it was not complimentary, either to the Society or to their representative, to suppose that he required to be coached up in the proceedings of the Council relative to the formation of Conjoint Examining Boards. We have been unable to discover that any adequate notice has been taken of the legal points raised by the Society of Apothecaries, and mentioned by them in the protest they presented to the Council. The Society state that they are informed on high legal authority that the Colleges cannot refuse to examine separately; and it was stated incidentally during the debate that the legal advisers of the Colleges hold a different opinion; but was any attempt made to procure a conference of the legal authorities on the subject? Or, supposing that really insuperable legal difficulties do exist, might not an effort be made to obtain, during the present session of Parliament, a short Act of one clause, empowering all the Licensing Bodies in each division of the United Kingdom to form a Conjoint Examining Board, all existing enactments to the contrary notwithstanding? Such an Act would do away with all difficulties, and prevent the

scandal and the confusion worse confounded with which we are at present threatened; and it does not seem possible that the Conjoint Examining Board system can ever be carried out without some help from the Legislature. We are supposing for the moment that the General Medical Council are quite right in all they are attempting for the raising of Medical education and the improvement of the examining system. But it must be observed that all that has been done, and is being done, by the Council tends to make it a more and more costly work to produce a legally qualified Medical Practitioner; and one cannot help wondering at times what is to become of those sparsely populated country districts and those densely crowded poverty-stricken parts of cities in which the general Practitioner of the present day is content to labour. Will his successor, of higher and more costly education, labour year after year for such a pittance as can be gained from such clients? We trow not. And what then? Is his place to be taken by the druggist, or, mayhap, by the Medical woman of the future?—or are Dispensaries and Hospitals still more widely to demoralise the poor by offers of "charitable Medical relief"?

Since the above was written, the representative of the Society of Apothecaries has again, on the last day of the session, spoken of the earnest desire of the Society to join the Conjoint Board, and make the English scheme more perfect; and we gladly learn from him that every means will be taken to overcome the difficulties which had arisen.

The consideration of the communications from Scotland regarding Conjoint Examinations led to a very long, and at times very warm, debate. It appears pretty clearly that by far the greater number of the Licensing Bodies in Scotland look with no little disfavour on a Conjoint Examining Board as understood by the Medical Council, but that, in order to satisfy or gratify the Council, they have been taking the matter into their serious consideration. Dr. Andrew Wood set forth at considerable length the points in which the relative positions of the Universities and Corporations to each other in Scotland differ from what obtains between the Universities and Corporations in England, and the consequent necessity of a differently constituted Conjoint Board; he suggested that the English Bodies might take some very good hints from the propositions already laid down by the Scottish Bodies, and thought that if they were allowed a little more time they would produce a better scheme than the English one, and "more in consonance with the object at which the Council were aiming." Dr. Humphry hoped that the Scotch authorities would persevere in their efforts to secure such an examination as would be recognised and sanctioned by the Council; he would "still hold open the door to Scotland and Ireland," and hinted that if they did not come in at it "they might fall into the hands of the Legislature." And he well added that "it was most important for the individuality of the Profession that they should as far as possible govern themselves. Any profession which relinquished self-government would relinquish one of its highest privileges and greatest duties." Dr. Alexander Wood delivered a long speech on the wrongness of the Council's ideal of a Conjoint Examining Board, on the *lâches* of the Council in the matter of the supervision of examinations, on the character of the Scotch Universities and Corporations, and on his idea of the principles on which a Conjoint Examining Board should be founded. "His views were of a much higher character than those on which the imperfect English scheme was founded, and he trusted before many months were over the Scotch Bodies would be in a condition to bring forward a scheme embodying those principles." Dr. Quain could assure Dr. Alexander Wood that he had not the slightest conception of the English scheme, and that the difficulties of Scotland would be entirely met by adopting the English scheme. Dr. Parkes was convinced that Scotland was as far from forming a Conjoint Board as Ireland, "and that was going as far as any human event could be";

and he thought there was nothing left but to proceed by the aid of the Legislature. Dr. Storrar said that any proposal from Scotland which did not contemplate a complete examination from the commencement, would not receive his consent; to which Dr. Andrew Wood promptly replied, "Then you will never get it." And Sir Dominic Corrigan said that he could not see that there was a reasonable hope that the Conjoint Scheme would be carried out in Scotland. "Dr. Humphry had talked about opening the door to the Scotch and Irish Bodies, but Ireland did not want a door opened. Dr. Parkes had insisted on decisive steps being taken. He had proposed decisive steps once before in the case of the Queen's University, but the Queen's University quietly held up its hands, and said to Dr. Parkes, in the words of Shakespeare, 'Come on.' Did he ever come on? He did not. Let him, then, take steps—such as those he took against the Queen's University." This was the amusing contribution to the debate, and Drs. Allen Thomson and Alexander Wood contributed a quarrelsome element, in a not very seemly squabble about an expression of Dr. Alexander Wood's implying that the Scotch Universities were striving to get rich by degrees. The debate ended in an expression of regret by the Council, that "no scheme had been passed and submitted to the Council by the Medical Authorities in Scotland for establishing a Conjoint Examining Board."

This was on Saturday, the third day of the session; but on Monday, the fourth day, the fray was renewed on Dr. Parkes's minatory motion—"That, in case the Medical authorities for Scotland have not succeeded in forming a proper scheme for the formation of a Conjoint Board for Scotland by January 1, 1873, the Council will endeavour to obtain a legislative enactment under which a Conjoint Board for Scotland may be constituted." This motion, recommended in a speech which Sir Dominic Corrigan politely characterised as even more ill-judged than the motion itself, was more than Scotch flesh and blood could bear, or could be expected to bear. Dr. Andrew Wood accordingly desired that Dr. Parkes would understand that "Scotland would not be dragooned into taking action. Scotland would judge for itself what was right, and, whilst it would be convinced by reason and argument, it would never yield to a pistol presented at its head," and he bade the Council recollect the emblem of Scotland, and its motto—*Nemo me impune lacessit*. A large amount of speaking was found necessary; but in the end the Council adopted a "courteous pressure" motion from Sir W. Gull instead of Dr. Parkes's pistol, and hoped that such a scheme as the Council may sanction may be submitted to them by July 1, 1872. Parallel resolutions were passed, but with much less consumption of time, respecting the Medical Authorities in Ireland. We have not time or space this week to examine at all into the merits or demerits of the Scotch or Irish ideas of what a Conjoint Examining Board should be—we may return to the matter at some future time; but it is interesting to observe that while Scotch representatives proclaim the vast superiority of their sketch scheme over the English scheme, we are assured from Ireland that the Irish plan will be "something more exquisite still."

The last business of any note before the Council was Dr. Acland's motion for a Committee to "consider and report whether the General Medical Council has power to make rules for the special education of women, such as may entitle them to obtain a qualification to be certified by the Council. And that the Committee do further report for what purpose such qualifications, if any, should be granted, and what are the most desirable means for educating, examining, and certifying in respect of them, with special reference to midwifery, the management of Medical institutions, dispensing, and nursing." This was passed by the very narrow majority of 11 to 10. We cannot this week consider the meaning of this motion, but, if it means only what Dr. Acland says it does, it seems

to propose that the Council shall set up a register of well-educated female nurses and dispensers, midwives, and Hospital managers. Why not male nurses, dispensers, and Hospital superintendents also? The remainder of the work consisted chiefly of formal votes; and the Council rose on Tuesday.

THE WEEK.

TOPICS OF THE DAY.

THE health of the Prince of Wales is now so far recovered that he will soon undertake the journey to the South of Europe, where he has been recommended by his Medical advisers to spend the spring. Dr. Vivian Poore is selected to accompany his Royal Highness.

The *coup de grâce* in the Tichborne baronetcy case was given when proof was produced that the real Sir Roger had certain tattooed marks on his arm, which were wanting on the arm of the plaintiff. The case is most remarkable in its Medico-legal aspects; but the General Medical Council excludes it, with many other things, this week. We reserve it, however.

Another subject of great interest and importance to the Profession is the proposed sanitary legislation now before the House of Commons. It will suffice now to say that much labour has been bestowed on Mr. Stansfeld's Bill by the Medical Department of the Privy Council. The large area of legislation over which its provisions extend will occupy us editorially in our next and succeeding numbers. Sir Charles Adderley's Bill embodies the recommendations of the Royal Sanitary Commission.

THE PRESIDENT OF THE MEDICAL SOCIETY OF LONDON.

THE President of the Medical Society of London, Dr. Andrew Clark, entertained the Fellows of the Society, with a large party of the Medical Profession and of ladies, at a *conversazione* at the Queen's Concert Rooms, on Tuesday, March 5. The band of the Royal Artillery discoursed excellent music from the gallery. The rooms presented a brilliant appearance, and a very pleasant evening was passed.

NETLEY HOSPITAL AND NAVAL MEDICAL STUDENTS.

It is stated by a correspondent of the *Army and Navy Gazette* that, notwithstanding the feeling now generally prevailing at that establishment in favour of a naval Medical officer being appointed to superintend the studies of the gentlemen sent there by the Admiralty with the rank of Professor, Staff-Surgeon J. D. Macdonald, M.D., etc., serving in her Majesty's ship *Lord Warden*, has been nominated to proceed to Southampton Water, with the inferior title of "Assistant-Professor."

LONDON WATER-SUPPLY.

THE agitation against the water companies is becoming "fast and furious." The important parish of St. James's, Westminster, has now joined in the struggle. The vestry have requested Dr. Lankester, their Officer of Health, to call the attention of the different water companies to the impure state of the water supplied by them. The vestry, also, intend to petition the House of Commons to give the Metropolitan Board of Works powers to enforce on the various water companies a pure and ample supply of water.

SMALL-POX AND VACCINATION IN JERSEY.

THERE is no law for compulsory vaccination in Jersey; small-pox is often very prevalent, and is so at the present time. A quarter of the children of the island are unvaccinated, and the mortality has been severe. At the sitting of "the States," on the 28th ult., it was sought to reproduce a Bill, which had been rejected in 1867, to enforce vaccination amongst the infant population. It was proposed, as an epidemic of small-pox was prevalent, that the Bill might be passed at once as "a measure of urgency." There was a sharp discussion on this point, and

though "the enemy was in the camp," the besieged were determined upon not resisting. One of the chief opponents of making the Bill urgent was the rector of St. Mary's, who was "prepared to show, by far more satisfactory figures than he produced two years ago, that vaccination was an evil, and that it did not produce any such marvellous results as it was pretended were due to vaccination; but, on the contrary, there was no guarantee as to whether the vaccination would be properly performed. Even in England, he believed, the restrictions on this subject would soon be withdrawn." The worthy rector afterwards made use of the following somewhat strong language:—"I repeat what I said on a former occasion: I would rather see my children die by the hand of God than by that of Dr. Low."

Is it to be wondered at that many of the lower orders should object to vaccination, when a beneficed clergyman—a man of education and position—should talk such nonsense and display so much ignorance? The majority of the deputies who spoke evinced a knowledge of the subject well worthy of them, and urged the necessity of legislation on the matter. The opponents of despatch, however, carried the day. The Bill was ordered to be printed, and discussed on the 13th of the present month. This delay of even a fortnight may be the cause of much disease and many deaths. We shall look forward to the discussion with interest. We believe that there is not a single Medical Practitioner in the island opposed to vaccination. At all events, Dr. A. Le Rossignol, who has taken great interest in the matter, and shown much commendable spirit respecting it, has published in the *Jersey Times* a list of thirty members of the Profession who have placed their signatures to the following document:—

"We, the undersigned members of the Medical Profession, residing in the island of Jersey, feel called upon at the present moment to make known our opinion that vaccination is the only means of preventing the development of an epidemic small-pox; and that as no possible bad effects, present or future, can result from the proper performance of that operation, it appears to us urgent that measures similar to those existing in Great Britain and Ireland be adopted so as to enforce the vaccination of all classes."

Will such a statement of opinion have its just and proper influence on the recalcitrant members of "the States"?—*Nous verrons.*

SMALL-POX JOTTINGS.

In the Islington district during the past week there had been four fresh cases of small-pox, against three in the previous week. There had been one death from the disease.—Only one death from small-pox was reported last week to the Camberwell Vestry. The disease was declining rapidly in the parish.—Small-pox has appeared in Rutland. It is reported that the clothing of a person who died at Sheffield from the disease imported it into the town.—Small-pox cases have occurred at Jersey. We have referred to the prevalence of this disease in a separate article. The disease was brought to the island by French sailors.—No death from small-pox had taken place in the Limehouse district in the past fortnight, but eight fresh cases had been brought under notice.—During the week ending the 29th ult. the number of new cases admitted to the Aberdeen Hospital was 11, bringing up the total of admissions to 108; the number discharged recovered during the week was 26, making 48 discharged in all. The deaths amount since the opening of the Hospital to 16, of which 2 occurred during the past week. The number of patients in Hospital on the 29th ult. was 41. It is to be regretted that the returns do not specify the number of vaccinated and unvaccinated persons attacked by the disease. The additional building has now been opened, and is authorised to receive 24 patients. The foregoing figures indicate a sensible abatement of the epidemic.—The Medical Officer of Lambeth reports that during the four weeks ending

the 26th ult. small-pox caused 40 deaths, or 11 less than in the previous four weeks. Of these 30 occurred in Stockwell Hospital, and 20 of these were strangers. "I, however," the Doctor adds, "fear we may expect an increase of the disease for the next month or two, in consequence of the masses of people congregated together during the last few days, many of whom I saw presenting the appearance of being but lately recovered from the disease, and no doubt hundreds came from neglected houses and localities, thus endangering the health and lives of others."—It was reported to the Hackney Board of Guardians that no patient belonging to the union during the past week had died in the Homerton Hospital, but eight had been discharged therefrom.—In the Homerton Hospital the number of small-pox cases had decreased to ninety-three.—In the Stockwell Hospital a fortnight ago the number of cases was 195, the week before 149, and at the present time 111.—In the Hampstead Hospital the number of cases had decreased from 210 last week to 184 this week.—In Sheffield 28 deaths occurred from small-pox last week; of these, 12 were unvaccinated, 3 vaccinated, and the remainder was not stated. The fatal cases on the two previous weeks had been 33 and 37. Since the beginning of October last, 673 deaths have resulted from small-pox within the borough.—Dr. Lankester, in his report last week to the St. James's (Westminster) Vestry, stated that no new cases of small-pox had been brought under his notice.—The Vaccination Officer reported to the Poplar Board of Guardians last week that 3 deaths from small-pox had occurred in the Union during the week, and that 13 new cases had been brought under notice. In the same period 66 persons were vaccinated at the public stations, and there were 8 small-pox patients now under treatment in North-street Infirmary. The Officer also stated that the new Vaccination Act had caused a great addition to the work he was required to perform. It was resolved by the Board to provide separate and suitable conveyances for the removal of small-pox and fever patients to the Hospital.—Small-pox is alarmingly on the increase in Erdington, especially in the immediate vicinity of the old workhouse, which is situated in the most populous part of the village, and is now being used as the small-pox Hospital. The situation is thought to be highly dangerous to the inhabitants, and the guardians are about to arrange for the reception of persons suffering from the disease in an isolated building at some distance from the village.—The weekly returns of small-pox cases presented to the Wolverhampton Board of Guardians last week showed in Wolverhampton 25, against 44 cases the week before; decrease, 19. In Bilston district, during the same period, there were 28 cases, against 19 the week before; increase, 9. In Willenhall and district there were 15 cases, against 9 the week before; increase, 6. There were 6 patients in the Hospital in the Union. The returns show a decrease in the whole Union of 3. Attention was drawn to the increase of the disease in the Bilston district, and it was stated that that morning a woman had walked from Bilston suffering from small-pox, and mingled with the other applicants for relief. Her case was a very bad one, and the woman was at once admitted into the small-pox Hospital in the house.—In Walsall, at the weekly meeting of the Board of Guardians, the report showed 6 deaths from small-pox last week, and 4 new cases had occurred during the week in the workhouse. Since the outbreak of the disease there had been 21 cases brought to the workhouse, making a total of 31; of these, 12 had been cured, 5 had died, and 14 remained.—A lodging-house keeper of Archibald-hill, St. Georges's-in-the-East, was convicted on Monday, at the Thames Police-court, of having kept a person upon his premises who was suffering from small-pox, without notifying the same at the nearest police-station. A fine of 20s. was inflicted.

PARLIAMENTARY.—PRESERVATION OF INFANT LIFE—EDUCATION OF DEAF MUTES—ADULTERATION OF FOOD AND DRUGS.

In the House of Commons on Wednesday, March 6, Mr. Charley moved the second reading of his Infant Life

Protection Bill. He drew attention to various facts proving the necessity of legislation on the subject. Mr. Hurst criticised the Bill, on the ground that its provisions do not extend to persons who trust children to baby-farmers. The Bill was supported by Mr. Kinnaird, Mr. D. Dalrymple, and Dr. Brewer, who hoped that public opinion would ultimately sanction the periodical inspection of baby-farms. Mr. Walpole complained that the Bill only dealt with part of the question. He urged the Government to make the registration of births and deaths compulsory. This drew from Mr. Bruce the information that the President of the Local Government Board is about to introduce a Bill for the compulsory registration of births. After some remarks by Dr. Playfair, Mr. Henley, and Mr. Winterbotham, the Bill was read a second time.

The Bill for the Education of Blind and Deaf-Mute Children, through the compulsory action of boards of guardians, was read a second time.

Mr. Muntz, in moving the second reading of his Bill for Preventing the Adulteration of Food and Drugs, intimated that, as Mr. Stansfeld's Public Health Bill would make it unnecessary, he should not proceed further with it if that Bill were carried. Lord E. Cecil, Sir D. Corrigan, and Mr. Stansfeld made some remarks in general approval of the Bill, and it was read a second time.

GENERAL CORRESPONDENCE.

THE ANALOGY BETWEEN SMALL-POX AND CHOLERA.

LETTER FROM DR. GEORGE JOHNSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Fulham Turner, having subscribed his name to his second letter, shall, with your permission, have a serious though a brief reply.

And first I must correct his statement that "the question was whether the eruption of small-pox is essentially curative." The real question is, whether "the choleraic discharges are as essentially curative as is the cutaneous eruption of small-pox?" It is obvious that the two questions differ materially. The variolous eruption, like the choleraic discharges, may be so copious as to kill. Neither the one nor the other, then, can be said to be absolutely and essentially curative; yet, in their general curative tendency, they are fairly comparable with each other.

In the treatment of small-pox, the main point is to insure a free ventilation of the sick-room, in order to remove the poisonous emanations which are thrown off from the patient's skin and lungs—just as in the treatment of cholera the primary object is by copious draughts of water to assist in washing out morbid secretions from the alimentary canal. The old heating method of treating small-pox was precisely analogous to the modern opiate and stimulant treatment of cholera. The two plans are about equally irrational and equally destructive.

If Dr. Turner will take the trouble to read carefully my paper on cholera which has recently appeared in your columns, he will find there no statement that can fairly suggest the question whether I try "to sweat out, or purge out, or pump out the poison of small-pox, scarlet fever, etc." This question is an indication that its author fails to distinguish the natural from the artificial elimination of poisons—a distinction which I have always endeavoured to maintain.

Perhaps your correspondent will inform your readers whether, in the treatment of these diseases, he attempts to drive in the eruption by the continuous application of cold wet sheets to the surface, and, if so, with what results. It would also be interesting to know whether he and others who disbelieve in the natural elimination of morbid poisons reject the doctrine of contagion; and, if not, how a disbelief in one can be reconciled with a belief in the other.

I look upon the throat affection and the swollen cervical glands of diphtheria as the local result of a morbid poison, on its way into the system, bearing nearly the same relation to the constitutional symptoms as the primary sore and the enlarged inguinal glands to secondary syphilis. In a less degree, and with less certainty, the sorethroat of scarlet fever and erysipelas admits of the same interpretation. In the treatment of diphtheritic exudation, the object is to disinfect and destroy the local deposit, in order to prevent the extension of the disease to the air-passages and the increase of blood infection. It is of vital importance to distinguish the symptoms

which indicate the entrance of a poison from those which are associated with its exit.

Let me add that, intending no discourtesy to my critics, I am too much occupied with other matters to reply to any further questions or comments. I am, &c.,

Savile-row, March 4.

GEORGE JOHNSON.

NEW INVENTIONS.

BISCUITS FOR BABIES' FOOD.

(F. H. Ulrich, 60, Deichstrasse, Hamburg.)

WE have received from Mr. Ulrich a tin of biscuits intended for infants' food. They are smaller in size, not so sweet, and of a paler colour than the Robb's biscuits, and they more nearly resemble the best specimens of Norwich biscuits. They are prepared in the same way as other biscuits of the class. The desiderata are, that the biscuits shall fall asunder and make a creamy or thin custard-like liquid, without the smallest lumpishness; that they shall be perfectly free from acidity, and that when prepared they shall keep for some hours without acidity; and that they shall be easily digested. Mr. Ulrich's biscuits answer these tests, and we venture to think that they will become competitors with the most favoured kinds of babies' food. The importance of wholesome, easily prepared food in diminishing infant mortality is great.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, February 29:—

Atkinson, John Charles, Kew, Surrey.
Collier, Nicholas Constantine, Turnham-green.
Eady, George John, Chertsey, Surrey.
Fendick, Thomas Rowing, Mylen-street, E.C.
Scott, Hubert Payne, Tiverton, Devon.

The following gentlemen also on the same day passed their first Professional examination:—

Bull, William, Dublin.
Clark, Frederick Cheesman, St. Bartholomew's Hospital.
Pridmore, Campbell William, Westminster Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ADDY, B., M.R.C.S., L.S.A.—House-Physician to St. Thomas's Hospital.
DICKINSON, E. H., M.A. Oxon., M.B., M.R.C.P.—Physician to the Northern Hospital, Liverpool.

HUNT, RICHARD.—Assistant Resident Medical Officer to the General Infirmary, Leeds, *vice* Simeon Snell, resigned.

LINDSAY, ALEXANDER, L.R.C.S. Edin.—Medical Officer and Public Vaccinator to the Shap District, West Ward Union.

ROBERTS, CHARLES, F.R.C.S.—Assistant-Surgeon to the Victoria Hospital for Sick Children, Queen's-road, Chelsea.

NAVAL AND MILITAR YAPPOINTMENTS.

CANNON, RICHARD, Assistant-Surgeon to the *Nereus*.

KEARNEY, EDWARD BARRETT (Staff Assistant-Surgeon), retires upon temporary half-pay.

L'ESTRANGE, GEORGE WADDINGTON (Staff Assistant-Surgeon), retires upon temporary half-pay.

MACDONALD, DR. JOHN D., Staff Surgeon to the *Duke of Wellington* (additional), for service at Netley Hospital.

WELLS, SAMUEL S. D., Staff Surgeon to the *Lord Warden*.

BIRTHS.

BLOMFIELD.—On February 29, at 20, Ryc-lane, Peckham, the wife of Josiah Blomfield, M.D., F.R.C.S., of a daughter.

COCKROFT.—On March 1, at Keighley, Yorkshire, the wife of T. H. Cockcroft, M.D., prematurely, of a son, who survived his birth only a few hours.

HUTTON.—On March 3, at Sandgate, Kent, the wife of George Allan Hutton, Surgeon Rifle Brigade, of a daughter.

LIDDARD.—On February 27, at 54, Lancaster-road, Westbourne-park, the wife of Dr. Thomas Liddard, of a son.

MURRAY.—On February 26, at 49, Buedleugh-street, Dumfries, the wife of Patrick Maxwell Murray, M.D., of a daughter.

MARRIAGES.

ADAMS—ELWIN.—On March 5, James Adams, of Hampton Gay, Oxon, to Elizabeth Jeken, daughter of the late Jeken Elwin, M.R.C.S., formerly of Broad-street-buildings, London.

BULLEN—JAMES.—On March 2, at St. John the Evangelist's, Redland, Bristol, W. P. Bullen, solicitor, to Elizabeth Wanklyn, widow of Joseph Wilmot James, Surgeon, of Stoke Newington-road, London.

GRATTAN—IRELAND.—On February 26, at St. Peter's Church, Dublin, Henry Grattan, Captain 35th Regiment, elder son of the late Lieutenant-General John Grattan, C.B., Colonel 17th Regiment, to Fannie Sarah S., only daughter of Richard S. Ireland, M.D., J.P., of Stephen's-green, Dublin, and Clofass, county Wexford.

HENDLEY—HULL.—On February 1, at Allahabad, N.-W. P. India, Dr. Thomas Holbein Hendley, Surgeon to the Political Agency, Johdapoor, Bengal, to Jane Elizabeth, third daughter of the Rev. J. D. Hull, vicar of Wickhambrook, Suffolk.

MILLAR—IBBETSON.—On March 2, Robert Millar, M.D., Surgeon-Major on the retired list of the Bombay army, to Annie, widow of the late Frederick James Ibbetson, late Captain 2nd Dragoon Guards.

WATCHER—LANKESTER.—On February 28, at the parish church, Hampstead, the Rev. J. Sidney A. Vatcher, B.A., Old Alresford, Hants, to Marion, second daughter of Edwin Lankester, M.D., F.R.S., Coroner for Middlesex.

DEATHS.

BRENT.—On February 26, at Sydney Cottage, Woodbury, Robert Brent, M.D., Colonel-Commandant 1st Ad. B.D.A.V., in the 53rd year of his age.

BIDDLE, HENRY, M.R.C.S., at 3, Angel-terrace, Edmonton, on March 4, aged 71.

EVANS, BENJAMIN, F.R.C.S., at Acre House, Brixton, on March 2, aged 70.

GATIS, JAMES, M.R.C.S., of North-street, Wolverhampton, on February 28, in his 61st year.

GRANVILLE, AUGUSTUS BOZZI, M.D., F.R.S., at 20, Folkestone-terrace, Dover, on March 3, in his 89th year.

HAIRE, THOMAS, M.D., at 5, Kildare-terrace, Bayswater, on February 27.

HICKEY.—On February 25, at Newtown Lodge, Gramore, Ireland, Matilda, wife of J. Lorenzo Hickey, Esq., Registrar of the United Diocese of Cashel, etc., and eldest daughter of the late John Briscoe, Esq., M.D., of Waterford.

HUNT, CAROLINE STAFFORD, youngest daughter of Thomas Hunt, F.R.C.S., at 23, Dorset-square, on February 28, aged 21.

MACTURK, WILLIAM, M.D., M.R.C.P., at Eldon-terrace, Bradford, Yorkshire, on March 2, aged 76.

POWER, CATHERINE, eldest surviving daughter of the late John Power, M.D., at Mancetter Cottage, Atherstone, on March 3.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM QUEEN'S HOSPITAL.—Resident Physician and Medical Tutor. Candidates must be Graduates in Medicine of a University of Great Britain or Ireland. Applications, with diplomas and testimonials, to Mr. H. C. Burdett, on or before March 22.

CARMARTHEN COUNTY AND BOROUGH INFIRMARY.—House-Surgeon. Must be M.R.C.S. and L.S.A. A knowledge of the Welsh language is necessary. Applications to Mr. H. Howell, King-street, Carmarthen, on or before April 10. Election on the 12th.

CAXTON AND ARRINGTON UNION.—Medical Officer for the Caxton No. 1 District of this Union. Candidates will be required to possess the qualifications prescribed by the General Orders of the Local Government Board. Residence within the district required. Applications to Mr. H. Mortlock, Clerk to the Guardians, on or before March 11. Election the following day.

COUNTY ASYLUM, BURNTWOOD, NEAR LICHFIELD.—Assistant Medical Officer. Must be duly qualified. Testimonials to be sent to Dr. Davis, Medical Superintendent, Burntwood Asylum, Lichfield.

EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK-BRIDGE-ROAD, S.E.—Physician to out-patients. Applications on or before Wednesday, the 13th inst.; to the Committee of Management.

LOCHMABEN, DUMFRIESSHIRE.—Medical Officer wanted for this Parish. Good scope for private practice. Applications to the Inspector of the Poor, on or before March 22.

RIPON DISPENSARY AND HOUSE OF RECOVERY.—House-Surgeon and Dispenser. Testimonials to the Hon. Sec., on or before March 25.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—Junior Resident Medical Officer. Candidates must possess a Medical or Surgical qualification. Testimonials to James S. Blyth, Sec., on or before Wednesday, the 20th inst.

ROYAL SURREY COUNTY HOSPITAL.—Assistant Honorary Medical Officer. Testimonials to be sent to the Hon. Sec., Rev. C. R. Dallas, Farncombe Rectory, Godalming, on or before Saturday, April 16.

SALFORD AND PENDLETON ROYAL HOSPITAL.—District Surgeon. Must be duly qualified. Applications to, and further particulars of, Mr. George H. Larmuth, Secretary, on or before March 11.

STOCKTON-ON-TEES DISPENSARY.—Registered Practitioner, to visit and dispense. Testimonials, etc., to Mr. E. E. Clapham, on or before March 9. The duties will commence early in April.

UNION AND PAROCHIAL MEDICAL SERVICE.

*. * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bury Union.—Mr. William Nuttall has resigned the Heap District; area 8996; population 22,537; salary £60 per annum.

Glanford Brigg Union.—Dr. R. B. Low has resigned the Messingham District; area 12,508; population 2970; salary £38 per annum.

Portsea Island Union.—The Workhouse is vacant; salary £315 per annum.

St. Thomas's Union.—Mr. W. H. Land has resigned the Littleham District; area 2068; population 3904; salary £42 14s. per annum.

Torteth-park Township.—Mr. Albert E. Carter has resigned the First District; salary £250 per annum.

Walsingham Union.—The Rainham District is vacant; area 14,225; population 2949; salary £38 per annum.

APPOINTMENTS.

Chelsea Parish.—William A. Bonney, M.R.C.S.E., L.S.A., to the North-West District.

Croydon Union.—Major C. Dukes, M.D., L.R.C.P., M.R.C.S., L.S.A., to the Third District.

MR. RITON OLDHAM, F.R.C.S., West Hartlepool, took the usual oaths, and qualified as a magistrate for the county of Durham on the 2nd inst.

SIR HENRY HOLLAND, BART., has accepted a Vice-Presidentship of the Society for the Encouragement of the Fine Arts.

MR. WILLIAM DUMAN has been appointed by the Paddington Guardians Vaccination Inspector for the parish.

At an adjourned meeting, last week, of the Society for Organising Charitable Relief and Repressing Mendicacy, it was, amongst other things, resolved that indiscriminate Medical relief should be replaced by the establishment of provident Medical associations.

BARNES, the American pseudo-doctor, who was charged at the Old Bailey, at the instance of the Treasury, with circulating indecent Medical books by means of the post, was discharged on his promising not to offend again, and on entering into recognisances to come up for judgment if called upon.

We understand that **Dr. A. F. Anderson, Assistant Colonial Surgeon at Singapore,** has, during leave of absence in this country, arranged for the publication of his very graphic photographic representations of true leprosy as seen in the Straits Settlements. The Secretary of State for the Colonies has shown his appreciation of these illustrations of leprosy by ordering the Crown agents to send out several copies for the use of resident officials.

THE Medical Officer of Health for Lambeth, in his monthly report, states that he has examined the water drawn from the main at Kennington-cross, and that supplied by the Southwark and Vauxhall Companies, and he came to the conclusion that both waters are totally unfit for human consumption.

THE Governors of the Worcester General Infirmary, at their annual meeting on the 3rd inst., passed the following resolution on the resignation of Dr. Williams:—"That the resignation of Dr. Williams be accepted, and that the thanks of the Governors of the Worcester General Infirmary be given to him for the efficient manner in which he has performed his duties as one of the Physicians to the institution during the past sixteen years."

NOTES, QUERIES, AND REPLIES.

Be that questioneth much shall learn much.—Bacon.

Dr. J. M. Drake, Montreal.—Your letter has come safely to hand. Please accept our best thanks for the enclosure.

Mr. J. Beswick-Perrin.—Your paper has been received, and shall have early insertion.

Mr. M. C. Macnamara, Calcutta.—Letter, with enclosure, received with thanks.

Spero Meliora.—The omission was quite accidental. By all means send something more.

Dr. Gibbon, the well-known Medical Officer of Health for the Holborn Union, and Dr. Holt Dunn are Medical candidates for the Coronership of the City of London.

A. B.—Order a little work on St. Moritz by the late Dr. Whitfield Hewlett, published by Churchills; or a similar work by Dr. Yeo. For Tarasp, consult Dr. Yeo's book, or write to Dr. Killias, at Coire.

Mr. Balding, Royston.—We know of no precedent for the fee being paid by the representatives of the insured person. We are not aware of such a practice being pursued by any other office. Whether it can be enforced must depend upon the terms of the original contract.

E. C.—It does not appear to us that Dr. Letheby favoured adulteration in any way, but that he takes things as they are, and aims at preventing and punishing those offences only which are clearly detectable, and which are not only frauds, but poisonous frauds.

The Manna of the Israelites.—That useful and interesting paper, *Hardwicke's Science Gossip*, contains an account of a nutritious lichen, in masses of the size and appearance of gum ammoniacum, which is found in dry sandy districts of Africa, Arabia, and Central Asia.

Sanitary Lectures at Brighton.—Such teaching of the laws of life and health as was given in Mr. W. E. C. Nourse's lectures at the Pavilion cannot fail to do their work in even a less enlightened community than that of Brighton. We hope the lecture on "Bad Air and Disinfectants" will be repeated and published for circulation amongst the unwashed and careless part of the people.

Autopsy of a Centenarian.—We have received a letter from Mr. W. J. Thoms respecting an article which appeared in this journal on November 25 last with the above heading. He asserts that the name of the alleged centenarian was Thomas Geeran, and that he had long traded on the credulity of the people of Brighton on the score of his great age and long and unrewarded service in the 71st Foot. Mr. Thoms has forwarded to us an article from *Notes and Queries*, which goes far to prove that Geeran was an impostor as to his age, that he was guilty of many falsehoods, and that his real age at the time of his death was 82.

Inquirer.—It was a mistake on the part of our contemporary, who has confounded one person with another. The "celebrated" Obstetric Physician of the name is still living, in tolerably good health, and at an advanced age. The deceased gentleman was, we believe, no relative whatever to his namesake, who was Lecturer on Midwifery at Guy's, and Obstetric Physician to that Hospital.

COMMUNICATIONS have been received from—

Mr. BALDING; Mr. METCALFE JOHNSON; Dr. LE ROFSIGNOL; Mr. CHARLES EGARR; Mr. HANNAY; Dr. E. H. DICKINSON; Mr. W. J. THOMS; Dr. G. JOHNSON; Dr. COUSINS; Dr. DIPLOCK; Dr. HOLT DUNN; Mr. F. W. LOWNDES; Mr. R. OLDHAM; Mr. ST. J. H. YOUNG; Mr. BLANEY; Dr. EDWARDS-CRISP; Dr. ROGERS; Dr. LETHBY; Mr. EDWIN SAUNDERS; Dr. BANTOCK; Mr. ADDY; OMNIA SINE LABORE; Dr. LATHAM; Mr. LETHBRIDGE; Mr. COPPIN; Mr. BRADFORD; Mr. J. CHATTO; Mr. H. MORRIS; Sir DOMINIC CORRIGAN; STUDENS; Mr. CURGENVEN.

BOOKS RECEIVED—

"Contagious Diseases Act." By the "Dean of Carlisle"—Drysdale on Syphilis—Epidemic Cholera in the Bengal Presidency, by Dr. James L. Bryden—Sanitary Report of the Board of Works, Whitechapel District—Lawson on Sciatica, Lumbago, and Brachialgia—Trench's Report on the Health of Liverpool—Gutch's Literary and Scientific Register and Almanac for 1872—Legg on Urine, third edition—Pereira's Elements of Materia Medica.

PERIODICALS AND NEWSPAPERS RECEIVED—

Birmingham Daily Post—New York Medical Journal—Hardwicke's Science Gossip—American Journal of Psychological Science—Eastern Morning News—British Press and Jersey Times—Food, Water, and Air—Monthly Microscopical Journal—Pharmaceutical Journal—Edinburgh Medical, March—Monthly Homœopathic Review, March—The "Clinic" Philadelphia Bulletin, February 13—Co-operative News, No. 9—Practitioner—Report of the Medical Council—Cambridge University Reporter.

APPOINTMENTS FOR THE WEEK.

March 9. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.
ROYAL INSTITUTION, 3 p.m. Mr. Moncure D. Conway, "On Demonology."

11. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

12. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. T. Holmes, "On the Surgical Treatment of Suppurating Ovarian Cysts, and on Pelvic Adhesions in Ovariectomy." Mr. Wm. MacCormac, "Case of Resection of the Shoulder- and Elbow-joints in the same Arm for Gun-shot Injuries."

13. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
EPIDEMIOLOGICAL SOCIETY, 8 p.m. Mr. J. N. Radcliffe, "On the Recent Diffusion of Cholera in Europe."
ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Croonian Lectures—Dr. Bristowe, "On Disease and its Remedial Treatment."
ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."
SOCIETY OF ARTS, 8 p.m. Meeting.

14. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

15. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.
ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Lumléian Lectures—Dr. Quain, "On Diseases of the Muscular Walls of the Heart."
ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."
ROYAL INSTITUTION, 9 p.m. Mr. J. Evans, "The Alphabet and its Origin."

VITAL STATISTICS OF LONDON.

Week ending Saturday, March 2, 1872.

BIRTHS.

Births of Boys, 1053; Girls, 1001; Total, 2054.
Average of 10 corresponding weeks, 1862-71, 2212.8.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	746	677	1423
Average of the ten years 1862-71	755.5	731.2	1486.7
Average corrected to increased population	1635
Deaths of people aged 90 and upwards

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.70 in. The highest was 30.04 in. on both Tuesday and Saturday evenings, and the lowest 29.33 in. on Sunday morning, 25th ult.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

THE SELF-ILLUMINATING OPHTHALMOSCOPE.

Arranged by Professor LIONEL BEALE, F.R.S. (King's College).

May be used to examine a patient in any position, in daylight, generally without atropine. Is held in the hand. No dexterity required in its management. Is adapted to form an Otoscope, Endoscope, Laryngoscope, &c. Descriptive Circular forwarded. *Vide* "British Medical Journal," April 2nd, 1870. Price, in case, 42s. Sole Maker, HAWKSLEY, Surgical Instrument Maker, Blenheim-street, Bond-street, London, W.

HAWKSLEY'S PATENT CLINICAL THERMOMETER.

HER MAJESTY'S LETTERS PATENT have been granted for this Thermometer, the index of which cannot be shaken into the bulb, or the black divisions rubbed out. Prices of the 6-inch patent instrument, in safety case, upon which are three engraved scales, 12s. 6d.; 5-inch ditto, in ivory case, 13s. 6d.; 3-inch ditto, in silver case, for waistcoat pocket (Prof. Beale's), 16s. Post free.

Hawksley's Improved Clinical Thermometer.

Section showing actual size, range 90 to 110.

Vide "Lancet" Report, July 3rd, 1869; Brit. Med. Association Reports, 1869.

At the last meeting of the British Medical Association, in a paper read by Dr. Cornelius Fox, on "Clinical Thermometers," it was announced that this instrument was far superior to that of any other maker. Prices of the Improved Clinical Thermometers, with indelible divisions, in similar cases to the patent instrument, 6-inch, 10s. 6d.; 5-inch, 12s. 6d.; 3-inch (Prof. Beale's), 15s. Post free. Temperature charts bound for the pocket. Descriptive Circulars forwarded. Inventor, Patentee, and Sole Maker, HAWKSLEY, Surgical Instrument Maker, Blenheim-street, Bond-street, London, W.

PRIZE MEDAL,
1862.

JOSEPH F. PRATT,

PRIZE MEDAL,
1865.

SURGICAL INSTRUMENT MAKER, ORTHOPÆDIC MECHANICIAN TO ST. BARTHOLOMEW'S HOSPITAL,
420, OXFORD-STREET, W.

SOLE AGENT FOR DR. E. STÖHRER'S GALVANIC APPARATUS.

ELASTIC STOCKINGS, LADIES' ABDOMINAL BELTS, IMPROVED WATER-PAD TRUSSES FOR SCROTAL AND UMBILICAL HERNIA.

GUY'S AND ST. THOMAS'S HOSPITALS. CAUTION.

J. MILLIKIN, Surgical Instrument Maker to the above Institutions, begs to announce that he has NO CONNEXION whatever with Nos. 7, Southwark-street, and 12, Palace-road, and that all communications intended for him must, in order to insure prompt attention, be addressed to

3, ST. THOMAS'S-STREET, BOROUGH,

where he is now conducting his business of Manufacturer of every description of Surgical Instrument and Appliance, Artificial Legs, Arms, and Hands, Trusses, Bandages for Prolapsus Ani, Uteri, Pendulous Abdomen, Moulded Leather Splints, Spinal and Orthopædic Apparatus, &c., Dissecting-Pocket, Amputating, and Minor Operating Cases.

MILLIKIN & WALTERS

(Late J. MILLIKIN),

7, SOUTHWARK-STREET, BOROUGH,
AND
12, Palace-road, Lambeth.

Mr. F. WALTERS (of 16, Moorgate-street) begs to inform the Medical Profession that, having taken over the Stock, Plant, and Business of the late J. MILLIKIN, he is prepared to execute all orders for Surgical and Orthopædic Instruments with which he may be entrusted, on the shortest notice and in the most workmanlike manner.

THE NEW PATENT AMERICAN ARTIFICIAL LEG.

SOLE LICENCEES:

F. WALTERS & CO.,
16, MOORGATE-STREET, LONDON.

ORIGINAL LECTURES.

CLINICAL LECTURES ON INTESTINAL OBSTRUCTION.

By THOMAS BRYANT, F.R.C.S.,
Surgeon to Guy's Hospital.

GENTLEMEN,—I purpose commencing this course of clinical lectures by bringing before you for your consideration some cases of intestinal obstruction, and to them I shall append such remarks as may suggest themselves for your instruction. This is a class of cases of considerable interest and immense importance to Surgeons, but one which I am disposed to think is insufficiently attended to by many of us.

It is not my intention, nor my province, to place before you the subject of constipation from the point of view of the Physician—nor, indeed, are we as Surgeons often consulted for this defect until the constipation has passed into the condition of obstruction. I must, however, remind you that constipation is a state due to a variety of circumstances. It may arise from a want of due relation between the ingesta and the intestines; or the intestines themselves, from deficiency of nerve or muscular power, may give rise to constipation of a chronic character. In old people you will not infrequently find this, and I am of opinion that many persons advanced in years commence to die by the bowel. The intestine is the first part to lose its power, and the gradual failure of vitality takes its start from this centre. I will give you the details of a case of this sort, as you are more likely to be impressed by recorded facts than by abstract remarks.

On December 15, 1870, I was called by the late Mr. Wright, of Clapton-square, to see a Mr. E., aged 74, of Dalston, who had been vomiting for three days. He had been the subject of a reducible right serotal hernia for many years, and had worn a truss. He had never had any trouble with his hernia. Three days before I saw him, his hernia came down in the morning when he got out of bed. He pushed it up without trouble, and then felt sick. He got into bed again. The sickness continued, and was accompanied with abdominal pain, although this was not seated in one spot. These symptoms lasted for three days, gradually becoming more severe. His bowels never acted during this period, although before he said they had been quite regular.

He sent for Mr. Wright on the morning of the third day, who at once sent for me. When I saw this patient, he was in bed and somewhat feeble. He was vomiting yellow, highly offensive matter, and was in great pain. No hernia was down, and nothing was to be felt by any external examination. I tried to get the hernia down, but failed, much to the patient's surprise, for he said it always came down directly he stood up. On the present occasion, however, this measure failed. It so happened, also, that from rising vomiting was excited; and yet no fulness, even at the internal ring, appeared.

Under these circumstances, an exploratory operation was suggested and performed. Nothing was, however, to be found in the sac, nor at the ring, except a distended cæcum, which was felt directly the finger was introduced into the internal ring. No band or other abnormal condition was felt. The wound was consequently closed, and opium given. The symptoms persisted, and sixteen hours after the operation the patient died.

At the post-mortem no hernia or intestinal complication was found beyond an enormously distended cæcum and transverse colon, this part of the bowel being completely filled with fæces.

This patient clearly died from a simple blockade of the large intestine. The hernia had nothing to do with the symptoms. The caput cæci had probably mechanically prevented the re-descent of the hernia after its reduction. I could give you another case in which no hernia was present to complicate the diagnosis, and the same symptoms existed; a third, also, in which retention of urine was the prominent symptom—but in all chronic intestinal obstruction from atony of the bowel was the cause of the symptoms and the immediate cause of death.

Another case suggests itself to me, in which the obstruction of the bowel gave rise to symptoms simulating stricture of the bowel. It was that of the mother of a Medical man, who had been bedridden for two years, and was supposed to have malignant stricture of the rectum. She had passed no normal motions for a long time, but small pieces of fæces, with blood

and mucoid fluid, were frequently voided. On rectal examination, I found the bowel completely blocked by hardened fæces, large quantities of which were scooped out. The lady lived five years after this date, and died eventually of old age.

It is not, however, only in the aged, but also in young adult persons, that this condition of blockade of the intestine is met with. There is a woman now in Dorcas Ward, 31 years of age, who was sent to me for the purpose of having an artificial anus in the right loin closed. Colotomy had been performed by an excellent Practitioner in the country, for obstinate constipation, associated with pain and fæcal vomiting of two months' duration. The operation was, in my opinion, justified by the long-continued and consecutive vomiting of fæcal matter. Previous to the operation the rectum and left loin were examined, and, as no obstruction was found in them, it was deemed right to open the colon in the right loin. This was done; and that the bowel was opened, the Surgeon at the time was quite convinced, as he saw the cæcum and vermiform appendix during the operation. No fæces, however, passed at the time, the bowel being quite empty; but three days afterwards fæcal matter commenced to flow through the wound, and continued to do so till the time of her admission. This fact shows that there could have been no organic obstruction above the cæcum. It is possible that there might have existed some twist of the intestines, which unfolded itself after the artificial opening was made. But the cause more probably was the impaction of fæces from powerlessness of the bowel to propel its contents.

These cases exemplify one class of the many kinds of intestinal obstruction. In them the existence of the obstruction is not due to bands without, or tumours within, the gut; but the condition is functional, and the cause resides in the want of power of the intestinal structure itself.

There are other ways, however, in which the intestines may be obstructed—causes external or internal to the wall of the intestines. Of the external, tumours, as of the ovary or uterus, may give rise to obstruction; but such cases are rare. The most remarkable case of this sort which has occurred to me was one in which a hydatid of large size extended upwards from the perineum into the pelvis and abdomen, so as to produce complete retention of urine and constipation. I recorded it in vol. xvii. of the Pathological Society's *Transactions*; but the following brief notes will suffice to put you in possession of the most salient points:—

It occurred in the practice of Mr. De'ath, Buckingham, in a farmer, aged 50. There was a history of the hydatid's growth for about fourteen years. I was asked to see him, on account of retention of urine of five days' standing; but the patient thought more of his constipation than retention. Relief by catheterism was impossible, the bladder having been pressed out of the pelvis to one side; and failure followed the attempt to puncture the bladder per rectum. Relief was only given when a free incision was made into the perineum, and three quarts of hydatid cysts evacuated. Much relief followed this operation; but the man died on the ninth day, the constipation of the bowels being insuperable. He had diseased kidneys, such as occurs where there has long existed any impediment to the free flow of urine along the urinary tract. This, however, was not considerable. He died really from the constipation.

Cancerous tumours are also amongst those which give rise to mechanical obstruction, and the following are the details of a case of the kind in which I was able to give relief for a time by colotomy, although death soon resulted from rupture of the tumour itself:—

On April 5, 1870, I was asked by Mr. Richard Phillips, of Leinster-square, Kensington, to see Mrs. M., of his neighbourhood, with him and Dr. West. She was a married woman, with several children, and 46 years of age. She had been ailing for some months at intervals, with irregular bowels, constipation, and diarrhoea, for which she had been under the care of Dr. Owen Rees, Dr. West, and Dr. Hctley, of Sydenham. For ten days before I saw her she had been the subject of constipation associated with vomiting, abdominal distension, and severe pain, it being quite evident that mechanical obstruction to the bowel existed. On making a pelvic examination some tumour was felt, which, after close examination, was clearly not uterine. On examining the rectum high up with the finger, a small tumour the size of a walnut was detected in its anterior wall, and higher up another mass, which seemed movable; but this was beyond the reach of the finger. Whatever the nature of the disease might be, it was evident that the lady was dying from intestinal obstruction, and, with the view of giving relief, if not of saving life, colotomy was suggested. Dr. West and Mr. Phillips, who met me in consultation, coincided in these

views. The patient accepted them, and at 2.30 p.m. on April 5 the operation was performed; Mr. R. Phillips, with his son and Dr. Hetley, kindly assisting. I operated on the left loin and made the oblique incision, and found the kidney so low down as to occupy the lumbar space. On pushing this up the bowel was found and opened, flatus and fæces at once passing. The bowel was carefully stitched to the margin of the wound.

Great relief followed this operation, and the patient passed a good night; she took food also kindly. The second day was also passed without one bad symptom. At noon, however, on the third, when the nurse was changing the draw-sheet, the patient suddenly collapsed and died. This happened after the patient had raised herself in the bed.

On making a post-mortem that evening, Messrs. Phillips and I found that a globular mass of medullary cancer, six inches by five, was hanging from the mesentery, covering the sacrum, into the pelvis; a smaller tumour, the size of a walnut, existing in the rectum—this being the tumour which was felt during life. The larger mass had ruptured its capsule, and its contents had escaped. This rupture of the tumour had clearly been the cause of the fatal collapse. The parts about the seat of operation were healthy and secure.

Here there was a case in which the constipation had been going on for months, till the obstruction at last became quite complete. The symptoms were chronic from the first. They were those of simple obstruction, and very unlike those now to be described, which are due to the existence of some intestinal band or other sudden constricting influence.

The two preceding cases illustrate the possibility of tumours causing the obstruction; but I have alluded to the occasional existence of bands of adhesions producing a similar result. These bands may be the remains of some foetal structure, or may have their origin in pathological changes which take place within the abdomen. These changes I will not now dwell upon, but will give you an example of the danger they excite by referring to a typical case of the sort, in which, however, unlike the other cases I have alluded to, the whole course of the disease was acute.

On February 12, 1871, I was summoned by Mr. R. Mathews, of Bickley, to see a Miss T., aged 26, who was suffering from some acute abdominal symptoms. I found this young lady rolling in bed in acute agony, with the legs flexed, in a severe paroxysm of a dragging abdominal pain, which she referred to the left side of the umbilicus; she was vomiting yellow matter. It appeared that three days before, when in excellent health, she went out for a drive, and from necessity was called upon to retain her urine for some hours. On her return home she micturated, and on emptying the bladder turned faint and vomited; some abdominal pain at once appearing. This pain recurred in paroxysms up to the time I saw her, associated with vomiting. Each paroxysm was accompanied with a strong desire to pass water, but inability to do it; a little passed at each time, but the inclination to do so lasted after the effort.

The abdomen was distended and tympanitic, and large coils of intestine could be made out through the parietes. No urine existed in the bladder. The pulse was feeble, and she was evidently sinking if not relieved. The symptoms clearly indicated intestinal obstruction from some cause outside the bowel, and nothing but an exploratory operation seemed to offer any prospect of success. This I suggested, and with permission performed; Mr. Mathews and Mr. Humphreys kindly assisting.

I made an incision in the middle line and opened the belly, a large coil of distended bowel at once protruding; on turning this to one side some empty bowel was found, and on following this up the intestine was found at the right side of the brim of the pelvis to be firmly bound down by an omental band passing from the right lumbar region over the brim of the pelvis to be connected with the bladder; several feet of small intestines were bound down by this band, and on its division the bowel at once escaped. The wound was then adjusted, and the patient left, but she never rallied, and died within two hours of the operation.

In this case the explanation of the symptoms is tolerably clear, starting with the fact that a band existed stretching from the right side of the abdomen to the bladder; for it would seem as if, when the bladder was over-distended on the day of the drive, the adhesion or band was raised well out of the pelvis, and during this time some coils of intestine passed beneath it. When the bladder contracted after micturition, the band fell, and in falling clipped this intestinal coil, and pressed it against the brim of the pelvis, in this way causing the obstruction; the futile efforts of the bowel to disengage itself dragging upon the band, and through it upon the

bladder, giving rise to the bladder symptoms, which were so distressing.

Had the operation been performed earlier the prospects of recovery would have been good.

I could not give you a better example of the whole course of acute intestinal obstruction than this case affords. It was, it is true, associated with bladder symptoms as well as intestinal, but this was merely accidental, and owing to the adhesion of one end of the band to the bladder itself.

Another case I should like to allude to is quite as clearly one of intestinal obstruction as the last. It bears, too, a resemblance to this last, with the exceptions that no symptom connected with the bladder was present, and that it was complicated by the presence of a hernial tumour.

On November 12, 1871, Mr. Mallam, of the Camden-road, asked me to see a Mr. H., aged 68, who had all the symptoms of strangulated bowel.

He had been the subject of a reducible inguinal hernia on the right side for years, and had worn a truss. He had always had good health, although he had a sallow aspect from long tropical residence. Three days before I saw him he had been suddenly seized with vomiting, abdominal pain, and constipation. The vomiting had been faecal for a day. The hernia was up, and had not been down for some time.

When I saw him he was very low, with a distended and tympanitic abdomen; it was tender all over, but in the right iliac fossa it was perhaps most so. There was no paleness or tenderness about the seat of the hernia. The symptoms were clearly those of intestinal obstruction, and as a hernia existed the necessity of exploring it appeared urgent.

This I accordingly did at once, with the patient under chloroform. I laid open the hernial sac, but found it empty. It was of the congenital form, the testicle lying at the bottom. The neck of the sac appeared also free from all obstruction. I then passed my finger into the abdomen, sweeping its end over the iliac fossa inwards towards the brim of the pelvis, where it passed over what appeared to be a ring with a crescentic border, through which bowel passed. With a guarded herniotome I increased the opening of this ring, and with my finger I worked out much of the bowel, and having thereby freed the parts somewhat, I moved my left index-finger upwards above a coil of distended and strangulated bowel, and found that one side of what appeared to be a ring was made up of a band. This was therefore divided with the same instrument, and relief was at once given to the intestine. The band gave with a snap, and the liberated intestines at once became free. After the operation all the symptoms were relieved, and the old man expressed himself as feeling very comfortable. Twelve hours after, however, he fainted and died.

At the post-mortem it was found that a band had been divided which passed from the convex portion of the centre of the ileum to the right side of the brim of the pelvis, and that about two feet of intestine had been strangulated by it, the lines of stricture in both the upper and lower ends being very marked. It seemed, also, as if the vermiform appendix had been likewise adherent. Evidence of early peritonitis existed. The viscera were healthy.

Two cases not unlike this I have described in a paper read before the Medical and Chirurgical Society in 1867, and published in the fiftieth volume of the *Transactions* of the Society. The subject of one of them is now alive. The existence of hernia in this case modified the operation somewhat, for had the patient not been ruptured I should have opened the abdomen along the median line. Still, in any case, my course would have been clear, and the existence of the hernia was not necessary to lead to the step which was taken. I am disposed to believe, then, that in many cases of intestinal obstruction, where the symptoms are marked, the pain fixed and paroxysmal, relief may be afforded by operative means.

I will now pass on to consider the changes *within* the bowel which may give rise to obstruction, and will relate to you a case illustrative of the action of this cause, though what the nature of the growth which is jeopardising the life of this patient may be I will not undertake to say. She is too young for the existence of cancer to be very probable. She now goes about well and comfortably, and it was but yesterday I saw one of her friends, who spoke favourably of her, but told me that she had quite lately been suffering from a discharge of "blood and corruption" from the rectum. This may be regarded as pointing towards the gradual destruction of the growth, whatever it may be, and its discharge by the anus. The case is as follows:—

On September 1, 1871, I was asked to meet Mr. Turner, of

Barnardsey-square, at the house of Mr. B., of Long-lane, to see Miss B., aged 18, who had been the subject of insuperable constipation for seven weeks. She was a healthy girl, and had not suffered much from constipation. The present attack commenced with abdominal pain, gradual distension, and vomiting, with complete constipation. Whatever she took in the way of medicine or food was rejected, and for some weeks the vomit was of a yellow colour. Enemata had been given freely and with care, but they returned unstained as they were injected.

When I saw her the abdomen was much distended and tympanitic; it was painful, but not tender. Coils of distended intestine could be seen through the parietes. The girl's powers were feeble. A rectal examination did not reveal anything. Nothing abdominal could be felt.

The symptoms being those of a chronic blockade of the bowel, and the pain not having anything of a paroxysmal character such as generally exists with some *external* mechanical cause of obstruction, I was loth to interfere Surgically until some powerful Medical means were employed. I therefore advised the use of some rue and turpentine enemata, and the internal administration of podophyllin; but this treatment not only did no good, but harm—it caused intense pain and much depression. Under these circumstances it became clear that Surgical means must be employed, and the operation of colotomy seemed the only justifiable one, constipation having been complete for seven weeks.

On September 6 the operation was performed, Mr. Rendle giving chloroform, and Mr. Turner, with his son and Mr. Douglas Duke, assisting.

I made the oblique incision in the left loin, and came down upon the bowel. I opened it, and stitched it to the wound by means of the quill suture. Fæces very soon made their escape, and great relief followed, the abdominal distension rapidly disappearing.

On the second day she took food well. On the fourth I removed the sutures, good union having taken place, and from that time everything went on well: she was free from pain, she took her food naturally, and slept well; the bowels acting regularly through the artificial anus.

On October 12 (five weeks after the operation) I made a careful examination of the pelvis, the girl for some ten days before having experienced some forcing action in the rectum. I found some foreign matter in the rectum, which had evidently been resting there for some time, and high up what appeared to be a fibrous polypus or growth filling the bowel. It felt just like a fibrous polypus coming down through the os uteri.

January 30, 1872.—At the present time the girl is going about in good health. She has still some straining in the pelvis, and the tumour formed in it is being forced downwards. Time will prove its true nature.

The case I have just referred to brings us on almost involuntarily to the consideration of intussusception; for it is undeniably true that a villous growth, or a polypus within the bowel, may give rise to intussusception of that portion of the intestine about and above which it springs. Nature, in her efforts to expel the foreign body, forces it down, and with it the bowel descends too, until it becomes invaginated into the portion of the gut below. Such a case I have witnessed in the rectum; and as the polypus could be felt low down at the time of the examination, I seized the opportunity to snip it off at once, and the preparation you may now see in our museum; and in the museum of St. George's Hospital there is also a specimen, figured in Holmes's "System of Surgery," of large intestine, a portion of which is intussuscepted, and has a fibroid polypus attached to it.

Intussusception is not, however, always caused in this way, although it is invariably provoked by some source of local irritation, such as scybala or some such-like cause. In some cases, Nature, in her efforts to get rid of the offending substance, excites a cure by promoting the sloughing of the invaginated bowel itself. But the successes of Nature in this way are rare, and more often death is the inevitable sequence. What can or ought the Surgeon do in these cases? Well, gentlemen, I confess the prospects of Surgical interference are not hopeful. With the exception of a case of Mr. Hutchinson's, the results of operations have been uniformly unsuccessful. By purely Medical treatment little or no good is to be achieved. The Physician can allay pain by opium, and leave the case in Nature's hands. He can do little more.

If the large intestine be the situation of the abnormality, then good may result from distending the bowel by water or air—by enemata or bellows. But when the small intestine is the seat, or when, as often is the case, the small bowel passes

through the ileo-colic valve into the large bowel, all treatment is unsatisfactory and, to a great extent, haphazard. In the last extreme it is justifiable to open the abdomen, as Mr. Hutchinson did in a child in whom obstruction existed for two days. He had the satisfaction of withdrawing the invaginated bowel; and his treatment was followed, if my memory hold good, by a successful issue.

LECTURES ON EXCISION OF THE HIP-JOINT.

By HENRY HANCOCK, F.R.C.S.E.,

Senior Surgeon to Charing-cross Hospital.

(Continued from page 215.)

I HAVE thus laid before you the laws which governed the performance of this operation down to the year 1857. I have done so not merely as a matter of interest connected with the progress of a novel proceeding; but, as many of the objections are urged against it even in the present day, it may not be without its use to consider them in detail, and to inquire how far they are or are not valid. They may be briefly summed up as follows:—

If the acetabulum is carious, the patient, whether operated upon or not, must die.

When caries attacks the surfaces of a joint, it is never limited to one of the bones which compose it; therefore, as the acetabulum does not admit of removal, the operation is useless, as it does not get rid of the whole of the disease.

That the operation is bloody and formidable.

That, to be successful, the head of the bone must have been previously dislocated.

That at the time of operation there must be no, or at all events very little, disease of the acetabulum.

That there should be no communication between the outer abscess and the pelvis.

That the disease must be in its last stage.

Whilst, lastly, it is objected that the disease may possibly be mistaken for one of the sacro-iliac synchondrosis or of the pelvis itself; and that, moreover, the operation is useless, as death in hip disease does not occur from local mischief, but from the exhaustion resulting from the constitutional malady.

Now, in the first place, Is the acetabulum always implicated or not? It may be in a very large majority of cases; it certainly is not so in all. Of eighty-one cases in which the fact is specially alluded to, I find that in eighteen, or rather more than one-fifth, the acetabulum is expressly stated to have been healthy.

Although these exceptions are too numerous to prove a general rule, they are by no means sufficient to divest disease of the hip-joint of its gravity and fatal character. If it be true that he who suffers from caries of the acetabulum *must die*, caries of the hip-joint must take its place amongst the most destructive and malignant diseases, even rivalling in its fatal character cholera, typhus fever, small-pox, etc., since for four-fifths of their number there is no hope, they must inevitably die. But is this actually the case? Is caries of the acetabulum of so peculiar a character that it is not amenable to the same laws as govern that disease elsewhere? Is the cotyloid cavity so entirely without the pale of vitality and so wanting in reparative power that when once attacked with caries it cannot be cured, and the patient must inevitably die?

This seems to me to be an extremely difficult position either to maintain or to prove.

There are many who assert that these cases, if left to nature, rest, and proper nourishment, will do well of themselves. There are many of these cases which recover without operative interference, and of which post-mortem examinations are never obtained. There are patients, again, who pass through the successive stages of the disease—inflammation, ulceration, suppuration, spontaneous luxation, flattening and absorption of the head and neck of the femur—and yet who preserve their lives at the expense of the joint. True it is that in these cases the acetabulum as an acetabulum is not cured—it is obliterated; it undergoes the double process of disintegration and filling up; it becomes, in fact, in process of time, a thing of the past. But the patient does not die; for whilst his life has been endangered by the progressive destruction of the joint, it has now been saved by completion of that destruction and the subsequent reparation and reproduction of bone and soft parts.

As illustrative of this fact take the case operated upon by Mr. Anthony White, in which there was not a vestige of the

acetabulum remaining; take also the following case, operated upon by Sir William Fergusson in 1849:—E. N., aged 10 years, two years and a half before had been knocked down by another girl, struck her left hip, and was at once lamed by the accident. In process of time abscesses burst around the joint, and she suffered much from pain and swelling extending from the knee along the back of the thigh. Twelve months after the disease began, the parents one morning observed that her thigh was altogether flexed across the abdomen, and that she was unable to move it from this position. Fresh abscesses occurred, and the suppuration with the constant pain destroyed her health, and she became weak and emaciated to the last degree. After remaining at a water establishment for six months she was taken to King's College Hospital. The left buttock was unnaturally prominent, smooth, and tense, and over the back of the ilium was a hard globular swelling, evidently the head of the femur dislocated upwards. Around this were various sinuses burrowing in all directions, and communicating with the carious head of the femur. Some of these sores were situated in the groin, some over the sacrum. A very large continuous one extended down the thigh, and they all discharged much unhealthy pus. The slightest movement or pressure caused her great pain. She lay on the sound side of her body, with the knee of her diseased limb thrown over the opposite thigh.

On January 11 Sir William Fergusson enlarged one of the sinuses, and removed a portion of dead bone which was loose. The head of the bone was found in a carious condition, and he consequently removed it on January 13. The head of the bone was much reduced in size, and carious. There was hardly any trace of the cotyloid cavity, it being filled up with new bone.

Do not these and analogous cases also offer a very cogent reply to the objection that the operation must have originated and been conducted in forgetfulness of the well-known pathological fact that when caries attacks the surface of a joint it is never limited to one of the bones which compose the articulation, and that as the acetabulum cannot be removed with any prospect of advantage in the living body, therefore excision of the head of the thigh-bone for caries of the joint should be regarded as no less erroneous in theory than objectionable in practice?

It seems to me that, so far from this being the fact—so far from regarding it as either one or the other—by performing excision of the head of the thigh-bone in caries of the joint we emulate the proceedings of nature, and assist those whose powers of constitution are too weak, and who are consequently unable to carry those proceedings to completion.

Mr. Rankin, of Carlisle, has an illustrative specimen in his possession. "The head of the femur in this case was discharged spontaneously, and bears the brand of what has long been called caries; yet after many years the person is alive and healthy, with a free joint over the pelvis, though the knee is flexed and ankylosed." According to Mr. Burford Norman, the late Mr. Liston possessed the head of a femur which had been detached and spontaneously expelled; and on the table before you is a similar preparation spontaneously expelled from a patient of Mr. Gant, to whose kindness I am indebted for the opportunity of exhibiting it to you. How frequently, also, has the head of the femur so separated been removed by operation. We have already seen that the very first removal of the head of the thigh-bone from the acetabulum was a case of this description performed by Schmalz in 1816. In 1730 John Daniel Schlichting dilated a fistulous opening over the hip of a young girl aged 14, long the subject of hip disease, and through it extracted the head of the femur, which had become detached. Similar cases are recorded by Vogel, Harris, Reid, etc.

Watch a patient suffering from scrofulous disease of the hip-joint: for many months the symptoms may consist only of stiffness, tenderness, and more or less weakness and limping, without hectic or constitutional disturbance of any kind. Watch that same patient during the progress of ulceration, suppuration, destruction of the ligamentum teres, and consequent dislocation: then the hectic and constitutional irritation are at their height. Watch the same patient again when dislocation has completely obtained: the disease now appears to have exhausted its rage, to have overcome all obstacles to its course, and to be satisfied with the mischief it has caused; the constitutional symptoms subside, the abscesses frequently heal up, and a cure takes place.

Can it be asserted that a case such as this is not one of caries of the joint? Can it be also asserted that the acetabulum is not here affected? that the fact of a cure is conclusive against such a proposition?

It would seem that in such instances the luxation of the head of the bone is essential to recovery; and when it does take place spontaneously, other symptoms being favourable, I would not urge too great haste in proposing an operation. But, alas! how frequently is it otherwise; how frequently does the strength of the patient prove insufficient to cope with the disease. The bone becomes carious, rough, or broken up; sinuses form, they continue to discharge, and still further to weaken the patient; hectic fever, night sweats, emaciation, loss of appetite, restlessness, cough, in some cases spitting of blood, ensue; the lungs become affected, and the patient dies. It is in such cases as these, when the irritable and frequent pulse, the hectic flush, the wasting strength, the anxious and suffering countenance too surely denote the undue severity of the trial and the too great probability of death, that the Surgeon should throw aside his doubts, should boldly confront the mischief, and, by imitating the wise and beneficent workings of nature, endeavour to snatch his patient from that destruction which otherwise inevitably awaits him. We have seen what takes place in the acetabulum when spontaneous dislocation of the head of the bone has taken place. What, I should like to ask, is there in the operation to prevent the same process taking place after the head of the bone has been removed artificially?

But if these objections have had their influence, and been allowed to prevail as they undoubtedly have done, what a signal triumph must excision of the hip-joint have achieved, since we find that, of 126 patients suffering from caries, who according to these theories must inevitably have died, no less than seventy-one recovered with more or less useful limbs!

Again, we are told that the operation for removal of the head of the thigh-bone should be restricted to those cases in which the head of the bone is dislocated. Although this was a point mainly insisted upon by those who advocated the operation prior to the year 1857, no one attempted to assign a reason for the restriction save Mr. Coulson, who says—"The first condition is the absolute displacement of the head of the bone; for as long as the neck and the trochanter are in relation to the acetabulum there is a chance of ankylosis taking place, which is the most favourable termination to be looked for."

This appears to me to be a scarcely tenable position; it has never as yet been proposed to operate whilst a chance of cure by other means has been apparent. Ankylosis, it must be remembered, is the last process of hip disease; it must have been preceded by the inflammation, ulceration, and suppuration, and by the hectic fever, constitutional irritation, and consequent weakness and emaciation. It is by no means all who die of hip-joint disease who have attained the stage of ankylosis.

We know that whilst in some cases the head and neck of the femur may be destroyed by caries, in some they are comparatively sound; and in others, again, both they and the acetabulum are free from disease, the patients dying from the intensity of the constitutional irritation rather than from the amount of local mischief. Take the following case, related by Sir Benjamin Brodie:—A young lady, aged 9 years, being at play on January 1, 1808, fell, and wrenched her hip. She experienced so little uneasiness, that she walked out that day as usual. In the evening she went to a dance, but while there was seized with a rigor, was carried home, and put to bed. Next morning she was much indisposed, and complained of pain in the thigh and knee. On the following day she had pain in the hip, and was very feverish. These symptoms continued; she became delirious, and died just a week from the time of the accident.

On inspecting the body on the following day, the viscera of the thorax and abdomen were found perfectly healthy. The hip-joint on the side of the injury contained about half an ounce of dark-coloured pus, and the synovial membrane, where it was reflected over the neck of the femur, was destroyed by ulceration for about the extent of a shilling.

In another case, the preparation of which was shown to the Medical Society of London by Mr. W. Smith, the patient, a boy in the employ of one of the railway companies, was delivering parcels on a Christmas morning. In getting out of the waggon he slipped, and sprained his hip. He thought nothing of it at the time, but after a few hours he became so ill that he was obliged to be taken home. The subsequent progress of the symptoms closely resembled those in Sir Benjamin Brodie's case, and the boy died within a week after the accident. The hip-joint after death was found to contain about a table-spoonful of decomposed blood and matter, and the synovial membrane presented a rent about three-quarters of an inch long at the point where it was reflected over the neck of the femur.

Fortunately, such cases as these are rare, but I think that in the present day few Surgeons would fail, when the delirium came on, to recognise the gravity of the case, or hesitate for one moment to excise the head of the femur, and thus get rid of the poisonous fetid discharge and its source, and at the same time afford the patient a chance of recovery, since the conformation of the joint is such as to render a mere opening into the capsular ligament insufficient for the evacuation of the pent-up discharge.

We know, also, that the head of the bone may be entirely detached from the neck, and still remain in the acetabulum; and, lastly, that caries and ankylosis may coexist in the same joint, and the patient sink worn out before the latter is completed, notwithstanding the head and neck of the femur have remained in relation with the acetabulum.

It is possible that the dread of exposing so large a joint-surface as the acetabulum, and of the supposed consequent tax upon the patient's power of endurance in getting rid of the joint structures and the obliteration of the cavity, may have influenced this recommendation; but experience has proved that the danger of exposing joint-surfaces is for the most part inverse to the extent of surface exposed, whilst it has also shown that in this operation the presence of the investing cartilage exerts but comparatively slight influence over the healing of the wound.

The stress laid by Mr. Anthony White upon the displaced head of the bone acting as a foreign body, and also upon the complete obliteration of the acetabulum, with the successful termination of that case, doubtless had its weight; but it is curious that in Schmalz's case—the first, as we have seen, on record—both conditions obtained. The head of the left femur was dislocated on to the dorsum ilii. That of the right was still in its cavity, which, however, was in a state of suppuration. It was the latter which Schmalz excised, and the patient did well.

A priori, it is reasonable to suppose that when the head of the bone has been dislocated for sufficient time for the acetabulum to be obliterated, the operation would offer a greater chance of success than when performed under other circumstances; that, in point of fact, the process of healing would be simplified and shortened. But against this must be placed the intense struggle of that fearful period preceding dislocation, which tries the patient's powers of endurance to the utmost limit; and it should, moreover, be remembered that the value of this recommendation, if any, exists, not in the mere displacement of the head of the bone, but in the obliteration, cure, or absence of disease, of the cotyloid cavity. And this coincides with the most part with what is proved by the statistics of the operation. Sixteen operations were performed in which spontaneous luxation had taken place, and wherein the acetabulum was found to be either entirely obliterated or in a healthy condition; of these 3 were cured, 2 died, and the results of 6 are stated to have been doubtful. Forty-three operations were performed in which spontaneous luxation had taken place, but wherein the acetabula were found diseased, and in many instances were gouged, in some few cauterised; of these 43 operations, 16 resulted in cure, 18 died, and the results of 9 were doubtful. Forty-four operations were performed in which the head of the bone was found in the acetabulum, but in which the latter was implicated in the disease; of these, 28 were cured, 10 died, and the results of 6 were doubtful. Eight operations were performed in which the head of the bone was found in the acetabulum, the latter being healthy; of these, 3 recovered, 4 died, 1 was doubtful. Ten operations were performed in which the head of the bone was found absorbed and the acetabulum diseased; of these, 5 were cured and 5 died.

Hence we find that, had the recommendation that the operation should be restricted to those cases in which spontaneous luxation had already taken place prevailed, the sphere of its utility would have been very much and very prejudicially contracted, since of 123 cases, 52 were performed in which the head of the femur remained in the cotyloid cavity.

It is sometimes extremely difficult, if not almost impossible, to tell with any degree of certainty prior to the operation whether the head of the bone be dislocated or not. And, after all, the success of the operation would appear to depend very much less upon this point than those who made this recommendation seem to have supposed; for we see that in the 16 cases where the head of the bone was dislocated and the acetabulum free from disease, the mortality was 12 per cent. In the 43 cases where the bone was dislocated and the acetabulum diseased, the mortality was 56 per cent. In the 10 cases where the head of the bone was absorbed and the acetabulum diseased, the mortality was 50 per cent. In the 44 cases where the head of the

bone remained in the cotyloid cavity which was diseased, the mortality was 28 per cent.; whilst in the 8 cases in which the head of the bone remained in the cotyloid cavity, the latter being healthy, the mortality is by far the highest, being 62 per cent.

(To be continued.)

ORIGINAL COMMUNICATIONS.

NOTES
ON THE PATHOLOGY OF MALIGNANT
NEW GROWTHS.

By HENRY ARNOTT, F.R.C.S.,

Assistant-Surgeon to St. Thomas's Hospital, and Joint Lecturer on Morbid Anatomy in the School.

VI.

SARCOMA—(Continued).

Glioma: its Clinical Characters of Malignancy and Microscopical Structure—Psammoma.

CLOSELY allied to the small round-cell sarcoma, illustrated in the last paper, is the special tumour of nerve, to which Virchow has given the name GLIOMA ($\gamma\lambda\iota\alpha$, glue), but which is still usually grouped with the medullary cancers by English Surgeons. This growth proceeds from the *neuroglia*, or delicate connective tissue which supports the nervous elements of the brain and its extensions, and more frequently comes under the observation of the ophthalmic Surgeon than of those of his brethren who practise general Surgery. It may occur in the brain, and so give rise to the special symptoms of brain tumour, according to its position; but it is more usually encountered springing from the retina of a child—for glioma is almost wholly limited to early life, the intra-ocular tumours met with in later years being generally sarcoma, or rarely carcinoma. The child is brought to the Surgeon blind, and with, perhaps, already a peculiar yellow metallic brilliancy of the pupil. Ophthalmoscopic examination reveals a whitish mass bulging into the vitreous, and interfering more or less considerably with the normal position of the lens and other parts of the eye. If now the eyeball be removed—as it should be without delay—a section through the globe will probably bring to light a pinkish-white brain-like mass with opaque yellow spots through it, springing from some portion of the retina, projecting forwards into the vitreous, and involving to a greater or less extent the other tunics of the eye.

After hardening this structure in suitable reagents, thin sections can be made, and it is then seen that the mass is made up of closely aggregated, very small corpuscles, round, oval, or tending in parts to a spindle form. These corpuscles are granular, with one or two bright central dots, and are embedded in a soft amorphous or obscurely fibrillated stroma. The stroma is usually so soft and scanty as to be with difficulty discerned, but about the edge of a very thin section it may happen that some of the corpuscles may be displaced, and the connecting substance is then more clearly visible (Fig. 16). In other cases the stroma is distinctly fibrillated; and this fibrous element seems particularly developed in the secondary gliomatous growths. The

corpuscles are mostly the size of leucocytes, or smaller; and, save for their delicacy and position, have little to distinguish them from the elements of round-cell sarcoma already figured. In certain cases, indeed, the cells may assume a much larger form, and, passing into spindle shapes, be wholly undistinguishable from the sarcoma elements furnished by the coarser forms of connective tissue. The yellow, opaque spots are cheesy masses, the result of the fatty degeneration of the new tissue, which has, doubtless, often led older observers to call this growth "tubercle" of the eye.

From this sketch of the tumour it will be inferred that glioma should exhibit features of malignancy, just as we have seen sarcoma to do; and there are not wanting records of cases which sufficiently justify the position of glioma amongst the cancers. Although rarely encountered as a secondary growth in the abdominal or thoracic cavities, Knapp has

FIG. 16.

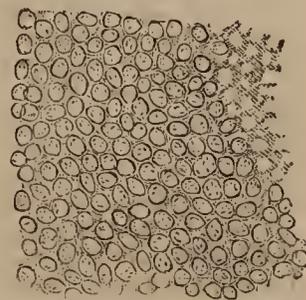

FIG. 16.—Very thin section of a glioma of the retina. Magnified 220 times.

recorded a case of secondary glioma of the liver, and Virchow a similar growth in the kidneys, and instances of extension to the brain and of infection of the neighbouring lymphatic glands and of the bones of the face have been mentioned by other observers. Growing commonly as a single nodule in the retina, multiple growths in the same tunic have been met with, and loosened tumour-cells from a detached retina may alight upon the choroid and give rise to fresh growths in that structure. In the later stages of the disease the growth freely involves the tissues with which it comes in contact, and finally projects from the orbit as a bleeding, fungating, unsightly mass, infiltrating the parts around, and causing hideous deformity of the face.

The history of these examples of malignancy warns the Surgeon not to delay an operation which may be completely successful in the eradication of the disease, if performed in time; and the practice of Mr. Hulke—to whose valuable researches on this, as on other points of ocular pathology, English Surgeons are so greatly indebted—of dividing the optic nerve close to the foramen, and of applying chloride of zinc paste to the interior of the orbit, lest some remains of infectious material light up fresh mischief, must commend itself to all operators. This precaution is specially desirable in those not infrequent cases in which the optic nerve, divided at first close to the globe, is found swollen, with a creamy fluid oozing from its cut surface.

Occurring in the brain, glioma assumes the form of a soft roundish tumour of grey semi-translucent material, not unlike recent infiltrated tubercle, but softer, more vascular, and larger than most tubercular masses, and with less tendency to extensive cheesy metamorphosis. Microscopically the structure of the brain tumours corresponds in all respects with those developed in the retina.

PSAMMOMA.—The tumour to which Virchow has given this name, from the circumstance of its containing "brain sand" (*ψαμμος*, sand), is sometimes classed with the sarcomata, although not much resembling any other member of this group; and it is included in this series more on account of its rarity and want of recognition by English writers, than because it presents many features likely to be taken for those of cancer. The growth is found usually springing from the membranous envelopes of the brain and spinal cord, or in the choroid plexus, and it derives its peculiar aspect from the fact of its holding amidst its other elements a varying proportion of the curious *corpora amylacea*, which, when infiltrated with salts, form the so-called "brain sand" so frequently met with in the choroid plexus and in the lining of the cerebral ventricles. MM. Cornil and Ranvier have styled this tumour "*sarcôme angiolithique*," from the close connexion found by them to exist between the sandy particles and the small bloodvessels; but little as this growth is known at all, it is perhaps more familiar by Virchow's original appellation than by the more recent French name.

Psammoma may occur as mainly a cystic formation, affecting the choroid plexus, and causing cerebral symptoms only when attaining a large size, or it may assume rather the appearance of a papillary or warty growth, springing from the arachnoid or dura mater, and under these circumstances the flattened, slowly growing projection may give rise to no symptoms during life, and will attract notice only as a curiosity in the eyes of the morbid anatomist. In a specimen of the latter variety kindly given to me some weeks since by my friend Mr. Marcus Beck, the tumour was about the size of a florin, and three times its thickness, and its wart-like papillæ sprang from the inner surface of the outer layers of the dura mater, lifting up its inner layer and projecting through this, thrusting aside the ulcerated thin membrane all round. The ragged-looking papillæ were barely held together by some scanty connective tissue, and evidently contained no small amount of gritty particles, although there were no large grains such as are often met with in the choroid plexus. Examined microscopically, scrapings and teased portions (for the loose construction of the mass rendered thin sections unobtainable) showed that the bulk of the new growth was made up of aggregated flattened fibre-like cells, having much the appearance of connective tissue elements when seen in groups. Isolated cells, however, bore a closer resemblance to delicate irregular pavement epithelium. Many vessels ramified through the growth, and the peculiar concentric bodies—the *corpora amylacea*—occupied a conspicuous place in every preparation. These bodies had generally so hard and black an outline as to resemble air-bubbles until more careful focusing brought into view a few irregular highly refracting particles in the centre, and faint concentric rings surrounding these, a bold black outline marking the circumference of the

tiny spheres. Outside this strongly marked border was generally a lighter fibrous zone (Fig. 17). Some of the bodies were

Fig. 17.

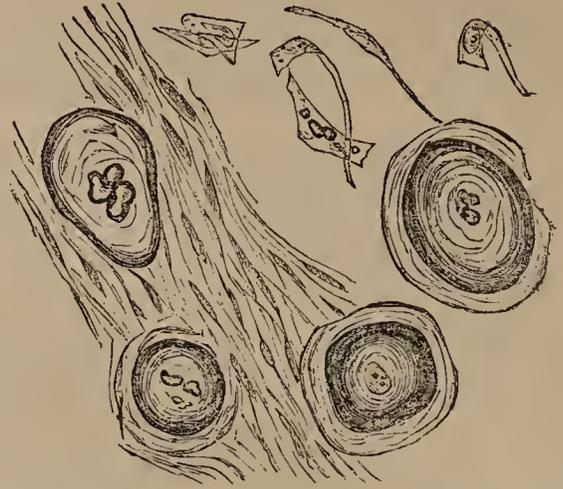

FIG. 17.—From a teased-out bit of a psammoma of the dura mater, showing the concentrically marked bodies and some detached epithelial cells. Magnified 220 times.

pale and free from calcareous incrustation, but the majority were more or less thoroughly infiltrated. Prolonged and careful examination, however, failed to discover any connexion with the vessels such as has been described as an essential characteristic by MM. Cornil and Ranvier. The concentric structure of the bodies seemed to be brought about by the regular superimposition of the delicate flattened cells constituting the bulk of the tumour, and they bore a close resemblance to the "*globes épidermiques*" of epithelioma, the tendency to infiltration with calcareous salts forming their chief distinction from these.

Whether these tumours should be classed with the epitheliomata or simple papillomata rather than with sarcoma, and what is their origin and history, are questions interesting to the pathologist rather than to the practical Surgeon, who is so little likely to encounter them that some apology is necessary for their introduction into these "Notes," whose scope is avowedly purely practical.

(To be continued.)

THE EPICONDYLOID FORAMEN.

By J. BESWICK PERRIN,

Demonstrator of Anatomy at King's College, London.

In my paper on the "Epicondyloid Foramen, etc.," published in the *Medical Times and Gazette* of January 13, I state in a footnote that "This foramen has been described by Professor Struthers (*Lancet*, 1863)." The Professor has kindly called my attention to the fact that the paper referred to was not his original communication on the subject. His first paper was published in 1848, in the *Edinburgh Medical Journal*, and illustrated with a full-sized woodcut. His second and chief paper appeared in the *British and Foreign Medico-Chirurgical Review* in 1854. Thanks to Dr. Struthers' kindness, I have had an opportunity of reading the latter paper. I regret that I had not seen it before I published my own. Since, however, I was not aware of it at the time, it is necessary that I should repair the omission, and do him this justice, which so exhaustive and valuable a memoir deserves. He there describes no less than fifteen specimens of the process, the anatomy of the soft parts in connexion with the process, and also specimens met with in the lower animals, etc. In one of his specimens he states, "There is also an intercondyloid foramen large enough to admit the little finger, and evidently natural," as in the specimen which I described. In his letter to me Dr. Struthers says—"I have often wondered that it has been so long in attracting much notice—it is so interesting and significant. . . . Though I find it common enough in nature, it is rare in museums. But I lately saw two specimens of it in the anatomical museum in Jena, and one of the skeletons in the anthropological department in the Jardin des Plantes shows it. I noticed also, in Cuvier's palæontological collection, the humerus of a bear with a well-marked supracondyloid foramen; the bear, you are aware, not having it normally."

Dr. Wilks has called my attention to a beautiful specimen of this process preserved in the museum at Guy's. He says that

"some years ago, when he revised the catalogue, he found it described as an exostosis."

Dr. Struthers does not think that the epitrochlear hole is of so much scientific value as that of the epicondyloid. Neither do I. The evident metamorphosis which the latter foramen undergoes, as met with in different animals, is uninfluenced by such a disturbing force as pressure, which is evident enough in the history of the formation of the epitrochlear foramen, though I am unwilling to admit that pressure has everything to do with it. Still, it must be admitted that it is of secondary importance to its neighbouring more interesting and suggestive epicondyloid process or foramen.

ON MITRAL STENOSIS, WITH SOME REMARKS ON CARDIAC PATHOLOGY AND THERAPEUTICS. (a)

By ALEXANDER SILVER, M.A., M.D.,

Physician to Charing-cross Hospital, and Lecturer on Physiology in the Hospital School of Medicine.

The following case of pure mitral stenosis, with presystolic but not malignant bruit—there being obstruction to the blood-flow, but no valvular incapacity—is of interest, not only on its own account, but on account of the many points connected with cardiac pathology on which it throws light.

The patient, G. J., aged 16 years, of 95, Union-street, Kennington, is a printer's boy. His father and mother are both alive and well. He has only one brother, who is young, but six sisters alive, five being healthy, the eldest aged 14, and one (the next born after him) the subject of heart disease. Two sisters died, one in infancy, and one of small-pox.

He himself is somewhat undersized, with badly developed muscles, and slight spinal curvature towards the left side—the scapula of which side projects. The left shoulder is somewhat higher than the right, and the left side of his chest is slightly flattened; but the whole chest in front and behind, and especially in front, is badly developed, rickety, somewhat pigeon-shaped, or perhaps better described as infantile; but the legs are straight. Breathing is somewhat imperfect, the walls of the chest being drawn in on each inspiration, and the abdominal and cervical muscles being used in ordinary respiration.

Up to six years of age, beyond the fact that he lived in a damp neighbourhood, no history was obtainable from the boy himself, but at that age he says he had an attack of rheumatic fever for which he was treated at St. George's Hospital. There is a vague history of heart complications at that date.

He says that, as far back as he can remember, he could never run as fast or as far as other boys of his age, being stopped by shortness of breath. He went to school in due course, but nothing unusual in his history happened for some years, till he had another attack of rheumatism in his knees, elbows, etc. He was ill six weeks, was treated at home, and was then sent into the country. He believes that his breathing was worse after the second attack. He remembers nothing about palpitation. After this he went to work at an ironmonger's, but could not do it well on account of shortness of breath.

Two years after he had another rheumatic attack, less severe than the former, in his knees and ankles. Still there is no history of anything except shortness of breath. At this time he was at work as a printer's boy, and had to take it in turn with the other boys to drive a small cylinder machine, which he could not work as long as the other boys on account of shortness of breath and afterwards of palpitation.

He also suffered somewhat from cough, and spat up phlegm streaked with blood. In November last the blood became more abundant, and he brought up some mouthfuls of blood without cough. He then applied for relief, and became an out-patient under Dr. Green, by whom the disease was diagnosed, and by whom he was transferred under my care, and he became an in-patient on December 11, 1871. He was then suffering from a bronchitic attack, and had been bringing up blood somewhat freely. He was ordered a mixture containing digitalis and ipecacuanha.

On inspecting the chest, after exercise, the impulse of the heart is visible over an area extending from the second to the sixth intercostal space, and from the right side of the epigastrium to a little outside the left nipple, over which the parietes

are dragged inwards at each recession of the heart's wall. Over nearly the whole of this region the impulse can be felt, but its maximum intensity is over the fifth interspace, some distance within the nipple-line. This impulse, as communicated to the hand, consists of a vibrating tremor and a beat, the thrill immediately preceding the beat; but the thrill, under ordinary circumstances, is not perceptible in the fourth, and but barely so in the sixth interspace. Neither is it felt over the cartilages of the ribs, nor beyond the line of the nipple. The "thrill area" is about one inch and a half in diameter, and its centre is situate two inches downwards and inwards from the left nipple, and two inches outwards from the ensiform cartilage.

Over the point where the vibration is greatest is heard a loud churning sound, apparently taking the place of the first sound, and ending in a short, sharp, clicking sound. The first of these is not ordinarily audible above the level of the fourth rib, and its maximum intensity is limited to a small space in the fifth interspace. On listening, with the finger on the pulse, it is, however, seen that this bruit precedes the pulse, and that the short sharp sound is coincident with the pulse. This is more noticeable with the wrist-pulse than that of the carotid—the former being apparently somewhat retarded. No true second sound is therefore audible at the apex, its place being taken by a pause; but above the line of the fourth rib the sounds are heard in their usual order, the second sound at the base being on the right somewhat prolonged, and occasionally reduplicated. The area of dulness is more extensive than usual over the right side of the heart, and an epigastric beat is well marked. The apex, too, or point where the heart impinges against the chest-wall, is within the line of the nipple and in the sixth interspace. The abnormal sound is heard, but not well, in the left axilla and at the left bladebone. The veins of the neck are not enlarged, neither are those of the lower extremities; the liver is not enlarged, and the bowels are quite regular and the urine natural. The legs are quite natural; they have never swollen. The only complaint has been shortness of breath, palpitation, cough, and hæmoptysis.

Exercise of any kind readily induces breathlessness and palpitation, with marked increase of the morbid sounds and impulse.

His pulse is ordinarily about 80, but varies in an extraordinary fashion. At first it intermitted every fifth beat; at other times it would intermit in a more irregular fashion; and anon it would be steady. Exercise speedily increases its rapidity, and then, too, I think I can detect, in the third left interspace, an impulse differing in point of time and not perceptible lower down towards that felt in the fifth. This is best made out by causing him to expire powerfully.

In studying this case we shall do well, first of all, to confine ourselves to certain of the most obtrusive symptoms. These are, this peculiar bruit and thrill, this abnormal apex-beat, and the general condition of the boy.

Of the bruit, it is exceedingly local in character, notwithstanding its intensity; for it is barely heard above the fourth rib. Moreover, as to its rhythm, it distinctly precedes the apex-beat and the pulse, whether felt in the neck or at the wrist. Then, too, its note is peculiar; it may be described as churning or rasping, but it has nothing of the blowing character more commonly characteristic of cardiac bruits. Its area is that of ordinary mitral sounds, but it is heard before the ventricle begins to contract, and so cannot be of the kind ordinarily called systolic. And here we may pause to reflect upon the alteration which the first sound has undergone. In tone it resembles a normal second sound, being short, sharp, and distinct, utterly unlike the prolonged sound commonly heard coincident with the impulse of the heart. The reason of that is, I think, and as I shall try to show, clear enough, and helps us to a more exact diagnosis of the actual condition of the boy's heart. The abnormal sound we hear is in point of time presystolic, and were we not careful to examine the pulse it would seem as if this presystolic bruit was systolic, and this altered first sound a healthy second one; for at the apex only two sounds are to be heard, the bruit and the sharp flapping or clicking sound; the true second sound is wanting. The reason may be that it is not conducted to that point, which not unusually happens in conditions called healthy. At the base the second sounds, both on the right and left sides, are clearly audible, as I shall have occasion to point out. The abnormal sound we hear, then, is a presystolic bruit—it is strictly confined to the mitral area; and so, from that circumstance alone, we are able to predicate the existence of some obstruction to the flow of blood from the auricle into the ventricle on the left side, which other circumstances lead us to

(a) Communicated to the Medical Society of London by the President, Dr. Andrew Clark.

assign to contraction of the left auriculo-ventricular orifice—what, for shortness, we call mitral stenosis.

With regard to the thrill, it, too, is peculiar. It communicates to the hand the impression of trembling or vibration similar to that communicated by a purring cat, and so, in various languages, it has been called a "purring tremor." This thrill is commonly put down as indicative of some valve-mischief, especially of the mitral valve, and has been looked upon as one of the common accompaniments of mitral insufficiency—probably in a certain number of instances, in cases similar to the present, owing to mistaking the true first and altered sound for an unaltered second. Certain it is that such a thrill as is here present has been commonly encountered in cases where mitral stenosis has been diagnosed during life.

Next, as regards the apex beat. That is seen and felt in an abnormal situation. It is too low down and too far to the right side. Yea, in the epigastrium itself may be felt the unmistakable impulse of the heart, not indirectly communicated, as is sometimes the case, but so that the wall of the ventricle may be felt almost as directly as over the ribs.

With regard to the general condition of the patient, I would especially note his imperfect development and badly formed chest; his long-continued breathlessness and his inability to undergo exertion; his troublesome cough; and, finally, his attacks of hæmoptysis. I would also specially allude to the character of his pulse when admitted, but now, fortunately, gone. It was exceedingly quick, very irregular, and often intermittent—on an average, about once in every fifth beat. In other respects the boy seems well, and it is on these points I mainly desire to comment.

Before, however, proceeding to do so, I fear I must inflict on you some remarks on the normal action of the heart, which, however profitless to you in themselves, seem necessary to a right understanding of this subject. For clinical purposes it is usual to consider the action of the heart with regard to two of its factors only. These are the contraction of the ventricles, which is commonly called their systole, and their subsequent dilatation, to which the term diastole strictly applies. So far as the former of these is concerned, this is strictly accurate; and the term systolic bruit—meaning thereby a morbid sound taking the place of the first or long sound of the heart, as occurring during the period of ventricular contraction, and owing its production to this contraction—is a strictly accurate scientific use of the word. But when we come to speak of a diastolic murmur, this is not so. During the period that the ventricle is filling and making ready for its next great contractile effort, two totally different sets of duties are being fulfilled by other portions of the heart's substance or of the adjoining and connected structures. One of these is the filling of the ventricle itself, the other is concerned with preventing the filling of it in an improper fashion. The former of these is ordinarily unaccompanied with sound; the latter is remarkably sonorous, and so has attracted to itself the major share of that attention which should have been equally assigned to its quieter contemporaries. Suppose the ventricle contracting with all the force necessary to drive the blood through every part of the body and back again into its own recesses; for it is necessary to have a clear conception how, for every volume of blood ejected from the ventricle, an equal volume must before its next stroke be returned to itself—otherwise, the balance of the circulation would be destroyed, and a fatal accumulation and stagnation would result. But having contracted on its contents and ejected them—and for this exit in a healthy heart only one way is open, viz., into the aorta—the muscular wall of the ventricle promptly passes from a state of rigid contraction to one *not* of perfect dilatation, indeed, but of general relaxation, with some degree of dilatation; whereas the parts just beyond it are in a condition of distension. The contracting ventricle has driven into the elastic aorta more blood than the latter can well accommodate, and has expended part of its force in expanding the elastic walls of the vessels so as to accommodate the surplus blood. This force is not lost—it is only in abeyance; for no sooner does the distending power of the ventricle come to an end, than the elastic aorta recoils on its contents, which, in turn, close fast those floodgates we call the semilunar valves; and so, the blood being under normal circumstances prevented from flowing back into the ventricle, the force stored up in the aorta is expended in driving the blood onward in its due course. The abrupt closure of these valves gives rise to such a sound as we hear when we close a tap of water running under high pressure; this sound we call the second sound of the heart. It is also, however, called the diastolic sound of the heart, unfortunately; for it is due to causes having their seat outside the heart—namely,

as I have said, to recoil of the aorta; and although it takes place during the diastole, it is not the only occurrence during that period which may give rise to sound.

We have seen that any backward flow of blood from the aorta is, in a healthy heart, promptly arrested; but the pressure of the arterial system may operate in an opposite direction; and so, as the ventricular wall grows flaccid, the blood pent up in the venous system and auricles whilst the ventricle was contracting, abruptly forces open the auriculo-ventricular orifice, and so the blood passes freely into the expanding ventricle. This takes longer time than it does to close the aortic valves, for the veins do not recoil so speedily as do arteries; and so the flow of blood from auricle into ventricle goes on after the second sound has ceased. This period, in the healthy heart, is characterised by no sound; it is part of what is called the pause. Nevertheless, seeing that the ventricle is filling during the whole of it, it is truly diastolic.

But the time comes when it is necessary for the ventricle to act; and to act with most advantage it must be quite full, or even distended. Moreover, as may easily be understood, it is essential that some provision should be made for the reception of blood during its contraction. And so, alike for filling the ventricle quite full and to make room for the blood which will come from the veins during the ventricular systole, the auricle contracts on its contents and empties them into the ventricle. This, too, it is plain, occurs during the ventricular diastole; for does not the ventricle receive the contents of the auricle, and become distended thereby? And so, too, this effort of the heart is strictly diastolic, though long subsequent to the second sound. Normally, this effort of the heart is accompanied by no sound; it too, occurs in what is called the pause, though, when the orifice is much contracted, an abnormal sound or bruit may be heard—a bruit which, occurring as it does immediately before the systole of the ventricle, is commonly called presystolic. Nevertheless, it is plain that such a sound can only take place during the diastole of the ventricle; and such a term as "post-diastolic," which I have heard applied to it, is rank nonsense—nay, more, it is the embodiment of error.

It is such a murmur and such a condition we have this night met to discuss, and I trust that these remarks may prepare the way for the better understanding of them.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

TWO CASES OF LATERAL LITHOTOMY.

(Under the care of Mr. HULKE.)

THE first does not present anything remarkable. The patient, a child; the stone, mulberry, and not very large; uninterruptedly favourable progress, and dismissal from the Hospital at the end of a month.

The second case has features of peculiar interest. The patient, a gouty, middle-aged man, whose excessively irritable bladder and albuminuria, the size of the stone and its evasion of the lithotrite when an attempt was made to seize it for the purpose of measuring it (which raised a suspicion of some peculiarity in the bas-fond of bladder), negatived lithotrity; whilst the unusual depth of the prostate from the surface, and a not inconsiderable enlargement of this gland, concurred to render lithotomy difficult. The reception of the stone in a sacculus—a circumstance thought by some persons to be not very exceptional, and by others never to happen—here constituted the principal difficulty in the operation, and a slight unavoidable laceration of the mucous lining of the sac led to urinary infiltration of the pelvic cellular tissue.

A boy, aged 7, from Buckinghamshire, was admitted August 16, 1870, into Percy Ward, with symptoms of stone in the bladder of uncertain duration. They were not very urgent. He was plump and hearty; he did not micturate very often, and did not seem to be in much pain. The urine was acid, sp. gr. 1027. On standing, it separated into an abundant whitish flocculent deposit of pus, with oxalate of lime.

26th.—Mr. Hulke removed the mulberry calculus by lateral lithotomy. Next day his temperature in the armpit had risen

to 99.5°; from the fourth to the ninth day, inclusive, it averaged 100°, and after this quickly declined to normal.

September 7.—All the urine was voided per urethram, and a few days later the wound had perfectly healed.

A very stout, gouty man, 55 years old, from Bedfordshire, was admitted into Forbes Ward, August 10, 1871, with unusually severe symptoms of stone. Very great pain in the end of the penis, in the thighs, and hips; urine expelled every five minutes day and night, turbid, often bloody, albuminous. Rest broken; tongue furred; pulse 100; temperature 100.5°. He said that he had suffered with his bladder six years. Five years ago he voided, per urethram, three stones, and another of the size of a horse-bean one year ago. On sounding, a large rather rough stone was detected. He was kept in bed, and ordered anodynes with an alkali. The urine was acid. Four days later the bladder was found to be less irritable; he only micturated four times per hour, the albumen had fallen to 1 in 60, and his temperature had fallen slightly. On trying to catch the stone with a lithotrite, in order to ascertain exactly its size, it would not be seized, and seemed to get out of the way of the instrument behind the enlarged prostate. Even when the beak was turned downwards, although the stone could be easily touched, it could not be laid hold of. The prostate could only just be touched with the finger in the rectum; it was enlarged. Lithotripsy being negatived by the great irritability of the bladder and large size of the stone on August 16, Mr. Hulke removed the stone (a large oval lithic acid one) by lateral lithotomy. The bladder lay so deep that the finger scarcely reached it, and though the stone was easily touched with the forceps, it could not be seized, even with a curved one, until the base of the bladder had been tilted up with a couple of fingers thrust high into the rectum. Before this manœuvre the impression received by the operator was that the greater part of the stone was overlaid by mucous membrane. The patient's heart was weak; he took chloroform badly, and was long in recovering consciousness.

Next day, August 17, his axillary temperature had risen to 102.2°, and his pulse was 102; he had slept half the night; the urine ran freely through the wound; he complained of a little soreness in the bottom of the belly.

18th.—Had a restless night; pulse risen to 130; and temperature fallen to 100.2°. Slight redness, with tenderness above the left groin; the urine still flows freely through the wound, but a few drops come by the urethra. In the afternoon he rather quickly sank, dying at seven o'clock.

At a post-mortem examination of the body made next day the muscular coat of the bladder was found to be greatly hypertrophied, and between the muscular fasciculi three pouches of mucous membrane protruded at the summit, and a fourth at the left side of the viscus; while between the bladder and the rectum was a fifth and very large pouch, the orifice of which lay just behind the prostate, evidently also an extension of the vesical mucous membrane. The shape of its vesical opening was a long transverse oval, and the posterior lip nearly overhung the anterior one, making it nearly valvular. There could not be any doubt that the stone had lain in this cavity. A purulent œdema of the pelvic cellular seemed traceable to a slight rent in its mucous lining. The pelvis and calyces of both kidneys were dilated. The aorta and mitral valve were atheromatous, and the heart laden with fat.

**TUBERCULO-SYPHILITIC DISEASE OF TESTES—
CONTRACTION OF SUBMUCOUS TISSUES OF THE
LARYNX—DEATH FROM APNŒA.**

(Under the care of Mr. NUNN.)

Henry S., aged 25, married; admitted February 7, 1871. He had been twice in the Hospital before; the first occasion was in November, 1867, and the second in January, 1869. On referring to the registers, the following notes were found of his condition at the times of these admissions:—

“1867. Henry S., aged 21, single; November 5. No previous venereal attack; a primary syphilitic sore on penis six months ago. On admission, an ulcer at left angle of mouth, others in throat; unhealed sore on glans penis.”

“1869. January 18; aged 24, married. Hardness of testicles of twelve months' duration. Fungating four weeks. At lower and anterior part of scrotum on the right side is a pale fungating mass the size of a walnut. Both testes hard, and the left much enlarged. An excavated ulcer in throat; voice husky, throat sore, very cachectic-looking.”

Admitted February 7th, when he complained of sore throat, huskiness of voice, and weakness. He had a very cachectic appearance. Both testes were enlarged, especially the left.

At the lower and front part of right testis the skin was adherent; at the upper and fore part of left, which was as large as a large pear, there was noticed slight fluctuation.

On the February 22 there were symptoms of dyspnoea; and death followed on the 23rd, suddenly, he having improved during the day. He was talking shortly before death.

The following is extracted from Mr. Morris's report of the post-mortem examination:—

Epiglottis, pillars of fauces, epiglottidean folds, and larynx as low as free edges of upper cords, contracted, thickened, and hardened. No vascularity of the parts, and the surface was of a dull whitish hue. There was no evidence whatever of recent ulceration, but at the base of the epiglottis, both in front and at the sides, were a few somewhat deep depressions, but without any breach of the surface; these were due, no doubt, to the contraction of the submucous fibrous deposit, and consequent puckering of the mucous membrane covering this. No soft œdema of larynx or glottis. Both testes on section showed well-marked whitish-yellow firm deposits in their substance. On opening tunica vaginalis on left side, a small encysted hydrocele was cut into. This was situated immediately above the testis. In this testis were three large and one small whitish-yellow firm deposits, which were surrounded by the tubular structure of the testis. This also was firm, and coarser than normal, and could not readily be teased out. The right testis was of the size of a hen's egg, and in it was a mass the size of a Kentish cob-nut at the lower and forepart of the organ; and running transversely across the cut surface was a distinct whitish-yellow streak of deposit, similar in character and appearance to that constituting the better-defined nodules. There was no deposit in any other organ; no nodes on the bones; no albuminoid degeneration of viscera.

This is a good illustration of the tubercular syphilitic sarcocele described by Hamilton, of Dublin, in which, distinct from more common varieties, in which deposit is uniform and outside tubes, it is usual to have patient in cachectic condition, both testes affected, and not usually, as in earlier stage of this instance, the protrusion of a fungus. It is thus distinct from the more common variety of syphilitic testis, in which the deposit is uniform throughout the substance of the organ and outside the tubules, and which affects only one organ, and occurs in patients in good health. Another feature of interest was the presence of an encysted hydrocele, which is an unusual occurrence in tubercular syphilitic sarcocele, but not uncommon in the other form of the disease. The sudden access of death was quite unlooked for. Though on the day before he had suffered from slight dyspnoea, there was nothing in his condition to lead one to expect so rapid a termination of the case. Nor did the post-mortem examination reveal any recent disease about the respiratory tract, although the well-marked results of former syphilitic ulceration were present about the larynx and epiglottis.

ST. PETER'S HOSPITAL.

**VERY LARGE STONE IN THE BLADDER—
LITHOTOMY—RECOVERY.**

(Under the care of Mr. TEEVAN.)

A. W., AGED 32, hawker, was admitted into the Hospital September 27, 1870.

History.—The patient stated that he first noticed pain at the end of penis, when urinating, as far back as three years. Two years ago he first passed a little blood, after running. Six months ago he suffered much pain when riding in an omnibus, and afterwards passed blood. Has never ridden in any vehicle since. Urine sometimes stops for a minute or so during micturition, but he has never had retention. No history of stone in his family. Is a native of Cork, but has lived in town nearly all his life.

Present State.—Is very thin, sallow, and depressed. Passes blood at times, but he is in the habit of slowly walking from twelve to twenty miles every day in the pursuit of his business. Suffers much pain when urinating, which act he can only accomplish when standing up. Sleeps pretty well, and has a good appetite. Urine only occasionally thick. Mr. Teevan then examined patient with a lithotrite, and found a stone so large as entirely to preclude lithotripsy.

On October 8, at 3 p.m., the patient was put under chloroform by Mr. Lovell. A rectangular staff was then passed by Mr. Teevan, and given to Mr. Walter Coulson to hold. A very free external incision was made, commencing low down, and the bladder was well laid open by the internal cut. Mr. Teevan found that the wall of the bladder was firmly adherent

to the upper surface of the stone, and it required some force to separate them. When the stone had been grasped by the forceps and its extraction commenced, it was necessary to introduce a probe-pointed knife three successive times, in order to cut outwards and downwards, that the calculus might glide out without the slightest traction being exerted. Considerable bleeding took place during the operation, but it only lasted for a couple of minutes. The calculus was a phosphatic one, of oval shape, measuring no less than seven inches in its longer circumference, and six and a half inches in its shorter. The weight when removed was five ounces.

At 9 p.m. the same day the patient was very comfortable: pulse 85.

On October 9 the pulse had risen to 100. Tongue clean. Skin cool and moist.

October 15.—Patient doing very well. Appetite good. Sleeps well.

October 26.—Some urine flowed through penis to-day. Wound looks very healthy.

November 6.—Nearly all the water comes through the penis.

On December 6 patient left the Hospital at his own request, as he felt so well, and afterwards attended as an out-patient. Wound was not healed till nearly five months after the operation.

Remarks.—There were several points of interest in this case. The stone was adherent to the mucous membrane of the bladder, and there was a rough depression, about the size of a farthing, on the upper surface of the calculus, corresponding to the union of the opposed surfaces; but no harm seemed to follow their separation by the finger. Although the stone was so large, the patient was walking from twelve to twenty miles every day up to his admission, and there was but little pus or albumen present in his urine, and blood was rarely seen. It will be observed that no attempt was made to tear the stone out of the bladder—it was cut out by free incisions; and there was thus an entire absence of irritative fever, hypogastric tenderness, and secondary hæmorrhage.

HUTTEESINGH'S HOSPITAL, AHMEDABAD.

MYXOMATOUS CYST—LIGATURE OF THE TUMOUR.

(Under the care of A. S. G. JAYAKAR.)

M., a healthy-looking infant of about 8 months, was admitted into the Dispensary attached to this Hospital on March 2, 1871, with a cystic-looking growth situated about half an inch behind the anus, and just over the lower end of the coccyx. It was about the size of a medium-sized apple, firm, and rather hard above, and soft and cystic in its lower part. It was first observed as a small growth a few days after the child's birth, and then kept on increasing in size. There was some amount of pain on squeezing the tumour; but it was, indeed, so slight that its connexion with the spinal cord may have been fairly disputed. On exploring the lower part of the tumour with a grooved needle, a viscid, transparent, mucus-like substance escaped; it was sticky in its feel, and heat seemed to have no effect on it. The tumour was tapped, and about four ounces of the same sticky viscid fluid removed. When the fluid contents were removed, the nature of the harder and firmer part of the tumour rendered the diagnosis of the case easy. The lower bagging portion of the tumour soon filled up again, and she was admitted into the Hospital as an indoor patient on May 22. The tumour having rather an undefined base, no active surgical interference was thought advisable, and a thick strong ligature was therefore passed through it, and tied on either side. Within twenty-four hours, the ligature seeming to give rise to convulsions, was loosened, and again an attempt was made gradually to tighten it, so that by the end of three weeks the tumour had mostly separated, and a few touches of the knife completed its final removal from the body, leaving a red granulating surface to heal gradually. The wound has now mostly healed up; there is still, however, a patch of the size of a shilling, but time and stimulant applications may fairly be expected to complete the cure.

Remarks.—Cases of myxomatous tumours are still very few on record—either owing to rarity of such growths, or their being easily mistaken for colloid and similar tumours of a malignant nature. The physical condition and general structure may often lead to a wrong diagnosis; but the total absence of any signs of malignancy, together with a microscopical examination of the contents of the growth, would soon

decide the question as to its nature. The upper part of this tumour, or rather the undefined pedicle described in the case, was solid; and, on making a section, the same glairy viscid fluid as in the lower part oozed out. Under the microscope, it was found to be principally composed of fibro-cellular tissue, with fat cells and oil globules scattered in places, showing that already degenerative changes had commenced. The lower or cystic portion of the growth was divided into small compartments by bands of fibro-cellular tissue, extending in all directions, with vessels ramifying over the greater part of its inner surface. The viscid glairy fluid under the microscope presented numerous large rounded cells (some were oval), with thready branches shooting forth from all sides of the cells, and freely anastomosing with each other.

Medical Times and Gazette.

SATURDAY, MARCH 16, 1872.

THE GENERAL MEDICAL COUNCIL.

WE mentioned last week the bare fact that the Council had agreed, by a majority of one, to Dr. Acland's motion, "That a Committee be appointed to consider and report whether the General Medical Council has power to make rules for the special education of women, such as may entitle them to obtain a qualification to be certified by the Council. And that the Committee do further report for what purpose such qualifications, if any, should be granted, what are the most desirable means for educating, examining, and certifying in respect of them, with special reference to midwifery, the management of Medical institutions, dispensing, and nursing." We have tried, by the light of Dr. Acland's speech, to find some good reason for approving his motion and the Council's acceptance of it, but we confess that the more we consider the matter the more unwise and inexpedient does it seem. Dr. Acland says that his motion has nothing to do with the question, "whether or no women were entitled to be entered on the Medical Register as ordinary Medical Practitioners"—and of course we believe him, and we suppose, further, that he does not at all intend his Committee to go into the matter of the education of women as Medical Practitioners; but we are quite certain that outside the Council, and still more outside the Profession, it will be believed that the Medical Council has appointed a Committee to examine into the desirability and the best means of enabling women to qualify themselves to be entered on the Register of Medical Practitioners. The terms of the motion are quite vague enough and wide enough to excuse, if not to justify, such a belief; and, as Dr. Acland intended no such thing, it was unwise not to have worded the motion more exactly and guardedly. The title of the Medical Act is plain and simple

enough—it is “An Act to Regulate the Qualifications of Practitioners in Medicine and Surgery,” and the preamble runs thus:—“Whereas it is expedient that persons requiring Medical aid should be enabled to distinguish qualified from unqualified Practitioners: Be it therefore enacted” so-and-so; and the first enactment is the appointment of a Council, “which shall be styled ‘The General Council of Medical education and Registration of the United Kingdom.’” The functions of the Council seem to be very plainly set forth, and to appoint a Committee of that Body to formally consider whether or no it can undertake work which has nothing to do with qualified Practitioners, or with either the Medical education or registration of Practitioners, would appear to most people, we think, an unwise and unjustifiable waste of time.

Dr. Acland speaks, or appears to speak, as if persons were kept outside the province of the Council, and prevented from registration on account of their sex. We conceive that sex has nothing whatever to do with it, so far as the Medical Council and registration are concerned. There is certainly one woman on the Register now, and she is on it by right, as a duly qualified Medical Practitioner. By the same right any number of women who may present themselves as fully educated and qualified Practitioners will gain admission to the Register; and, in the same way as men, women who can prove they have gained a licence in midwifery recognised by the Act of 1868 will have a right to have the licence registered. But we do not know that any man is registered as a Licentiate in Midwifery alone; all, we suspect—certainly the vast majority—of those so registered have been educated as Medical men, and possess some other licence or diploma besides the licence in midwifery.

Further, Dr. Acland’s motion sins in the very direction that he deprecates. He would have the Council institute a special register of duly trained and qualified nurses, dispensers, and managers of Medical institutions, but confines it to persons of one sex only. Why shut out men from this new province of the Council and this new Register on account of their sex? There are very many male nurses, “invalid attendants,” and dispensers; why should not the Council “exercise some control over the qualifications and certificates” of these persons, as well as over those of women acting in the like capacities? If we are to believe the accounts that reach us from lunatic asylums, the male nurses and attendants would be none the worse for some training and some education, especially, for instance, with reference to the fragility of the ribs in certain conditions of ill-health. Again, how will Dr. Acland draw the line between dispensers—that is, makers-up of prescriptions—and druggists? Perhaps we may very safely leave him to settle that question with the “chemists and druggists,” who are well able to take care of themselves. The Pharmaceutical Society would, we suspect, have very strong objections to the manufacture of a race of dispensers “registered by the General Medical Council”; while assuredly the public would be very apt to confound them with Medical Practitioners, and, seeing that they were registered by the General Council of Medical Education and Registration, would insist upon consulting them as to “what is good for” this and that disease. Could Dr. Acland’s suggestion be carried out, it would throw an immense amount of additional work on the Council, which has already plenty to do; by stepping outside the strict province of the education and registration of the actual Medical Practitioner, it would be entering on a field to which it would be very difficult to place any limits; and it would most likely produce great confusion and mischief. We protest against it, therefore, in the interests of the public, of the Profession, and of the Council itself.

The rest of the acts of the Council during their Session have been all sufficiently recorded in the account we last week published of each day’s work, and do not call for any remarks here. The one great object of the meeting of Council was the

formation of a Conjoint Examining Board in each of the three divisions of the kingdom; and though no one scheme for the forming of such a Board for any division of the kingdom could be produced, and, of course, no such Board was formed, yet enough was done towards the establishment of the system to gratify and encourage those who believe in the plan as a highest good as regards examinations, and to perturb and discourage those who look upon it as a mistake or fear it as an evil.

A scheme which unites all the English Medical Authorities but two received the approval and sanction of the Council, and the two Bodies at present outside the scheme—the Society of Apothecaries and the University of London—are kept outside by legal difficulties, which they will earnestly endeavour to get removed; and, according to the statements of their representatives in the Council, we may expect that those endeavours will be successful. In Scotland the Medical Authorities do not appear to have any marked love for, or desire to adopt, the Conjoint Examining Board system; but out of deference to the wishes of the Council they have seriously considered the possibility of forming such a Board, and sent in to the Council various sets of resolutions on the subject.

The Authorities appear at present to consider that the formation of a Conjoint Examining Board should be confined to clinical examinations, “to test, clinically, the knowledge of Medicine, Surgery, and Midwifery possessed by the candidates for registration, as also their ability to practise the same;” while, in other respects, the examinations should be conducted as at present, supervised by the inspectors appointed by the General Medical Council—no one, however, being “admitted on the Medical Register who had not passed the examination of the Board.” This plan, it is to be observed, would not lessen the number of Examining Boards, which is one of the great objects of the Conjoint System, but would add to them a new and additional one. And it is to be remarked that, so far as we gather from the speeches of the Scotch members of the Council, even these resolutions in favour of the formation of a Clinical Conjoint Examination Board have not received the approval of the “ruling powers” of some, if they have of any, of the Scotch Licensing Bodies and it is certain that many of the most eminent men in Scotland very strongly disapprove of the Conjoint Examining Board Scheme. The Council, however, “hope” that Scotland will present by July next such a scheme as they may be able to sanction.

In Ireland the five Licensing Bodies joined in a Conference on the examination subject, each Authority sending to it three representatives. These gentlemen held sixteen meetings, and passed a series of resolutions which, carried out, would form a full and large scheme for a Board “for a Joint Examination in Medicine, Surgery, and Pharmacy.” The scheme is, as was observed by the President of the Council, “actually more complete than the English scheme, because, in fact, it will include all the five Bodies in Ireland; and more comprehensive, because it includes proposals with regard to preliminary education as well as Professional education.” But—and the “but” is a very important and significant one—the scheme has not yet been accepted by the Bodies represented at the Conference. The Apothecaries’ Hall of Ireland is apparently the only Body that has fully approved of it. The Board of Trinity College “are disposed to give a general assent to the scheme,” but “entertain a strong objection” to one of its clauses; the Royal College of Surgeons raises a pecuniary difficulty; and the Queen’s University sends to the Council a very characteristic communication on the subject. The Senate desires it to be understood that, in sending their representatives to the Conference, “they were not thereby expressing any opinion on the principle of establishing a Joint Examining Board for each division of the United Kingdom, and their representatives were empowered only to report to the Senate the proceedings of the Conference.”

and the opinion of the Senate on the scheme of the Conference cannot be considered very encouraging. The Senate is of opinion that "it would be useful to have one or more Examining Boards, before which all candidates desirous of having their names placed on the Medical Register of the United Kingdom should undergo a test examination, in addition to holding the degree or licence of a competent authority." But the Senate fears that, if such Board or Boards are formed by voluntary agreement, they would be liable at any time to be broken up by a repeal of the union by any one or more of the Bodies, and is of opinion, therefore, "that such Examining Board or Boards could be effectively established and maintained only by legislation"; and, further, "whenever a Bill may be introduced into the Legislature proposing to deal with Medical reform," the Senate "will give its attention to the subject, and will be ready to co-operate with the other Universities and Colleges in promoting the attainment of a satisfactory measure." Considering how the Queen's University has resisted the "moral suasion" of the Council with regard to some of its proceedings, and, when the Council talked of compulsory measures, "stood with folded arms, fixed and immovable, and with lips barely apart, said, in the words of Shakespeare, 'Come on!'"—remembering this, the last part of the message of that University is simply delicious.

The Council, however, hope that Ireland as well as Scotland will have a satisfactory scheme ready by July. And we think the Council were wise in allowing time to work for them, and in rejecting Dr. Parkes's rather threatening motion, which we noticed last week; for, seeing the difficulties the English Medical Authorities have met with, and the imperfectness of their scheme as at present formed, there was not a little appositeness in Sir Dominic Corrigan's humorous remark that "Dr. Humphry's and Dr. Parkes's taking upon themselves to lecture the Irish and Scottish Bodies reminded him of the fable of the old crab teaching the young crab to walk straight, and the young crab's reply: 'Mother, would it not be well if you would set us the example.' Let the old English crabs set us the example of straight walking before they presume to lecture the young Irish and Scottish crabs."

As to the rest of the deeds of the Council, we will only observe that they directed "the Executive Committee to obtain premises where the meetings of the Council can be held, and the general business carried on with comfort and convenience"; and that the statement of income and expenditure of the Council was satisfactory, showing a balance in favour of income for the year 1871 of nearly £900. We observe that an application from Messrs. Bell and Thorpe, "for remuneration for extra work in connexion with the investigation into the accuracy of the Register," was referred to the Executive Committee. We venture to hope that it will meet with a favourable response, as these gentlemen have always shown themselves highly courteous and obliging, as well as efficient clerks to the Council.

THE TICHBORNE CASE.

WE had intended giving a commentary on the Medical points in this case, but really, after the unprecedented duration of the trial and daily publication of the evidence, there has come a sort of lull. Curiosity is satiated for the present; "the Tichborne case" falls flat on the public ear, and we shall reduce our comments to the shortest possible space.

The first point that strikes the Medical annalist is the surprising circumstance that an illiterate slaughterman from Wagga-Wagga should be sent over from Australia on the pretext that he was the long-lost heir to the name, rank, and estates of one of the oldest families in England. The next wonder is that any people should have believed in him; but here it must be said that if there were no dupes, there could be no impostors. Of the dupes in the present case, some

believed in the Wagga-Wagga butcher because his story was wonderful; others said that his conduct was so extraordinary and inconsistent that if he were not really Sir Roger he never could have dared to come forward as he did. The more evidence, therefore, there was against the Claimant, the more they believed in him. Others were not so much dupes as vehicles of private spite or religious animosity. There are some people who can derive satisfaction from the annoyance which this litigation has inflicted on an ancient and honourable family; and others—persons of some weight—who have publicly declared that the opposition to the "Claimant's" undoubted title was all the work of Popish priests or Jesuitical conspirators!

The Claimant attempted to prove his identity with Roger Charles Tichborne, who was lost in the *Bella* in 1853. Now, identity is of two kinds—mental and bodily.

The only instance we know of an attempt to establish identity of mind simply is that of Pythagoras, when he asserted that his soul was the same as that of Euphorbus, the son of Panthous, and, by way of proof, selected his own shield, as it hung in the temple of Juno near Mycenæ—

"— clypeo Trojana refixo
Tempora testatus, nihil ultra
Nervos atque cutem morti concesserat atræ."

In these days of spiritualism we are sometimes asked to believe that the spirits of great and good men deceased make use of vulgar charlatans as *mediums* through whom they communicate certain messages to this world by means of *rappings*; but it seems to us easier to believe in spiritualism than to believe that Roger Tichborne should so far lose his mental identity as, after his alleged escape from the wreck of the *Bella*, and his being put on shore at Melbourne, to forget father, mother, relatives, and one dearer than all these put together; that he should forget his station in life, his balance at a banker's, and all his previous tastes and habits; that he should live the life of a hired groom, jockey, butcher, horse-dealer, and horse-thief; that he should abide contentedly amongst a criminal or half-criminal class of the coarsest description, and should marry a woman who is said neither to read nor to write; and then, at last, should be moved to return home, and to make known his existence to those who had mourned him as dead, neither by affection for his widowed mother, nor by the promptings of love, nor the honourable desire to fill his proper place in society, but by the instigations of an attorney, or of an agent who traded in the recovery of "missing friends"! On his return, does he seek out his family, challenge recognition, and fly to the arms of friends only too willing to receive him? No; he skulks down to Wapping to inquire after the Ortons, and secludes himself at Gravesend. When unearthed, his French had vanished, he spoke Wappingese instead of English—"cousing" for cousin, "I never done it," "I never were tattooed," and the like—and, for a climax, makes a brutal attack on the honour of a virtuous and estimable woman, whom, if his story were true, it would have been an act of purposeless villainy to have deserted and betrayed. "*Nemo repente fuit turpissimus.*"

Bodily identity may be established by the hair, eyes, features, and general stature and conformation, or by special and accidental marks, such as scars and traces of injury or disease. So far as the photographs in the shops are to be relied on, there is no resemblance in hair, eyes, or ears. Roger Tichborne's face is long and feebish, that of the "Claimant" square, and full of penetration and energy. As for the accidental marks, Roger Tichborne is said to have had many—including a scar on the head from a fall on the rocks at Pornic, the mark of an issue on the left arm, of a wound from a fishhook in one eyelid, of bleedings in the arm and ankle, and above all a regular tattooing of his initials and certain devices on the forearm. On the Medical evidence relating to these marks we shall preserve a respectful silence, further than to notice that common Medical evidence often agrees on the

facts but disagrees as to their interpretation. But the uncommon Medical evidence in the Tichborne case was dubious as to the very facts—such as the position of certain scars, whether on the right ankle or the left, whether eyelid or eyebrow, etc.

As the matter stands, the Claimant has shown himself possessed of prodigious astuteness, cleverness, and staunchness; and, in accordance with a well-known law, very likely by this time implicitly believes his own story. Various careers have been sketched for his possible future. We would venture, in all humility, to suggest that talent of so high a forensic order ought not to be wasted, and that a very little preparation would enable the Claimant to qualify himself for practice at the Old Bailey, where from being a client he might become a colleague of "Brother Ballantine." The firm of Baxter and Norton could show their faith in him by sending him briefs.

THE WEEK.

TOPICS OF THE DAY.

THE health of the Prince of Wales is steadily improving. The Paris telegrams announce that he was sufficiently well to attend the Gymnase Theatre on Tuesday, and afterwards to entertain the Duc d'Aumalé at supper. He left Paris on Wednesday, and was to be in Rome on Saturday, the 16th. We announced last week that Dr. Vivian Poore had been selected to accompany the Prince as his travelling Medical attendant, and he is now in the Prince's suite.

We learn from the Twenty-seventh Annual Report of the Enclosure of Waste Lands Commission that there are now eight millions of uncultivated acres in England and Wales. Of these, three millions are in lowland districts, and a large part of them might be brought under cultivation. To do this requires only the sanction of the Legislature and the aid of the Government. Considering the indisputable evidence which has now been collected that the increase of urban and manufacturing populations is directly injurious to race-development; that agriculture, as it was the first, so it is the healthiest, occupation for man; that the accumulation of great masses of the people in large towns is almost necessarily accompanied by an increase of pauperism; and that the feeding of the great bulk of the nation from foreign sources mainly is at the best an artificial expedient, liable to serious disturbance in times of political change, and greatly dependent on the development of the mineral and other resources of foreign countries, and on the progress of scientific discoveries,—it requires no argument to show that it is the duty of the Legislature to give the greatest development to the food-producing capabilities of the country. If Sir Robert Walpole's aphorism be true that the man is a true patriot who makes two blades of grass grow where one grew before, our law-makers have a grand opportunity yet. The subject is one of sanitary as well as of political importance, and we commend it to the consideration of the Medical Department of the Privy Council.

There have been no matters of great Professional interest before Parliament during the past week. A question, indeed, was asked of Mr. Cardwell as to the duties to be performed by Militia Surgeons under the new Army Regulations. He was understood to say that their services would be required during the time that their regiments were called out, but that they would not be employed at other times in the examination of recruits.

The Association of Poor-law Medical Officers met at the Medical Club, Spring-gardens, on Tuesday last, for the purpose of discussing Mr. Stansfeld's Public Health Bill in relation to Medical Relief. Dr. Rogers presided. Amongst those present were Mr. Corrance, M.P., Mr. Charles Reed, M.P., Mr. A. Pell, M.P., Dr. Brady, M.P., and Dr. Lush, M.P. Mr. Corrance moved, and Mr. B. Baker seconded, the following resolution, which was carried unanimously:—

"That the Local Government Board Bill contains a partial

recognition of the principles of local sanitary legislation which have been accepted by this Association, and although it fails, as at present constituted, to meet many great and urgent requirements, these are of a nature which may be remedied by amendments in committee. Under the circumstances the support of the Association may be safely given to the second reading of such a measure, and their future efforts be mainly directed to the general extension of its provisions to all suitable localities, and the independence and adequate remuneration of the sanitary and Medical officers appointed."

A committee was appointed to watch the progress of the measure through Parliament.

We are sorry to learn that a Hindoo gentleman, Mr. Lal Mitra, who has been studying Medicine in Edinburgh, and is a Member of the Edinburgh Royal College of Surgeons, has been taken to the Lambeth Workhouse in a state of insanity—it is said from over-work—and that it was reported to the guardians that, although he is possessed of large wealth in India, he has no means of procuring a passage out; that his passage-money will be sent over in June, but until that time he would have to remain in the workhouse. Surely the College to which he belongs, or some other Professional body, such as the Medical Benevolent Fund Committee, might take means to ascertain the truth of these representations, and to provide a suitable retreat for the unfortunate man.

At the Lincoln Assizes, on the 13th instant, a man named William Frederick Hovey was found guilty of the wilful murder of his wife, and was sentenced to death by Mr. Justice Quain. The convict is a person of respectable connexion, and he deliberately shot his wife in his father's house. The motive was jealousy, and the prisoner's counsel sought to reduce the crime to manslaughter by establishing the fact that the prisoner had been suffering from delirium tremens, and that he was of unsound mind from drink at the time of the commission of the crime. Mr. Justice Quain, however, would not allow the plea. He said that the plea of jealousy, the effects of drink, and the attack of delirium tremens formed no legal answer to the charge. It would seem from what he stated that the law does not recognise any unsoundness of mind from drinking as a bar to responsibility. He suggested that these circumstances, however, might be a sufficient reason for a recommendation to mercy on the part of the jury. The jury, however, returned a verdict, "Guilty of wilful murder," without acting on the judge's suggestion. We presume, nevertheless, that a patient suffering at the time from an undoubted attack of delirium tremens, although the result of drink, would not be held accountable for his acts. In this case the man had previously suffered from more than one attack of delirium tremens, and, according to his own account, had been drinking brandy for six weeks before the murder.

Dr. Quain's lectures on "Diseases of the Muscular Structure of the Heart" commence this day (Friday) at the Royal College of Physicians, at five o'clock. They have been looked forward to with considerable interest.

Institutions presumably established for the sake of charity pure and undefiled are just as apt to degenerate into nests of cabal and enmity as those that are set up as mere private speculations. The Orthopædic Hospital is a case in point. The Medical Staff and the Committee have, it seems, for some time been at loggerheads, and at last things have come to a climax. Mr. Tamplin and Mr. William Adams have withdrawn from the institution, and we think that a perusal of the report we publish in another column will prove that they had quite sufficient grounds for the course they have taken.

THE WATER-SUPPLY OF SOUTH LONDON.

TOWARDS the close of last year the Association of Medical Officers of Health, at the instigation of one of their number, drew the attention of the Board of Trade to the reports of Dr. Frankland, published in the Registrar-General's Weekly Returns,

on the bad quality of the water supplied to the metropolis by certain companies south of the Thames, and, at the same time, they urged the Board to appoint an independent water analyst, in accordance with the provisions of the Metropolis Water Act (1871), in addition to the water examiner whom they understood had been appointed under the Act. In due time an answer was received, declining to accede to the request, and, indeed, implying that the appointment of a water examiner to supervise filtration rendered analysis unnecessary. It appears, however, that the Board perceived the necessity of some investigation of the turbid and alleged impure state of the South-wark and Lambeth Companies' waters; for the water examiner under the Act has recently presented a report on Thames water, and made recommendations which form an admirable commentary on the reply of the Board to the Association's request. The examiner reports that the companies referred to have for two months supplied imperfectly and hurriedly filtered water, but this through no fault or wilful negligence on their part. The cause was, he says, unavoidable, and due to extensions in the works going on at the time, coupled with river floods. He recommends that for the filtration of a given volume of water a minimum area of filter-bed should be compulsory, and that a standard of filtration should be fixed. Further, that suspicious or doubtful water should be analysed, and a standard of quality fixed. After this expressed opinion of one of their own officers, can the Board of Trade any longer refuse to grant the (as we conceive) reasonable request of the Association of Medical Officers? Already the Metropolis Water Act (1871) has been six months in force, and it is difficult to see what good has resulted from it. Better filtration was promised, but appears not to have been achieved; turbid and polluted water is not unfrequently supplied, and we seem to be as far off a constant supply as ever.

ACTION FOR NEGLIGENCE AGAINST A MEDICAL MAN.

At the assizes recently held at Winchester, before Mr. Baron Martin, the following case of *Pope v. Maul*, which was an action against a Surgeon for unskilful treatment of the plaintiff's son, a lad aged 18, involved some points of interest to the Medical Profession:—The son was, in October, 1870, suffering from a pain in the hip, and the defendant was called in by the father. In November the defendant recommended the patient's removal to the Infirmary. There Dr. Maul, who was one of the Surgeons of that institution, continued to attend him till December 19, when, at the patient's own request, he was removed again to his own house. From that time Dr. Maul did not attend, but the young man was treated as an out-patient, and Dr. Maul prescribed for him, the prescriptions being made up in the Infirmary. This continued till March, when a Mr. Pomery, who had formerly practised as a Medical man, was asked by a relative of the sufferer to go and see him. This he did, and found the patient suffering from an abscess in the hip. This was confirmed by two other Medical men who were also called in, and who, after the death of the patient, made a post-mortem, and found the hip-joint dislocated from the effects of the abscess, and the lungs diseased. The negligence alleged was that the defendant had treated the case as one of sciatica, and that he had not attended the deceased after his leaving the Infirmary. In support of this view, Mr. Pomery and the two other Medical gentlemen were called. The case for the defence was that the deceased suffered from inherited scrofula, which had produced both the lung disease and that of the hip-joint, and that the defendant had treated him for this complaint. It also appeared that the rules of the Infirmary do not permit an out-patient to be attended at his own house. The evidence of Dr. Bancroft and Dr. Ware, the other two Medical men, was quite consistent with this defence. Baron Martin expressed an opinion that the contract between the plaintiff and the defendant terminated

when the deceased went into the Infirmary, and after he left the Infirmary it was doubtful whether there was a contract with anyone; but if such a contract was made at all, it was made with the son, and therefore this action could not be maintained by the father. The learned Judge declined to amend the pleadings, but stayed execution if the Court above should be of opinion that there was evidence to go to the jury, or that the amendment should have been made. Plaintiff nonsuited.

THE MEDICAL SOCIETY OF LONDON.

THIS Society held its ninety-ninth anniversary dinner on Friday last, the 8th instant, at Willis's Rooms, King-street, St. James's, Dr. Andrew Clark, F.R.C.P., President, in the chair. Among the visitors were Mr. George Busk, President of the Royal College of Surgeons; Mr. Curling, President of the Royal Medical and Chirurgical Society; and the President of the Obstetrical Society. The usual loyal toasts having been drunk, the President gave the toast of the evening—"The Medical Society of London," coupling with it the name of Mr. Thomas Bryant, the President-elect. In a few remarks Dr. Clark referred to the prosperous state in which the Society was approaching its 100th year, when it would be found necessary to provide more ample accommodation for the increasing number of its Fellows. He then briefly reviewed the business of the past year, and, in proposing the health of his successor, he referred to the character of Mr. Bryant and the work he had done in his Profession, and expressed his confident belief that he would guide the Society with ability and judgment. The names of the Society's prizemen for the year were announced as follows:—*Fothergillian Gold Medallist*: Dr. Edwards-Crisp, for the best essay on "Croup." *Silver Medallists*: Dr. John C. Thorowgood, for special services rendered to the Society during his secretaryship; Dr. Silver, for his paper on "Mitral Stenosis."

At the election of office-bearers for the year, the following was the result of the ballot:—

President: Thomas Bryant, F.R.C.S. *Vice-Presidents*: J. L. W. Thudichum, M.D.; Sir Henry Thompson, F.R.C.S.; W. Cholmeley, M.D., F.R.C.P.; Francis Mason, F.R.C.S. *Treasurer*: John Gay, Esq., F.R.C.S. *Librarian*: Samuel Day-Goss, M.D. *Secretaries in Ordinary*: H. Royes Bell, F.R.C.S.; Alfred Wiltshire, M.D. *Secretary for Foreign Correspondence*: Arthur E. Sansom, M.D. *Orator*: Andrew Clark, M.D., F.R.C.P. *Council*: J. Wickham Barnes, F.R.C.S.; William Bloxam, M.D.; F. W. Braine, F.R.C.S.; T. C. Weeden Cooke; Richard Davy, F.R.C.S.; F. J. Gant, F.R.C.S.; William Gill; George Gregson; S. O. Habershon, M.D.; F. J. Lilley, M.D.; Thos. Franklin Lloyd; Jno. Macpherson, M.A., M.D.; P. Marshall, F.R.C.S.; C. F. Maunder, F.R.C.S.; Victor De Méric, F.R.C.S.; R. P. Middlemist; J. T. Sabben, M.D.; E. Symes Thompson, M.D., F.R.C.P.; J. C. Thorowgood, M.D.; T. Harrington Tuke, M.D., F.R.C.P.

DR. MOUAT ON BENGAL PRISONS.

DR. F. J. MOUAT, late Inspector-General of Prisons, Lower Bengal, on the evening of Tuesday, February 20, read before the Statistical Society a most interesting and able paper "On Prison Discipline and Statistics in Lower Bengal." We regret that we are prevented by want of space from giving a full abstract of the paper. Dr. Mouat's remarks on the advantages of the conversion of prisons into schools of industry as a sound and safe middle course between the extremes of the two systems, of which one would render a prison a terror to evil-doers by the infliction of as much pain as can be endured without injury to health or risk to life, and the other by which physical pain as a cardinal element of correction is eliminated, and the prisoner is allowed to work his way to freedom and mitigation of sentence by mere good conduct in gaol, were most judicious. In the subsequent debate, the propriety of allowing gaol labour to compete with free labour was discussed, the balance of argument being in favour of the opinion

that the amount of this competition is so small that it should not be allowed to interfere with the benefits as respects both health and moral culture conferred by industrial training on the prisoners. Dr. Mouat had charge of all the prisons in Lower Bengal for fifteen years. Before they were put under his charge, the annual death-rate was 83 per 1000, of whom about 17 per 1000 died from cholera. In the last five years of his administration the death-rate varied from 105 per 1000 in 1866—an exceptional rate, in great part caused by the famine of that year—to 43 per 1000 in 1870: a very striking diminution, equivalent to an annual saving of between 600 and 700 lives, calculated on the mean deaths of a quarter of a century. Dr. Mouat may well remark that had he been instrumental in an equal amount of destruction of life in a military capacity, he might probably have been deemed deserving of some special mark of distinction from the Crown. He considers that a further diminution may yet be affected, and that a death-rate of 36 per 1000 would more correctly represent the amount of risk of life which a prisoner ought fairly to encounter. During the subsequent discussion, reference having been made to the assassination of Lord Mayo, Dr. Mouat had an opportunity of explaining that, beyond being concerned in the selection of the Andaman Islands as a penal settlement in 1868, he had nothing whatever to say to the discipline or management of the prisoners confined there.

DR. TRENCH ON THE TYPE OF SMALL-POX.

DR. TRENCH'S Annual Reports on the Health of Liverpool are always eagerly perused by the sanitary world for the sake of the copious array of facts and common-sense commentary which they present. In his Report for 1871, his remarks on Small-pox, on Irish Wakes, on Mortuaries, and on the method of Fumigating Rooms with Sulphur, and Disinfecting Clothes, are very interesting. We can afford room this week only for a few words on the small-pox. Dr. Trench's observations bear out those of Dr. Scrivener, and, in fact, of every writer on epidemics, on the increased virulence and extension given to contagious diseases by the movement of population, in such a manner as to submit any race to a new disease, or to a new variety of an old disease. Thus it seems that the special small-pox which devastated Liverpool in 1870-71, and destroyed 1909 lives in the latter year, was imported from Spain in the persons of two Spanish sailors, who came to Liverpool from Corunna with the disease upon them. During the earlier months of the epidemic, a large percentage of the victims of the disease and propagators of the contagion were persons connected with shipping. This small-pox was "a wave of special malignancy." Hæmorrhagic and confluent cases abounded, and primary vaccination in childhood failed to insure protection. In this, and probably in every similar case, universal revaccination of the whole population is the only safeguard. But meanwhile can nothing be done to root out the poverty, intemperance, and filth which characterise those populations in which epidemics are always most prone to spread?

HOSPITAL SUNDAY IN LIVERPOOL.

We learn from a correspondent that the total amount received from the Sunday collections in Liverpool this year amounted to £7302, and that from the Saturday boxes to £720. There was a balance in hand from last year of £140, and the expenses this year were £305. Of the above amount, £25 represented special donations to certain of the selected charities. The Committee were, therefore, enabled to distribute £7800, which was apportioned to fourteen Medical charities, as follows:—Royal Infirmary, £2418; Northern Hospital, £1209; Southern Hospital, £1053; Dispensaries (N. S. and E.), £858; District Nurses' Institution, £624; Ladies' Charity and Lying-in Hospital, £468; Children's Infirmary, £390; Eye and Ear Infirmary, £312; Homœopathic Dispensaries, £156; Consumption

Hospital, £78; Stanley Hospital, £78; Cancer and Skin Hospital, £78; Skin Dispensary, £39; Dental Hospital, £39. Total, £7800.

A JURY OF MATRONS.

THE relic of a semi-barbarous age—the institution called a jury of matrons—it is to be hoped will soon cease to exist. They afforded on a late occasion another example, added to many previous ones, of their perfect unfitness for the duties they are called upon to fulfil. It is preposterous to suppose that a dozen women, without any special fitness or education, can solve questions which sometimes puzzle the most acute and experienced obstetricians. Rachel Busby, who was sentenced to death at the last assizes at Oxford for the murder of her child, has just given birth to a stillborn infant at the county gaol. Twelve "matrons" were empanelled at the trial, but they found there was no ground for a respite, and but for the exertions of some philanthropic gentlemen at Oxford the convict would then have been executed.

A FRENCH FACTORY ACT.

"THEY manage *some* things better in France." Might we not follow the example of our neighbours in some of their regulations regarding factory labour? It is impossible to over-estimate the evil effects on life and health of too early or too prolonged labour in the young. The Committee on Child Labour in French Manufactories has decided not to allow children under 10 years of age to work at all; between 12 and 13 only six hours per day. No nightwork will be permitted until after 15. Nightwork on the part of women and girls is strictly prohibited at any age.

A VACCINATION MARTYR.

"EXAMPLE is better than precept." Acting upon this wholesome maxim, a Medical Practitioner stated during the progress of a case in the Court of Queen's Bench the other day, that he had been vaccinated 477 times. It was his practice to vaccinate himself when parents objected, to prove that there was no harm in it.

SMALL-POX JOTTINGS.

IN the last fortnight there had been three deaths from small-pox in the City.—In the Holborn district during the last fortnight only 1 fresh case of small-pox was reported, and no death from the disease in the same period.—From the Cape of Good Hope we learn that the *Medway* arrived on January 24, and was put in quarantine, a case of small-pox having occurred on the voyage. The patient (one of the crew) died.—Thirty-two persons died from small-pox last week in the metropolis.—Small-pox is stated to be now declining in Norwich; it has carried off 350 persons in the city.—At Newmarket there have been no fresh cases lately. Vaccination is being rapidly carried on.—The Birmingham return of small-pox cases in the week ending the 2nd instant shows that the number of new cases was 42, being equal to those in the previous week. Of these 40 had been previously vaccinated, 1 not vaccinated and 1 not known. There were 67 cases in the Workhouse Infirmary, none at the General Hospital, and 9 at the Queen's Hospital. Cases recovered during the week, 53; deaths, 5; cases remaining on the books, 111; total number of cases reported, 962.—Both the cases of small-pox reported last week in the Bromsgrove Workhouse have ended fatally. There has been no further spread of the disease.—In the past three weeks there had been no deaths from small-pox in Chelsea, but there were several fresh cases. The Vestry have resolved to grant the Vaccination Officer the use of the large hall and ante-rooms one day per week as a vaccination station.—Three fresh cases of small-pox were reported last week in the Medical Relief Districts of Islington, as against four in the previous week.

There had been two deaths from the disease.—Eight fresh cases of small-pox were reported last week to the Kensington Board of Guardians, and one death.—Small-pox is now fairly on the decline in Aberdeen, very few cases having been admitted into the Hospital for the past fortnight. The past week's return shows—Total number of cases admitted into the Hospital since opening, 118; number of patients in Hospital, 35; total discharged recovered, 66; total dead, 17. The proportion of deaths is much smaller than in several of the larger towns. In Edinburgh, for instance, the proportion has been nearly one death in every six or seven cases.—The Town Council of Wakefield have decided to erect a Small-pox Hospital. One death from small-pox had occurred in Wakefield in the past fortnight, and four deaths in the workhouse of the Stanley district.—There were 24 deaths last week in Sheffield from small-pox; of these, 14 were returned as unvaccinated, 3 as vaccinated, and 7 were not stated. In the two previous weeks the fatal cases from the disease were 37 and 28.—Five deaths were reported during the past week from small-pox in the Poplar Union, and ten new cases had been brought under notice. In the same period twenty persons were vaccinated at the public station. Five cases of small-pox were under treatment in the North-street Infirmary.—In the Walsall Union six deaths from the disease are reported during the past week. Since the outbreak of small-pox 31 cases have been treated in the workhouse—21 of them had been brought in from various parts of the union, and 10 arose within the house; of these, 12 had recovered and 5 had died, leaving 14 under treatment.—The returns last week in the Wolverhampton Union show for Wolverhampton 4 deaths from small-pox, 13 new cases, and 24 recovered; remaining under treatment 29, as compared with 44 the previous week. In the Bilston district, 2 deaths, 14 new cases, leaving 28 cases under treatment. In the Willenhall and Wednesfield district 2 deaths, 11 new cases; remaining 15. The total number of cases under treatment for the whole union was 72, as compared with 77 the week before.—Dr. Aldis reports four cases for the week ending Saturday, March 9; two were sent to the Hospital.

FROM ABROAD.—BROMIDE OF POTASSIUM IN EPILEPSY—A CONTRAST DURING A FRENCH CAMPAIGN.

THE distinguished psychologist, M. Legrand Du Saule, of the Bicêtre, in a communication to the *Gazette des Hôpitaux* of February 20 and 23, furnishes an interesting review of the results of his employment of the bromide of potassium in 207 cases of epilepsy.

The bromide, he says, does not produce any mischievous effects, provided that it is of irreproachable chemical purity, and that its operation be attentively watched by the Practitioner—say, every fortnight. He has patients who have been taking from one to two drachms daily for a very long period without any ill-effect upon their health. Frontal cephalalgia, stuffing of the nares, lacrymation, gastric irritation, loss of strength, torpor of movement, acne, partial abolition of general sensibility, indifference, apathy, somnolence, intellectual obtuseness, stupor, inordinate appetite, constipation, and especially emaciation, have been justly indicated as consequences of its employment; but such effects have only been produced when the bromide has been of doubtful quality or has been ill-administered. If we place ourselves under favourable conditions for carrying on the experiment, we are not long in finding out that it may become as the daily bread of the patient, and so far from inducing emaciation, it rather favours the gain of flesh. It must, however, be well borne in mind that when, even with the purest salts, the daily dose of one drachm is approached, the reflex sensibility of the pharynx, base of the tongue, and epiglottis is considerably diminished or abolished, and that the genital desire is sensibly blunted. It is at about the same dose that acne commences, and it is an error to suppose that its intensity should influence the prognosis.

If the dose be too large at first, or too rapidly increased,

bromism may be easily induced. M. Legrand commences with from twenty to thirty grains a day, and, according to the nature of the case, increases this by from seven to fifteen grains every fortnight or month—"mounting only slowly the steps of the therapeutical ladder." The ultimate daily quantity which he reaches oscillates between ninety and 135 grains, but to attain this from three to six months are required. In one case only was a maximum of 210 grains reached, but for this twenty-six months of treatment were required. While at least from sixty to seventy-five grains daily will be required for males before any efficacious therapeutical effect will have been attained, in young girls and women well-marked and sufficient action may be obtained by from forty-five to sixty-five grains.

In 207 cases in which he has used the bromide, the following results were obtained:—In seventeen, absolute suspension of all epileptic symptoms during from two to four years; in twenty-eight, absolute suspension from twelve to twenty-two months; in thirty-three, considerable amelioration, no epileptic attack having occurred from six to ten months; in nineteen, a relative amelioration, the remissions lasting from two to six months, and the various symptoms being much abated in severity; in 110, failure. This last item is rendered larger by the inclusion of patients that have been too short a time under observation to speak positively about, others who have been lost sight of during recent events, and others, again, for whom the medicine proved too dear to secure their perseverance with it. The proportion of cures is sensibly greater in private practice than in the Bicêtre or Salpêtrière, most of these last presenting cerebral complications. In the unsuccessful cases, also, the bromide often abates much of the violence of the symptoms.

When an epileptic has passed a year without an attack, M. Legrand administers the bromide only on alternate days during the first half of the month, and every day during the second half; and, after eighteen months' suspension of the attacks, he gives it every third day during the first, and every day during the second half of the month. At the end of the second year it is given every fourth day during the first fortnight, and so on. He considers a rigid perseverance in this plan essential, and believes the usual plan of administering decreasing doses as improvement occurs a deplorable error. Relapse is sure to occur if any truce be thus given to this obstinate disease, the bromide being, as already said, as it were, the daily bread of the epileptic. Medical superintendence during its employment is always essential; and surreptitious augmentation of the dose, as sometimes practised by patients, may lead to aggravated symptoms. The acne which accompanies the use of the medicine is often very obstinate, and ignorance of its bromic nature has led to the useless employment of various agents. Great fetidity of breath attends the prolonged use of the bromide, and this is best met by taking it only a minute or two before meals, or receiving it as an enema twenty minutes before.

During the siege, M. Legrand, having had to treat, at Bicêtre, 1427 soldiers suffering from variola, found that in sleeplessness, and various nervous and ataxic complications, the bromide, given in daily quantities of from thirty to sixty grains, proved a most excellent remedy.

M. Beaunis, in his account of the adventures of his ambulance near Belfort during the Campaign of the East, published in the *Gazette Medicale*, describes a remarkable contrast which he met with:—

"During all this time passed at Pont-sur-l'Oignon we had many sick, and among them some from small-pox. I placed the former in the schoolroom, and the small-pox cases in an uninhabited wing of the old castle, in spite of the opposition of the mayor, who was one of its proprietors. The first day there being but a single small-pox patient, I was unwilling to take one of our few *infirmiers* to attend upon him. I was obliged, however, to do so, for throughout the village I could not find a single person, except the schoolmaster, who would

venture to enter even for a minute the room in which was the small-pox patient in order to carry him in fuel or give him his medicine. Rarely indeed have I ever met with such harshness, selfishness, and cowardice as in this village. The mayor and those he governed were one as bad as the other. He absolutely insisted that I should place the small-pox cases in the house which the schoolmaster and his aged mother inhabited, and on my decided refusal he turned all his rage on the schoolmaster, declaring that when the Prussians returned he should know how to deal with him.

"On January 12 I received a visit from the schoolmistress of Esprels, who, to my great astonishment, informed me that there were wounded still lying there—a fact of which neither the Mayor of Pont-sur-l'Oignon nor the military authorities, although aware of it, had informed me. I immediately went with her, and found a small ambulance perfectly well organised, the sick and wounded being tended by the ladies and girls of the village. What a difference to Pont-sur-l'Oignon! In a small room filled with small-pox cases, I found seated at a table, in a nurse's costume, a charming girl, only 15 years of age. She it was who, in the midst of all these men upon whose faces were seen all the phases of this horrible disease, nursed them, dressed their wounds, and gave them drink, breathing the pestiferous air; and all that without the slightest ostentation, but simply, and little suspecting that what she was doing was really sublime. Such sights as these console one for all the infamies and cowardice one is obliged to witness.

"Whence the difference between these two villages, so close to each other, and separated only by a river some feet in breadth? Why on one side of this was there devotion and self-sacrifice, and on the other selfishness and cowardice? Do they not belong to the same race? For my part, I see here the influence of a noble mind. Whether for evil or for good, it often suffices that some one shall set the example; the crowd, an oscillating mass, is influenced either for good or evil, and, possessed neither of initiative nor decision, follows the impulse imparted to it. Greatness is just as contagious as baseness. The schoolmistress of Esprels, still young, of an active and vivacious nature, impassioned for the beautiful and good, a little finical perhaps, but possessing remarkable intelligence and a thoroughly feminine delicacy, seems to me to have been the soul and organiser of this good work. What a contrast with the Mayor of Pont-sur-l'Oignon!

"They will never be known, all these obscure sacrifices among the insignificant, the weak, and the unknown, which are all the more noble as they are disinterested, and have no other motives than compassion and charity. It has been especially among school teachers that I have met with them. In all the villages which we have traversed we have met with, among these, the most absolute devotedness, and the most enlightened and sincere patriotism. Whenever we wanted something for our sick and wounded, and whenever the interests of the soldiers were in question, we were able with every confidence to address ourselves to them. I cannot say as much for the village mayors, who—with some exceptions but the blind instruments of the Empire—were finished types of selfishness, poltroonery, and platitude. Insolent to the French, and grovelling to the Germans, they were possessed of but one idea—saving their purses and their skins. As to patriotism, honour, or charity, they would hear nothing."

MEDICAL SOCIETY OF LONDON.

At a well-attended meeting of this Society on Monday evening last, Mr. Thomas Bryant, the newly-elected President, delivered a short introductory address, in which he truthfully and adroitly sketched the influence the Society had exercised upon Professional opinion from its foundation to the present time, and the relation which it has borne and still bears to the other younger and more "specialistic" societies.

Afterwards a very interesting discussion was raised on a specimen shown by Mr. Maunder, as to the value or expediency of trephining for abscess of the brain consequent upon disease of the internal ear.

This was followed by the exhibition of some preparations of aneurism, and some propositions as to the treatment of this disease by the President, as follows:—

1. From the pathological evidence we possess it appears that

for the cure of a sacculated aneurism its mechanical closure by a clot is all that is required. The typical laminated clot only takes place when the cure is chronic; it is in no way to be considered as an essential part of the cure, although to a degree most clots are laminated.

2. From pathological evidence before us it likewise seems probable that the coagulation of the blood in an aneurismal sac may be obtained by obstruction either to the afferent or efferent vessel; that distal as well as proximal pressure are both capable of producing the same result.

3. Accepting the facts as proved, that obstruction to the afferent vessel may be secured by forced flexion of an extremity as well as by digital or instrumental pressure, clinical evidence is wanting to determine the conditions under which these forms of practice may be expected to succeed separately or combined.

4. Accepting the fact, likewise, that all aneurisms of the extremities cannot be successfully treated by forced flexion and compression of the afferent artery, it is desirable to know under what circumstances such a plan of treatment is inapplicable.

5. Acknowledging also the great principle of practice which most Surgeons now accept, that no large vessel should be ligatured for aneurism unless the treatment by compression in one of its forms has failed or is inapplicable, it is desirable to know under what circumstances the treatment by ligature should be primarily applied.

6. Complete obstruction to the afferent vessel appears to be the more rapid mode of cure than the incomplete.

7. Digital pressure to cover the artery and mechanical pressure by a weight to save muscular force seems to be the best mode of applying pressure when it can be carried out.

8. Mechanical pressure should only be had recourse to when digital cannot be employed, the elastic pressure being probably its best form.

9. When the afferent vessel cannot be occluded by Surgical means, there is reason to believe that the same coagulation in an aneurism may be secured by the occlusion of the efferent, either by pressure, ligature, or other means.

10. The tubular or fusiform aneurisms are probably cured only by some inflammatory action in the walls of the dilated vessel, the fibrinous secretion being probably of the plastic kind, bearing a certain analogy to the adhesive process in other parts, as pointed out by Luke (*Med. Times and Gaz.*, 1845). But this subject is not one upon which I propose to raise a discussion.

Mr. Bryant stated that his object was to draw the opinion of Surgeons upon several very important particulars in the treatment of aneurism. He produced for inspection some interesting and typical specimens of the kinds of clot formed in aneurismal sacs. Prominent amongst these was an aneurism of the abdominal aorta, close to the coeliac axis, in which he had applied pressure on the distal side, with a large non-laminated clot as the result. Another, also from the museum of Guy's, was a well-marked laminated clot, removed from the sac of an axillary aneurism, twelve years after the ligation of the subclavian by the late Mr. Key. This specimen Mr. Bryant stated had been copied into many books as a typical illustration of the mode of formation of the clot in the process curative of aneurism. But this was a slowly formed plug, and it should not be inferred from such as it that all clots must be, or are, similar in their appearance or construction. Each one of the propositions above given was prefaced by some remarks from the President, and in reference to proposition 5, Mr. Bryant stated it was his opinion that in all quickly occurring, especially traumatic, aneurisms the ligature should be employed primarily. Finally, the author referred to the statistics of Guy's Hospital for the fourteen years preceding 1870, which show that the ligature has been employed twenty-four times with only one death, and pressure has been used seventeen times with eleven successes; in the other six cases ligation had to be resorted to. The discussion which followed was taken part in by Mr. H. Smith, Mr. Gay, Mr. De Méric, and Mr. Maunder; and at the suggestion of Mr. Davy and Mr. Gay the discussion on the subject is to be resumed at the next meeting of the Society.

STATISTICS OF AMPUTATIONS.—Those of our readers who are interested in this subject will find a valuable document contributed as an appendix to the *Boston Medical and Surgical Journal* for January 4, 1871. This gives the statistics of 699 major amputations of the limbs which have been performed at the Massachusetts General Hospital.

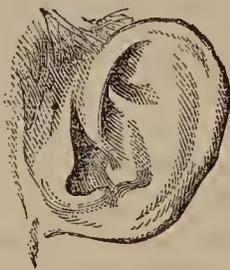

PROF. LAYCOCK ON EARS:

LOBED AND LOBELESS EARS; MONKEY EARS; ROGER TICHBORNE'S AND "THE CLAIMANT'S" EARS.

IN the *Medical Times and Gazette* for March 22, 1862, appears a lecture by Professor Laycock on the coexistence of weakness or defective organisation of the brain, with certain peculiarities of formation of the face, and especially of the parts answering to the "ribs" of the cranial vertebræ. For instance, congenital defect of brain and tendency to tubercular or other tissue-degeneration are so often associated with a defective and receding chin that artists and novelists, when they wish to describe a person of unusual strength of character, are sure to give him a well-developed square-cut chin. An upper jaw contracted from side to side, with a very narrow and highly arched palate; the "rabbit jaws," with upper teeth projecting so that they cannot be covered by the lips; peg-like deformity of the upper lateral incisors; imperfect development of the upper lip, going so far as hare lip and cleft palate; and noses, either snubbed and turned up, showing the cavities of the nostrils, or preternaturally big and sausage-like, as in the Aztecs,—are all familiar examples.

But we wish to recall attention especially to Professor Laycock's remarks on the ears, for they refer by anticipation to the difference between the ears of Roger Tichborne and those of the "Claimant" who is now awaiting his trial for perjury.

"The form," says Professor Laycock, "of the external ear depends upon two fundamental elements—namely, first, the cartilage with its muscles; secondly, the helix and lobule. In man the cartilage of the perfect ear is comprised within an ellipse or ellipsoid proportionate to the head, and to this is attached a geometrically-formed helix and a pendent ellipsoid lobule. In proportion as these parts are defective, or as the ear is monstrous, triangular, square, or of irregular form, it indicates a tendency to cerebral degeneration or defect. Monstrous ears, with defective helix or lobules, are very

Square lobeless ear in case of dementia.

Ear of chimpanzee. (British Museum.)

common in idiots and imbeciles. You will note the defective form and absence of lobule in the female Aztec and in the case of dementia. The ear of the male Aztec cretin is also defective, but it more nearly resembles the ear of the chimpanzee.

"*Angle of Position of the Ear.*—You will find that the ears of persons differ much as to the angle of position on the head. The ear points either backwards towards the vertex of the head, as in the chimpanzee, or upwards to the crown. Ears pointing backwards are usually defective in form and development of parts, as the helix or lobule.

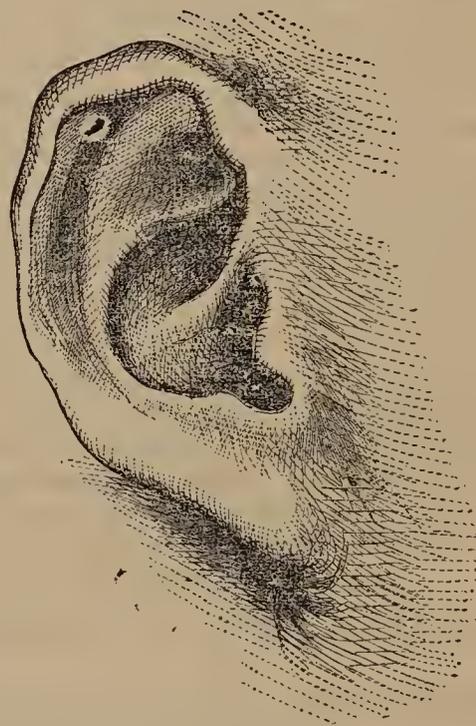

"*Modifications of the Helix and Lobule.*—Race has, I think, an influence on the development of the external ear, although I speak with reserve, not having had numerous opportunities for observing and comparing. But, so far as I have had them, I conclude that the ear in coloured races more nearly approximates that of the chimpanzee than in our Anglo-Saxon race, in which the helix is full and the lobule large and pendent as compared with men of the darker races that I have seen, whether African or Malay. Sex has certainly an influence, for it appears to me that women generally have not only the whole ear smaller than men, but the helix and lobule smaller in proportion to the ear. And I think I may venture to say, as the result of numerous examinations of the ears of female lunatics and imbeciles, that from one-third to one-fourth are below the standard of development as to the lobule. *In men somewhat feminine in form, and comparatively defective in force of character, the ears are often feminine as to the helix and lobule.* You may have such men manifesting great refinement and sensibility, and perhaps considerable intellectual power; but, at the same time, even with marks of genius, there is often

scen less capability of endurance mentally, less force of character, less tenacity of purpose, and even less clearness of ideas than in standard men.

"Men of high intellectual attainments, great capacity for mental labour, and great force of character, have a full, perfectly ovoid ear, the helix well developed, the lobule plump, pendent, and unattached to the cheek at its anterior margin. These characteristics are seen in all the portraits of great men which Lavater gives, and are easily observed in living celebrities. I was much struck with the highly characteristic ear in these respects of the Prince Consort, as he stood without his hat when laying the foundation-stone of our Industrial Museum in October.

"Activity of the instincts and appetites, and perhaps of vegetative or nutrient force in general, seems also to coincide with a well-developed lobule. It is worthy of remembrance that these parts are not constituted wholly of cartilage; the helix is cartilage covered with a layer of condensed cellular and adipose tissue, but the lobule is made up wholly of such a layer, without any cartilage whatever. This layer and the skin covering it are highly vascular. Now, in proportion as the helix is simply cartilaginous and the lobule defective, or, in other words, as this vascular elastic tissue is wanting, you seem to have imperfect encephalic action and development. And with certain reservations, the plumpness and vascularity of the lobules may be considered to coincide with extent of vascular activity within the encephalon. I say within the encephalon, because I am satisfied we must not restrict our consideration of the question to intellectual activity alone, for that implies only activity of a certain kind. You may have great volitional activity, as in the day labourer, or great sensual activity as in the sensualist, who seeks only the indulgence of his appetites, whether sexual or others. But it is further to be noted that this vascular activity may be wholly local and due to exclusively local causes, as constant exposure to the atmosphere.

"*Defective and Adherent Lobule.*—In a perfect ear the ovoid lobule hangs from the cartilage with a rounded lower margin, which at its inner border is not confluent with the face. Now, if this inner margin be adherent to the cheek, and at

Ear in general paralysis. Lobule soldered anteriorly and cut away posteriorly, helix defective. (Clinic of Mental Diseases.)

the same time the lobule be only a segment of an ellipse, there is more or less tendency to imperfect cerebral action. A more important form is seen when the lobe is not only soldered to the cheek, but its posterior half cut away, as it were, and the helix defective."

The significance of Professor Laycock's remarks is obvious. Roger Tichborne had a soldered and ill-developed lobule. This was quite consistent with his whole character and person—overbred, not well developed, and undersized. On the other hand, the well-developed lobule of the Wagga-Wagga slaughterman seem consistent with his audacity, strength of purpose, and power of will. That one condition can be changed into the other we hold to be incredible.

THE PUBLIC HEALTH BILL.

THOUGH not, of course, dealing with the whole of the questions which every sanitary reformer would wish to see energetically disposed of, the Government Bill to amend the law relating to the Public Health forms a very valuable instalment. Leaving to other hands, or to a future time, the consolidation of sanitary law, Mr. Stansfeld, in this Bill, cuts at the root of a vast number of those evils which the Royal Sanitary Commission pointed out for remedy.

The Bill is in ninety clauses, and extends only to England, exclusive, with certain exceptions, of the metropolis. It provides for the division of the country into urban and rural sanitary districts which are to be subject to the jurisdiction of urban and rural sanitary authorities. The following are to be, with certain exceptions, the urban districts and authorities respectively :—

Urban Sanitary District.	Urban Sanitary Authority.
Borough constituted such either before or after the passing of this Act.	The Council.
Elective Improvement Act district, constituted such before the passing of this Act, and having no part of its area situate within a borough or local government district.	The Improvement Commissioners.
Local government district, constituted such either before or after the passing of this Act, having no part of its area situate within a borough, and not coincident in area with a borough or Elective Improvement Act district.	The Local Board.

The urban sanitary authority is to be invested with powers under the Local Government Acts, Sewage Utilisation Acts, Nuisances Removal Acts, Common Lodging-houses Acts, Diseases Prevention Act, Artisans and Labourers' Dwellings Act, Bakehouse Regulation Act, and amending Acts; Baths and Washhouses Act and Labouring Classes' Lodging-houses Acts, if already in force. If not in force the two latter Acts may be adopted by the urban sanitary authority.

Subject to certain exceptions, the area of a rural Poor-law union is to form a rural sanitary district, and the guardians of the union to be the rural sanitary authority.

To the rural sanitary authority are to be transferred powers under the Sewage Utilisation Acts, Nuisances Removal Acts, Common Lodging-houses Acts, Diseases Prevention Act, Bakehouse Regulation Act, and amending Acts.

Within three months from the passing of the Act each urban sanitary authority is to appoint a Medical Officer of Health, and every rural sanitary authority is to appoint, but not within any specified time, one or more Medical Officers of Health, inspectors of nuisances, and such other officers and servants as the authority may deem necessary. In respect of Medical Officers of Health, the Local Government Board are to have the same powers as they now have with regard to officers of unions; so that it will rest with that Board whether the Officers of Health shall or shall not enjoy permanency of appointment.

Any Poor-law District Medical Officer may be appointed a Medical Officer of Health, either urban or rural.

The powers of Local Government Board inspectors are to be similar to those of Poor-law inspectors.

Seaport sanitary authorities are to be formed, either permanently or temporarily, by an order of the Local Government Board from amongst authorities having jurisdiction in or near the port, and the expenses of the port sanitary authority are to be borne by the riparian sanitary authorities.

The Local Government Board may, after local inquiry, issue provisional orders for the consolidation of areas and of local authorities, and may apply urban sanitary provisions to rural districts. This latter is an important provision, as meeting the cases of mushroom towns springing up around newly developed industries—towns having in an aggravated form many of the evils of cities, without, at present, the machinery for combating those evils.

For the prevention of pollution of streams, procuring a common supply of water, carrying out a system of sewerage, or for other purposes of the Sanitary Acts, the Local Government Board may, after inquiry and notice, form several

sanitary districts into a united district, governed by a joint incorporated board, and the individual districts so united are then to lose their powers in respect of the purposes for which the joint board is formed.

The above are the principal provisions of the Bill so far as they relate to authorities, areas, and officers. They appear to provide satisfactorily for a termination of the existing confusion in respect of the two first. With respect to the last, it seems advisable that in committee such alterations should be introduced as will render it imperative upon rural sanitary authorities to appoint Medical Officers of Health within a limited time. That much in the interest of the country at large. The interests of the Profession seem to demand that there should be sought from the President of the Local Government Board a pledge that the Board will confer upon Medical Officers of Health, whether appointed by urban or rural sanitary authorities, the same tenure of appointment as that bestowed upon Poor-law Medical Officers in compliance with the recommendations of Select Committees. Without permanency of tenure there can be no independent discharge of duty. Medical members in Parliament should see to this.

The portion of the Bill which defines and deals with Nuisances must inevitably meet with considerable opposition in the House; unless, indeed, the present excited state of public feeling in regard to sanitary matters should forbid members to care for their own interests as manufacturers, whilst compelling them to discharge faithfully their duties as trustees for the nation. These provisions of the Bill are very stringent, and spread a net that should take offenders of all sizes; the wording is careful and evidently intended to admit of the passage of no "coaches and six"—e.g., every person allowing "the solid refuse of any manufactories, or any rubbish, cinders, or other solid matter" to fall into a stream in such quantities as to interfere with its due flow, or to pollute its waters, is to be deemed guilty of a nuisance punishable in penalties of five pounds, ten pounds, and twenty pounds for first, second, and third convictions, and with further daily penalties for continuance. Any person to be subject to like penalties who allows any solid or liquid sewage matter, or any filthy or noxious water, or washing of manufactories, or other *polluting liquid* to fall into any stream. For the purposes of the Act, the following liquids are to be deemed *polluting* :—

"1. Any liquid containing in suspension more than three parts by weight of dry mineral matter, or one part by weight of dry organic matter, in 100,000 parts by weight of the liquid; or,

"2. Any liquid containing in solution more than two parts by weight of organic carbon, or .03 by weight of organic nitrogen, in 100,000 parts by weight of the liquid; or,

"3. Any liquid which exhibits by daylight a distinct colour when a stratum of it one inch deep is placed in a white porcelain or earthenware vessel; or,

"4. Any liquid which contains in solution, in 100,000 parts by weight, more than two parts by weight of any metal except calcium, magnesium, potassium, and sodium; or,

"5. Any liquid which, in 100,000 parts by weight, contains, whether in solution or suspension, in chemical combination or otherwise, more than .05 part by weight of metallic arsenic; or,

"6. Any liquid which, after acidification with sulphuric acid, contains, in 100,000 parts by weight, more than one part by weight of free chlorine; or,

"7. Any liquid which contains, in 100,000 parts by weight, more than one part by weight of sulphur, in the condition either of sulphuretted hydrogen or of a soluble sulphuret; or,

"8. Any liquid possessing an acidity greater than that which is produced by adding two parts by weight of real muriatic acid to 1000 parts by weight of distilled water; or,

"9. Any liquid possessing an alkalinity greater than that produced by adding one part by weight of dry caustic soda to 1000 parts by weight of distilled water."

Then, in strong contrast with the mildly permissive clauses of past Acts, comes the concluding phrase of the section which deals with these nuisances—"It shall be the duty of every sanitary authority to enforce within its district the provisions of this section."

The sanitary authority is distinctly authorised to take legal proceedings with respect to the pollution of streams, and to spend moneys for removing or diminishing the effect of any pollution.

Sewer ventilation has taken lately so large a share of public attention that we give in full the clause dealing with the question :—

"All sewers and drains, whether public or private, shall be

constructed, provided with means of ventilation, and kept so as to effectually prevent such sewers and drains from being dangerous to health; and any sewer or drain not so constructed, ventilated, or kept shall be deemed to be a nuisance under the Nuisances Removal Acts, and, whether it be on public or private premises, may be dealt with under the said Nuisances Removal Acts, as if it were on private premises."

It is to be the duty of every urban sanitary authority to properly cleanse streets,—(Pity that the Bill does not apply to the metropolis!)—to remove house-refuse, and empty earth-closets, privies, ash-pits, and cesspools; and on the failure, after notice, of any authority to fulfil duties of this kind, the occupier in respect of whose premises the default arises may sue for a penalty of ten shillings for each day during which the neglect continues. The *auri sacra fames* probably renders it unnecessary to make this last provision more than permissive.

Power of entry upon private premises, for the purposes of inspecting drains, water-closets, privies, cesspools, and ash-pits, is to be given to officers of sanitary authorities; and not only so, but any occupier may require an inspection. This latter should prove a valuable provision in cases where the occupier is suffering by reason of the neglect of the owner; but it can only be really operative if the officer holds his office upon such terms as will enable him fearlessly to execute his duty as against the owner—a man, in most cases, of more local influence than the occupier.

The second section of the Nuisances Removal Act of 1863 is to extend to milk and to tea, and all milk of any animal suffering from contagious, infectious, or tubercular disease is to be deemed unwholesome and unfit for the food of man.

As to unwholesome food, the following should prove effective if carried; but its passing seems very doubtful. Numbers will be found to suggest that its enactment would be an unfair check upon "legitimate competition," and to recommend a reliance upon the time-honoured maxim, *Caveat emptor*:—

"If any animal, carcase, meat, poultry, game, fish, fruit, vegetables, corn, bread, flour, milk, or tea which has been sold to a purchaser as human food, is proved to the satisfaction of any two justices to have been so diseased, unsound, or unwholesome as to be unfit for the food of man when so sold as aforesaid, the person who has sold the same shall, on conviction by such justices, be liable to a penalty not exceeding twenty pounds, and such justices may, if they think fit so to do, order the purchase money to be refunded."

The next clause provides for search by the officers of a sanitary authority for any articles of the above kind which may be diseased, unsound, or unwholesome, with a view to such articles being seized, carried away, and dealt with according to law.

The penalty imposed by the first section of the Food Adulteration Act in respect of the adulteration of food or drink it is proposed to increase from five pounds to twenty pounds.

Provision is made for the closing, on the application of a sanitary authority, of any foul pump or well, and for prohibiting the habitation of any unfit building.

This concludes the more important of the provisions of the Bill in respect to nuisances. We shall have more to say hereafter on the parts relating to water-supply, gas-supply, Hospitals and provisions for the sick, etc. Meanwhile, it is but fair to state that, whatever may be the fate of the Bill, or the degree of completeness with which, if carried, its provisions may be worked out, there can be but one opinion as to the earnestness of its framers. It does away with much that is bewildering in the machinery for enforcing existing enactments; it deals with many evils hitherto untouched; and, even if it do no more, should be of service in clearing the ground for a consolidation of sanitary law. The one great blot is the exception of the metropolis from its provisions. But it cannot be doubted that, should the Local Government Board deserve well of the country by enforcing sanitary authorities in general to work thoroughly the provisions of this Bill, power will hereafter be given to that Board to deal in like manner with the metropolis.

ROYAL ORTHOPÆDIC HOSPITAL.

THE annual Court of Governors was held on Wednesday, March 13, at the Hospital, Oxford-street, to receive the annual report and balance-sheet, and on general business. The chair was taken by the Right Hon. Lord Abinger, Vice-President. The Court was subsequently made special, and passed a resolution that the Medical staff of the Hospital shall consist of

three Surgeons and three Assistant-Surgeons, instead of two Surgeons and two Assistant-Surgeons, as formerly. A proposition that when an Assistant-Surgeon has performed his duties uninterruptedly for twenty years he shall be appointed full Surgeon without being subjected to the usual form of election was also passed by a large majority.

The annual report was read, and followed by a discussion of the warmest kind, several of its statements regarding the Surgeons of the Hospital giving rise to earnest contention, and ultimately to their resignation. These statements were—firstly, that Dr. Murchison was called to examine the Hospital because its Surgeons would not take the responsibility of declaring what was necessary to render it perfectly healthy and efficient after the outbreak and subsidence of scarlatina; secondly, that at the inquest held on the child Henry Bard, who died of diphtheria last year, Dr. Bourne and Mr. Adams sought to cast the blame of the death on the Committee; and thirdly, that the Surgeons of the Hospital failed to give the Committee the co-operation to be expected in seeking the welfare of the institution.

Mr. MONEY WIGRAM moved the adoption of the report.

Mr. R. W. TAMPLIN, F.R.C.S., one of the Surgeons, said: Before this report is accepted, it should be pointed out in what way we have not co-operated with the Committee, as stated in the report. There have been occasions on which we could not co-operate with the Committee, and I could show the reason why. At all events, I am not aware that we have ever refused to co-operate in the interest of this Hospital with the Committee.

Mr. WM. ADAMS, F.R.C.S., said: I would direct attention to three paragraphs, at least so far as I could catch them, in the report. I heard that in reference to the sanitary condition of the Hospital Dr. Murchison was consulted because the two Surgeons declined the responsibility of advising what was necessary to be done. If this is stated in the report, then it is totally opposed to all that I know of the facts. Dr. Murchison happens to be a personal friend of my own, and, seeing the very grave nature of this outbreak, I was only too glad to ask him what steps he would advise the Hospital to take; and I did so with the sanction of the Committee and the Hospital. I saw Dr. Murchison yesterday (March 12), and he said that he perfectly recollected the circumstance of coming as a personal friend of my own in consultation with me to see a child. This is totally opposed to the statement which I have just heard from the Secretary. Now, gentlemen, I never declined any responsibility; you never knew a Surgeon decline responsibility—he has responsibility day and night, therefore I have no more to say on that head. The next paragraph ran in this way—that the coroner's inquest on the child Henry Bard was held at the private request of a single Surgeon, with the apparent object of relieving the Surgical staff from the blame of the late sad events in the Hospital. Gentlemen, this is horrible language—observations that no Medical officer could sit under—and one only wants to know whether it is true or not. Now, I am not going to occupy your time with details of the coroner's inquest. I say with regret that the poor patient who died was one of my own; but I was in the country for my holiday. I came back on the day of the inquest. I was not summoned to attend it. I attended at great personal inconvenience; but that that inquest was to be held I heard with regret. This inquest afforded an opportunity for party feeling to break out. Dr. Bourne assured me, in answer to questions put by me as to why the inquest was held, that it was only in defence of his own personal character against the aspersions of the Committee. He felt bound as a Medical man to clear himself. I asked him how his character had been attacked, and he said by observations on his treatment of the child. But this child died of diphtheria on the fourth day, and because he had not given it beef-tea his treatment was impugned. It is not a question of beef-tea, but a question as to the intensity of the poison. Moreover, it had been said that the child had not been prescribed for; but Dr. Bourne had attended to that child every hour day and night for the three days of its illness. The Prince of Wales during his illness never received more attention than this child—I am glad to state it—for it would be a sad thing for the country to know that that child had died of starvation. The verdict of the inquest did not damage this institution—it was the second verdict of the Committee; and for that I leave you to say who is responsible. All must deplore that so valuable an institution should be damaged in the public estimation and in the estimation of the governors, by whatever it was that called for the

second inquiry. Now, gentlemen, in another paragraph it is stated that the Committee of Management have not received that co-operation and support which they are entitled to from the Surgeons of the Hospital. I can only regret that the Committee have inserted that paragraph. I have been for twenty years a Surgeon to this Hospital, and I think I have in every instance worked cordially and well. I have thought only of the good of the Hospital. Dr. Murchison will tell you the time we spent in drawing up these rules for its benefit in his own room. I beg, then, to vote against the report, as containing incorrect statements, unfair and uncourteous to the Surgeons of this Hospital, and hope that the governors will not receive the report containing such statements.

The CHAIRMAN then moved that, before any discussion should take place at all on so vexatious a question, the report be adopted wanting the three offensive statements referred to by Mr. Adams.

The Rev. Mr. WRIGHT seconded this proposal; but

Mr. MONEY WIGRAM insisted on vindicating the Committee's conduct and the adoption of the report as it stood, replying at length to the statements of Mr. Adams.

Mr. HENRY WALKER, one of the vice-presidents, said that the Committee of Management had only under a sense of duty laid a faithful report before the Governors as to the state of the Hospital. The impediments they had met with and the opposition shown to them by the Surgeons had greatly increased the difficulty of management.

It was then put to the vote whether his Lordship's amendment should be adopted, or the report as it stood. For the amendment, 33; for the report as it stands, 50.

Mr. TAMPLIN then rose and resigned his position as Surgeon to the Hospital; and Mr. ADAMS followed his example, saying that, if he had stood in Dr. Bourne's position, he should have said and done all that Dr. Bourne had said and done. Both gentlemen then left the room amid great excitement.

Amongst other business, Mr. GEORGE DAWBARN proposed that the resignations of the Surgeons be not accepted.

Professor Bentley, the Rev. Stanley Leathes, and the Chairman retired from the Committee.

Mr. COOPER proposed an infusion of new members; but Mr. SHAEN thought such a proposal altogether humiliating to the governors of the charity. This was not a case that had cropped up suddenly, but was a grievance of long standing.

Messrs. Broadhurst and Hill were reappointed Assistant-Surgeons to the Hospital.

A vote of thanks to the Chairman terminated the proceedings.

REVIEWS.

Memoranda on Poisons. By the late THOMAS HAWKES TANNER, M.D., F.L.S. Third and Completely Revised Edition. London: Renshaw. 1872.

THIS edition of Tanner's "Memoranda on Poisons" is in some respects almost a new book. The former editions were intended chiefly for the Medical Practitioner. Dr. Tanner appears to have been a believer in the frequency of the crime of secret poisoning, and he compiled his "Memoranda" "to put the Physician on his guard, and prevent his attributing to natural disease symptoms due to the villanous administration of deadly drugs." The present editor seems, however, to have thought that the book would be of more use if it contained a tolerably full notice of the chemistry of toxicology as well as of its symptomatology, and accordingly has introduced a sufficient account of the toxicological tests, and of the method of separating poisons from organic mixtures. That he has thereby improved the book there can be no doubt; it is, in fact, now become a useful hand-book for the student. The scientific precision of chemistry is that alone which has raised modern toxicology above the superstition of the middle ages. We are not of those who believe that secret poisoning is a frequent crime amongst English people, but if it were, there is scarcely a poison the effects of which can be distinguished from those of natural disease with any certainty without the aid of the test-tube. A new classification of poisons, however, is the chief novelty in the book. The editor divides poisons into—corrosives; simple irritants, mineral, vegetable, and animal; irritant gases; specific irritants, mineral, vegetable, and animal; neurotics—subdivided into narcotics, anaesthetics, inebriants, delirants, convulsives, hyposthenisants, depressants, asphyxiants—and abortives. Opium and its preparations, and morphia, constitute the group of narcotics; anaesthetics include chloroform, chloral, bichloride

of methylene, ether, amylene, and nitrous oxide. Alcohol, nitro-benzole, cocculus indicus, and fungi form the group of inebriants. Delirants comprehend hyoscyamus, belladonna, stramonium, datura alba, and nightshade; convulsives—nuxvomica, strychnia, and brucia; hyposthenisants—aconite and prussic acid; depressants—digitalis, Calabar bean, tobacco, and hemlock; and asphyxiants—noxious gases. This classification is certainly an improvement on the old unscientific and untrue one of "Irritants, Narcotics, and Narcotico-Irritants." We can give hearty commendation to this new edition of a well-known little hand-book. Its preparation reflects considerable credit on the editor.

The Urine and its Derangements, with the Application of Physiological Chemistry to the Diagnosis and Treatment of Constitutional as well as Local Diseases. By GEORGE HARLEY, M.D., F.R.S., etc.; formerly Professor in University College and Physician to University College Hospital. London: J. and A. Churchill. Pp. 376.

THOSE of our readers who may remember these lectures as they appeared in our columns—now a good long time ago—will, we think, join with us in an expression of regret that they have not sooner seen the light in a connected form. This is the more to be regretted on the author's account, inasmuch as the good work he has done is apt at this time of day to be overlooked; for since the first of these lectures appeared in our columns the world has not stood still, and many things which were then new have now become part and parcel of the public stock of knowledge—and so what was really new then does not seem to be new now.

Nevertheless, the book having appeared we are prepared to give it a hearty welcome, and, whilst not agreeing with it in every particular, we are constrained to pronounce it one of the most suggestive books of the kind ever published. It consists of eleven lectures: the first is an answer to the question "What is urine?" To this the author replies—"The effete products of our thoughts, feelings, and actions, together with those of the various functions of animal life." To this definition we take objection, not for what some may carp at—the taking note of the effete products of thought, etc.—but rather because it does not recognise the much greater importance of another waste product—viz., that excreted by the lungs; for, in accordance with more modern philosophy, we recognise the combustion of carbon as being the main origin of the force expended in the body; the conversion of nitrogenous matter into urine being altogether secondary to the other.

Dr. Harley divides all urines into two groups, solid and fluid. Well, this is a good practical grouping; but inasmuch as the main object of urine is the excretion of nitrogenous waste, it is perhaps better to classify urines according as the bulk of this appears in the shape of urea, hippuric acid, or uric acid.

Chapter II. deals with some of the changes in the composition of the urine induced by food, drink, medicine, and disease, and about it there is not a great deal to be said. Chapter III. introduces us to the study of the separate constituents of urine—first dealing with urea, its chemistry, physiology, and pathology. Here we first encounter a peculiarity which some may consider a blemish and some an advantage—in short, it is one on which a difference of opinion is allowable. Dr. Harley gives us the formula for urea thus: $C_2H_4N_2O_2$ —whereas, to the best of our knowledge, there is not a chemical school in London where urea is not represented by some form or modification of the symbols CH_4N_2O . We have here the difficulty of deciding between the old notation and the new. Inasmuch as the book is intended for men already in practice, perhaps Dr. Harley's adhesion to the old notation is an advantage for them; nevertheless, it is free for those who care to say so that the plan is antiquated. For our own part, we are prepared to accept the doctrine of convenience. Another doctrine laid down by the writer—viz., "that urea is not the special product of any one particular time or organ, but the united product of all nitrogenised matter"—is, we think, accurate. Dr. Harley points out—wisely, we think—that the increase of urea so often noted in diabetes is partly due to the animal diet. That is worth bearing in mind; but it is a fact, nevertheless, that with ordinary diet the urica is greatly in excess of health. We wish Dr. Harley had said something more on the subject of uræmia; to our mind its phenomena are far from clear, nor will a separation of uræmia from ammonæmia do all that is desired.

Uric acid furnishes the topic of the next chapter. The author's plan for estimating the acid is wise; he avoids volumetric methods, which as yet are exceedingly unsatisfactory, and

advises precipitation and weighing. He mentions, but hardly lays sufficient stress upon, the entire absence of uric acid from the urine of some carnivora. He also, we think, does well to point out that the precipitation of uric acid in ordinary samples of urine by no means depends on its abundance in the system, but rather on some such side-cause as increase of acid or diminution in water. Dr. Harley advocates the view that uric acid is the direct cause of gout; this, though the current belief, we can with difficulty accept. At all events, Dr. Harley's remarks on the pathology of uric acid are well worth reading.

Hippuric acid and chloride of sodium constitute the subject of Lecture V. Of the former there is not much to be said. The author does not point out, however, that this acid seems to be a compound of glycochol and benzoic acid when the latter is given internally. When dealing with chloride of sodium, the author points out, in opposition to Scherer, that it has nothing to do with the colour of the blood. Our present knowledge of hæmoglobin quite confirms that belief.

Lecture VI., however, deals with Dr. Harley's chosen subject—viz., urohæmatin; in the study of this subject he has really done good service. We hold with Dr. Harley that urine contains a pigment derivable from, and not very greatly different from, hæmatin. Bilirubin, the red colouring matter of the bile, is by a goodly number of physiologists accepted as identical with hæmatoidin of old blood-clots; and very recently Maly has announced the possibility of transforming bilirubin into urohæmatin. If, therefore, bilirubin is derived with little change from hæmoglobin, it is fair to admit that urohæmatin originates from the same source. But Dr. Harley freely admits the presence of indigo or indican in many samples of urine. Surely some of the instances given in these pages of urohæmatin indicated by acid, and unobserved before, are really cases where indigo was unusually abundant.

In Lecture VII. the phosphates are considered. Dr. Harley admits the increase of phosphates in certain nervous diseases, but of course takes care to distinguish this from the apparent increase of phosphates in certain diseases accompanied by alkaline urine. The excess of phosphates in the urine in rickets Dr. Harley proposes to neutralise by the giving of bone-earth internally. In connexion with this subject it may be said that Dr. Harley insists on the formation of renal calculi being due to a local causation. This we are hardly prepared to admit; nevertheless the argument is interesting.

The next lecture is devoted to a consideration of oxalates and sulphates. Dr. Harley points out (as we think, well) that it is possible to mistake oxalates for uric acid or phosphates—only carelessness could lead to such a mistake; but we have known the same cause lead to confounding small oxalate crystals with blood corpuscles. By the way, we do not observe any reference to one of the most characteristic shapes of oxalate crystals—viz., the star. This is best seen in crystals manufactured in urine, as is also the star shape of phosphates. Dr. Harley is, we think, right in looking upon oxalates as a normal urinary constituent. By standing for a time most urines will throw down some oxalates along with their so-called mucus. With regard to sulphates we cannot agree with Dr. Harley that they are derived from food. We strongly believe that just as glycin goes to form hippuric acid, so does taurin to form sulphuric acid. Sulphates are excretory products as much as urea is.

The ninth lecture deals with such substances as inosite, creatin, creatinin, cholesterin, cystin, xanthin, leucina, and tyrosin—very interesting, but perhaps more curious than useful in daily practice.

Not so the succeeding lectures, on diabetes and albuminuria respectively. These lectures were, however, republished some years ago, and so do not come to the mass of the Profession for the first time, as do the others just alluded to.

As to diabetes, the author recognises two forms—that from defective assimilation and that from excessive formation—the two calling for different lines of treatment. The distinction may be somewhat doubtful in certain cases; nevertheless, it does good, if only to warn us against a routine treatment.

In the last lecture—that on albuminuria—there is a very long table giving the various causes producing albumen in the urine. This is, without entirely concurring with the arrangement, a good plan. Of late our ideas of albuminuria have been too much limited to that form which originates in the kidney, and we have even seen albuminuria and Bright's disease used synonymously, which is certainly the reverse of accurate. But, both in this chapter and in the foregoing, we find much food for discussion, for Dr. Harley, if not at all times convincing, is certainly very suggestive. We have only been able to give a superficial view of his treatise, but we have said enough to indicate to our readers its general tenor.

To those not in possession of the original lectures we can recommend the book as giving a very good view of urinary physiology; and even those who may have read the original lectures will find in the present issue a good deal that is new and important.

NEW BOOKS, WITH SHORT CRITIQUES.

The Origin of Species by means of Natural Selection; or, the Preservation of Favoured Races in the Struggle for Life. By CHARLES DARWIN, Esq., M.A., F.R.S., etc. Sixth Edition, with additions. London: Murray. 1872. Pp. 460.

* * * Twelve years ago the origin of species was a mystery and a superstition. Common people believed what is told in Gesner's "Death of Abel," where the creation of animals is described as taking place just below the surface of the earth, which was raised into heaps, out of which the fully formed animals walked, as a mole does out of a molehill. The origin of new species was therefore regarded as a rare, occasional, preternatural act, requiring a special fiat of Omnipotence. Species were regarded as having been cast as it were in certain moulds framed by the Divine Intelligence, and limited in form and variety by narrow bounds which could not be passed. A respectable writer, Mr. Gosse, in his work entitled "Omphalos," believed that adult animals were created with navels and all other marks of quasi-fœtal development, and that full-grown trees were created with the marks on their stems as of leaves which had fallen off. The only loophole for doubt was the perplexing fact, that with regard to the most vigorous and prolific plants—as *Salix*, *Rosa*, *Rubus*—it was almost impossible to agree in the amount of distinctive marks which should be held *specific*, as contrasted with the lesser amount of change which might be called *variety*. But now what a change! The doctrine of evolution, which some naturalists twenty years back would have considered a wicked absurdity, is calmly admired for the grand and comprehensive views it gives of Creation; and its establishment as a matter of popular belief is due to the author of the book before us. The laws of organic nature, he says, include Growth with Reproduction, Inheritance, "Variability from the direct and indirect action of the conditions of Life, and from use and disuse; a Ratio of Increase so high as to lead to a Struggle for Life, and as a consequence to Natural Selection, entailing Divergence of Character, and the Extinction of less improved forms." The present edition discusses at length the principal objections raised against the sufficiency of Natural Selection and the accumulation of minute variations, and the validity of the theory upheld by Owen and Mivart of sudden and occasional variations of considerable amount, proceeding according to fixed law. This after all is but a secondary and subsidiary subject; the one step is the doctrine of evolution, which once established, the precise details must be left to be settled by the gradual accumulation of facts.

On the Therapeutical Importance of Recent Views of the Nature and Structure of Cancer. By HENRY ARNOTT, F.R.C.S., Assistant-Surgeon to St. Thomas's Hospital, etc. (Reprinted from St. Thomas's Hospital Reports, Vol. II.) 1872. Pp. 28.

* * * Mr. Arnott, being a Surgeon, and an *alumnus* of the Middlesex Hospital, naturally takes up the idea that cancer is at first a local disease, and that if thoroughly and early extirpated before there has been time for the diffusion of cells, the patient may be saved. On behalf of this view it must be admitted that it is hopeful, and allows of something being done. Thus a cancer may be compared to a thistle in a cornfield. If thoroughly eradicated before it has flowered, there is an end of it; but if allowed to go on till its ripe feathery seeds are wafted about by the wind, or if merely cut down, so that portions of its root are left to spring up again, the whole cornfield may in time be covered with young thistles. To make this similitude perfect, we need to have it explained how the original thistle came into the cornfield, and how the first spot of cancer came to be deposited in the living body. It is very well to say that it is at first purely *local*; but the word "local" is a trap, and capable of half-a-dozen meanings. Peculiarities of form and of chemical composition are hereditary, and, as they come from variations of one germ-cell, must be constitutional. Cancer seems to be hereditary, as any other bodily or mental peculiarity may be; and it is mere begging the question to call it "merely local," until we know what is meant by "local." But this is no argument against the "therapeutical importance," which Mr. Arnott shows, of a treatment that offers some hope over a treatment which offers none.

St. Thomas's Hospital Statistical Report—Surgical. By F. CHURCHILL, F.R.C.S.

* * * This Report differs from those previously issued by this and other Hospitals in several important particulars. An endeavour has been made to supply the statistician with a "hand-guide" to the different diseases, so that he may be saved the labour of wading through a farrago of uninteresting tables and may be able to find the information he requires condensed upon one page. The statistical reports published at some of our Hospitals of late years have been needlessly expanded; the main feature, or at least the predominating element, appears to have been a succession of blank columns and black lines, wearisome to the eye and very confusing. In this Report blank spaces have been avoided as far as possible. The five tables have been condensed and so arranged that the statistics of any disease may be seen at a glance instead of compelling the statistician to pass on to a different part of the Report for each tabular item. Some idea may be obtained of the great saving of space effected by this arrangement by referring to the *disease* column, where the name of the disease, instead of being repeated three or four times, only occurs once. The Standard Nomenclature has been turned to account and found very useful. By printing the indices of disease and putting them in bold figures much space is saved, and the eye may travel across the page for further information without embarrassment. By the habitual use of the Standard Nomenclature these figures may in course of time be understood to represent "constant qualities," by which the name of the disease is identified or represented. By placing the "sex" column first, the column for "totals" is not required—the numbers, being for the most part in units, may be easily calculated. Some very condensed information is supplied in the column for remarks, but this is supplemented by the summary at the end. The Standard Nomenclature has in a few instances been found wanting, of which are subjoined some specimens selected from the Report. Under No. 787 there is "Spinal weakness;" under No. 812 "Inflamed bursa patella;" under No. 1103 "Compound fractures of humerus," and "Arm torn off." Similar additions follow after fracture of thigh- and leg-bones. Burns are also separated from scalds.

The wording of the special tables is abrupt but systematic, as they were intended, we believe, for a tabular arrangement, but altered to save expense.

GENERAL CORRESPONDENCE.

ON INFLAMMATION OF THE UTERUS AS A BAR TO IMPREGNATION.

LETTER FROM DR. G. G. BANTOCK.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the discussion which followed the paper read by Dr. Phillips at the last meeting of the Obstetrical Society, and reported in the *Medical Times and Gazette* of the 2nd instant, Dr. Tilt threw out the suggestion that chronic inflammation of the womb might have existed in some of the cases recorded, and had been the cause of the abortions. I took occasion to express my conviction that inflammation of the womb was an effectual bar to the occurrence of impregnation. Dr. Barnes expressed his dissent from my views, and stated that "women frequently conceive while under treatment for this affection," though in the preceding sentence he limits himself to "inflammation of the cervix uteri." It will be observed, on reading the report, that Dr. Tilt distinctly spoke of inflammation of the womb in its chronic form, and that my words were "inflammation of the uterus," by which I meant either acute or chronic. If Dr. Barnes meant something else, there is an end of the matter; but I conceive that one of Dr. Barnes's practice in writing and speaking would not commit such an error as this in discussion, and I must be allowed the supposition that he meant the same thing.

Now, I have the greatest respect for anything which falls from the lips or pen of Dr. Barnes—a feeling which I believe to be shared by a large number of the Profession—and I would not, without good reason, enter the lists with him; but I challenge him to produce the particulars of a single case in which he has witnessed the occurrence of impregnation of an inflamed uterus. I will not admit that so-called inflammations of the cervix are cases of inflammation at all. These are really congestions of the mucous membrane covering the cervix and lining the os, and they leave the body of the uterus

unaffected. It is no argument against my views that "women frequently conceive while under treatment for this affection," for it may be assumed—and it is in accordance with my own experience—that the disease had first been cured, and that impregnation had followed as a consequence. Moreover, I would not, with the evidence before me of impregnation during the existence of cancer of the cervix uteri in its various forms, have stated that inflammation of the cervix uteri—if I had believed in such a condition—was an effectual bar to impregnation. In these cases it is well known that the body of the uterus is not affected in the early condition.

All authors on the diseases of women with whose writings I am acquainted speak of sterility as one of the results of inflammation of the uterus, whether acute or chronic; and I have never seen anything to the contrary, though I would not for this reason be supposed to deny such an occurrence.

I have so late as to-day seen a case of well-marked vaginitis—redness, swelling, tenderness, copious muco-purulent discharge—which, according to the history, preceded and is now concurrent with pregnancy; but in this case the os was found to be perfectly healthy and closed.

Dr. Barnes further observed, with reference to Dr. Tilt's remarks, that it was "hardly possible to find a pure case of retroflexion." If by this he means that there hardly exists a case of retroflexion without inflammation of the uterus, I am entirely at variance with him. If by it he means congestion, which is not inflammation, but a condition of passive distension of the venous system from pressure, I am equally in accord with him.

I adhere, then, to my original statement, that inflammation of the uterus, whether acute or chronic, is an effectual bar to the occurrence of impregnation, and I believe the voice of the Profession will be in my favour. I am, &c.,

GEORGE GRANVILLE BANTOCK, M.D.,

Physician to the Samaritan Free Hospital.

44, Cornwall-road, Westbourne-park, W., March 5.

POOR-LAW MEDICAL OFFICERS OF HEALTH.

LETTER FROM DR. JOSEPH ROGERS.

[To the Editor of the Medical Times and Gazette.]

SIR,—A full report of the proceedings at the conference on Poor-law Medical Relief, on the 5th, and at the deputation to Mr. Stansfeld, on the 13th ult., having been forwarded to our members during the last few days, I have received from all parts of the country a large number of letters. In these the writers express their objection to the proposition of the Royal Sanitary Commission, which, if adopted, would constitute them the sole Medical Officers of Health of their respective districts.

The enclosed copy of a resolution adopted at a meeting of the Medical Officers of the Cardiff Union places the matter in so clear a light that I believe you would be doing us a service if you find space for it in your columns. I am, &c.,

Dean-street, March 5.

JOSEPH ROGERS.

At a meeting of the Medical Officers of the Cardiff Union, held on the 27th of February last, it was unanimously agreed that—

"We are most strongly of opinion that the recommendation of the Sanitary Commission that district Poor-law Medical officers be sole sanitary officers would be impracticable, as private practice would seriously interfere with the necessary independence. We believe the greatest efficiency would be obtained by charging them with the duty of reporting to a superior officer, independent of practice, who might preside over a wide area, and accept the responsibility of taking action for the removal of reported nuisances. Further, if this higher office were made open to the deputy officers who might prove their fitness for it, we think it would be a valuable stimulus to the thorough discharge of the duties of the subordinate post.

"JOHN EVANS.

"DAVID EDGAR JONES."

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY'S COUNCIL.

[To the Editor of the Medical Times and Gazette.]

SIR,—An observation of yours in last number respecting the principle of selecting officers and members of Council of this

Society cannot fail to challenge remark. You say, "It does not appear that any gentleman who contributes to the *Transactions* or the practical working of the Society is overlooked." A little study of the list of Fellows will quickly satisfy anyone that contributions to the *Transactions* or to the practical working of the Society have not hitherto been considered to be a claim to selection to take part in its government. The list contains numerous names of contributors who have never been on the Council; and also numerous names of men who have never contributed a paper or a scientific idea thought worthy of being printed in the *Transactions* who have been put on the Council.

I am, &c.,

March 6.

OMNIA SINE LABORE.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

March 1.

At no period within the memory of the present generation has the death-rate of Liverpool been so low as it was last week. The number of deaths was 110 below the weekly average of the last ten years, and 155 below the average of the corresponding week of the same period. The mere fact of thirteen out of the eighteen large towns from which returns are made having a higher mortality than this, is so unprecedented as to deserve to be put on record. This exceptional condition is the result, no doubt, of the concurrence of several causes, among the more prominent of which are the mildness of the weather, which permits doors and windows to be thrown open and many of our black holes to be at least partially ventilated; the continued rains, which flush out the sewers; and the abundant demand for labour, which keeps away want, one of the ablest coadjutors of disease. Any or all of these causes might suddenly cease to operate, and then our death-rate would surely rise.

For some years past the increasing numbers of students entering at the Royal Infirmary School of Medicine have called for the provision of greater accommodation, and year by year additions and alterations of a most useful kind have been carried into effect. The time has now come, however, when, in the opinion of the managers of the School, an undertaking of a more extensive nature than any contemplated since its formation must be set on foot, and it is proposed shortly to commence such a series of changes as shall nearly double the present accommodation, and give additional usefulness to an institution which is one of the very first of its kind in the provinces.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

FRIDAY, MARCH 1.

T. B. CURLING, F.R.S., President, in the Chair.

ANNUAL MEETING.

THE President opened the meeting at 8 p.m. He declared the ballot open, and nominated Dr. Samuel Jones Gee and Dr. William Johnston as scrutineers.

The Treasurer's account of the income and expenditure of the Society for the year 1871, with the auditors' report, was then read. The total ordinary income from subscriptions and other fees, sale of *Transactions*, payments of other societies, and interest was £1477 5s. 3d., and the ordinary expenditure £1046 3s. 7d. The extraordinary expenditure was very large, owing to the cost of the new reading-room and other alterations in the Society's premises, etc., but this had been met by the sale of £1000 stock and the balance remaining from the previous year, leaving a current balance of £496 5s. 5d.

The report having been read, Mr. CHARLES HAWKINS, after some objections to the form of the report, moved its adoption.

Mr. WEBSTER seconded the motion. He was glad to hear of such important additions to the library, but sorry to hear of the deaths of so many Fellows.

The report of the President and Council was next read.

This report referred also to the above particulars, and stated that 23 new Fellows had been elected, 16 being resident and 7 non-resident, and 24 Fellows had died, 3 of them being honorary, 9 resident, and 12 non-resi-

dent, leaving the present total number of Fellows, honorary, resident, and non-resident, at 658. The report mentioned that the new reading-room would be open in the course of the session, and that the delay in opening had been caused by the dampness of the walls, which had hindered the completion of the bookcases, etc. A new arrangement of the busts was contemplated on pedestals, instead of the double rows on brackets on the columns, as heretofore. The back room on the first floor, now connected by a new staircase with the vestibule of the meeting-room, would become an integral part of the library, and it was recommended by the Council that the Society for the Relief of the Widows and Orphans of Medical Men, which till now had had exclusive possession of this room, should in future have it only on occasion of their meetings, and that this and the entire occupation of the small room now used by their secretary should be allowed them rent-free. The Council also recommended that the Society should undertake the administration and management of the "Marshall Hall Memorial Fund," for which application had been made to them by the Committee.

The report relative to the library stated that 361 works had been added (not inclusive of journals, etc.), of which 189 were purchased and 172 presented. There had also been a donation from Sir Trevor Lawrence of above 300 tracts on anatomy, physiology, and Medicine, from the library of the late Sir William Lawrence. The report also referred to the large amount of book-space which had been gained by the alterations, giving additional shelf-room for about 27,000 volumes, which would not only allow of the library being increased to double its present size (covering any prospective increase for the next thirty years), but would permit of great improvements being made in the general arrangement of the whole library.

Mr. HENRY LEE moved that the report of the President and Council be received and adopted.

The motion was seconded by Dr. CHOLMELEY.

Mr. HAWKINS praised the liberality of the Society in giving up the rent received from the Society for the Relief of the Widows and Orphans of Medical Men. He thought the alteration of the time of meeting from afternoon to evening had not been followed by good results. He also suggested that now they had got new premises it would be a good plan to give an annual reception. He had long wished to see a bust of their lady patron the Queen worthy of the Society in the place of honour in their rooms.

Dr. PITMAN then moved a formal vote as to giving up the rent of the Widows and Orphans Society.

This was seconded by Mr. HAWKINS.

Dr. GEE next moved that the Society receive the Marshall Hall Memorial Fund, and award the simple interest accruing from it once every five years to the author of the best work in English on the nervous system.

Mr. COOPER FORSTER seconded the motion.

Mr. T. SMITH explained, with regard to the fund, that there was to be no competition in the ordinary sense. They could award the prize without any work being sent in, or, indeed, without the author being at all aware of his claims being considered. They might also withhold it, or alter the terms of its awards as they liked.

Mr. HAWKINS next moved that the Council be authorised to procure the execution of a bust of the Queen for the Society.

This motion was also seconded by Dr. WEBSTER.

Dr. BUZZARD said he was loth to interfere, but he thought the artistic effect of the room would be spoiled by placing the Queen's bust over the President's chair. He objected to the funds of the Society being so used; if anyone liked to present a bust to the Society, that was another matter. There was, in the meantime, considerable delay in getting books; it would be better to get duplicates of these, or to reduce the annual subscription.

Dr. CHOLMELEY warmly opposed this utilitarian argument. It was not a question of gratitude for benefits received, but a mark of deference due to themselves as a Royal Society.

The motion was carried.

Next, Mr. HAWKINS moved, and Dr. WEBSTER seconded, a proposition that the Society give a reception at the end of the session. This, too, was carried.

The PRESIDENT then proceeded, in a very interesting and rhetorical address, to review the life and labours of the Fellows of the Society who had died during the past year. The list included the names of Dr. Tanner, Dr. Hennen (son of the well-known Army Surgeon, who died at Tunbridge Wells in June last, aged 71), Dr. Cursham, Dr. Hyde Salter, Mr. Samuel Solly, Mr. Langston Parker, Mr. Robert Wade, Dr. George Blackman,

Dr. George Edward Day, Mr. Thomas Hammerton, Dr. James Abercrombie, Dr. John G. Goulstone, Dr. William England, Mr. Simon Murehison, Mr. Charles Herbert Miles, Mr. John W. Hubbard, Dr. George Seratehley, Mr. Charles Revan Alexander, Dr. G. F. Dorsett Evans, Dr. Patrick Miller, Mr. Henry Derviche Jones, and Mr. Charles Beevan. The President also referred to the deaths of two distinguished honorary Fellows of the Society, Sir John F. W. Herschel and Sir Roderick Impey Murchison. He concluded with a memoir of a celebrated honorary Fellow, the Baron Paul Dubois, son of Baron Antoine Dubois, who died on November 29 last, at the age of 76.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 23.

J. B. SANDERSON, M.D., F.R.S., Vice-President, in the Chair.

MR. BRUDENELL CARTER exhibited by the demonstrating ophthalmoscope the retina of a boy about 14 years of age, in which pulsation of the large vessels was observed.

Dr. ANSTIE, who had examined the patient, said there were no signs of valvular lesion.

Mr. THOMAS BRYANT read a paper on two cases of "Rectovesical Fistula successfully treated by Colotomy." The first was that of a gentleman, aged 64, who had had diarrhoea, tenesmus, and the passage of blood and mucus three months before he had begun to pass fæces in his urine. Colotomy was performed on August 16, 1869, with complete relief. The patient was up and out of the house in a month. At the present time he passes his urine naturally, and the motions through the loin, some little urine at times finding its way into the rectum and upwards through the loin. The ulcer in the bowel has clearly long healed, the fistula alone remaining. The second case was that of a gentleman, aged 49, who for three years had been passing urine and fæces per urethram. He was much reduced in health, and most miserable from the local pain and irritation caused by his disease. On July 5, 1870, colotomy was performed, complete relief being given to his symptoms almost immediately. In three weeks he was up, and in another week out. Six months later, he reported that he was getting quite fat, that he was free from all pain, and that his only trouble was the passage of water at times up the bowel through the artificial anus. At the present time, a year and a half after the operation, he remains well. In both these cases Mr. Bryant remarked that there was good reason to believe that the ulcerative action that had caused the fistula was of a simple nature, and had commenced in the rectum; that after the operation the ulcers soon healed, although the fistulous opening remained. He stated that the two cases in every way supported the remarks he appended to a similar case which he had read at a sister society, and which were published in the *British and Foreign Quarterly Journal*, 1869, and still more prove the truth of Mr. Holmes's remarks made in the *Medical and Chirurgical Transactions*, 1869-70, on the same subject. Mr. Bryant added that these cases and all others he has had since 1868 have made him think more highly of the oblique incision in the operation than the transverse.

Mr. HEATH had recently operated on a female who twelve years ago had a child, followed by a pelvic abscess. This opened externally, and by-and-by closed. After a time the bladder sloughed, and flatus and fæces came away. He satisfied himself the communication was with the large intestine, so he opened the colon in the loin. This was followed by immediate relief, and now she had no trouble with her urine.

Dr. HABERSHON spoke to the great benefits of the operation in Mr. Bryant's second case; for before it the man's life was a burden to him. The difference such an operation made was sometimes very great. He recalled to mind a case where the operation was not done, and he now regretted it. The patient was passing flatus by his penis, but the adhesions of the gut to the bladder gave way, peritonitis came on, and he died.

Mr. HULKE urged that colotomy should not be limited to such cases only, but should be extended to other obstructive diseases of the rectum. Thus, a woman under his care for cancer had lived in comparative comfort for two years and a half after such an operation. Still more was it likely to be useful in simple ulceration into the bladder.

Mr. CARTER recalled to mind a case where he had operated, and subsequently used wood charcoal to deodorise the fæces with complete success. The colotomy gave very great comfort.

Mr. MAUNDER had now done this operation nine times, and

twice in cases like Mr. Bryant's. In one the relief was exceedingly great, though the patient did not live long. In another case of simple stricture there was very great relief. The operation was comparatively simple. The peritoneum should not be injured, or, if injured, it should be stitched up.

Mr. BARWELL narrated a case supposed to be one of opening of the sigmoid flexure into the bladder. After death it was seen that the opening communicated between the middle of the colon and the fundus of the bladder.

Mr. T. SMITH asked if one could always avoid the peritoneum, and, if not, was it very dangerous to injure it. He remembered opening the peritoneum of a child, and a portion of gut was a good deal handled. After death, which happened in a month, no trace of an opening could be found. What was the best truss to use?

Mr. HULKE said a vulcanite shield with a knob was best.

Mr. BRYANT thought these remarks would lead to the more general use of the operation. He never regretted doing the operation; often that he had not done so. He did not like opening the peritoneum, as one patient died after such a mishap; he accordingly turned the bowel round, so as to get well behind it before opening it. After the operation he used an indiarubber ball cut in two bound on to the opening; this received any moisture or flatus.

Mr. WARRINGTON HAWARD read a paper on "Three Cases of Distension of the Antrum." The first was a boy, 4 years old, in whom, after pain in the upper jaw and discharge from the nostril, the antrum became distended, and an opening formed on the prominence of the cheek. Several other cases were mentioned in which an opening formed in the same situation. The treatment consisted of puncturing the antrum through a tooth-socket, and syringing the cavity with astringents. The second patient, aged 26, had what he thought to be a boil on the cheek, which during eight months had discharged matter. This proved to be an opening leading to the antrum, which was slightly distended. He was treated by syringing through the opening. The third patient, aged 50, had a solid tumour growing from the alveolus of each upper jaw, and one which had been soft, but had become bony, on the alveolus of the lower jaw. There was marked distension of the right antrum by fluid. The tumours and adjacent alveolar process were removed from the upper jaw, and the floor of the antrum opened to evacuate the fluid and allow examination of its cavity. The antrum contained no solid growth. The tumours were oval-celled sarcomata. The patient died from recurrence of the growth and the development of secondary tumours in the abdomen and elsewhere. The first cases showed with how slight a distension of the antrum an opening might form on the cheek, and pointed to the necessity of obtaining an exit for the fluid into the mouth as early as possible. The last case showed that when distension of the antrum occurs in connexion with a solid tumour of the upper jaw, it does not follow that this distension is due to solid growth—a point sometimes of much clinical importance.

Dr. ANSTIE asked what amount of neuralgic pain was present.

Mr. HAWARD called it neuralgic because it was in the course of the nerves. It did not regularly remit.

Dr. ANSTIE thought there was no neuralgia without great peripheral tension.

OBITUARY.

A. B. GRANVILLE, M.D., M.R.C.P., M.R.C.S.,
SURGEON R.N., F.R.S., ETC.

THIS well-known and accomplished Physician died last week at Dover at the great age of 89. He was born at Milan in 1783. He was the third son of Signor Carlo Bozzi, Postmaster-General of the Lombardo-Austrian Provinces, and was educated at Milan and Pavia, where he took his degree. After visiting many of the most celebrated islands of the Mediterranean he went to Lisbon, and in 1807 became Assistant Surgeon in the British Navy, where he remained until 1813, when he settled in London, having previously, with the consent of his family and in due legal form, added his maternal surname, Granville, to his own patronymic. Before entering into actual practice he became a Member of the Royal College of Surgeons, and in 1817 he was admitted a Licentiate of the Royal College of Physicians. In the same year he was elected a Fellow of the Royal Society. At first, we believe, it was his intention to practise generally; but he soon abandoned this idea, and, on becoming a licentiate of the College, determined to make

obstetrics and the diseases of children his study and special line of practice. He was elected Physician-Accoucheur to the Westminster General Dispensary in Gerrard-street, which office he held for many years, and on retiring was appointed Consulting Physician-Accoucheur to that institution. He was also Physician to the Metropolitan Hospital for Sick Children. But his active and suggestive mind took him into various subjects of experiment and inquiry. He published "Reports on the Practice of Midwifery," and "Graphic Illustrations of Abortion"—a book of rare merit, and (for the time) illustrated in a manner which excited general admiration. He claimed to be the first to introduce prussic acid into the practice of Medicine in England. This claim, we believe, he established fully; and though some years after an attempt was made to detract from his work on hydrocyanic acid in consumption, he entered into a controversy with his opponent, who, being no match for him either as regarded facts or brilliancy of writing, soon succumbed. Granville was a man, as we have said, of a most suggestive mind, and perhaps it might be said of too discursive an intellect to be great on any one subject; but he was more than respectable in all the various works which he published. To enumerate these will indicate his varied acquirements. Thus he published at various times the following:—"The First Reports on the Supply of Pure Water and the Purification of the Thames, and the Saving of Sewage for Manure," 1836; "Egyptian Mummies;" "Spas of Germany;" "Counter-Irritation;" "Spas of England;" "Kissingen;" "Catechism of Health;" "St. Petersburg; or, Travels to Russia;" "History of the Royal Society in Nineteenth Century;" "The Sumbul, a New Asiatic Remedy in Epilepsy;" "Sudden Death;" "New German Mineral Baths Cure;" "Letter to Lord Palmerston in July, 1853, predicting the Sudden Death of the Emperor Nicholas;" "Mineral Springs of Vichy;" "The Great London Question of the Day, or Can Thames Sewage be Converted into Gold?" 1865. Dr. Granville never had an extensive practice, but for many years he was one of the leading London Obstetric Physicians. More erratic in his movements than Sir H. Holland, he did not succeed in retaining his business so successfully as the now venerable Baronet did. As age advanced, Dr. Granville gradually retired, but he published his last work no longer ago than 1865. It should be mentioned that he conducted the *London Medical and Physical Journal*—a quarterly publication of good repute—for some years with much ability.

Dr. Granville was rather a brilliant than a profound Physician. Versatile, witty, charming in conversation, and of most polished manners, it may be remarked, without injury to his memory, that he wanted that plodding industry, that earnestness of purpose in one pursuit to entitle him to be regarded as a great Physician. Formerly, he was a frequent attendant at the Old Westminster Medical Society, and spoke at their meetings at an advanced age, with the clearness, the vivacity, and energy of a man half his age. He was a formidable opponent in debate, but he displayed more skill in the use of the rapier than the tomahawk. He was so inherently a gentleman that he never condescended, either in manner or language, to lower himself to indecent attacks or bullying. In person he was about the middle height, somewhat slightly built, but of a vigorous and elastic constitution. His face, so far as his features were concerned, was Italian, but his complexion was Saxon, and his eyes blue. In manner and bearing he was a good specimen of "a high-born and a high-bred man."

J. F. C.

WILLIAM MACTURLE, M.D.,

DIED at Bradford, March 2, 1872, having been in practice there forty-eight years as a Physician. He was born at South Cave, in the East Riding of Yorkshire, in 1795. His parents were Scotch. He commenced practice as a general Practitioner in Scarborough, having obtained the Licence of the Apothecaries' Company of London in 1816. He only remained in Scarborough for four years, and then went and studied in Edinburgh and Glasgow, taking the degree of M.D. at the University of the latter city in 1823. He went to Bradford in 1824. He was appointed one of the first Physicians to the Bradford Infirmary on its establishment in 1825, and continued to be one of the active staff till within two years of his death, devoting a very considerable portion of his time to the institution. He was a man of upright character and pleasing manner, and was very highly respected in the town and neighbourhood, both by the public and the Medical Profession. For many years he enjoyed the principal consulting practice in Bradford and the surrounding district. He died of senile gangrene

after a painful illness of four months' duration. He was twice married, his second wife and one son and three daughters surviving him.

ROBERT BRENT, M.D., F.R.C.P., EDIN.

THIS gentleman was educated at St. Bartholomew's. He became M.R.C.S. Eng. in 1844, in 1845 graduated at St. Andrews, and became a Fellow of the Edinburgh College of Physicians in 1846. He commenced practice at Woodbury, near Exeter, Devon, about the year 1846, and retired from practice about four years ago. On his retirement, a testimonial to his great worth, in the shape of his portrait painted in oil by Mr. Sydney Hodges, was presented to him by his numerous friends. He was Lieut.-Col. of the 1st Administrative Brigade Devon Artillery Volunteers, and held the Captaincy of the Woodbury Battery, of which he was the founder. He died at Sydney Cottage, of apoplexy, on February 26, in the 53rd year of his age, deeply regretted by his relatives and friends. Of the latter he had a large circle.

BENJAMIN EVANS, F.R.C.S., L.S.A.,

DIED a few days ago at his residence, Acre House, Brixton, in his 70th year. He was formerly in practice in the borough of Southwark. He retired from this some years since. He was a man of energy and of liberal opinions, both as regards his Profession and politics. He occupied some parochial and other public appointments, and at the time of death was a member of the Metropolitan Board of Works for St. Mary's, Newington. He took a prominent part in the formation of the British Medical Association—we mean the first of that name, of which the present Dr. Webster, of Dulwich, was the first President, which office he filled for several years. Mr. Evans was Consulting Surgeon to Southwark Lying-in Charity. He was author of a case of "Hydrocele of the Neck," and "Case of Perforation of the Stomach."

JOHN A. WALSH, L.R.C.S. EDIN., L.M., L.A.H. DUB., OF Thurles, died on the 25th ult. from the effects of a fall from his horse. It appears that on the evening of the above day he rode on horseback to the residence of Mr. Thos. L. Power, of Clearagh, where he dined. He left Mr. Power's house about nine o'clock; at eleven o'clock two men who were proceeding home found Mr. Walsh lying in the middle of the road with a fearful wound at the back of his head. The stirrup iron of the saddle was on his left boot. The unfortunate gentleman was not quite dead when first seen, but he expired in a few moments after being conveyed to a house near where he was found—a place called Pouldine, about three miles from Thurles. An inquest was held on the body. Medical and other evidence having been given, the jury returned a verdict "that the deceased was accidentally killed, he having fallen off his horse."

The deceased was only 30 years of age, and was a native of Carrick-on-Suir. He was Medical Officer to the Littleton Dispensary, had been in practice in the town of Thurles for the past eight years, and had the goodwill and respect of all classes of the community, who deeply deplore his untimely end.

JAMES GATIS, M.R.C.S., ETC.,

DIED suddenly a few days since at Wolverhampton. The deceased was born at Cockerthorpe, and went to Wolverhampton in 1834 as House-Surgeon to the old Dispensary in Queen-street. He married, in 1837, the daughter of the late Mr. W. Clark, the well-known ironfounder of that town. In 1851 the late Mr. George Edwards and Dr. Bell, at that time two of the leading members of the Profession, joined Mr. Gatis in partnership, which was only dissolved by the death of those gentlemen ten years afterwards. It was at this period Mr. Gatis removed to his residence in North-street, and, as evidence of the high esteem in which he was held, he was soon after elected among the first chosen aldermen of the borough. He was in active Professional work within a few hours of his decease, and had only a few minutes before the fatal seizure returned from visiting a patient. At the time of his death Mr. Gatis was the senior Practitioner in the town. His removal has left a gap in the town and neighbourhood that will not easily be filled. His loss will be deeply felt by the poor.

It is expected that Prince Arthur will open the bazaar for the new Southern Hospital, Liverpool, as well as the Hospital itself, at Whitsuntide.

NEW INVENTIONS.

VIN DE QUINQUINA, TITRÉ AU FER ET CAÇAO.

(E. Lambert, Pharmacie Beaujon, 171, Boulevard Haussman, Paris; Melein, Titchborne-street, London.)

In French Pharmacy, the manner is of as much importance as the matter. Elegance of form to please the eye, and agreeable taste to please the palate, are characteristics of their therapeutical *spécialités*. The example before us is a compound of cinchona, iron, and the active principle of the caçao. Moreover, stress is laid on the fact that it is prepared with the finest old Malaga wine; for it is a singular fact that, whilst the Anglo-Saxons look to a dry wine as their chief help in debility and anæmia, the Latin races have a prejudice in favour of strong sweet wines, and all over France and Italy the wine of Malaga is believed to be exceptionally nutritive. It is with a wine of this sort, we believe, that the traditional old black steel wine is made at Apothecaries' Hall, which was always recommended by Sir Benjamin Brodie. M. Lambert's Vin de Quinquina resembles that preparation, but contains besides the bark and caçao, and seems well worth the notice of the Physician who is prescribing for blighted children.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the examinations for the licence to practise Medicine, held on February 6 and 14, the following candidates were successful:—

Browne, Thomas Henry.	Irwin, Andrew.
Clarke, Richard Ashmore.	Stoker, William Thornley.
Clune, Michael Joseph.	Wigmore, Patrick Stephen.
Hannan, Francis Bayley.	

At the examinations for the Midwifery Diploma held on February 8 and 16, the following passed:—

Browne, Thomas Henry.	Irwin, Andrew.
Clarke, Richard A.	Stoker, W. T.
Clune, Michael J.	White, Richard D.
Hannan, Francis B.	

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, March 7:—

Duncan, Andrew, Henrietta-street, Covent-garden.
Nix, Edward James, West Ham, Stratford.
Shemilt, George Richard, Tean, Staffordshire.

As an Assistant in Compounding and Dispensing Medicines—
Griffin, Alfred William, Havant.

The following gentlemen also on the same day passed their first Professional examination:—

Collins, Henry Beale, King's College.
Foreman, Joseph, Guy's Hospital.
Hawton, James W. H., Guy's Hospital.
Moore, Henry Cecil, Birmingham.
Smith, Richard, Birmingham.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ANDERSON, WILLIAM, M.R.C.S.—Surgeon to the Dispensary, Newcastle-on-Tyne.

CARR, CHARLES, M.R.C.S. and L.S.A.—Surgeon to the Dispensary, Newcastle-on-Tyne.

CHALMERS, J. D., M.B., F.R.C.S., late House-Surgeon to the Northern Hospital—Assistant Medical Officer to the Infirmary for Children, Liverpool, *vice* Dr. Davidson, who has been elected one of the Physicians to the Northern Hospital.

HAMMOND, ROBERT E., M.R.C.S.E. & L.R.C.P., and BREBNER, GEORGE R., M.B. & C.M.—Medical Officers and Public Vaccinators for the divided District No. 6 of the Chorlton Union, Lancashire, *vice* John Henry Brown, M.R.C.S.E., L.S.A. Lond., deceased.

HUGHES, W. R., L.K.Q.C.P.I., L.R.C.S.I., L.M.—Junior House-Surgeon to the Southern Hospital, Liverpool, *vice* R. Leigh, M.R.C.S.E., resigned.

KING, GEO., M.B. Lond., M.R.C.S., L.S.A. Lond.—Surgeon to the Royal South Hants Infirmary.

SIMS, W., M.B., etc., Administrator of Chloroform to the Royal South Hants Infirmary—Assistant-Surgeon to the Royal South Hants Infirmary.

SUTHERLAND, JAMES, M.B., C.M.—Senior House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester, *vice* Orchard, resigned.

NAVAL AND MILITARY APPOINTMENTS.

MEDICAL DEPARTMENT.—To be Staff Assistant-Surgeons: Ernest Wyndham Cottle, Robert Vacy Ash, M.B., Paul Connolly, Charles Edward Dwyer, John Godfrey Rogers, M.B., Benjamin Bloomfield Connolly, John Dallas Edge, M.D., Frank Edward Barrow, Robert Blood, M.D., Henry John Waller Barrow, M.D., William Percy Bridges, Robert Drury, M.D., and William Cameron Grant, M.B.

The undermentioned officers have been confirmed as Assistant-Surgeons in her Majesty's Fleet:—Mr. Thomas Harvey, Mr. William Algeo, Dr. Michael Kearney, Mr. John Lyon, Mr. William Brown, Mr. John Tyndall, Dr. Matthew Reed, Mr. Alexander Richard Joyce, Dr. Charles Atkinson Rathborne, Mr. Thomas Power, all with seniority of March 2, 1871; Mr. Brien Patrick Sarsfield M'Dermott, Mr. Richard John Parry, Mr. Gerard James Irvine, all with seniority of March 7, 1871; Mr. George Woods Low, Mr. Scudamore Kidley Powell, both with seniority of March 10, 1871; Mr. Alexander William Flood, with seniority of March 11, 1871; Dr. John Francis Enright, with seniority of March 16, 1871.

BIRTHS.

DEACON.—On March 11, at Ottery St. Mary, Devon, the wife of H. Pelham Deacon, M.R.C.S.E., of a son.

HATHERLY.—On March 7, at Wellington-street, Park-side, Nottingham, the wife of Dr. Henry R. Hatherly, of a daughter.

MCNAB.—On March 3, at St. Oswald's-terrace, Fulford, near York, the wife of R. McNab, M.D., Staff Surgeon-Major, of a son, stillborn.

POTTER.—On March 11, at Collumpton, Devon, the wife of Samuel Reginald Potter, M.D., of a son.

SPYERS.—On March 8, at Faversham, the wife of Thomas C. Spyers, M.D., of a son.

MARRIAGES.

BRADLEY—MARTIN.—On March 7, at Holy Trinity Church, Upper Tulse-hill, William Henry Bradley, Staff Commander R.N., to Edith Louisa Agnes, youngest daughter of Robert Martin, M.D. Heidelberg, Victoria, Australia.

FINDEN—ROBINSON.—On February 10, at Trinity Church, Allahabad, Woodforde Finden, M.R.C.S., L.R.C.P., 11th Bengal Lancers, to Valence Aimee, youngest daughter of the Rev. Julian Robinson.

LUKE—PERROTT.—On March 6, at St. Barnabas, Hornsey-road, Henry Luke, M.R.C.S., of Tollington-park, N., to Matilda Duerdin, eldest daughter of the late Richard Perrott, Esq., of Tollington-park.

LUNDSTRÖM—LEWIS.—On March 7, at St. John's Church, Upper Holloway, Fredrik, second son of Johan Fredrik Lundström, Esq., of Göteborg, Sweden, to Augusta Mary, younger daughter of the late Thomas Lewis, M.R.C.S., of St. Albans, Hertfordshire.

MEYERSTEIN—HESS.—On March 7, Emile Meyerstein, Esq., of 14, Fellowes-road, Haverstock-hill, to Pauline, eldest daughter of Augustus Hess, M.D., M.R.C.P. London.

TONNIES—OLGUIN.—On March 7, at All Souls', Langham-place, Augustus Ove Tonnies, Esq., of Crosby House, Bishopsgate-street, to Ramona Zella, eldest daughter of Joseph Olguin, M.R.C.S. Eng., of 11, Hinde-street, W.

WATSON—GWILLIM.—On March 5, at Chertsey, H. Watson, Esq., of Hackney, to Selina Waring, youngest daughter of William Gwillim, M.D.

WILSON—POLLOCK.—On March 7, at Zetland House, Bridge of Allan, George Wilson, M.D., L.R.C.S., Huddersfield, to Jane, youngest daughter of the late David Pollock, Esq., Stirling.

DEATHS.

BURNETT.—At Balbithan House, Aberdeenshire, Mary Stuart, daughter of Charles Stuart, M.D., of Dunearn, and widow of the late John Burnett, Esq., of Kemnay, aged 86.

PARKER, CONSTANCE ROSE, eldest daughter of the late William Parker, M.R.C.S., of St. Osyth, Essex, at Collingwood College, Lee, Kent, of gastric fever, aged 19.

TYRRELL, SOPHIA EVELYN, daughter of W. J. Tyrrell, Army Medical Staff, at Netley, aged nine months.

WILLIAMS.—On March 10, at his residence, Foregate-street, Worcester, Philip Henry Williams, M.D., M.R.C.P.L.

WOOD.—On March 8, at Woodhouse Eaves, Leicestershire, Ann, the wife of Charles Walker Wood, F.R.C.S., aged 70.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BECKETT HOSPITAL AND DISPENSARY, BARNSELY.—House-Surgeon and Secretary. Candidates must be duly qualified. Applications and testimonials, on or before April 8, to Messrs. Newman and Sons, Solicitors, Barnsley.

BIRMINGHAM QUEEN'S HOSPITAL.—Resident Physician and Medical Tutor. Candidates must be Graduates in Medicine of a University of Great Britain or Ireland. Applications, with diplomas and testimonials, to Mr. H. C. Burdett, on or before March 22.

CARMARTHEN COUNTY AND BOROUGH INFIRMARY.—House-Surgeon. Must be M.R.C.S. and L.S.A. A knowledge of the Welsh language is necessary. Applications to Mr. H. Howell, King-street, Carmarthen, on or before April 10. Election on the 12th.

LOCHMABEN, DUMFRIESSHIRE.—Medical Officer wanted for this Parish. Good scope for private practice. Applications to the Inspector of the Poor, on or before March 22.

QUEEN'S HOSPITAL, BIRMINGHAM.—Dental Surgeon. Candidates must possess the Dental Diploma of the Royal College of Surgeons of England. Applications and testimonials to be sent to the Medical Committee of the Hospital, on or before March 21.

RIPON DISPENSARY AND HOUSE OF RECOVERY.—House-Surgeon and Dispenser. Testimonials to the Hon. Sec., on or before March 25.

ROTHERHAM HOSPITAL AND DISPENSARY.—House-Surgeon. Must be duly qualified. Applications and testimonials to the Honorary Secretary, on or before March 26.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—Junior Resident Medical Officer. Candidates must possess a Medical or Surgical qualification. Testimonials to James S. Blyth, Sec., on or before March 20.

ROYAL SURREY COUNTY HOSPITAL.—Assistant Honorary Medical Officer. Testimonials to be sent to the Hon. Sec., Rev. C. R. Dallas, Farncombe Rectory, Godalming, on or before April 16.

ST. MARYLEBONE GENERAL DISPENSARY.—Surgeon. Candidates must be M.R.C.S. Eng., and must attend personally on Wednesday, April 3 next, at eleven o'clock in the forenoon, with a written application. No canvassing allowed.

WALSINGHAM UNION.—Medical Officer and Public Vaccinator. Candidates must be duly qualified in accordance with the General Orders of the Local Government Board. Applications with testimonials to be sent to Mr. J. Wright, Clerk, Bridge-street, Fakenham, on or before March 26.

WEST SUSSEX, EAST HANTS, AND CHICHESTER INFIRMARY AND DISPENSARY.—House-Surgeon. Candidates must be duly qualified. Testimonials, etc., to be sent to Mr. E. W. Barton, on or before April 1.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Alderbury Union.—Mr. F. R. P. Darke has resigned the Fourth District; area 18,077; population 3155; salary £60 per annum; also, the Workhouse, salary £40 per annum.

Leeds Union.—The Headingley-cum-Burley District is vacant; salary £55 per annum.

APPOINTMENTS.

Salford Union.—Thos. N. Orchard, B.M. & M.C. Marischal College and University, Aberdeen, as Assistant Medical Officer at the Workhouse.

Toucester Union.—Arthur Hill, M.R.C.S. Eng., L.S.A., to the Blakesley District.

MR. DYSON WOOD has been appointed Medical Officer and Public Vaccinator for Stanley-cum-Wreathorp.

We understand, in consequence of there being so many candidates attending the next session of the Army Medical School at Netley, that there will be no room for Medical officers.

ROYAL COLLEGE OF SURGEONS.—Mr. Busk, F.R.S., the President of the College, entertained a large and distinguished party at Willis's Rooms on Saturday last. Amongst those present were the heads of the Navy and Army Medical Departments, the President and Master of the Royal College of Physicians and Society of Apothecaries, Sir Ranald Martin, Professors Owen, Allman, Flower, and Holmes, etc.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—SESSION 1871-72.—The next meeting will be held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Saturday (this day), March 16, at 7.30 p.m., Robt. Druitt, M.R.C.P. Lond., F.R.C.S., President. Dr. C. O. Baylis, Medical Officer of Health, Birkenhead, will be balloted for as an extra-Metropolitan Member. Dr. A. W. Barclay will introduce Mr. Stansfeld's Public Health Bill for discussion, and will make some remarks on the principal clauses. A short paper, by F. W. Lowndes, Esq., of Liverpool, will be read (should time permit), "On the Criminal Deaths of Infants, as shown by the Records of the Coroner's Court at Liverpool."

THE BELGIAN MINISTER OF JUSTICE has declared in the Chamber that in consequence of the facts respecting the cruelties and maladministration of the lunatic asylum at Evere, which we noticed in our columns a few weeks since, a general inspection of all lunatic asylums is to take place.

DR. CORFIELD'S Report on the Sanitary Condition of St. Mary, Islington, for February, 1872, states that the total number of deaths during the four weeks ending February 24 was rather less than that during the corresponding weeks of the last two years. Hooping-cough, among the miasmatic diseases, has caused most deaths. Measles have very much abated, and the other miasmatic diseases have shown a slight decrease in fatality, but there have been one or two stray cases of typhus fever.

POOR-LAW MEDICAL REFORM.—At a meeting of the Union Medical Officers of Worcestershire, held at the Medical Library, Worcester, on Saturday, March 9, 1872, pursuant to notice, the following resolutions were unanimously adopted:—
1. That the whole system of Poor-law Medical relief in England is highly unsatisfactory, and urgently requires reform.
2. That this meeting considers the extension of the Dispensary System to county towns as most desirable; but at the same time deems it especially necessary that areas of districts shall be diminished, where in excess, and that the whole of the Medical Officers' salaries shall be paid out of the Consolidated Fund; also that those salaries be revised so as to meet the requirements of the present time.
3. That in revising the salaries of Union Medical Officers, the present large—and increased—cost of provisions, etc., be taken into consideration.
4. That if Union Medical Officers are appointed Medical

Officers of Health, the salaries shall be adequate to the responsibilities of the office; and also some independent offices appointed to superintend large areas. 5. That copies of the resolutions passed shall be forwarded to the local papers, members of Parliament, and Medical journals."

INDIAN MEDICAL SERVICE.—The following were the successful candidates at the recent examination for forty appointments as Assistant-Surgeons:—

Order of Merit.	Names.	Total number of Marks (3400 maximum).
1	Crombie, A.	2920
2	Murphy, W. R.	2630
3	Joubert, C. H.	2525
4	Russell, E. G.	2365
5	Fasken, W. A. D.	2360
6	Branfoot, A. M.	2330
7	Hall, G. C.	2300
8	Scully, J.	2265
9	Watson, G.	2095
10	Gopaul Chunder Roy	2085
11	Reid, A. S.	2070
12	McNally, C. J.	2055
13	Zorab, J. M.	2005
14	Duke, J.	2000
15	Lang, J. A. T.	1960
16	Russick Lal Dutt	1950
17	{ Butler, W. J.	1945
18	{ Palmer, E.	1945
19	McConaghey, J.	1920
20	Wilson, J.	1905
21	Mulvany, E.	1885
22	{ Bookey, J. T. B.	1870
23	{ Young, J.	1870
24	Daphtary, G. R.	1810
25	Holmes, R. A. K.	1795
26	Lawrie, E.	1775
27	{ Beavan, G. F.	1730
28	{ Little, C.	1730
29	Johnson, W. E.	1690
30	McGregor, A.	1685
31	Bankabehari Gupta	1665
32	Dobie, S. L.	1640
33	Lloyd, C.	1615
34	Williams, A. H.	1605
35	{ Dobson, A. F.	1600
36	{ Ferris, J. E. C.	1600
37	Lawrenson, J. C.	1580
38	Lombard, D. E. T.	1565
39	Mayne, T.	1530
40	Aylen, T. V.	1520

ELECTION AT THE ACADEMIE DE MEDECINE.—The election into the Section of Surgical Pathology on March 5 was attended with considerable excitement. "The position in which M. Voillemier was placed by the Section," says the *Union Médicale*, "is a marked example as to the instability of opinion. Two years since, when a vacancy had to be filled up in the Section of Operative Medicine, M. Voillemier headed the list, and, although he was not successful, everyone admitted his long-established claims as a distinguished Surgeon. In the list presented on the present occasion he occupied the sixth and last place only. It is true the members of the two Sections of Surgical Pathology and Operative Medicine are different; but they are all Surgeons, and the candidates were the same. The Academy to a certain extent, although not completely, rectified this injustice; and it was found at the first round of the ballot-box that M. Voillemier was second on the list, as he was on the second and third rounds. Still he only polled thirty votes, while M. Dalbeau, a much younger man, but with all the prestige of a Professor of the Faculty, polled forty-three." Another vacancy has occurred in the Section of Operative Medicine through the death of M. Langier, and it is stated that this will be made the occasion for a full reparation to M. Voillemier.

SANITARY STATE OF PARIS.—As will be seen by the *Bulletins Hebdomadaires des Décès*, for some months past the mortality has ranged between 750 and 850 deaths per week, which is a moderate mean. No epidemic, since the period of the siege, has occurred to raise it. Small-pox has disappeared, and typhoid fever does not prevail to an extent to cause disquietude. Diphtheritic affections have ceased to menace infantile life. Affections of the digestive organs are below the minimum figure, and the little epidemic of benign

jaundice seems to have come to an end. The dominant maladies are thoracic affections and eruptive fevers, and especially measles. There are few persons who have not had to pay tribute, although often a very light one, to influenza.—*Gazette Médicale*, March 2.

THE FRENCH PATRIOTIC SUBSCRIPTION.—La Société des Médecins des Hôpitaux de Paris, at its meeting on February 23, voted with acclamation from its funds the munificent sum of 10,000 francs (£400), independently of the individual subscriptions which will be made by its members.

DISGRACEFUL ADVERTISING IN HIGH QUARTERS.—The *Presse Méd. Belge* of March 3 gives publicity to the fact of a member of the Profession, holding a very high position, circulating in the fashionable quarter of Brussels two cards of a most reprehensible character. The one contains his name, with his titles of Commander of the Order of Leopold, and Officer of the Legion of Honour. On the other "we read with stupefaction as follows:—'The consultation-room of Dr. X, No. —, of — street, is open every day (Sundays and holidays excepted), from nine o'clock until three. Terms of consultation: From nine to ten, 3 fr.; from ten to twelve, 5 fr.; from one to three, 10 fr. By written appointment or at the patient's house, 20 fr. Every Monday, from nine to ten, gratuitous consultation. Vaccination and revaccination, £0 fr.'"

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

We are glad that Dr. Gutteridge is satisfied with the milk obtained at the Friern Manor Farm Dairy.

Lauke.—We really cannot tell. There has been nothing settled as yet.

X. Y. Z.—Try a knee-cap. Obtainable at Salmon's, 87, Wimpole-street.

Mr. A. Paterson, Bahia, Brazil.—Note, with enclosure, received with thanks.

P. Q. R.—1. Fresh registration only can make him a legally qualified Practitioner. The General Medical Council would not register him without a full inquiry. 2. We do not think that the Licensing Body from which he obtained his diploma could have been aware of his antecedents.

Mr. Spencer Smith.—As some surprise has been expressed by a contemporary at the election of this distinguished Surgeon as a member of the Court of Examiners of the Royal College of Surgeons, it may be interesting to the numerous friends and pupils of the new Examiner to state the numbers polled on the occasion; they were—For Mr. Smith, 11; Mr. Birkett, 5; and Mr. Holmes, who was only nominated at the last moment, 1. So, as the *Lancet* naively observes, "Mr. Smith was elected by a majority."

BONES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Could you or any of your readers inform me of a method of cleaning and whitening bones. I am, &c., STUDENS.
March 7.

. Quicklime and macerating in hot water.

Only a Doctor.—Everyone will concur in the sentiments expressed; but we suspect that if we were to publish such a note, the person chiefly interested would say, "Save me from my friends." Nothing injures a man so much as the holding him up as a "martyr," or insisting upon it that he is much injured. Pity is nearly allied to contempt—*Principibus placuisse viris haud minima laus est*; but the reverse is not necessarily a disgrace. Every tub must be left to stand on its own bottom.

Chelmsford.—Complaints have reached us of the manner in which the appointment of Medical Officer of Health to this town was made. It is said that long before an advertisement appeared stating that an election would take place, canvassing had been resorted to by one gentleman, at least, in the most persevering and unblushing manner. The appointment was, it is stated, made before any public announcement appeared respecting the office. It is moreover complained that the recipient of office and his partner already held seven public appointments, which are, it is considered, made subjects of party warfare.

POISONING MADE EASY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As a fitting pendant to my letter, headed as above, which appeared in your issue of February 24, I send the following extract from last Saturday's *Times*. The sale of strychnine-poisoned grain has very properly been put a stop to; and if you, Sir, or some gentleman of influence in the Medical world, were to take the matter in hand, the sale of strychnine poisoned powder would likewise be prohibited.

I am, &c., THOMAS W. SALTER, F.C.S.

St. John's Cottage, New Wandsworth, S.W., March 11.

"INQUEST.—Yesterday evening an inquest was held at the Board-room, Mount-street, Grosvenor-square, on the body of Charles Thompson, aged 39, who committed suicide by taking vermin powder, at No. 26, Robert-

street, under the following circumstances:—The deceased lodged at the above address, and at half-past eight Mrs. Godley, the landlady, took up a letter, which she pushed under the door. Within an hour after he called out for assistance, and asked for a Doctor. He said he had taken some vermin-killer, and before Medical aid could be procured life was extinct. Dr. W. Bloxam said the cause of death was poisoning by strychnia. Evidence was then given showing that deceased had lost money at the Stockton steeple races, that he was worried to death about three illegitimate children, also that he was interested in the Tichborne bonds, and it is supposed that the letter given to him contained information of the foreman's intimation on the previous day, the effect of which caused him to commit the act. Verdict, 'Suicide while in an unsound mind, brought on by an accumulation of misfortunes.'"

The *London Students' Gazette* is the name of a new monthly periodical issued under the direction of Mr. Barton Smith, of St. George's Hospital.

It is not exclusively Medical, but intended as a medium of communication with the students of all the arts and sciences who find in London more of a *habitat* than a home. It is intended to mitigate some of the evils attendant on the London University system, as distinguished from those of Oxford, Cambridge, and Edinburgh—especially the isolation and want of *esprit de corps*, the want of means whereby men may know each other, and the spirit of *cram* by which the London University is unhappily distinguished.

"Scattered over our vast metropolis lie Colleges and Medical Schools in every direction, attended by young men who scarce know an individual in their lecture-room, and who leave their education to branch off into the various professions, utterly forgetful of the institution to which they owe their knowledge and livelihood, and without that pride in it which distinguishes and elevates our contemporaries of Oxford and Cambridge. . . . To members of the University of London we have a particular motive in addressing ourselves: from all parts of England, their 'academical' residences situate in almost every street of London—their thoughts concentrated upon two lists, the synopsis of subjects and the divisional table of graduates—they provide themselves with fodder and intellectual 'Thorley's food' to be periodically slaughtered or adorned with ribbons at the pleasure of a Senate and Board of Examiners, with regard to whose names, far less acquirements, they are totally ignorant or very slightly enlightened. It is a subject of regret that so many hard-working men should be reduced to cadaverous complexions and longitudinal dimensions, deceived by the specious motto '*Cuncti adsint*,' when a more intelligent curriculum, a more effective union, and a more thorough solicitude for their welfare would make them 'healthy, wealthy, and wise'—more charitable, courteous, and friendly one with the other, and prouder of their University or Alma Mater than of their degrees, as at present."

The object of the publication is good, and if it can induce students to be more social, more practical, less of bookworms, and more inclined to look on degrees and academical distinctions as means than as ends, it will do great good. Some of the articles need more careful revision.

THE INCOME-TAX GRIEVANCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you be good enough to state what deductions are usually considered allowable in making a return for income-tax under Schedule D; or, in other words, from profits arising from the Profession of Medicine, Surgery, etc.? I have always acted in accordance with the directions published in your journal some years ago—viz., "State the gross annual amount actually received for Professional services, then deduct two-thirds of rent of house, if part thereof be used as a surgery, etc., the salary and board of assistant or assistants, the board and wages of groom, expense of horse or horses and carriage, if used solely for Professional purposes, and the amount paid for drugs, phials, instruments, etc.; the remainder is liable to the tax"—and have had no reason to complain before last month, when the demand made upon me included a surcharge upon the sum I had returned of £125. Upon my asking for an explanation from the district surveyor of taxes, I was interrogated as to what deductions I had made, and was curtly informed that I might appeal if I chose, but that the Commissioners of Income-tax would not allow deductions in the proportions I had set down.

Well may Mr. Morley, M.P., in the late deputation to the Chancellor of the Exchequer, have said "the tax had been made intolerable during the past two years, and unless the right hon. gentleman exercised his ingenuity to discover some mode of making those under Schedule D pay by a process less offensive, he might depend upon it that there would be no rest for him."

It is generally thought that the collector, or surveyor, or assessor, or whoever the official or officials may be that determine the assessment, receive a commission on surcharges, and hence there is no difficulty in believing how such a conclusion may be arrived at as that A must have a larger Professional income than that represented by the sum returned by him, in order to account for his living in the style he is known to do.

But I need not say there may be, and often is, a great source of fallacy in this argument, inasmuch as A may have a private income from which the tax is deducted before he receives a farthing of it.

I suppose there are but few members of our Profession who would not rather pay the surcharge than go through the ordeal of appealing, which implies waste of time and much vexation of spirit; but I would suggest that, if the income-tax is to be continued, authoritative directions in full should be issued as to the mode of filling up the return for assessment. I think this is needed, because several of my brethren to whom I have mentioned the subject make no return, but allow themselves to be assessed by the Commissioners, and probably they are assessed under these circumstances at a sum lower than they could conscientiously furnish if they made a return. I am, &c., UNJUSTLY SURCHARGED.

. The only way is to appeal, and show the Commissioners that the deductions are fair. But we concur in our correspondent's demand for fuller directions. With a Poor-law, with trades unions and strikes, and with the notorious improvidence of the working-classes, Schedule D is felt to be a most unjust impost.

Kelly's London Medical Guide—Report of the Rotunda Lying-in Hospital—Madras Monthly Journal, February—La Régénération du Cristallin chez quelques Mammifères, par le Dr. Benjamin Milliot—Agricultural Returns of Great Britain—A Plea for Scientific Reform—L'Extraction des Projectiles, par le Dr. Benjamin Milliot—Twenty-first Report of the Wilts County Asylum—Simpson's Diseases of Women.

PERIODICALS AND NEWSPAPERS RECEIVED—

Medical Press—Nature—Wolverhampton Chronicle—Pharmaceutical Journal—Chelmsford Chronicle—The Clinic, February 24—Gazette des Hôpitaux—The Medical Investigator—United Service Gazette—Dark Blue—Birmingham Morning News, March 13.

APPOINTMENTS FOR THE WEEK.

March 16. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. Dr. A. W. Barclay will introduce Mr. Stansfeld's Public Health Bill for discussion, and will make some remarks on the principal clauses. Mr. F. W. LOWNDES (Liverpool), "On the Criminal Deaths of Infants, as shown by the Records of the Coroner's Court at Liverpool."

ROYAL INSTITUTION, 3 p.m. Mr. Moncreu D. Conway, "On Demonology."

18. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting. MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. W. B. Dalby, F.R.C.S., "On a Case of Temporary and Extensive Loss of Hearing thought to depend on Constitutional Syphilis." After which the Adjourned Discussion on the "Treatment of Aneurism" will be continued.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

19. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Mr. Sebastian Wilkinson, "Congenital Extension of the Conjunctiva over the front of both Eyes (a living subject)." Mr. Jonathan Hutchinson, "A Meningocele Cyst removed by Operation;" "Specimens of Dislocation and Fracture of the Vertebrae;" "Specimens from a Case of Chronic Rheumatic Arthritis." Mr. Durham, "Hydatid Tumour of the Thigh." Mr. W. Anderson, "Recurrent Tumour of the Breast;" "Hernia of the Liver." Dr. Whiphham, "Tumours of the Kidney." Mr. Arnott, "Enlargement of the Tongue." Dr. King, "Malformation of the Heart." Mr. Thomas Smith, "Aneurism of the Sinuses of Valsalva, Clubbed Fingers." Dr. Thorowgood, "Stricture of the Oesophagus."

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

20. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Lumleian Lectures—Dr. Quain "On Diseases of the Muscular Walls of the Heart."

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

SOCIETY OF ARTS, 8 p.m. Meeting.

21. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Mr. F. J. Gant, "On Impacted Fracture of the Neck of the Femur: its Diagnosis and Treatment."

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

22. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. Southey, "On Two Cases of Persistent Omphalo-mesenteric Duct leading to Fatal Intestinal Obstruction." Mr. Teevan, "On the Treatment adopted in Four Cases of Impermeable Stricture." Mr. Gant, "Spontaneous Gangrene of both Feet from Disease of the Heart—Amputation, Recovery, etc." Dr. Broadbent, "Case of Paralysis due to Tumours in Pons and Medulla Oblongata."

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Meeting. ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Lumleian Lectures—Dr. Quain, "On Diseases of the Muscular Walls of the Heart." ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 p.m. Prof. Flower's Lecture "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata." ROYAL INSTITUTION, 9 p.m. Mr. J. Norman Lockyer, "F.R.S., M.R.I., "On the Results of the last Eclipse Expedition."

VITAL STATISTICS OF LONDON.

Week ending Saturday, March 9, 1872.

BIRTHS.

Births of Boys, 1309; Girls, 1259; Total, 2568. Average of 10 corresponding weeks, 1862-71, 2174.0.

DEATHS.

PART VI.

Pleurisy, a local inflammation producing its effects by its effusion, liquid and solid: Varieties: Serous: Empyema: Euplastic, Cacoplastic, and Aplastic Lymph—Treatment of Pleurisy—When, why, and how the chest should be tapped—Cases requiring operation—Successful cases without operation.

PLEURISY has by no means the same relations to the blood which I have pointed out to exist in pneumonia. Pneumonia is essentially a blood disease, although attacking a particular organ. Pleurisy is essentially a local disease; and its relations to the blood are incidental on the extent of the inflammation and the amount and quality of the effusion which it produces. We may further trace out the evils and dangers of pleurisy in connexion with these results under four heads:—

(1) The quantity of the liquid effusion, (2) its quality; (3) the quantity of the solid effusion, (4) its quality.

When the quantity of liquid effusion is moderate, it is remarkable how little inconvenience it causes. After the pain (if any be present) subsides, which it commonly does in a few hours, or in a day or two, the patient often thinks himself well, till he finds on exertion his breath shorter than usual. Thus it frequently happens that the existence of the effusion is not discovered until long after it has taken place. Its easy detection by auscultation constituted one of the earliest and most striking triumphs of that mode of examination. (a) But if the effusion is very copious and rapid, the functional disturbance may be very great, in consequence of the extent to which the lungs, heart, adjacent organs, and chest-walls are pressed on and displaced. The symptoms are those of oppressed and restricted breathing, quickened, partially impeded, and weakened circulation, and deficient and depraved secretion; and, if these are not soon relieved, they may end in suffocation or exhaustion. Fortunately, in a large proportion of cases, medicinal treatment does bring relief; so that fatal cases of pleurisy with serous effusion are rare, and it is not often necessary to resort to the operation of tapping the chest.

The case is quite different when the effusion into the pleura is either purulent at first or is so charged with protein matter that it becomes purulent in the course of the malady. Pus, when once formed, is rarely dispersed or largely absorbed; and it remains in the pleural sac, not only oppressing and displacing organs by its bulk, as serum does, but also doing mischief, both by its solvent and irritative operation, exciting suppurative inflammation in adjoining parts, and tending to find vent through them, and also by its influence on the system through its partial absorption, causing irritative fever and other concomitants of pyæmia.

(a) Note added in 1872.—I take this opportunity to remark that some of the most recent writers on pleurisy seem neither to appreciate nor to understand the nature and value of the physical signs of pleurisy, which were nevertheless sufficiently explained and defined more than thirty years ago. In my lectures on "The Physiology and Diseases of the Chest," published in the *Medical Gazette* in 1833; in the article "Pleurisy" in the "Library of Medicine," vol. iii., 1840; and in the last edition of my "Pathology and Diseases of the Chest," 1840, (now long out of print), the physical signs previously known were carefully considered, and new ones described with a precision that removed much perplexity from the subject, and made the diagnosis of pleurisy, with all its results, sufficiently plain to anyone who would take the trouble to master it. Although so many years have elapsed since the date of those publications, I have met with nothing in my own longer experience, or in the writings of others, to invalidate the statements there made. There may be found the first complete description of the varieties and signs of partial effusions in the pleura; the true nature and significance of ægophony; and the first announcement of tracheal and tubular sounds on percussion, the discovery of which Trousseau and others ascribe to Skoda, whose pretensions to it are of a much more modern date. My acoustic explanations of the noisy bronchophony and loud amphoric breath sounds of pneumonia are quite different from those of Professor Skoda. They were annually given in my lectures in University College before 1850; but as I hardly published anything on diseases of the chest for twenty years after, I do not think that they appeared in print until I mentioned the subject in a note in the chapter on physical signs in our recent work on "Pulmonary Consumption," p. 171.

It is very obvious, therefore, that the purulent quality of the effusion in the pleura increases greatly the gravity of the case, so that failures or imperfect recoveries are likely to occur if early relief be not given by tapping the chest. It is quite true that recoveries do take place, especially in young subjects, without any operation, by the matter making its way through the lung into the bronchial tubes, or outwardly through the walls of the chest; but in the first case there is great distress from the violent prolonged cough and expectoration, which must harass the patient for a long time, and cause much risk of permanent disease of the lungs; and in the latter case the matter often burrows in the walls of the chest, doing them more or less injury, before it is discharged through the surface. I have known several cases of empyema complicated with caries of the ribs; and in a few of these it has been difficult to say whether the caries was the sequel or the cause of the empyema; but in some it was clearly the former, and, by long maintaining an offensive wound in the chest-walls, materially retarded the local and general improvement.

In different cases of empyema there is some variety as to the quantity and quality of the pus formed. In some cases the quantity is large and continually increasing, so as to cause much pressure, displacement, and oppression in a short time, and if it does not speedily make its own way out, leaves no alternative between an operation and a fatal result. In other instances the matter is more slowly formed, with much less pressure and displacement, giving time for deliberation and hope that the effusion may be simply serous, until after the lapse of several weeks the frequent pulse and hectic symptoms, perhaps with some local signs of pointing in the walls of the chest, give evidence of its purulent nature. Again, in some cases the matter is inodorous—"laudable"—not differing from that of healthy abscesses; in others it is highly offensive, with the rotten-egg or sulphuretted-hydrogen stench characteristic of decomposed pus, quite distinct from that of fetid abscess which I have before described. Sometimes this fetor seems to be caused by diseased bone, but it certainly occurs also independently of that cause. I have known it in several instances follow the operation for empyema, where the admission of air was not prevented; but I can also recall several cases where no fetor ensued, although air was admitted. This offensive character of the matter must be regarded as unfavourable, both as implying its instability or proneness to decomposition, and also because the sulphuretted hydrogen evolved is deleterious in its influence on the animal economy. Nevertheless patients do sometimes recover, both where the matter originally discharged was offensive, and where it became so after the operation.

I have mentioned varieties in the quantity and quality of the solid effusion as tending also to affect the results of pleurisy, favourably or otherwise. When the lymph thrown out is in moderate quantity and of good quality (*euplastic*, as I term it), it is either absorbed, or forms soft, flexible, membranous adhesions between the pleuræ, which little, if at all, interfere with the movements of the lungs. This is a favourable result. But when the fibrinous exudation is very abundant (I recollect a case in which it was from half an inch to an inch thick on the inflamed pleura), it can neither be reabsorbed nor can it be so highly organised: it has more or less of the *cacoplastic* or contractile character, shrinking and becoming dense as it is organised—and, binding down the lung and drawing in the walls of the chest, causes those permanent contractions which are the sequels of severe pleurisy. Again, in highly scrofulous subjects we may have the inflammatory lymph entirely *aplasic*—thrown out in a curdy mass, devoid of all organisability, and yet in such abundance as nearly to fill the pleura. I remember the case of a boy aged 10, whom I saw twenty years ago, who was attacked with right pleurisy, and lingered for several months without any return of resonance or respiration on the affected side. After death the pleural sac was found full of soft, solid cheesy matter, not at all purulent, the lung being partly compressed, as is usual in pleurisy, and in other parts in a state of caseous consolidation.

The treatment which is successful in a large proportion of cases of acute pleurisy is chiefly antiphlogistic, and more local than in pneumonia. Venesection is required only in the plethoric and robust, and then only in the earliest stage of the sthenic form; but leeches or cupping may be used with advantage so long as there is pain with increased temperature. In very many cases there is little or no heat of skin; and in these I prefer a large blister at once, keeping it on not more than six or eight hours, and following it with a large poultice covered with oiled silk. This promotes the discharge from the blistered surface, and, acting as a comfortable

fomentation on the side, may well be continued till the parts are ready for further blistering, should it be required. Of internal medicines, mercurial and saline diuretics are the best for the early stage of the inflammation. If there be severe pain, I give a few doses of calomel combined with morphia, till the pain is relieved, and then substitute small doses of blue pill, with squill and digitalis, two or three times a day, until an effect is produced on the bowels, kidneys, or gums. Salivation is by no means necessary or desirable, the best operation of mercury being on the liver and kidneys; and when these are brought to act freely, the effusion, if serous, generally is stayed, and will diminish—quickly in some cases, and very slowly in others—without any further active treatment. Saline diuretics of citrate and nitrate, or acetate, of potash are useful in most cases. In mild forms of the disease mercury is not necessary; blisters and saline diuretics are sufficient, and may soon be changed for iodide of potassium in a bitter infusion, with daily painting the affected side with tincture of iodine. But sometimes we meet with cases of extensive pleuritic effusion, which, either from original intensity or from not having been treated soon enough, will not yield to any or all of these remedies; and whenever the effusion is so much as to cause such distress in breathing as to interfere with the comfort of the patient, and especially to prevent sleep, there should be no delay in puncturing the chest. We may be more confirmed in recommending this treatment if the symptoms render it probable that the effusion is purulent, and we may often guess this to be the case when there is general pallor, with partial hectic flush, alternations of chills and sweats, very frequent pulse, much weakness and tremulousness of movement, and more than usual tenderness and puffy feeling of the walls of the affected side.

I must admit, however, that I have noticed tenderness and even swelling of the integuments of the walls of the chest in some cases which yielded to treatment without tapping, and probably were not purulent. Still the symptom is suspicious, and, if in conjunction with others above-mentioned, may be taken in favour of the effusion being purulent. In doubtful cases the grooved needle may be used to settle the point, if there be any question about the propriety of operating; but I would repeat that when there is great and continued oppression—such as to prevent sleep—I think the operation should be performed, whether the effusion is purulent or serous only. In case of serous effusion, tapping to the removal of two or three pints may be enough to relieve the oppression; the respiration and circulation being thus set free, the rest will probably be absorbed. But in cases of empyema it is desirable to evacuate more matter, and we may require repeated operations. As it is impossible to evacuate all the matter, a long time is required for the lung to re-expand, and for the pyogenic membrane to become covered with lymph, which obliterates the cavity by the adhesion of the pleural surfaces.

I do not propose to dwell on the details of the operation of tapping the chest, but I must remark that my experience is in favour of avoiding the admission of air if possible. I know that cases have done well where no attempt was made to exclude the air; but these were healthy subjects, in whom the matter resists decomposition, and whose constitution supplies a healing power in spite of difficulties. On the other hand, I have seen several instances in which serous effusion has become purulent, and purulent matter has become fetid, with the evolution of sulphuretted hydrogen, so shortly after the admission of air, that it was impossible to doubt the injurious influence of the air in those cases at least. In young subjects the walls of the chest are somewhat compressible, and by pressure steadily applied whilst the fluid is flowing, and continued till the puncture is closed, it is quite possible to prevent the admission of air without any special apparatus for this purpose. In older patients, in whom the chest is more rigid, this is less practicable; and of the various contrivances to prevent the admission of air in such cases, the simplest and most effectual is the attachment to the canula of the trocar of a few inches of a perfectly flaccid tube, such as rabbit's intestine, or soft, thin indiarubber, which permits the liquid to flow downwards freely, but, collapsing as the current flags, effectually prevents any air from passing upwards. (b)

The treatment after the operation, as well as for all the more chronic forms of pleurisy, should be of a sustaining and corroborative kind. The solid products of inflammation are the more mischievous in proportion as they degenerate; and they are more likely to be absorbed or to form harmless adhesions

if the body is well nourished and under salubrious influences. A course of cod-liver oil with a mild tonic, a generous but not too stimulating diet, and moderate exercise in a healthy air, greatly conduce to convalescence, and may prevent many evil consequences. In cases of empyema with a permanent opening in the chest, little improvement may take place till the patient goes to a healthy country place or to the seaside; and then the discharge soon begins to diminish, and the health and strength are simultaneously improved.

On turning to my case-books to illustrate the successes and failures in the treatment of pleurisy, I find the cases successful without operation so numerous and commonplace that it would be superfluous to dwell on them. As samples, two cases will suffice—one in a young subject, the other in advanced age. (The latter and a third case—which exemplifies an imperfect success, which is not uncommon—have been added since the lectures were delivered.)

Case 1.—December 11, 1850: A young gentleman, aged 13, eight days ago, after long riding in the wet, was attacked (in the country) with sharp pain in left side, sickness, occasional fits of cough, short breath, and fever, with quick pulse and hot skin. Two days ago he was brought to town, and has been under the care of an eminent Physician, who prescribed only salines. The breathing has become worse, pulse 124, urine very scanty and high-coloured; pain less, and skin cool. Complete dulness and absence of breath and vocal vibration throughout left chest, and extending an inch to right of sternum, including dorsal spines, and pushing the heart two inches to right of sternum. Ægophony in mid regions. Breath-sound puerile on right side. Blister six inches square to left side. Blue pill, squill, and digitalis, and an effervescent saline every six hours.

14th.—Pain and breathing better; pulse 96; urine free, alkaline. Motions being loose and bilious yesterday, grey powder and Dover's powder given thrice daily instead of pills. Signs the same, except that the heart is three inches to right of sternum, and tubular voice and breath are heard in left upper front.

16th.—Breath better, but is faint from sitting up; urine alkaline. Dulness and displacements continue, but ægophony heard lower down in the back, and bronchophony within left scapula. Another blister six inches by three inches. Iodide and nitrate of potass in orange and cascarilla infusion substituted for the citrate of potass mixture. The blister rose well, and next day the gums were slightly affected. From this time the patient made a speedy and complete recovery, being convalescent in a fortnight. Examined four years after, the chest showed no signs of disease or contraction.

Case 2.—A distinguished Physician to the navy, aged 72, consulted me on November 15, 1863; subject to bronchitis in winter. Ten days ago, after exposure and chill, had sharp pain of right side, cough, short breath, restless nights, scanty urine; pulse 90, weak; respiration 30. Dulness from second rib down whole right front, and throughout side and back below spine of scapula; no breath-sound or vocal vibration; ægophony in mid-regions of side and back up to spine of scapula, where, and above second rib, bronchophony and tubular stroke-sound; heart-apex below left mammilla.

A blister six inches square to right side; blue pill, squill, and hemlock three times a day, with effervescent citrate of potass; nutritious diet, with a moderate amount of stimulants.

The kidneys soon acted freely, and the breath and restlessness were relieved. In a week another blister was applied, and iodide of potassium in a cascarilla mixture substituted for the saline and mercurial. After this the signs of effusion gradually diminished, and the health and strength were re-established in a few months under tonics, cod-liver oil, and country air. I did not see this patient after 1864, but I heard of him as pretty well in 1867, although suffering from cough. He died in 1868. This case shows that advanced age is no bar to success in the treatment of subacute pleurisy by the recommended means.

Case 3.—Master H., aged 10, June 26, 1863; previously delicate, but not ill till a fortnight ago, when he fainted at church. Since weak, with slight cough, pain in the chest, and shortness of breath, which has much increased in the last two days, and the left front of the chest is swollen. Complete dulness, without breath-movement or sound through whole of left chest and to right of sternum and dorsal spine; heart two inches to right of sternum; bronchophony above left scapula; protrusion and tenderness of intercostals about mammilla.

Citrate and nitrate of potass were prescribed, but I considered the case so urgent that I arranged with my friend, Mr. T. Tatum, the following day, to tap the chest. When he came we found the swelling and dyspnoea less, and, as the boy was

(b) Note added in 1872.—The more modern improvements in the operation introduced in the last ten years will be noticed in the next portion of the lectures.

very timid, it was agreed to postpone the operation, and try a blister in addition to the saline diuretic and a few nightly doses of blue pill. This treatment proved successful in removing the liquid effusion in three weeks, but the side contracted, and the penetration of air into the lung was imperfect. In the following August, under the constant use of cod-liver oil and tonics, with regulated exercise and diet, the lung expanded, and the youth outgrew the deformity, so that, in 1865, he was in good and active health, with little remains of the contraction. He continued well till 1867, when, at Harrow, he had another attack of inflammation of the left chest, which has recurred since repeatedly, and has induced chronic phthisis. He is still living, but in an invalid state.

(To be continued.)

LECTURES ON THE COMPARATIVE ANATOMY OF THE ORGANS OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE III.

THE *Simiida*, or anthropomorphous apes, constitute a natural group, composed of the gorilla, the chimpanzee, the orangutan, and the several species of gibbons, or long-armed apes. The question which is the most *anthropoid*—and, therefore, should be placed first in the list—has provoked much discussion among naturalists, the fact being that in certain points of structure one of them, and in other points another, may approach most nearly to the highest grade of organisation; but a review of the *toute ensemble* of their characters has led to the prevailing idea that the gorilla is the nearest, while the gibbons are the most remote from this grade. It must be remarked, however, that this conclusion has been arrived at with only a very imperfect knowledge of the anatomy of the first-named animal.

All naturalists who have had an opportunity of observing the three first-mentioned members of this group in a state of nature agree in assigning to them a strictly vegetarian diet, consisting chiefly of fruits, seeds, or succulent shoots and young leaves. It is possible, however, that the gibbons (whose habits when wild are very little known) may occasionally eat insects, or even small vertebrate animals, as a tame one has been observed to seize and devour a lizard.

Genus *Troglodytes* (Geoff. St. Hilaire).—*The Chimpanzee*.—It is still uncertain whether the considerable variations observed between different specimens indicate several distinct species, or whether all chimpanzees should be included under the one specific name of *Troglodytes niger*.

The large number of specimens which have been brought to Europe alive have afforded anatomists abundant opportunity of becoming thoroughly acquainted with the anatomy of this species; but, unfortunately, they have mostly been immature animals, and the bones, the muscles, and the brain have been more fully described than the organs which especially form the subject of this course. The chief peculiarities of these have, however, been more or less fully recorded in three excellent memoirs on the anatomy of the animal—those of Tyson, Vrolik, and Gratiolet and Alix.^(a) It is partly from these, but chiefly from original dissections and examination of specimens in the Museum, that the following account is drawn up.

The aperture of the mouth is wide, extending as far back (at least, in a young animal with the milk dentition) as behind the upper canine on each side.^(b)

The lips are large and extensible. The under lip especially is capable of being protruded forwards, assuming a spoon-like form when the animal is feeding. When the mouth is shut they meet by flat edges, and none of the mucous surface appears externally, as in man, the outer skin of the upper and

(a) Tyson—"Orang-outang, sive Homo Sylvestris; or, the Anatomy of a Pygmic, compared with that of a Monkey, an Ape, and a Man;" London; 1699. Vrolik—"Recherches d'Anatomie comparée sur le Chimpanzé;" 1841. Gratiolet and Alix—"Recherches sur l'Anatomie du *Troglodytes aubryi*" (*Nouvelles Archives du Muséum*, tome 2me); 1866. To these must be added the "Observations on the Anatomy of the Orang-outang," by Dr. Traill (*Mem. Werner Soc.*, 1817, vol. iii., p. 1), the animal described being really a chimpanzee from the Gaboon.

(b) In the adult specimen described by Gratiolet, "behind the second molar" (premolar?).

under lips, covered with scattered short hairs, coming into apposition. The frænum connecting the inner surface of the upper lip with the gum is but slightly marked, and is quite absent in the lower lip, a circumstance which aids in its extensibility.

The mucous membrane covering the gums is reflected back on to the lining of the cheeks, immediately behind the posterior molar teeth; and, though the cheeks are tolerably full, there are no distinct "cheek-pouches," such as we shall see developed in the inferior monkeys. The lining membrane of the lips and cheeks is smooth and soft.

The buccal cavity is nearly twice as long as broad. The palate very little arched, especially in its anterior part, which is marked by irregular transverse ridges. The isthmus of the fauces is extremely contracted compared with that of man.

The soft palate terminates in a distinct uvula, more pointed than in man, and the free border and apex of which, as remarked by Gratiolet, is formed by a very thin membranous border, which extends considerably beyond the thick tissues, which form, as it were, the nucleus of the uvula. The pillars of the fauces and the tonsils are developed much as in man.

The tongue is longer and narrower proportionally than the human tongue, its length being double its breadth, and the lateral borders are nearly parallel for the greater part of their extent. It becomes slightly broader anteriorly than behind, and is obtusely rounded in front. The anterior free portion is flat, with thin edges; posteriorly, the dorsal surface is more rounded, and the edges are thick, and it becomes much compressed from side to side as it approaches the isthmus of the fauces. About one-fourth of the whole length of the tongue projects beyond the frænum. Posteriorly, the median fold of mucous membrane connecting the dorsum of the tongue with the epiglottis is very little marked. The papillæ are much like those of the human tongue, the fungiform being scattered among the filiform in much the same proportion. The circumvallate papillæ offer some peculiarities. Huxley(c) compares their arrangement to a letter T with the top turned forwards, Gratiolet to a Y. I find that they vary considerably in different individuals, but that there is always a large one on each side, a little way in front of the junction of the anterior pillar of the fauces with the tongue, representing the anterior pair in the V-shaped set in man, two or three smaller ones in a transverse line between them, and two or three more in the median line behind these. If the transverse line is, as usual, quite straight the inverted T is the result; if, as sometimes happens, the middle papillæ of this line stand behind the others, the form is more like the Y. The usual number of the circumvallate papillæ is seven. The posterior part of the tongue, where it approaches the epiglottis, is beset with large conical soft papillæ, which are wanting in the human tongue. The vertical ridges, with deep depressions between, on the lateral edges of the tongue just in front of the palato-glossal fold, which are indicated in man, are in the chimpanzee very strongly marked. On the free under surface of the anterior portion of the tongue a pair of narrow projecting ridges or laminae of mucous membrane, with a free wavy or crenated edge directed outwards, pass on each side of the frænum from close to the apex, backwards and outwards, for rather more than a fourth of the length of the entire organ, becoming gradually less conspicuous. As previously mentioned, similar folds exist in the corresponding situation in the human tongue, though not commonly described in anatomical text-books. The length of the tongue of an adult male chimpanzee, sent to the Museum in spirit from the West Coast of Africa by Captain Burton, from the epiglottis to the apex is 4.4 inches; the greatest breadth is 1.8 inch; the breadth between the palato-glossal folds is 1.1 inch. This tongue has probably contracted somewhat from the action of the spirit. The corresponding dimensions of a human tongue are 3.4, 2.1, and 1.8 inches. The frænum is long and loose, and on the lower part of its anterior edge are a pair of soft, pointed, conical, nipple-like projections, distinct from each other, and placed one on each side of the middle line, about one-tenth of an inch long, on the summits of which are the orifices of the submaxillary ducts.

The salivary glands and ducts are generally arranged as in man, but Gratiolet notices a greater relative development of the parotid.

Abdominal Digestive Organs.—The great omentum is broad, and in a young specimen in which I examined this point, was connected, much as in man, by its posterior layer with the whole of the transverse colon.

The stomach is large, in form much like that of man

but the lesser curvature is rather shorter compared with the greater. The pyloric portion is more elongated, recurved upon the lesser curvature, and more distinctly marked off by a constriction from the rest of the cavity.

Tyson remarks that "The convolutions and windings of the small guts in our pygmy, and their situation, were much the same as in a man." He found the small intestine, from the pylorus to the colon, measured nine feet ten inches, and the colon and rectum three feet five inches, "so that the length of the guts here in proportion to the length of the body is much the same as 'tis in a man," though the colon "he thought proportionally longer." Gratiolet gives six metres eighty centimetres as the length of the small intestines, and about three metres as that of the large intestine—measurements which give a much larger proportion for the latter than those of Tyson.

Vrolik says, "The small intestines of the chimpanzee have the same situation as in man; the valvulæ conniventes and the villous tunic are found in them as in man." Other observers have not found any trace of valvulæ conniventes, and Gratiolet and Alix, in their dissection of a nearly adult specimen, expressly mention that, "Nous avons vérifié l'absence de valvules conniventes et la grande finesse des villosités."

The colon is very voluminous, and greatly sacculated by three strongly marked longitudinal bands, arranged as in man. It commences by a large conical cæcum about three inches long, terminating in a slender vermiform appendix of five inches in length in two young specimens I examined, but even longer in the adult. Its thickness is rather less than that of a goose-quill. The passage from the cæcum to the appendix is not quite so abrupt as it usually is in man, the latter opening into the former by a slightly funnel-shaped orifice; but there is great variation in this respect in different individuals of both species. The muscular bands of the colon can be distinctly traced to the commencement of the appendix. It is placed much as in man, though not quite so near the ileo-cæcal valve, thus representing the condition met with in man before it has fully undergone its characteristic alteration of form; but there appears to be considerable variation in its exact position, as well as in its length.

FIG. 6.

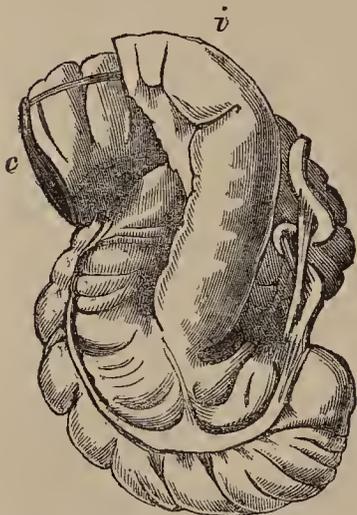

FIG. 6.—The cæcum and commencement of the colon of a young chimpanzee: *i* ileum, *c* colon.

The liver appears to be smaller in proportion to the size of the animal than in man. It is compact and solid in form, and thick from before backwards, especially the right lobe. The upper surface much resembles that of man, the only indication of division being the well-marked umbilical notch and the attachment of the suspensory ligament, marking the separation between the very unequal right and left segments, the former being about double the latter in transverse extent.

On the under surface (Fig. 7), the umbilical fissure, *u*, is bridged over in the middle part of its course in two specimens examined, though to a different extent. The fissure of the ductus venosus is distinct, and the fissure of the vena cava is covered over by hepatic substance connecting the posterior margin of the right lobe with the Spigelian lobe in one example, while in the other the vein lies superficially.

There are no traces of lateral fissures subdividing the

(d) Gratiolet's figure (Pl. ix., Fig. 6) shows a far more terminal (and therefore less human) position of the appendix than in either of the two specimens of chimpanzees dissected by myself.

right and left segments or lobes. The Spigelian lobe, *s*, is prominent, with a rounded projection overhanging the portal fissure; but what chiefly distinguishes the liver from that of man is the development of the ridge, which in him represents the caudate lobe, into a distinct pyramidal—or, rather, triangular—pointed body, *c*, connected at its base with the Spigelian lobe, but separated by a fissure for nearly the whole of its

FIG. 7.

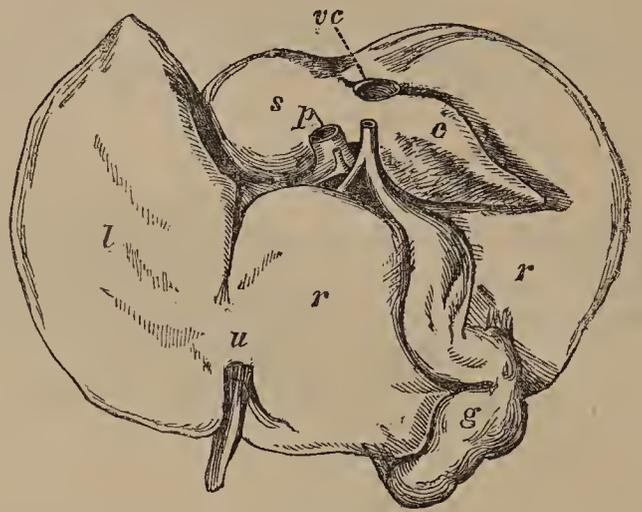

FIG. 7.—Under surface of the liver of a chimpanzee: *r* right lobe, *l* left lobe, *s* Spigelian lobe, *c* caudate lobe, *u* umbilical fissure, *p* portal vein, *vc* vena cava, *g* gall-bladder.

length from the under surface of the right lobe. Its apex reaches to more than half-way from the right end of the portal fissure to the right margin of the liver. This form of caudate lobe was found in both the specimens examined by me, but is not specially mentioned by Gratiolet and Alix, who show that they have not particularly studied the essential characters of the hepatic organ in mammals, when they remark that "this liver, as well by its form as by its size, bears more resemblance to the liver of those ruminants which have a gall-bladder than to the liver of man, of which the size is in relation to his, at least, semi-carnivorous instincts."

The gall-bladder, as noticed by Tyson, Vrolik, and Gratiolet, is very long, narrow, and loosely connected with the liver, beyond the margin of which it projects; and, as Tyson remarks, "when inflated with wind, seemed more to represent an intestine, by its anfractus and length, than the usual shape of the bladder of gall, which commonly is more belying out."

The Gorilla.—Notwithstanding all the interest which has been taken of late years in this huge African anthropoid, and the elaborate care with which the external characters, the bones, (e) and the muscles (f) have been described, its visceral anatomy is at present almost entirely unknown.

Except a slight allusion to the liver by M. Broca, the only notice of the structure of the abdominal digestive organs yet recorded is the following, from the abstracts of Professor Huxley's lectures delivered in this theatre in 1864 (g):—"The stomach is of the same form as in man, and the cæcum very large, and provided with a long vermiform appendix. The liver, in the only specimen examined, departs remarkably from the human type, inasmuch as both right and left lobes are subdivided by deep fissures." This description was taken from specimens in the stores of this Museum, and which, though in a very mutilated and partially decomposed condition, still afford the opportunity of adding some further details.

Duvernoy has figured and described the tongue and some other parts of the mouth. The caliciform papillæ are few, and present no regularity in their disposition. There was one large one on the left side at the base of the tongue, a large and a small one at the right side opposite to this, and four more behind, situated irregularly, and still smaller. The parotid glands are of large size, the submaxillary relatively small.

The stomach does not appear remarkably large, compared with the bulk of the animal. In its empty state, when laid flat on a dish, its greatest diameter is twelve inches and a half; its height, from the oesophageal orifice to the opposite point on the great curvature, seven inches. The lesser curvature measured six inches and a half, the great curvature thirty-one inches. The only apparent difference in form from that of the human

(g) *Medical Times and Gazette*, May 21, 1864, page 564.

stomach is caused by the great development of a constriction two inches and a half from the pylorus, marking off a "pyloric antrum," which is more elongated and bent back on the lesser curvature than the corresponding part usually is in man. The walls are thick and muscular. The mucous membrane is very loose and smooth in the cardiac portion; it is thrown into rugæ, most of which have a more or less longitudinal direction in the smaller or left end, as far as the constriction which marks the pyloric portion, which is chiefly formed by a strong crescentic ridge on the upper and posterior wall. Between this and the pylorus the mucous coat is smooth, very thick, and adheres closely to the muscular tunic, but all the coats are here thrown in several longitudinal folds. The pylorus is a circular aperture which will just admit the thumb.

Neither the duodenum nor any part of the small intestines show any traces of valvæ conniventes, though the mucous surface is richly covered with villi. The length of the small intestines measured twenty-eight feet; but, as they had been divided into several portions before I examined them, it is possible, though not probable, that this might not have included the whole.

The large intestines are of great capacity, and, including the cæcum, eight feet and a half in length; so that the proportions of these viscera are much the same as in man. The walls of the first portion of the colon measure, when laid open, fifteen inches across. They are greatly sacculated, the usual three longitudinal muscular bands being strongly developed. In the cæcum and first portion of the colon, as far as a strong constricting band, extending all round the intestine, one foot from the apex of the cæcum, the mucous membrane is remarkably corrugated, being everywhere raised in ridges, which have a great tendency to form circles, from a quarter to a third of an inch in diameter, giving a general "pock-pitted" appearance to the whole surface. I have not observed a similar disposition in any of the allied animals. Unfortunately the cæcum is so mutilated that its true size or form cannot be determined, but the vermiform appendix remains attached to it, eight inches and a half in length, and of uniform thickness, about that of the barrel of a swanquill. It opens into the side of the cæcum by a small valvular orifice.

The liver is rather small for the size of the animal. After being a long time in spirit it weighed three pounds and a half. When lying on a flat surface it measures from side to side twelve inches, from before backwards six inches. The upper surface has a very large triangular space devoid of peritoneum, having been attached to the diaphragm. The suspensory ligament passes from this surface to the umbilical fissure, which is a well-marked notch on the free border, nearly an inch in depth, placed only one inch to the right of the middle line, so that the right and left segments are more nearly equal to one another than in man or the other anthropoid apes. The borders of the liver generally are very thin, especially the upper edge of the left lateral lobe.

FIG. 8.

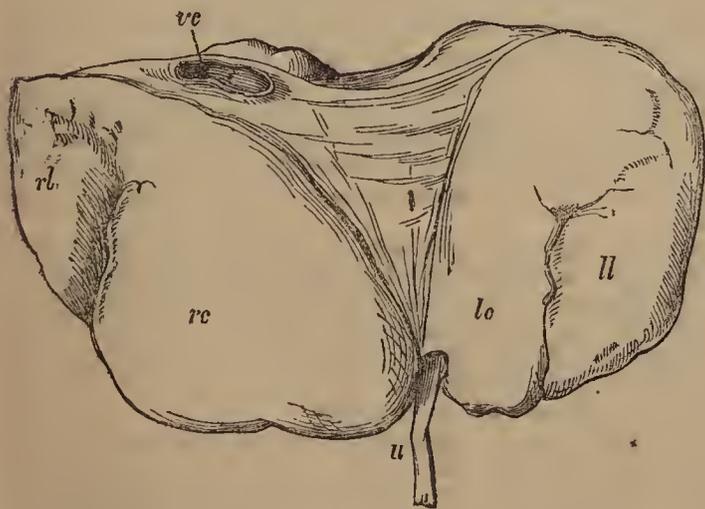

FIG. 8.—Upper surface of liver of adult gorilla: *u* round ligament, *vc* vena cava, *rl* right lateral lobe, *rc* right central lobe, *lc* left central lobe, *ll* left lateral lobe.

The left segment is divided into two distinct lobes by a cleft extending from the anterior more than half way to the posterior border. Of these the lateral, *ll*, is much the largest, and is triangular in shape. On the upper surface it is overlapped by the left central.

Similarly the right segment is divided into two lobes by a

deep fissure; but of these the central, *rc*, is very much the largest, and of quadrate form, the lateral, *rl*, being small and triangular, and overlapped above by the central.

On the under surface the portal fissure is placed very near the posterior border, and is three inches in width. The duct, artery, and vein have their usual arrangement on entering it. The right and left fissures almost reach to its two extremities. The umbilical fissure extends for nearly two inches from the anterior border; thence to the portal fissure the round ligament is buried beneath the hepatic substance joining the right and left central lobes.

FIG. 9.

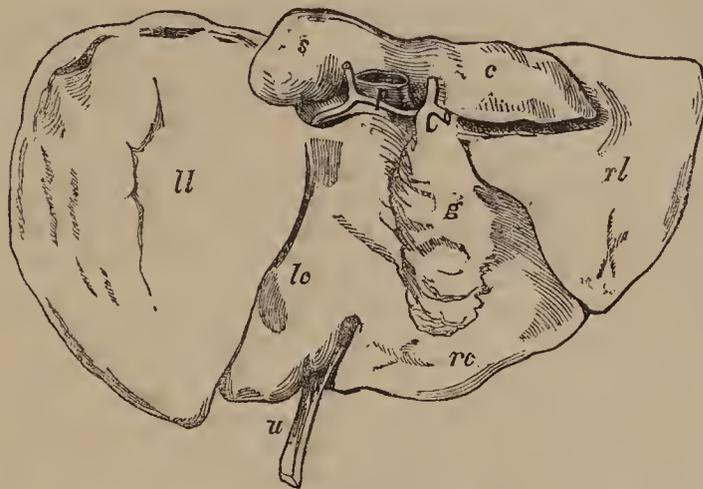

FIG. 9.—Under surface of the liver of the same gorilla: *u* round ligament, *p* portal fissure, *g* place from which the gall-bladder had been removed, *ll* left lateral lobe, *lc* left central lobe, *rc* right central lobe, *rl* right lateral lobe, *s* Spigelian lobe, *c* caudate lobe.

The Spigelian lobe is small but conspicuous, narrow from before backwards, forming a prominent transverse ridge, continued into a trihedral free process, projecting to the left. Of nearly the same size is the caudate lobe, continuous with the Spigelian on the left, and passing as a ridge on to the under surface of the right lateral lobe, close to its posterior border, marked off from it anteriorly by a deep groove, and terminating in a pointed apex, free for the distance of one inch. This is separated from the right lateral lobe posteriorly by the great fossa for the vena cava, which fills the fossa, and is not bridged over by any hepatic substance.

The posterior part of the right lateral lobe is very little developed, so that the caudate lobe is unusually posterior in position. The distance from the left apex of the Spigelian lobe to the right apex of the caudate lobe is six inches; from the latter point to the margin of the right lateral lobe is an inch and a half. The gall-bladder had been removed from the specimen before it came under examination.

It will be of great interest to examine the liver of another gorilla, to ascertain whether the characters above described are peculiar to the species, though I have very little doubt but that such will be found to be the case. (h) The presence of the two great lateral clefts, though not quite so deeply marked as in many of the lower monkeys, completely distinguishes this liver from that of man or of any of the *Simiide*. It gives countenance to the views of those zoologists (as Isidore Saint-Hilaire, and Duvernoy) who separate the gorilla generically from the chimpanzee, and even lends support to Gratiolet's somewhat fanciful idea, derived chiefly from cerebral characteristics, that the gorilla is more closely related to the baboons, being the highest development of that section of the quadrumana, than it is to the other so-called anthropomorphs. (i)

(To be continued.)

HABITUAL DRUNKARDS.—Statistics in reference to dipsomania or habitual drunkenness have been supplied to a Committee of the House of Commons by Mr. Mould, Superintendent of the Manchester Royal Asylum. Amongst other facts it was stated that about 15 per cent. of certificated lunatics were cured and about 7 per cent. of the dipsomaniacs.

(h) It is partially confirmed by M. Broca's statement that "Sur le gorille de M. Auzoux, le lobe droit est, il est vrai, subdivisé en deux grands lobes par une échancrure d'ailleurs peu profonde."—"L'Ordre des Primates, Parallèle Anatomique de l'Homme et des Singes," p. 117. Paris. 1870.

ORIGINAL COMMUNICATIONS.

ON MITRAL STENOSIS, WITH SOME
REMARKS ON CARDIAC PATHOLOGY AND
THERAPEUTICS. (a)

By ALEXANDER SILVER, M.A., M.D.,

Physician to Charing-cross Hospital, and Lecturer on Physiology in the
Hospital School of Medicine.

(Concluded from page 310.)

IN making use of cardiac bruits for the purpose of diagnosis we are wont to rely mainly on two things—their rhythm and their seat of greatest intensity. As regards this particular sound, its rhythm is plainly diastolic as far as the ventricle is concerned, and it immediately precedes the systole. It does not, however, occupy the whole of the diastolic period, but only its latter portion. At the apex no second sound is heard; so that this period of the rhythm is unoccupied, and constitutes an abnormal pause between the altered first sound and the new and superadded murmur. The bruit itself exactly fills the normal interval of the pause.

Then as to its site; that is not difficult to make out, for it closely corresponds with that spot where the apex comes in contact with the wall of the chest, rapidly diminishing in intensity if traced in any direction from this point; and as this is the only spot where the left ventricle reaches the chest-wall, we are fain to relegate the abnormality to that side of the heart—in short, to the mitral orifice.

So, then, we have to deal with a bruit originating at the mitral orifice during the period in which the ventricle is filling, but not occupying the full space of time so taken up, the period of the second sound being clear, and the bruit terminating as the first sound begins. But how do we ascertain this last fact? Three plans are open for adoption. The first is to compare the period of the bruit with the apex-beat; but in a case like this that is by no means easy, for vibration is too freely communicated to the chest and to the hand for us to readily discriminate the exact period of the apex-beat. Besides, there are other reasons, to which I shall not now refer, why some other sign of the ventricular contraction should be adopted as a guide. Obviously, the pulse suggests itself as a thoroughly reliable sign of the ventricular systole—and so it is, if due precautions be taken; if otherwise, it is not so. Here I am reluctantly compelled to disagree with the teaching of my lamented colleague, Dr. Salter, whose extremely interesting lecture on this subject may be fresh in the minds of some of you. He taught that the guide to be relied upon in forming a diagnosis, whether a bruit was systolic or presystolic, was the radial pulse. But I cordially agree with Dr. Hilton Fagge, who, in an admirable paper in the Guy's Hospital Reports, has pointed out that the proper test is the pulse indeed; but the pulse noted as near to the heart as possible—namely, in the carotids. To enforce this the more strongly upon you I have brought here to-night another patient the subject of a mitral bruit. I shall not discuss the question as to whether this man is the subject of mitral stenosis or no. There are certain signs which, to my mind, indicate that he is; but to confine ourselves to the bruit and the pulse. If tested by the pulse at the wrist, the bruit is clearly presystolic; if tested by the pulse in the neck, apparently as clearly systolic. There is a marked interval between the carotid pulse and the radial pulse, the reason of which we need not here consider; but the fact clearly proves the danger of relying on the wrist-pulse as a guide to the exact moment of the ventricular systole. In the boy whose case we are now considering, the bruit, whether tested by the wrist-pulse or carotid-pulse, is clearly presystolic. It occupies the whole period of the ventricular diastole, save that in which the second sound occurs—that is to say, this bruit occurs during the normal pause when the auricle is normally inactive, and also fills that period during which, in health, the auricle contracts.

To understand aright the origin of this bruit let us for a moment concentrate our attention on the orifice where the sound originates, during the full period of the ventricular diastole, and let us consider the motive powers concerned in driving the blood through it. As I have pointed out, the moment the ventricle begins to expand the blood rushes into it from the auricle. What is the motive force here? Not the

auricle, for that does not act till later in the pause; and if not the auricle then it must be the pulmonary veins. It is true that, owing to the elastic character of its endocardial wall, and still more to its peculiar diastolic circulation, the heart has some self-dilating power which may ordinarily suffice to empty the auricle of its accumulated blood; but this force plainly enough does not suffice here. But inasmuch as these possess no self-contractile power of any importance, their action must be of the nature, mainly if not entirely, of a recoil on some previously distending force; and it is plain, on further consideration, that this distending force must have been that of the right ventricle. So thus we come to the conclusion that, up to the time when the auricle begins to act on its contents, the motive power concerned in driving blood from the left auricle into the left ventricle is the right ventricle acting through the vessels of the lungs—arteries as well as veins. This it is which fills the ventricle, the abrupt contraction of the auricle fairly distending it. And so, if any sound is produced through the agency of the force transmitted from the right ventricle, it should occur during the period of the second sound, or of the pause which in health follows this; and if it produces no sound during the former of these periods, there is no reason why it should during the latter of them. In the case before us no sound occurs during the former period—that of the second sound—but the bruit begins during the latter—that of the pause. It is clear, therefore, that the motive power which produces this noise must be looked for somewhere else than in the right ventricle; and as it is plain that the acting power in the next division of the diastole is the auricle itself, it is fair to infer that its contraction begins here earlier than usual, and is the sole motive power in producing this abnormal sound. The auricular systole is, so to speak, antedated, its force being necessary, not only to the distending, but also to the filling, of the ventricle, and so its action is prolonged—not in the usual sense, but in one which means beginning earlier rather than ending later than ordinary.

Confining our attention still to this portion of our case, let us try next to make out the immediate cause of the abnormal sound and thrill so characteristic. The factors are these: we take for granted a narrow orifice, through which rushes the blood-current, driven from behind by the right ventricle and the left auricle. The bruit and thrill must be the product of these. We think again, and we consider that only a portion of the time, during which these factors are at work, is characterised by sound; the first part is passed in silence. So, then, it is plain that blood may pass through the contracted orifice without giving rise to sound, provided only it is not driven too violently. This provides, therefore, by means of the force of the right ventricle, a certain amount of blood at rest, comparatively speaking, in the left ventricle before the violent effort of the auricle begins (and it begins earlier than usual) to drive the blood through this narrow orifice in sufficient quantity to fill the ventricle, and keep up the circulation. Well, we all know what is the result when a full-pressure tap of water is allowed to fall into a pool beneath—how sound is thereby produced; and, if delivered into a vessel of sufficient size, how the agitated water communicates its agitation to the receiving vessel. Now, this exactly applies to the condition we are examining, only for water we read blood—a more viscous fluid, and one which will consequently give rise to a slightly different kind of sound, and will affect the walls of the heart somewhat differently than water would. Nevertheless, I think we can fairly account for our churning sound and purring tremor in this way.

In working out this explanation we have taken it for granted that there is opposition to the flow of blood from the left auricle to the left ventricle, and we have also taken it for granted that this is due to contraction of the auriculo-ventricular orifice. It may be fairly asked—What are the grounds for this opinion? and, supposing it justified, how are we to account for this condition of mitral stenosis?

Obstructions are of various kinds and degrees—from a slight roughening of the cardiac isthmus, to a narrowing through which the point of the little finger can hardly be passed. Of the former there may be but little sign beyond the bruit, but of the latter there must be physiological proof; for it is a law in animal mechanics, where repair and waste go hand-in-hand, that if an organ is called upon to do more work than usual—if this call is persistent, and sufficient time is allowed to arrange the compensation needed—the organ will strengthen as the demand for strength increases; and so the balance of life (almost of health) is kept even. If, therefore, we have here a considerable and permanent obstacle to the flow of the blood from auricle to ventricle, we should expect

(a) Communicated to the Medical Society of London by the President, Dr. Andrew Clark.

to find a compensating addition of strength to those organs concerned in driving the blood onward in its course. Now, the organs so concerned, as we have already seen, are the right ventricle and the left auricle; not one, but, if our theory be true, both. Referring again to the condition of the patient, we find it noted that there is a thrill in the third interspace not due to the ventricle; furthermore, that the apex beats too much to the right, though there is no bodily displacement of the heart from any cause; and that this beat is also felt in the epigastrium. In short, we have unfailing indications that the right ventricle is enlarged; of course it is a question whether by dilatation or by hypertrophy; but that too can be readily solved by further inquiry. There are no signs of dilatation, but there are evidences of, as well as reasons for, the existence of hypertrophy. There is no tricuspid regurgitation; no venous pulse in the neck; no enlargement of the liver or intestinal congestion, such as would arise from dilatation of the right ventricle; and so we are forced to the conclusion that there is only hypertrophy.

Moreover, there is no reason why there should be dilatation; all that is wanted is increased muscular power, which dilatation would not give, but would rather diminish. There is no increased stowage space wanted, for there is no regurgitation, and so, again, no reason for dilatation. It does not by any means follow that in course of years a heart which has habitually to fight against such obstructions may not, owing to accumulation of blood in it, become dilated. All I say is, that here, meanwhile, there is no evidence of dilatation, whereas we have every reason to believe that there is hypertrophy; and if hypertrophy of the left auricle is less directly evident, it may from the circumstances of the case, as well as from indirect evidence, be safely enough inferred as extant.

Supposing that mitral stenosis does exist, to what are we to trace its origin? In accordance with our ordinary beliefs the repeated attacks of rheumatic fever to which the boy has been subjected constitute ample ground *à priori* for supposing he might be the subject of valvular lesion. But I have here to point out that there is no evidence whatever of valvular lesion. We are apt, in our own minds, to confound the valves of the heart with the site they occupy; but of valvular disease there is only one certain sign—incompetence and regurgitation—and of that there is here no evidence. True, there is contraction of the mitral orifice, and this gives rise to an abnormal bruit; but the valves of the heart are intact; at all events, they fulfil their duties aright, for the first sound of the heart is clear, sharp, and ringing, altogether untainted with the signs of mitral regurgitation. Now, in rheumatic fever, it is the valvular instead of the more deeply seated structures which are most frequently attacked. In this way obstruction may arise as well as incompetence; but the condition I believe to exist here is one of true stenosis—narrowing of the mitral orifice—not of any excrescence from its surface. In dealing with the history of the case I have elicited the fact that as long as he can remember he has been unable to contend with other boys in running and such-like exercises. True, his first attack of rheumatic fever occurred when he was six years old, and no good history is to be obtained antecedent to that date. Nevertheless, it is well at the same time to bear in mind the fact that such bruits and such morbid conditions most frequently occur in badly developed youths—those who are characterised by badly formed chests, such as this boy has got; in short, are probably congenital rather than acquired.

Once more this case may be looked upon as in some respects peculiar; there is a diastolic, but no systolic bruit. This leads us to reflect upon the condition of valve and orifice which can give rise to such a phenomenon. The two malformations most commonly associated with mitral obstruction are—that when the two cusps of the valve grow together at either extremity, leaving only a button-hole-like slit through which regurgitation may also ordinarily take place; and that other form where, owing to a narrowing of the orifice, with some adhesion of the edges of the valves, the valvular apparatus projects, something like a funnel, into the left ventricle. With the latter malformation it is plain that regurgitation need not take place; the valves may fit perfectly—nay, more, projecting in this funnel-shape into the ventricle, they may, in closing, come together face to face, and not edge to edge, as is the case with the ordinary mitral valve. In the case before us there is no regurgitation, and the first sound is altered in a peculiar way. I think it fair to conclude that the condition of valve is funnel-shaped, for that would at once account for the absence of regurgitation and the alteration in the character of the sound. The sound becomes assimilated to the second just

because the mechanism of the valve is assimilated to that of the semilunars, which touch not by edges but by surfaces.

It seems to me that this morbid condition throws some light on the normal sounds of the heart, the origin of which is even now uncertain. The second sound is doubtless connected with the semilunar valves, but the first has been assigned to various causes; chief among these are the closure and vibration of the mitral valve, the motion of the muscular mass of the heart itself, and the churning of the blood in the cavity of the ventricle. Now, of these, that relating to the churning of the blood has been already referred to, and accepted as the essential cause of the abnormal bruit here present. It clearly has nothing to do with the production of this altered first sound, whatever may be its importance in health. Whether the muscular contraction may produce sound is hardly within the range of our inquiry, but the researches of Ludwig and Dogiel show clearly that it can; but the short, sharp click of this first sound has none of the characters of a muscular bruit—it is essentially valvular, and, being so, tends, I think, to show that the ordinary first sound is not a purely valvular production, but is the outcome of all three factors already referred to. So that, though it is most convenient for us to think and speak of the valve action as being the main cause of the normal sounds, this is not absolutely correct.

But it is time for us to inquire how far the general symptoms conform to the state of things we have shadowed forth. If they do not conform, there is a chance that we are altogether wrong. Well, the main symptoms were these—breathlessness, cough, hæmoptysis, and irregular or intermittent pulse. To understand these aright, I must again invite your attention to the vascular connexions of the right and left sides of the heart. On the left side is an obstruction to the blood-flow, which has been sufficient to give rise to hypertrophy of the right ventricle, and as this could only be produced through the lung, a distended condition of the pulmonary vessels must inevitably be habitual. But this congestion is exceedingly likely to give rise to cough, and, if the blood-pressure becomes excessive, to hæmoptysis—two things we almost invariably find associated in a history of mitral stenosis. But the two other symptoms just alluded to are associated in like manner. To produce the sensation of easy breathing, due provision must be made for the removal of the blood from the lung, as well as for the renewal of air in it, and arrest of either will give rise to symptoms of dyspnoea. Thus it must be within the cognisance of all that one of the most prominent symptoms of syncope is what the patient calls want of breath—an indication still more marked in pulmonary thrombosis or embolism. In mitral stenosis the pulmonary vessels are habitually distended; the blood does not pass away freely; nevertheless, from long use the balance is fairly kept up, and the functions of life go on. But suppose the body called upon to undergo some exertion which demands an unusual supply of aerated blood; the forces for driving the blood through the lung and into the left ventricle remain the same. Any increased exertion for them means increased rapidity. But increased rapidity will not drive the blood faster through the narrowed mitral orifice; and so, the blood not escaping from the lung, there is speedily dyspnoea—it may be, from the increased blood-pressure, hæmoptysis—and irregular or intermittent pulse. For if the right ventricle works fast the left must do so also—their action being coetaneous; but if the right is full, the left, owing to this mitral stenosis, is not, and so there results an imperfect contraction, an imperfect ejection of blood, and so an irregular, or, if the pulse-wave be too weak to reach the wrist perceptibly, an intermittent pulse. This condition gives rise to much distress; the heart is beating powerfully but ineffectually, for it is out of equilibrium, and its force is spent uselessly. In point of fact I know of no more apt simile for this condition than that of a strong man, who is no swimmer, drowning in deep water. He beats the water with all his might, but his exertions are useless because not rightly directed; every succeeding effort serves only to exhaust him more and more, and to sink him deeper in the water; whereas, were the same force duly directed in the long and steady sweeps of the powerful swimmer, safety, instead of disastrous death, might ensue. Exactly the same terms apply to this form of heart disease.

There is one other point respecting the diagnosis to which I would allude. I have already pointed out that, in the case before us, the sounds at the base seem normal. In such conditions—i.e., of mitral stenosis—it is not unusual, on listening at that situation, especially over the point where the two sides of the heart are joined, to hear two second sounds instead of one; that is to say, the pulmonary somewhat

before the aortic. Such reduplication, as it is called, is not now to be detected in the case before us, though at one time it was fairly distinguishable. Nevertheless, we may still distinguish between the characters of the sounds as heard on either side. That on the left side—I mean the pulmonic—is clear, sharp, and distinct, following quickly on the systole; that on the right—the aortic—is more prolonged, though beginning equally early with the other. The reason is not hard to seek; the difference in character is due to difference in tension in the two vessels. In the pulmonary artery the blood-pressure is greater than usual, and the valves close with a sharp jerk; in the comparatively unfilled aorta the blood pressure is less than usual, and so its recoil is less prompt, and the closure of its valves less speedy, and their vibration more prolonged than on the right side of the heart.

There is another condition which in certain respects is the exact opposite of this, and yet which bears to it in many respects a curious likeness. It is a fact now generally recognised, that in the chronic form of Bright's disease—that especially characterised by the small, contracted kidneys—there is a curious change in the minuter arteries. Their walls become hypertrophied, and their calibre diminished. As an immediate consequence, the blood-pressure in the larger arteries is increased, and the left ventricle, having excessive work to perform in driving the blood through these contracted arteries, becomes hypertrophied. And so in the arterial system there occurs a state of matters exactly similar to that in the pulmonary system in the case now before us. In that condition, too, if we listen at the base of the heart, the short, sharp second sound, the product of increased vascular tension, may be heard, but this time at the aortic orifice.

And now, having so fully discussed the diagnosis in such cases, a word as to their prognosis and therapeutics.

But before saying much on the subject of prognosis, I would beg leave to draw your attention to this one prominent fact: *heart disease commonly kills mechanically*, from interference with the circulation. It is true that in the so-called ulcerative endocarditis, or when what is called fibrine has been deposited on the valves, a portion may be swept away and set up disease elsewhere; but, as a rule, it is the interference with the circulatory functions which proves fatal. That being so, regurgitant disease, which interferes most with the circulation, which leads to dilatation, dropsies, and the like, is likely to prove more speedily serious than a simple obstruction which may be overcome by sheer strength—such as the force of a hypertrophied organ. But to form a fair estimate of the evil influence of mitral stenosis, we must compare it with two other diseases. The forces concerned in driving the blood through the mitral orifice are, as we have seen, the auricle acting close at hand, and the right ventricle acting through the pulmonary vessels. With these we should compare aortic stenosis and the contracted arteries of Bright's disease. In both cases there is hypertrophy of the left ventricle—but in the one case this organ acts directly on the obstruction, in the other through the greater systemic arteries—and we know what then happens: when the blood-pressure becomes excessive a weak vessel gives way, as the weakest part is bound to do; and as this commonly occurs in the brain, an apoplectic clot is the result. So, in mitral stenosis with hypertrophy of the right ventricle, there is risk of a weak artery giving way in the lung, and hæmoptysis with pulmonary apoplexy as the result. This, we know, does frequently happen, and this, or something similar, is the main danger to be dreaded. Were it not for this risk of intermediate rupture, almost any amount of power could be applied to overcome the obstacle. Nevertheless, with care the prognosis must be much more favourable than in regurgitant disease.

A word or two next as to the treatment of these and such-like cases, and I have done. The heart is not an organ we can touch and handle as we please, and yet we are able to deal with it almost as if we were—to make it go faster or slower, to make its beat powerful, or weak and uncertain; this we do through its nerves. I need hardly say that where hypertrophy is compensatory for difficulties in the way of the blood-stream, it is a thing to be encouraged; and therefore we must give iron, quinine, and such-like remedies, which contribute to the general strength. But I desire now to refer rather to those special remedies which rule the nerve-supply of the heart. This nerve-supply is derived from two sources—or perhaps I ought rather to say, from the same source by two channels. The source is the medulla oblongata; the one channel is the vagus, the other is the spinal cord and ganglionic system; the special ganglia concerned in the movements of the heart being the lowest cervical and two upper dorsals, which receive their motor filaments from the spinal cord.

Now, stimulation of the vagus slows, but does not necessarily weaken, the action of the heart (if very strong, of course it does both); so that gentle irritation of that nerve exercises on the heart an action similar to that of a fly-wheel on a steam-engine—it slows and steadies it. Now, we have seen that this is exactly what is wanted, and in digitalis we have a remedy which exactly answers our purpose; so that to it, combined with tonics, we must mainly look for overcoming the tendency to irregularity we have noticed as commonly extant.

But sometimes we desire a remedy which has the opposite effect—an effect nearly identical with that of section of the vagus—and such a remedy we find in belladonna. Its effects are most noticeable where digitalis does no good or does harm. I call to mind one case where a man had been taking digitalis. One day I found him in extreme distress, the heart beating feebly, tumultuously, and imperfectly. He promptly had the fifth of a grain of extract of belladonna injected beneath the skin of his arm, and in a few minutes he began to get better. In these two remedies we have two most powerful engines—engines which, it is true, require carefully handling, but which, being well handled, are capable of rendering good service. Nevertheless, they are only means to an end, and the end is only satisfactorily to be obtained by the avoidance of everything which will disturb the equilibrium of the circulation or of the economy at large.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,

Student of Guy's Hospital.

No. IV.

The Clinical Value of the Instrument—Typical Forms of the Pulse found in Intermittent Fever—The Puerperal State—Bright's Disease—Atheromatous Arteries—Paraplegia—Hepatic Dropsy—Phthisis—Dyspnoea.

(Vide Plate published with Medical Times and Gazette, February 24.)

THE chief error to be guarded against when using the sphygmograph clinically is that of expecting too much from it. Many imagine that the upholders of the sphygmograph profess to have found in it a royal road to diagnosis. Nothing can be more erroneous and more certain to lead to disappointment. The information which the sphygmograph affords can only be looked upon as an important symptom in any disease; it teaches the pathology of the circulatory system, and in those diseases in which this is involved it is especially useful—it indicates the mechanical and vital conditions of the circulation, and affords information on these points unobtainable by other means. In some diseases it forms an aid to diagnosis, in many to prognosis and to treatment; occasionally a diagnosis may be based on its authority alone. Its sphere of usefulness is the widest possible, as it may be employed in all forms of disease, whether Medical or Surgical. Though in private practice it is of course unnecessary to apply the sphygmograph every time the pulse of a patient is felt; still, in Hospital practice, or wherever a case is carefully and scientifically investigated, surely the pulse deserves attention as much as the urine and the temperature. It might especially be employed with advantage in clinical teaching, for no teacher can impart to each member of his clinique the knowledge which his highly educated finger supplies him of the character of the pulse; but a student can easily learn to recognise and appreciate the movements which he sees recorded in a tracing. The progress of acute disease may be watched throughout by daily observations, and tracings thus obtained form a record as perfect, if not more so, than a thermometric chart.

The pulse-tracing of each individual in health possesses a constant form, dependent chiefly on the constitution and general habits; it may be hard or soft, large or small, good or bad tone, excitable or phlegmatic, and is as characteristic as the tone of voice or mode of carriage; but in disease the pulse loses this individual form, and varies with the general condition.

In the present paper it is proposed to give examples of a few leading types of abnormal pulses, assigning to each, as far as possible, the cause of its production, in order that in future observations on special diseases the presence of any complication affecting the pulse may be recognised, and due allowance made for it.

Tracings obtained from the apex-beat of the heart will occasionally accompany the corresponding pulse-tracings, owing to

the method adopted to obtain them, though, giving the leading characters, they are wanting in the finer details. For information on cardiographic tracings, reference may be made to the researches of MM. Marey and Chauveau, and the papers of Mr. Garrod on the cardiograph. The leading characters of the apex-beat recorded in the tracings are the following:—The mode of contraction, whether sustained or unsustained, and whether reaching its greatest intensity at the commencement or termination of systole; variations in rhythm; the presence or absence of a well-marked auricular contraction.

The first series of tracings in Pl. ii., published on February 24, were obtained from a case of intermittent fever; it will serve not only to throw light on the pathology of ague, but also to illustrate the various forms assumed by the pulse in acute disease, and especially the several degrees of dicrotism.

J. S., aged 27, was admitted into Guy's, under the care of Dr. Wilks, June 21, 1871. It will be unnecessary to enter into the details of the case, it being in all respects a typical one. Suffice it to say that he was a strongly-built and well-nourished man, by trade a brickmaker, and was suffering from well-marked quotidian ague of one month's duration. On June 22 (the day following his admission), at 12 noon, his temperature was 98.8°, pulse 84, and respiration 20, his condition being apparently normal. At 3 p.m. the cold stage commenced. During the rigors, which were very severe, his temperature rose to 104.4°, pulse 140, and respiration 30. The tracing obtained in this stage is represented in Fig. 1. His arteries may be seen to be tightly contracted; the pulse small and hard, six ounces of pressure being employed. The tidal wave is too convex—that is, the systolic expansion is sustained, owing to the contracted arteries permitting the passage of but a small wave, which is consequently prolonged. The characters of the pulse point to one condition for their production—namely, powerful sympathetic irritation acting through the vaso-motor nerves and contracting the vessels. The countenance at this time had a dusky hue; the veins were turgid—and, as we have seen the arteries contracted, if dicrotism depends on increased venous tension, surely now is the time that it ought to be apparent; but we do not find it at all prominently indicated.

The temperature continued to rise during the cold stage, and at 4 p.m., in the middle of the hot stage, the temperature reached 105.3°, pulse 132, and respiration 32. Fig. 2 represents the tracing now obtained. How great a change is apparent. The pulse is full and strong; the heart's contraction is sharp and powerful, six ounces of pressure being again required to develop the pulse-tracing. It is now extremely hyperdicrotic, the aortic notch being far below the line of the lowest points of the percussion upstrokes. A slight imperfection is noticeable in this tracing, indicated by the flatness of the bottom of the aortic notch; it is produced by the downfall of the lever being cut short by touching the framework of the instrument. According to Mr. Garrod's tables, the systole appears to be prolonged. As a reaction to the excessive sympathetic irritation present during the cold stage, vaso-motor paralysis now seems to have occurred, and the elastic coat comes prominently into action, producing the huge diastolic expansion. This has not time to subside before the next systole occurs, and the percussion upstroke is seen in the tracing. It was formerly thought that hyperdicrotism occurred only in exhausted states of the system, or as a bad form of pulse in fevers; but here it may be seen to come and go in the course of a few hours, and must apparently be due merely to mechanical causes. The venous turgidity has now disappeared, and arterial distension taken its place; the countenance has become flushed by the dilatation of the arterioles and capillaries; the eyes bright, and the sensation that of extreme heat—the condition being exactly the reverse of the preceding.

At 8 p.m. the hot stage had given place to the sweating; the temperature had decreased to 104.2°, pulse 108, and respiration 36. The pulse had altered its character, as seen in Fig. 3; still full and strong, the same pressure being employed. The upstroke is seen to be very great, the tidal wave remarkably large, and the duration of systole prolonged. The pulse is still hyperdicrotic, but the diastolic expansion is comparatively slight. The vaso-motor nerves appear to be recovering themselves, and peristalsis is becoming re-established, so that the cardiac contraction with its aid is almost competent to carry on the circulation without producing over-distension of the aorta, and a consequently excessive degree of dicrotism. The febrile symptoms have to a great extent disappeared, and copious perspiration has taken place. At 10 a.m. the temperature was still falling, it being 100.6°, while the pulse was only 88, and the respiration 36.

At noon the following day his temperature was 97.8°, pulse 80, and the respiration 20. The tracing was similar to that represented in Fig. 4, which is the form the pulse always assumed while the condition was normal; the pressure employed was only three ounces, though this varied from three to five ounces. The pulse is seen to be very full, but the arterial tone bad. The duration of systole in relation to that of diastole has greatly diminished, and is now rather less than normal, the heart apparently requiring time to rest and regain strength after its excessive exertion. The temperature also is below normal. This decreased temperature was always present after an attack, and was most marked when the temperature during the attack had been higher than usual.

On the four following days he was injected subcutaneously with one grain of quinine at the commencement of the cold stage or a few minutes before it, but without checking the fever, though the cold stage was less severe, the time of occurrence of the attacks becoming two or three hours earlier than usual; and on three days the sweating stage was absent. The sphygmographic tracings obtained during the fever possessed the same characters as those already noticed, with the exception that the arteries were much less contracted during the cold stage, and the dicrotism was much diminished during the hot; but whether these effects were due to the quinine injection does not appear evident, for on the fourth day of its repetition the fever was almost as severe as on the first occasion, notwithstanding that the cold stage was diminished, this apparently being a constant effect of the quinine, which thus seemed to partially counteract the malarious poison. The tracings obtained on this day are represented in the plate. The cold stage commenced at 12.50 p.m., which was earlier than usual; he was immediately injected with one grain of quinine. The temperature was 102.6°, pulse 100, and respiration 32. The tracings obtained showed the arteries to be much less contracted than on the previous occasion, though the pulse was still hard, requiring six ounces of pressure, the systolic portion bearing rather more than its due proportion to the diastolic. The pulse is fully dicrotous. At 2 p.m., during the hot stage, his temperature had risen to 104.5°, pulse 136, and respiration 34. Though the temperature was not so high as on the 22nd inst., the pulse was more hyperdicrotic, though much softer, only requiring three ounces of pressure; the prolongation of systole was still more marked. It may be suggested that the apparent increase in dicrotism was owing to the diminished pressure employed; but this was not the case. If six ounces had been used the pulse would have been almost annihilated; and on the previous day, when also the pressure used had been three ounces, the temperature being exactly the same as on this occasion, the pulse was very much less dicrotic. These tracings demonstrate the incorrectness of the statement that the amount of dicrotism bears an exact relation to the temperature; but this will be still more evident in studying the continued fevers.

At 5 p.m., during the sweating stage, the temperature was 102.8°, pulse 100, and respiration 30, the pulse being hyperdicrotic, and the systole much prolonged, as on the former occasion. It was, however, very much softer, only requiring one ounce and a half of pressure. At 9.30 p.m. the temperature had fallen below normal, being 98°; pulse 74; respiration 24.

On the following morning ten grains of quinine were administered in a draught, and Figs. 8 and 9 were obtained before and after its administration. The following effects were produced on the pulse:—The rapidity of the pulse increased; the percussion-wave, excessive before the quinine, was reduced; the tidal wave was increased; and the duration of systole, too short before the quinine, was increased to its normal length after it. An attack of fever again occurred on this day; and, though the rigors were much decreased, and the duration of the fever shortened, the temperature was raised to the same height as on the first occasion. The next day, the dose of quinine being repeated, no fever occurred; and the same treatment being pursued, it never returned.

Figs. 11, 12, 13, and 14 in Pl. ii. represent tracings obtained in the puerperal state. The leading character of the first three is the fulness of the pulse, the tidal wave being more sustained than in the normal tracing; the general condition appears to be that of hyperæmia; the form of the pulse is similar to that accompanying hypertrophy of the left ventricle. This form of pulse appears usually to occur in the first stage of labour, and is, probably, persistent throughout, though the inconvenience of applying the sphygmograph in the second stage prevents any observations being obtained. It is, however, present after labour, and the fulness gradually disappears during the first week or ten days. Dr. Braxton Hicks

suggests that this character of the pulse may be due, not to the occurrence of labour, but to the hypertrophy of the heart said to take place during pregnancy. Sufficient opportunities have not yet presented themselves for me to ascertain the truth of this. Figs. 13 and 14 were obtained from a delicate, weakly woman, the action of whose heart during the first few days after labour was irregular, though no abnormal sounds were audible. The heart recovered its regularity, and the pulse assumed its normal form, as seen in Fig. 14, on the seventh day.

Figs. 15, 17, and 20 are types of a form of pulse found under two conditions—namely, Bright's disease and arterial atheromatous degeneration. The leading feature in each is the prolonged systolic expansion. This, though occurring in both conditions, is produced by different causes, and admits of distinction by one almost unvariable sign. Fig. 23 represents the tracing obtained from a woman in the clinical ward, under the care of Dr. Habershon, a few days previous to her death. She was found, on examination, to have the small contracted kidneys of chronic Bright's disease; the heart was hypertrophied, but not dilated; the muscular coat of the arteries had undergone the usual thickening, and were free from atheromatous disease. The tracing shows the contraction of the heart to have been sharp and forcible, producing a well-marked percussion-wave; this is followed by a full and well-sustained tidal wave, equalling in height that due to percussion, indicative of and produced by hypertrophy of the left ventricle; succeeding the tidal wave is a well-marked dirotic wave, and then a secondary undulation during the diastole. Let it be noted that the pressure required to produce a perfect tracing was six ounces, indicating a considerable amount of hardness about the pulse. Fig. 16 is a tracing of the heart's apex; it is very imperfect, owing to the difficulty she experienced in holding her breath to fix the chest-wall. It indicates, however, the well-sustained contraction which accompanies hypertrophy of the heart.

Fig. 17 was obtained from a man admitted into Guy's, under the care of Dr. Wilks, suffering from the usual symptoms of the contracted kidney of Bright, the cerebral symptoms being especially severe. An autopsy revealed the same condition of kidney as in the former case; but the heart was more hypertrophied, and considerably dilated. This accounts for the greater size of the pulse and the increased pressure required—*i.e.*, nine ounces. Fig. 18 represents the tracing obtained of the apex-beat; it is more perfect than the preceding one. The tracing is characteristic of a hypertrophied heart, the contraction being powerful and well sustained, the summit of the tracing being square and broad, the period of systole prolonged, and that of diastole shortened, thus accounting for the tendency of the muscular fibre to degenerate from the want of its proper amount of rest, or time of repair. Fig. 19 is a tracing obtained from the same patient, immediately after an uræmic convulsion. The alteration in the pulse-wave is of a threefold character:—1st, the rapidity is greater; 2nd, the percussion-wave is increased, owing to a corresponding increase in the force of the cardiac contraction; and 3rd, the proportion which the systolic portion of the tracing bears to the diastolic is augmented. The other characters of the tracing are unchanged.

The next tracing in the plate (Fig. 20) presents very similar characters to those above noticed. It was obtained from a patient, under the care of Mr. Cooper Forster, suffering from popliteal aneurism, whose arteries had undergone extensive atheromatous degeneration. Arteries in this condition have much the effect produced by inelastic tubing on experimental tracings—the percussion-wave is always well marked, and distinctly separated from the tidal wave; the expansion caused by the tidal wave is prolonged from the absence of the steady contraction of the elastic coat producing a gradual collapse; the rigid artery is suddenly distended, and as suddenly collapses; the dirotic wave is visible, but I have never found it much developed; and the secondary undulation during diastole due to the elastic coat is but faintly discernible, and often absent, while in the pulse produced by hypertrophy it is usually well marked. Lastly, the pressure required to obtain a perfect tracing is generally slight; the more calcareous the arteries, the lighter the pressure required. In this instance three-ounce was used. This is more than usual, one-ounce being frequently sufficient. The slight amount of pressure employed serves especially to distinguish between the pulse of atheromatous arteries and that of hypertrophy of the heart, as in chronic Bright's disease. Though Bright's disease has been referred to above, it is only as affording a type of pulse simulating that of atheromatous arteries, with which it is necessary to become acquainted, as it occasionally complicates other diseases; but

the discussion of the pulse in the different forms of Bright's disease, and the mode of its production, must be deferred till a future occasion.

The two tracings represented in Figs. 21 and 22 have been introduced here to exhibit the effect produced on the pulse by loss of nervous power. Charles Y., aged 33, was admitted into Guy's Hospital on June 5, 1871, under the care of Dr. Wilks, in whose paper on "Diseases of the Nervous System," published in the Guy's Hospital Reports for 1872, a report of the case, with remarks, may be found. It will suffice to say that on admission he was suffering from almost complete loss of both voluntary and reflex movement, and partial loss of sensation in the lower extremities. The muscles of these parts were also insensible to the interrupted current of electricity. The upper extremities were also slightly affected, but the muscles replied to the stimulus of faradisation. About the head motion and sensation were perfect; there was no loss of power over the sphincters. He was ordered pot. iodid. gr. x., liq. hyd. perchlor. ʒj., ex aqua, to be taken thrice daily. This patient left the Hospital in a fortnight, recovery being complete. Dr. Wilks regarded it as either a mere functional disorder, or a syphilitic disease (which the history sanctioned), cured by specific remedies. The effect produced by the deficient nerve-power over the muscular coat of the arteries is well seen in Fig. 21, the pulse being large and soft, requiring only an ounce and a half of pressure, and the various waves remarkably distinct, owing to the diminished tension of the arterial wall. The same effect is produced on the pulse when blushing occurs, or by fear or excitement. Fig. 22 was obtained from the same man six days afterwards, when his condition had very greatly improved, he being able to walk with a stick. The nervous tone was restored, the pulse was smaller, harder (requiring four ounces of pressure), and the vibrations in the blood-column much less distinct, the percussion- and tidal waves being blended, owing to the increased tension of the arterial walls.

Figs. 23 and 24 are examples of well-marked dirotism apparent in the pulse, produced mechanically, and by causes other than fever. In both these cases the pressure employed was considerable; the dirotic wave must therefore have been of considerable power to be so well marked. In Fig. 23 it was caused by hepatic dropsy. The cause is evident, there being obstruction to the blood returning from nearly all the abdominal viscera, thus causing capillary obstruction throughout an extensive part of the circulatory system; and this is one of the chief causes of dirotism, as we have seen above. In Fig. 24, obtained from a patient in the last stage of phthisis, the cause of the well-marked dirotism is not clear; it may be due to the loss of power in the muscular coat of the arteries.

The last pulse in this plate shows an undulation in the respiratory line, the tension of the blood-column varying with each act of respiration. It was obtained from a lad suffering from extensive cardiac and pulmonary disease. This respiratory undulation appears to occur especially under two conditions—namely, when the heart is feeble and more especially dilated, or when there is much dyspnoea.

(To be continued.)

NOTE ON A CASE OF ATHETOSIS (?)

By C. CURRIE RITCHIE, M.D.,

Physician to the Hulme Dispensary, Manchester.

In his treatise on diseases of the nervous system, Dr. Hammond, of New York, has lately described an affection to which he has given the name *Athetosis* (from *Atheros*, without fixed position), and which is "mainly characterised by an inability to retain the fingers and toes in any position in which they may be placed, and by their continual motion." The following may prove of interest, taken in connexion with a similar case under the care of Dr. Clifford Allbutt, which was reported in this journal for January 27:—

J. G., an engineer, aged 59, consulted me on October 10, 1870, in consequence of his having been for some time previously subject to involuntary movements of the extremities. He was a short, thin man, with sallow complexion and somewhat anxious expression. He had, however, always enjoyed good health till about three years before, when he began to suffer from occasional headache and giddiness. One day in November, 1868, when about to sit down to dinner, he suddenly lost consciousness, and fell to the ground. No account of involuntary muscular movements during this seizure could be elicited.

He remained insensible for about ten minutes, and was then put to bed, where he continued for five days. His speech was impaired for about three months afterwards. About this period (February, 1869) he noticed a slight sensation of numbness in the right arm and leg, accompanied by severe pain, which was worst at night. Shortly afterwards, curious movements began to occur in the fingers and toes of the right side; these were at first slight and under the control of the will, but they had gradually increased, and were now quite involuntary.

When I saw him, he could not flex the fingers of his right hand without the aid of his left, and even with this assistance seemed to have considerable difficulty in doing so. On desiring him to keep the right hand flexed and still as long as he could, in a few seconds, in spite of his efforts, the fingers became extended and assumed a variety of curious movements, which were continuous and somewhat complex in their nature. They began when the patient held out his arm before him, and took place slowly and deliberately; he could stop them by placing his right arm by his side and firmly grasping the wrist with his left hand. The movements usually consisted of alternate abduction and adduction, combined with partial flexion and extension; no regularity, however, was observed in their occurrence, and frequently the hand assumed a "sprawling" appearance, from the simultaneous abduction and partial extension of the radial and ulnar portions of the hand; sometimes the thumb would remain in a state of extreme abduction, while the little finger was semi-flexed and drawn across the palm. These movements were accompanied by a feeling of numbness and pain. The toes were almost always in a state of flexion, having their tips pointed to the ground. When he wished to extend the toes, he had to plant his heel firmly on the ground, and gradually draw the foot backwards, at the same time raising his heel. During these movements the muscles of the forearm and calf were hard and rigid. The tactile sensibility of the affected arm and leg, and also the temperature, were less than in the others. He suffered frequently from headache, which was always relieved by sleep; tongue tremulous; complained occasionally of vertigo and "flashes of light" before his eyes; articulation normal; intelligence fair. He had been a temperate, steady man; no history of tubercle or syphilis, congenital or acquired. There was no tenderness or pain on percussion over the spine. He was ordered ten-grain doses of bromide of potassium three times a day, and requested to see me again in a week, when, if there was no improvement in his condition, I proposed to employ galvanism for his relief. When he came to me on October 22 (twelve days after I first saw him), he told me that he had been able to do a little work, which he had not done for six weeks before, on account of the pain in his hand, which was now much relieved; the movements were not so troublesome, and he was able to sleep much better. He was recommended to continue the use of the bromide. I regret that I did not see the case again, in consequence of the patient having changed his place of residence; but, as it corresponds closely to the description of athetosis as given by Dr. Hammond, I venture to submit these details, imperfect as they are.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

SEAMEN'S HOSPITAL, GREENWICH.

[For the notes of the following cases we are indebted to Mr. H. Campbell Pope, House-Surgeon.]

CASES OF FRACTURED CRANIUM.

(Under the care of Mr. W. JOHNSON SMITH.)

Case 1.—*Compound Fracture of Cranium in Left Temporal Region—Death on the Seventh Day from Lesions of the Right and Opposite Hemisphere of Cerebrum.*

C. R., aged 37, was admitted on the morning of February 22, with injuries of the head and back, due to a fall into the hold of a steamer, a height of about twenty feet. He was brought to the Hospital immediately after the accident. On admission, the man was cold and pallid, and under the influence of well-marked shock. He was quite conscious, and there were no symptoms of either general or local nervous lesion. Immediately behind the left ear was a scalp wound, small in superficial extent, but laying bare a small portion of temporal bone. Above and behind this was another wound, still smaller, and very superficial. The integument between and around these wounds was much bruised, and

there had been considerable hæmorrhage. The patient complained of intense pain across the frontal region, and also of great tenderness over the left sacro-iliac articulation, in which region, however, there was no swelling or any other symptom of injury of any important structure. He could move both legs freely, and the left as well as the right. Shortly after admission he passed about half a pint of clear and healthy urine. He was put in bed, and the ward was darkened; the scalp on the left side was shaved, and an ice-bag applied over the seat of injury. During February 22 and the following day the patient complained of persistent and very acute headache. Shortly after admission he vomited. The ejected matter was simply the contents of the stomach, and was unmixed with blood.

On the 23rd some calomel was prescribed, and in the evening he took a draught containing twenty-five grains of hydrate of chloral. From the morning of the 24th, after a good night, he progressed very favourably, and without any bad symptom, up to the evening of the 26th, when he became slightly delirious, and afterwards very drowsy. He slept very soundly during the night, but at eight o'clock on the following morning suddenly changed for the worse, and at the hour of the visit presented the following symptoms:—Insensibility and occasional unconsciousness, much restlessness, and incessant attempts to sit up in bed, stertorous breathing, paralysis of the left arm and distortion of the left side of the face, and retention of urine; the pupils were equal and normal in size, but did not act on applying or withholding the stimulus of bright light. These symptoms increased in intensity in the course of the following twenty-four hours, the most marked affection being excessive restlessness and even violence, which necessitated constant exertion on the part of a strong male attendant. The treatment during this stage consisted in the administration of turpentine enemata, and draughts containing bromide of potassium. On the morning of the 28th the patient became comatose, and rapidly sank. Death took place at 3.30 p.m.

Post-mortem Examination, 10.30 a.m., March 1.—Moderately rigid mortis. Body that of a very muscular, well-developed, and well-nourished man; both testes enlarged; some small superficial ulcers about both patellæ; no old cicatrices on surface of limbs or trunk. There was considerable ecchymosis of left lower eyelid. About one inch posteriorly to the left pinna, and in a line with its upper margin, was a scalp wound about one inch in length. This communicated directly with bare and fissured bone. Four inches above this wound, and nearer to the occiput, was another small wound, which did not involve the whole thickness of the scalp. The whole scalp was much bruised, and the left temporal muscle was of a deep red colour, its fibres being contused and mixed with large masses of coagulated blood. On cleaning the surface of the cranial vault a fissured fracture (without depression) was found, coursing from the lower and back part of the left parietal bone across the squamous plate of the corresponding temporal bone and the outer part of the sphenoid bone, to the temporal portion of the os frontis, where it ceased immediately behind the external angular process. This fissure passed through the base of the lower scalp-wound, and here a piece of the external table of about the size of an apple-pip was broken off. No fracture could be seen at any other portion of the outer surface of the cranium. On removing the top of the skull, a thin layer of dry, granular, and dark-coloured clot was observed between the fracture and the subjacent surface of the dura mater. The vessels of the whole of the exposed dura mater were much engorged. On removing this membrane, the vessels on the upper surfaces of the cerebral hemispheres were observed to be large and distended with blood. The arachnoid was thickened and opaque, but very much more so over the right than over the left hemisphere. The arachnoid cavity on the right side contained dark semi-purulent fluid, and soft white flakes. The portion of cerebrum corresponding to the seat of fracture was paler, much less vascular, and more healthy in appearance than the rest of the surface of the organ. At the lower and external part of the convolution surrounding the Sylvian fissure there was extensive laceration of the cerebral substance, and the medullary portion of the hemisphere beneath was dark in colour and softened. There was also extensive effusion of blood in the middle fossa of the right side of base of cranium. The osseous processes and the edges of the cerebral impressions of the interior of the skull were in this patient very prominent, and at some parts quite sharp. On stripping off the dura mater from the base, it was found that the fracture in the temporal region had extended inwards for a short distance across the anterior fossa, and had detached the outer half of the left lesser wing of the sphenoid. No lesions were found in any other part of the body.

Case 2.—Extensive Fracture of Skull.

John M., aged 52, was admitted on December 16, 1871, at 6 p.m., with an injury to the head caused by a fall from a scaffold, a distance of about eighteen feet.

The patient was comatose and almost pulseless. Immediately to the left of the occiput was a scalp wound, about one inch in length, exposing bare bone and a linear fracture. No depression could be made out. The patient died about twenty minutes after admission.

At the post-mortem examination made on December 17 the following lesions were observed:—The whole scalp much bruised, and considerable effusion of blood under temporal aponeuroses. The fracture seen before death under the wound in the scalp was found to extend around both sides of the skull as far as the external angular process of the frontal bone on the left side and the centre of the temporal fossa on the right, involving the occiput immediately below its apex, both parietal bones, both temporal bones, and the left sphenoid and frontal bones. This fracture along its whole course had passed through both tables of the skull; but there was no depression or internal splintering. On examining the base of the skull, the roof of the left orbit was found to be fractured, and on the right side there was a fissure across the middle fossa, which was an inward extension of the fracture observed on the right side of the skull, the fracture along the anterior fossa on the left side being evidently an analogous continuation of the fracture along the left temporal region. There was considerable effusion of blood over the surfaces of the hemispheres and at the base of the skull, and also laceration of the brain substance in front and on the left side.

LIVERPOOL SOUTHERN HOSPITAL.

CASE ILLUSTRATING THE EASY REDUCTION OF DISLOCATION OF THE HIP-JOINT BY MEANS OF MANIPULATION AND TRACTION, WITHOUT THE AID OF PULLEY.

(Under the care of Dr. NOTTINGHAM.)

[Reported by Mr. HENRY HARVEY, Senior House-Surgeon.]

THE patient, T. R., aged 27, moulder, was brought to the Hospital on January 24, suffering from injuries caused by the sudden swinging round of a heavy crane, which threw him to the ground and inflicted a severe wound in the back.

On examination, there was found to be dislocation of the left hip, with more than usual shortening. To the left of the sacrum there was a deep lacerated wound, from which large quantities of dark venous blood were welling up. The wound admitted three fingers easily; it was plugged, with the effect of partially staying the hæmorrhage. The man died about two hours after admission.

After death, it was found that the wound communicated with the interior of the pelvis, which was completely fractured across the posterior part of the left iliac bone, with considerable displacement of that side of the pelvis upwards. Immediately after death, and of course before any rigor mortis had set in, the body was placed in the horizontal posture, the left thigh was seized by an assistant, who, bringing it into a position nearly at a right angle with the body, and having previously planted one foot firmly on to the brim of the pelvis, made steady traction upwards. The head of the bone, which was lying on the dorsum ilii, then readily slipped into its socket. After reduction had been effected there still remained some shortening, which was due to the displacement upwards of the fractured side of the pelvis. In effecting the reduction not more force was used than would have been employed in reducing an ordinary and recent dislocation of the shoulder-joint.

IN-GROWING NAIL.—M. Verneuil, in a recent clinical lecture, adduced many examples in order to show the fallacy of the usual statement that this is caused by the pressure produced by ill-made shoes. In the first place, it is rare to meet with it on both feet; and M. Verneuil refers to several cases in which it occurred in which the patient had, in consequence of disease or injury, been bedridden for months, or even years. "From all these facts," he observes, "must we not conclude that, if it is true that 'mechanical cause' may give rise to in-growing nail, there are many cases in which this cannot be recognised? and in such are we not justified in regarding it as a dermatosis—as a dystrophic condition of the nail, produced under the influence of some circulatory or nervous disturbance?"—*Presse Belge*, March 3.

SATURDAY, MARCH 23, 1872.

THE LONDON WATER COMPANIES.

ZEALOUS sanitarians have for years been contending for a constant water-supply to London houses, and recent legislation has brought it within their reach; but we suspect there are a good many persons who do not know what is meant by constant water-supply, nor yet what they will have to pay for it.

The common dea is, that cisterns of all sorts are to be abolished, and that the water is to be brought into every house (some have demanded it in every room), where, by merely turning a tap, fresh water may be drawn direct from the Company's "main" without the deterioration which it is subjected to in cisterns, exposed to all kinds of vapours and to heat. But it is manifest, at a glance, that two dangers at the least have to be provided against.

In the first place, if the pipes and fittings are not of great strength, they may yield to the constant pressure of water urged on by a force that suffices to drive it to the tops of the highest houses; or they may be injured by accident or by malice, and in either case the house would be flooded, and in a very short time enormous damage done to property, and the house be made as uninhabitable as if it had been half-burned. In the next place, without stringent precautions the waste of perpetually flowing water would be enormous.

For example, we well recollect hearing an experienced householder, years ago, say, "My drains are always sweet; I take off the ball-cock from my cistern, and let the water run away freely as long as it is turned on." Moreover, it is notorious that in poor houses all over London so inefficient are the cisterns and taps that the water runs profusely through the closet when turned on, and thus cleanses that source of mischief. But, on the other hand, if the lodgers do not come and catch it in their tubs and pitchers, they will have no supply till the next day.

Now, no Company's store of water could stand such waste as this if the flow were constant. It is perfectly reasonable, therefore, and is secured by law, that the Companies should be protected, the fittings such as to guard against accident and waste, and that the Companies may make regulations, which, when duly advertised and sanctioned by the Board of Trade, shall be binding on the public. The existence of such proposed regulations was duly advertised by all the Companies in the *London Gazette* of February 27 and in the daily papers, with a notice that they might be inspected at any of the Companies' offices during the ensuing month.

An inspection of these proposed regulations will be a disagreeable surprise to anyone who holds the simple Arcadian views of the matter which we have described above.

In the first place, with the exception of a few houses of the poorest class, it is proposed that every house must have cisterns capable of holding twenty-four hours' consumption; and "constant supply" will be found to mean, not drawing water direct from the main, but the having the cisterns kept constantly full. Then, in order to prevent bursting of pipes, they must be made of such weight per foot, in proportion to the bore, as will satisfy the Company; they must be connected with the main, and laid at a given distance under ground to protect them from the frost; the ball-taps, to shut off the water when the cistern is full, must be approved by the Company; waste-pipes, to allow of surplus water running away surreptitiously into a drain, will be prohibited; the waste-pipes must be "warning pipes"—*i.e.*, so placed as to cause a visible stream of water to give warning of an overflow; "waste water preventers"—that is, certain machines which only allow a certain quantity to flow at a time, on once turning the tap—will have to be put to water-closets, pipes, and sinks; baths will be under regulations as to their overflow-pipes—and, in fact, wherever this system is introduced, the householder will be subject to constant visits of inspectors, and must submit to have entirely new water-fittings, which the engineer of one of the Companies told us would cost about £20 for a house worth £100 per annum, and this entirely at the cost of the householder.

This new system, with proper provision against waste, will doubtless be a great improvement in the case of the worst class of houses; and, by the way, all *waterbutts* are to be done away with. But for persons whose cisterns are ample and well placed, it is a boon which we do not see the value of. One thing is clear, every prudent householder will shut off the water when he locks his doors at night.

There is no doubt that the water-supply of London is groaning under the huge monopoly of the Companies. We pointed out, two years ago, that the East London Company was spending half a million to bring water from the Thames past the door of the New River Company. This useless expenditure will have to be paid for in the shape of water-rates.

We see the presumed effect of impure water in the frightful mortality of Holland. At Utrecht, for example, the death-rate in 1871 was 435, and at Rotterdam 456 per 1000—almost double that of London. At present, with regard to the Thames water, our cry must be for efficient filtration, public and private.

FORESTERS AND PROVIDENT DISPENSARIES.

THE Committee and Medical staff of the Plymouth Provident Dispensary have been called upon to decide a very important question, and, in our opinion, they have decided most justly. A Court of Foresters applied for admission to the benefits of the institution in their corporate capacity. The Court numbered 270, and the annual subscription for the Medical attendant was 3s., that to the Dispensary being 4s. 4d., besides an entrance-fee. The Dispensary authorities determined not to accede to the request of the Foresters, mainly, apparently, because they dreaded that they in their own corporate capacity would be likely to come in collision with the Court in a similar capacity; but they seemed to hold out hopes that the men, if they came individually, might be accepted. At all events, their cases would be considered, as would those of anyone not being a Forester. It is true that some of the members of the Committee seemed to think that admitting such a body would injuriously interfere with practice in the town, whilst some seemed to think that the members of the club belonged to a class above that which the Dispensary was intended to help. Both were, we think, quite right. This is the first attempt of the kind; but if this system of Provident Dispensaries offers superior advantages to clubs, no doubt the men immediately concerned will be wise enough to see

that, and will strive to take advantage of them, and it is important that a definite line of action should be taken up by the Profession. We have no great love for the Provident Dispensary system, for we have no belief in the regenerating influence it is supposed to exercise on the minds of the thriftless poor. Mankind cannot be regenerated at the rate of ninepence or even threepence per quarter; if it could, the money would be well spent. We hold the Provident Dispensary system a mischievous thing, inasmuch as it tends to introduce the idea of aid to men who are and should be independent. Moreover, it may be used as a means of cruelly aggrandising one Practitioner at the expense of another. These evils we have insisted upon before, and here is one of them exemplified. A Court of Foresters comes and seeks admission to the benefits of an institution which we take to be, in part at least, supported by charity. Heretofore they have engaged some independent Medical man to attend upon them, and it is evident they have been able to secure the services of such in an independent fashion. Were they admitted to the Dispensary, they would be reaping the benefits of a charity at a nominal cost, and their former Medical attendant would be the worse off by the amount he formerly received from them. Neither, we take it, are things to be desired.

When Provident Dispensaries have been established it behoves all concerned to see that they are properly worked; and this we greatly fear is not generally done. Plymouth may be an exception, but we do not think the following looks like it. Their bill begins thus:—"Plymouth Provident Dispensary.—The Committee desire to make it known to the public that *all* persons can provide themselves and families with Medical advice, attendance, and Medicine, etc." We cannot think this is so—there must be some qualification; and in the interests of their brethren the Medical gentlemen belonging to the institution are bound to see that no improper cases are admitted. This is the more important, inasmuch as those who take Provident Dispensary work are of the same class as those who are excluded. They do not belong to the consulting class of Practitioners, as do Hospital Physicians and Surgeons, and in some instances such appointments are made to unfairly handicap men in the race of life.

If Provident Dispensaries are to be adopted, the system imperatively demands that there be an efficient working committee, so as to insure that no improper candidate be admitted; secondly, that every Medical man in the neighbourhood be invited to join in working the Dispensary. A member having been admitted, he should be at liberty to carry his card to whom he pleases, and the gentleman so selected is entitled to his share in the funds of the Institution. They talk of the out-patient system at Hospitals as having a pauperising effect on the public: we cannot see anything more likely to pauperise our Profession than the Provident system inefficiently worked. The rule in this country is to encourage self-help. To substitute a Provident Dispensary Committee for a Court of Foresters or a Lodge of Odd Fellows is not a step in the right direction. It may be more efficient and it may be more economical, but we question if even these advantages outweigh the value of independence. We are heartily glad that the Plymouth authorities have decided not to take such a step in the wrong direction.

THE WEEK.

TOPICS OF THE DAY.

THE changes introduced by Mr. Cardwell's new system of localisation and transference of head-quarters of militia regiments are likely, we are informed, to inflict a serious loss on those of our brethren who serve as Militia Medical Officers. Mr. Cardwell, in his answer to Mr. Wheelhouse last week, said that Militia Surgeons would not be required for attendance on the staff, nor for the inspection of recruits; but he presumed

they would be required during the annual training. It seems that there are nearly 100 Militia Surgeons in England and Wales, and a correspondent informs us that the average annual income of each of these gentlemen for attendance on the staff and the inspection of recruits, apart from their training-pay, calculated on the last twenty years, has amounted to about £100. The total amount of revenue to the Militia Surgeons for their duties has been, therefore, on an average £10,000 per annum. This the present economical Government intends to abolish. We hope that the Militia Surgeons will obtain representatives in the House of Commons, who will take care that at least their interests shall not suffer, except it can be shown that a large and unmistakable benefit to the public service must accrue—a result which, we suspect, Mr. Cardwell will have some difficulty in demonstrating.

The question of admitting cases of measles into the Metropolitan Fever and Small-pox Asylums was last week discussed by the Metropolitan Asylums Board. Dr. Cortis supported the opinion that cases of measles should be admitted on the same grounds that cases of scarlatina and typhoid are received. Sir M. Beach, M.P., and Mr. J. G. Talbot, M.P., argued that the Legislature never had any intention of providing accommodation for cases of measles. Dr. Bridges, the Government Inspector, also gave his opinion that it would be unwise to admit them. In this, as far as ordinary cases of measles are concerned, and in ordinary epidemic constitutions, the Profession would be generally, we think, agreed. It would be wrong to expose a child suffering from ordinary measles to the chance of catching typhus or small-pox by sending him to one of these Asylums. But, on the other hand, it must be remembered that at certain times, and amongst the children of the poor in unhealthy districts, measles assumes an epidemic and malignant form which might well qualify its unfortunate victims to be received into a public Hospital for contagious fevers. Such conditions, however, are exceptional, and ought to be met exceptionally.

Mr. Dale, of Scarborough, has had to vindicate his Professional character by bringing an action for libel against a Mr. Strickland Constable, of Wassand, near Hull, who has attacked him in a pamphlet entitled "Letter on Vaccination to a Medical Practitioner from H. Strickland Constable." The plaintiff, Mr. Dale, was requested to revaccinate the daughter of the defendant in March last. This he did, using all care in the selection of the lymph and the performance of the operation. On the evening of the day on which the child was vaccinated, a rash showed itself on the child, which proved to be the rash of scarlatina. The child was attended by Mr. Dale, Dr. Hutchinson, and Mr. Taylor until April 4, and her parents then put her under the care of a homœopathic practitioner. The defendant published his pamphlet containing the libel complained of, dedicated the first edition to Mr. Dale, and sent copies of it to the most influential of Mr. Dale's patients. The counsel for the plaintiff, Mr. Digby Seymour, said in his opening speech that "thirty-five pages of the pamphlet were a continuous libel on the plaintiff's skill and knowledge, as regards his treatment of the defendant's child, both in revaccinating her and his subsequent treatment, as well as his want of skill in other cases. The plaintiff was not alluded to by name, but no one reading the pamphlet and being acquainted with him could mistake for whom it was intended. The pamphlet, in fact, charged him with ignorance, incompetence, mercenary motives, and unscrupulousness in his Profession, and neglect and disregard of its duties." The case was tried at York on March 19, when Mr. Marson, of the Small-pox Hospital, Mr. LeGros Clarke, and Mr. W. D. Husband, of York, proved that the rash could have nothing to do with the revaccination. After hearing the evidence, the defendant's counsel, Sir John Karlake, made an apologetic speech, in which he stated that the defendant had written and published his pamphlet under the firm belief

that his child's serious illness was the result of the revaccination. After hearing the evidence, however, he felt that view was untenable, and he apologised for the statements he had made and the injury he had done the plaintiff. Mr. Digby Seymour said that the object of Mr. Dale in bringing the action was to vindicate his character, and not to obtain damages, and that he accepted the apology on the understanding that all charges of Medical and moral malpraxis were withdrawn. A verdict was then entered for the plaintiff, the defendant undertaking to pay all his expenses. We think that Mr. Constable got off very cheaply.

Mr. Ruskin has withdrawn all claims to the Rectorship of St. Andrews University. It is proposed to elect Professor Huxley.

Amongst the law reports of last week is a case in which it was sought to recover damages for the loss of two valuable colts killed by eating the clippings of a yew tree, which it was alleged had been carelessly thrown on the plaintiff's premises. Cattle have often been killed by eating yew.

The *London Gazette* of Friday, March 15, announced that on the preceding day the Queen conferred the honour of knighthood on Dr. John Rose Cormack.

Mr. Liebreich's theory, that the decadence in colour to be observed in Turner's and Mulready's earlier and later paintings is really to be ascribed to colour-change in the humours and lenses of the eyes of those distinguished painters, which he broached in his recent lecture at the Royal Institution, is a very ingenious one, and is quite worthy of investigation. For our own part, we do not think it in any degree accounts for what the *Saturday Review* calls Turner's "colour-madness"—for the vast chasm, for instance, between the glorious "Crossing the Brook" and the white-and-yellow daub of "Going to the Ball." Brain-change as well as eye-change can alone account for such a deterioration. But still, Mr. Liebreich's theory is very suggestive, and a thoroughly scientific one. He will only be amused by Mr. Ruskin's characteristic criticism in the *Pall-mall Gazette* of March 16—"That Mr. Liebreich is an ingenious and zealous scientific person. The public may derive much benefit from consulting him on the subject of spectacles—not on that of art."

Dr. Quain's Lumleian Lectures "On the Diseases of the Muscular Structure of the Heart" at the Royal College of Physicians are just now of particular value, because they recall the attention of the Profession to the great fact that, practically speaking, the condition of the propelling organ is the vital matter, that of the mere outlets and valves is only comparatively of secondary importance. All who have had much experience in heart disease will recall cases similar to those related by Dr. Quain, where persons have gone on to extreme old age with undoubted valvular disease, which, as long as the muscular structure of the heart was sufficient to overcome or compensate, was absolutely of no importance. Another point which Dr. Quain brings out is the serious increase in heart affections in our male population between the ages of 20 and 45—no doubt attributable to the high-pressure living of the present day. The evidence by which he is establishing hyperplasia of the connective tissue of the heart in some cases of cardiac enlargement is also a point in these lectures which should not be missed. To-day (Friday, March 22) he treats of Fatty Degeneration, Rupture, and Aneurism.

SANITARY REPORTS, AND GRUMBLINGS THEREON.—LEEDS; BOMBAY;

DR. BRYDEN ON THE INDEPENDENT EXISTENCE OF EPIDEMICS.

DR. ROBINSON'S report on the sanitary condition of Leeds for the year 1871 speaks to the eye, for it contains two capital maps, showing the habitat of every patient affected with fever

or small-pox in the year 1871. The spots where the two diseases prevailed are almost identical. We hope that some day, out of the mass of material accumulated by Officers of Health, Dr. Ballard, or someone equally competent, will deduce some law whereby the relative or alternate prevalence of each may be explained; for, as things are now, it seems as if we expel one epidemic only to make way for another. Thus (says Dr. Robinson), during the last six years, typhus has declined, typhoid has increased; measles goes down, scarlatina takes its place; if there is a decrease in zymotic mortality one year, there is an increase the next—there were more deaths from zymotics in the last three than in the first three of the six.

We very much doubt the policy of including diarrhoea amongst the zymotic diseases, because, although we fully believe that it is, under many circumstances, infectious, yet by far the greatest number of cases clearly arise, not from infection or the spread of a ferment, but from the influence of heat and improper food on infants under one year. Nothing is a better test of the moral and physical condition of a population than their ability or not to rear their young children.

The more we read of sanitary reports, the more we see that conditions prevail in towns and villages which Medical Officers of Health may report on and condemn, but which they are helpless to prevent. For instance, Dr. Robinson says that, "if the Building Clauses Committee could be induced to expunge the by-law which permits the building of back-to-back houses, still further sanitary progress would be made." Of course it would. But what a fact this is: that, past the middle of the nineteenth century, landowners should be permitted to build human pigsties in which fresh air is unattainable. It is some comfort to learn that the Sanitary Committee of Leeds have determined to buy up and destroy 293 of the most unwholesome houses, and that the midden system is to be abolished.

Dr. Robinson's report contains one provision of unusual liberality, to the effect that in any new epidemic hospital provided by public authority patients may, if they choose, be attended by their own Medical advisers. This provision would remove much of the objection which many persons feel to entering such institutions, and thereby losing the services of their own Medical advisers. There are many institutions for persons of the better classes to which such liberality might well be extended.

Dr. Hewlett's report on the health of Bombay for the fourth quarter of 1871 takes us into a very different part of the world, but we meet with the same well-known evils—zymotic disease, defective sewerage, and impure water-supply. Of 3914 dead bodies, 2582 were buried, 1097 were burnt, and 235 taken to the Tower of Silence, to be devoured by birds, after the Parsee custom. Prostitutes are submitted to a weekly examination, and less than this is not sufficient in Dr. Hewlett's opinion; but of 275 names added to the list of prostitutes during the quarter, very nearly one-half were of widows, who may be supposed to have been victims of want.

Dr. Bryden, the Statistical Officer attached to the Sanitary Commissioner with the Government of India, has issued a clearly reasoned "Note on the Epidemic Connexion of the Cholera of Madras and Bombay with the Cholera Epidemics of the Bengal Presidency." This "Note" is in reply to the conclusions of Mr. Cornish in his "Report on Cholera in Southern India," and the question involved is, "What is Cholera, and How does Cholera Move?" Is there such a thing as a cholera miasm, having an existence and a life of its own, existing apart from mankind, and transported by the wind; or is the cholera dependent on the human race for its existence and movements? Dr. Bryden upholds the former, Mr. Cornish the latter view; and Dr. Bryden in this "Note" supports his own view by reference to the great cholera invasion of 1818. We could not enter into a discussion of the matter without details and maps which we cannot introduce. We will observe

thereupon that in India, where earth, air, and water, as well as the human race and its appurtenances, must be pretty thickly sown with cholera seeds, the conditions of diffusion must be more complex and uncertain than in Europe, where cholera appears rarely, and every step can be traced; and on this point we would call attention to the Rev. Dr. Haughton's paper, which appeared some time since in this journal, in which he demonstrates the propagation of the disease in Ireland by human intercourse only. Secondly, it is curious to notice the kind of independent existence which these writers ascribe to a cholera epidemic—speaking of its *life* and its *death*, its *life-period*, etc. "Every student of the natural history of disease in India," says Dr. Bryden, "knows the broad fact how, when cholera and malaria die, typhus and small-pox step forward to take their place; and how, when typhus and small-pox die, cholera and malaria resume their sway"—a dismal, but only too well ascertained fact. Now, as these diseases seem to be alternate, but not mutually exclusive, is it not probable that each depends on some special condition of human impurity, and that what we want to learn is, What can we do to destroy this impurity at its roots?

Dr. Bryden has favoured us also with a "Report on the Age and Length of Service as affecting the Sickness, Mortality, and Invaliding of the European Army," which gives a terrible history of the cost in human life of our Indian possessions. There is one class of diseases which affect the young soldier on first landing, others that affect the old soldier; and it is a significant fact that a man above 30 is regarded as an old soldier. Dr. Bryden tells us in his concluding paragraph what has been in eight regiments the result of twelve years of Indian service amongst men who landed with the regiments when they came out to India. The aggregate of the body on landing was 5836. Out of this body 676 men embarked for England with the regiments on their return. The deficit of 5160 was made up thus:—Died, 1356; killed in action, 89; invalided for wounds, 64; invalided for disease, 1226; discharged, time expired, 1129; purchased their discharge, 131; transferred to other regiments, or removed otherwise, 1165. In round numbers, during twelve years' service, a fourth of the men die of disease; a fourth are invalided for disease; the deaths and invaliding for wounds do not amount to 3 per cent.

Dr. Bryden shows, with the utmost clearness, that young soldiers suffer from fever, heat apoplexy, and dysentery; old soldiers from heat apoplexy, hepatitis, and intemperance. His commentary on the causes of death will command the most earnest attention of the statesman who desires to diminish the drain of English lives. His observations on the typhoid of India are appalling. It is a disease which especially attacks the young recruits during their first hot season, and, as he believes, may be self-developed, but, however engendered, is pre-eminently infectious and contagious. It is not known amongst the natives, as tested by the experience of the native army and gaol population. He shows that one form of lung infiltration leading to phthisis is a consequence of typhoid.

MILITARY POST HOSPITALS.

UNDER the title "Circular No. 2—Approved Plans and Specifications for Post Hospitals, Surgeon-General's Office, Washington, July 27, 1871," the War Department of the United States has issued a short but most comprehensive account of the construction of Hospitals for military posts. Provision is made for earth-closets, and for warming and ventilation; and in malarious regions and Southern climates the sick are to be accommodated on the first-floor. Let us observe that the "first-floor" or "first storey" of a house means that which is above the ground-floor—*au première*, as the French say. It is perplexing to have a divergence of meanings, even on an unimportant point.

GUY'S HOSPITAL BIENNIAL FESTIVAL, 1872.

Guy's may well be proud of its *esprit de corps*, which is especially shown at its biennial gatherings. On Friday, March 15, 289 sat down to dinner in the large hall at Willis's Rooms, King-street, St. James. Old Guy's men from all parts of the country met together, and some few guests were invited. Those guests present were the President, Treasurer, and Chaplain of the Hospital; the President of the Royal College of Surgeons, and the Master of the Apothecaries' Society (Dr. Burrows, the President of the Royal College of Physicians, being prevented from attending); Lieutenant-Colonel Beresford, M.P. for the borough; Mr. John Locke, M.P.; and Mr. Amphlett, M.P., Q.C. After the usual loyal toasts, that for the "Army, Navy, and Volunteers" was responded to by J. W. Jeston, Esq. (for twelve years—from 1812 to 1824—in the army during the Peninsular War, with Lord Wellington, at the battle of Salamanca, and throughout the rest of the campaign), J. T. Musgrave, Esq., and Lieutenant-Colonel Beresford respectively. The toast of the evening was—"Success to the School of Medicine and Surgery attached to Guy's Hospital." Then followed others—viz., "The President, Treasurer, and Governors of Guy's Hospital," by Dr. G. Owen Rees; "The Universities and Royal Colleges, and the Society of Apothecaries," by R. P. Amphlett, Esq., M.P., Q.C., the uncle of one of the present students at the Hospital; "The Medical and Surgical Staff, consulting as well as acting," and "The Teachers in the School of Guy's Hospital," to which Mr. Cock, Sir W. W. Gull, and Mr. Birkett responded; and finally "The Honorary Secretary, Mr. Durham." We may here add that this gentleman deserves the thanks of all old Guy's men for the efficient and cordial manner in which he works, and succeeds in making these biennial festivals comfortable and enjoyable. The whole arrangements of the meeting, and especially those by which nearly every man was placed amongst his friends, must have given enormous trouble to the Honorary Secretary; but it must be gratifying to him to feel that the result was appreciated. Another source of pleasure was the musical element, which was contributed by the Guy's Hospital Glee Club. This gave great satisfaction, and the men who sang, entering as they did so thoroughly into the spirit of the gathering, roused much more interest in their performances than could be produced by those of ordinary professional singers.

MEASUREMENT OF TEMPERATURE BY THERMO-ELECTRICITY.

MR. SIEMENS, in a discourse at the Royal Institution on the evening of March 1, took for his subject the method of measuring temperature by the application of thermo-electricity. After a few preliminary remarks, the lecturer proceeded to state the purpose he had in view—to explain the principle, and demonstrate the use of an instrument which he had succeeded in contriving to supply a present double want—namely, the means of estimating the temperature of places practically inaccessible, and of estimating temperatures exceedingly high. Hitherto the particular effect of heat which physicists have most frequently availed themselves of, in the instruments they have devised to determine its amount, is that of the expansion or contraction of the body which the heat affects; this is seen in Galileo's air thermometer; in the ordinary thermometers in daily use; as well as in pyrometers—for example those of Wedgewood and Daniell. In respect of the pyrometers, the lecturer showed that they were by no means thoroughly reliable, from this very principle on which they worked; and it was to replace these instruments by one that could be absolutely depended upon that he had availed himself of the electrical effects of heat in estimating its amount. Before, however, describing his new pyrometer, Mr. Siemens illustrated some of the principles of thermo-electricity by experiments. The powerful influence of a very small increment of heat at one point in a galvanic current was first demonstrated by the deflexion of the magnetic needle it produced. Two symmetrical thermo-piles were next

produced, each in the form of an iron spiral on a wooden cylinder, the whole being enclosed in a silver tube. The wires of the two being connected with a differential galvanometer, it was found, as was to be expected, that as long as the piles were subjected to exactly the same temperature, the needle remained at zero; whilst, on the other hand, the least alteration of the temperature of either pile was followed by a visible deflexion. By way of example, the lecturer placed the one pile in a vessel of warm water, the temperature of which was known by an ordinary mercurial thermometer it contained, and the other in the hand of the President—Sir Henry Holland. At once the needle was deflected, proving that the amount of heat affecting the two piles was unequal. So far the measurement was comparative only, but it was easy to make it positive. For example, the temperature of the President's hand could be taken by heating, or by cooling (as the case might be) the water surrounding the first pile until the needle pointed to zero, when the mercurial thermometer in the vessel of water was found to indicate the temperature of the skin in contact with the second pile. One manifest advantage of this method of determining temperatures is, that by it the heat of inaccessible places may be accurately estimated. For example: of the sea at any depth, one thermo-pile has in this case simply to be sunk the necessary distance, and the other with the galvanometer kept on the ship's deck.

Here we might ask, Could not this means of estimating temperature by the thermo-pile be made more available than it at present seems to be for the determination of the relative amount of vital heat in the different parts of the body? The ease and accuracy with which their relative heat could thus be determined might, we should hope, have the happy result of bringing to a more satisfactory agreement the conflicting statements with which we are at present supplied on the subject. The principle has indeed been made use of: on one occasion with which most of us are familiar, in the experiments of Mr. Simon upon the temperature of inflamed blood. Two small thermo-piles of platinum and iron, sharpened terminally into pins, so as to be readily pushed into the tissues, were inserted into different vessels, and the relative heat of the blood which these contained accurately determined by the deflexion of the needle of a galvanometer. By this means Mr. Simon was enabled to state that the blood returning from an inflamed limb is warmer than that going to it, and warmer, also, than the blood of the corresponding uninflamed limb.

After the illustrative experiments which we have mentioned, Mr. Siemens proceeded to describe his new pyrometer. This consists essentially of a cylinder of fire-clay supporting a platinum spiral, from the extremities of which the wires are conveyed in a protecting metal tube. The thermo-pile so constructed is subjected to the heat, whose amount has to be estimated; and the relative effect on it and on the second pile is estimated, not by a galvanometer, but by a voltameter. To illustrate to the audience the use of his instrument, Mr. Siemens estimated in succession the temperature of melting ice, of boiling water, of molten lead, and of iron at a dull red heat. Even the last, however, is low compared with the exceedingly high temperatures which have been measured by this pyrometer, which is already in frequent use.

SMALL-POX JOTTINGS.

IN Aberdeen the return of small-pox cases last week shows—Total number of cases admitted at the Hospital since opening, 132; new case admitted on the 14th inst., 1; number of patients at present in Hospital, 38; total discharged recovered, 76; total died, 18.—Two deaths occurred last week from small-pox in Mile-end Old Town.—In the Limehouse district there had been no death from small-pox in the past fortnight, and only three fresh cases brought under notice.—In the Stockwell Hospital, during the past fortnight 63 patients had been received; 4 died, and 53 were discharged, leaving 117 at present under treatment, as against 111 at the date of

the last return. The number of fresh cases during the last fortnight has been higher than in the preceding one.—In Homerton Hospital, during the two weeks ending the 12th inst., there had been 63 admissions, 7 deaths, and 24 discharges, leaving 125 under treatment.—In the Poplar district, in the past week, 4 deaths from small-pox were registered in the union, and 12 new cases were brought under notice. In the same period 65 persons were vaccinated at the public stations. There were at that time 4 small-pox patients under treatment in the North-street Infirmary.—Dr. Whitmore, in his report to the Marylebone Vestry last week on the question of epidemic outbreaks, observed that “it is useless to expect either to shorten their duration or lessen their frequency unless some legislative enactments be passed which shall effectually prevent personal communication or intercourse between the infected and the healthy. Neither pure water, efficient drainage, or free ventilation will prevent one person from taking small-pox or fever from another if the two come into personal contact. I have been often astonished and disposed to form a very low estimate of the feelings of natural affection common to the poorer classes to observe their total disregard of precautionary measures when any of their children are suffering from contagious and infectious maladies; but what surprises me more is that some Medical Practitioners will be content to attend a child forming one of a family of six or eight persons through an attack of scarlet fever or small-pox, and will take no steps for isolating it, although the entire family occupy at most but two small, dirty, ill-ventilated rooms. Pauper cases have in this respect great advantage.”—Twenty-four deaths occurred in Sheffield from small-pox last week. The deaths from the disease in the three previous weeks had been 37, 38, and 24. Considering the frequent and severe epidemics of small-pox which have recently prevailed in the borough, the continued neglect of vaccination is remarkable. Of the 24 deaths from the disease last week, 14 were unvaccinated cases, 1 was reported as vaccinated, while the 9 were not stated as to vaccination.—Dr. Aldis reports one case, vaccinated, which was sent to the Hospital.—The Registrar-General’s return for the year 1871 shows that in London alone 7876 persons died from small-pox, and that during the same period 13,174 deaths occurred from the disease among the population of seventeen large English towns.—There was only 1 death from small-pox in the City last week.—Two fresh cases of small-pox during the past fortnight were reported in the Holborn district.—Forty-two deaths occurred in London from small-pox last week.—In Dublin 54 fatal cases of small-pox were reported last week, against 37 and 41 in the two previous weeks. At nearly all the Hospitals a fresh increase of the epidemic in extent and severity has been experienced during the last fortnight. The hæmorrhagic form has been very frequently observed.

TANNER PRIZE AT KING’S COLLEGE.

A LITTLE over £150 has been received towards the proposed Tanner memorial. Before closing the subscription-list, we are asked to state that whatever sum of money is collected will be handed over to the Medical Board at King’s College to invest, and with the interest to establish an annual prize of books or instruments, to be selected by the student proving himself by examination most proficient in Obstetrics and Diseases of Women. A prize of this kind is much wanted, and it is hoped, therefore, that many King’s College men will join in making the amount worthy of the name of Tanner, and of the College of which he was a distinguished member. Subscriptions are to be forwarded to Dr. Percy Boulton, Treasurer, 6, Seymour-street.

FROM ABROAD.—SUPPOSED DEATH FROM CHLOROFORM—THE FRENCH TEMPERANCE ASSOCIATION—FIBROID TUMOURS OF THE UTERUS—COMBINATION OF INJECTION OF MORPHIA WITH INHALATION OF CHLOROFORM.

M. TRÉLAT brought recently (*Gaz. des Hôpitaux*, March 5

and 9) under the notice of the Société de Chirurgie a case of “Sudden Death during an Operation,” in which the question arose whether this was due to chloroform or to the admission of air into the veins. The patient, who was 32 years of age and in good health, was operated upon for the removal of a small tumour at the anterior edge of the sterno-mastoid, this tumour having appeared in the angle of the wound left six weeks before after a similar operation successfully performed under chloroform. On the present occasion, complete resolution was produced by chloroform; and the first incision had hardly been made when the patient was found to be colourless, and without pulse or sounds of the heart. In spite of all attempts at resuscitation, he died. At the autopsy a small vein opening into the external jugular was found to have been obliquely opened. The jugular contained a long clot segmented by some bubbles of air; other bubbles existed in the mediastinal and posterior cardiac veins. The right ventricle contained a notable quantity of air, and some small ecchymoses were the only thing remarkable observable in the lungs.

Although air was thus found in the veins, M. Trélat felt disposed to attribute some influence to the chloroform; for while death at once and finally takes place when it is due to the admission of air, life during the efforts made in this case was for an instant partially restored. M. Perrin was of opinion that death here arose from the chloroform. On closer examination, cases of death from admission of air are found to be much rarer than supposed; and M. Claude Bernard, in his experiments on animals, rarely found air enter in consequence of wounds of the neck. The bubbles of gas observed in the veins in this case were probably due to putrefaction and decomposition of the blood. In attempts at restoration, M. Perrin believes that insufflation by means of a tube passed into the trachea, and a bellows, is a far superior means to the from-mouth-to-mouth procedure, or to Marshall Hall’s procedure. There is little fear of lacerating the pulmonary tissue or of inducing emphysema. M. Le Fort, on the contrary, believed that death was due to the admission of air, and that chloroform should not be charged with it. He had met with a case very analogous to this one. Performing tracheotomy for asphyxia in laryngeal phthisis, the trachea being very short and the thyroid gland very large, immediately after the incision along the median line, which gave rise to a large flow of blood, the patient dropped down on the bed quite dead. After chloroform, the patient is at first blue, and then pale, death ensuing in a less rapid manner. At the autopsy a large vein which had been divided contained air, and through it this gained access to the large veins and the heart. In attempts at resuscitation, M. Le Fort prefers Sylvester’s procedure. M. Giraldès believed that death here was produced by chloroform, and he referred to various cases of death from it in which air was found in the veins. M. Sée took a similar view, and did not believe in the admission of air, inasmuch as the vein was small and superficial, and not gaping; there was none of the characteristic sound which takes place when air enters, and after death there was no intimate, spumous mixture of air and blood. The air found resulted from incipient putrefaction, such as is indicated in the marbled appearance of bodies which are still fresh. M. Depaul, on the contrary, believed that chloroform was not here the cause of death. The openings made in the veins in the cases of MM. Trélat and Le Fort constitute the capital fact; and any explanation of the presence of air by putrefaction is defective, inasmuch as the air was only found in the divided veins and those which led from them to the heart, the other veins being devoid of it. He has no confidence in any treatment but insufflation; but while he thinks as highly as M. Trélat of its performance by a tracheal tube, he has a good opinion of the efficacy of the from-mouth-to-mouth procedure. M. Blot could not see how the effect of the entrance of air here could be denied, but he at the same time admitted that the chloroform may have contributed

to the result by preventing the individual from reacting against the effects of such entrance of air. Such entrance was the primary cause of death, although the state of complete resolution in which the patient was facilitated the fatal issue. He advanced cases to show that the admission of a small quantity of air need not be fatal, and patients who have not been chloroformed can better resist its effects. M. Demarquay believed that death had resulted from the chloroform, relying chiefly on the fact that the blood was not spumous, as it would have been had a sufficient quantity of air to cause death been introduced. A small quantity may be introduced with impunity. To appreciate the quantity contained in the vessels, the autopsy should be performed under water.

It seems strange, in face of the gigantic organisations in America and England which have been so many years in operation, that France has still her first "Association against the Abuse of Alcoholic Drinks" to organise. The Committee appointed for this purpose consists exclusively of Medical men, and, although these are of high position, it is to be regretted, in reference to the influence to be exerted upon society at large, the aid of other classes has not been sought. The annual subscription, too, of 20 fr. is far too high to allow of any extensive co-operation of the poorer classes, whose enthusiasm and energy have done so much for the cause of temperance in England. A nominal subscription of a franc or two, with donations from wealthier members, would be more likely to set the Society afloat. A mere society of Professional persons will occupy too much time in dissertations on evils which everyone acknowledges, and employ too little actual exertion in securing the active co-operation of the masses. One of the proposed objects of the Association tends in this direction, and, if realised, will also check adulterations which so much add to the mischief. It is "to favour, principally by means of co-operative societies of consumption, the replacing of spirituous liquors as the ordinary drink by means of coffee, natural wines, beer, and cider."

That the Association has ample justification for its appeal may be seen from some of the figures which it publishes, indicating an "alarming progression in the abuse of alcoholic drinks." While, in 1820, the consumption of alcohol was only 350,000 hectolitres, it increased to 585,000 in 1850, and to 970,000 in 1869, without comprising the amounts which escaped the excise dues. In 1850, of 950,000 hectolitres manufactured in France, 850,000—*i.e.*, nine-tenths—were the product of distillation of the vine; but in 1869, of 1,410,000, the vine only furnished 410,000—scarcely three-tenths. The remainder was produced by the distillation of beetroot, molasses, grain, and other farinaceous substances. The hectolitre of alcohol, which in 1850 was worth 200 fr., is at the present time sold for 50 fr., and the number of places for the sale of drinks has progressively increased to one for 102 inhabitants. Some of the consequences of this increase of consumption have been disastrous. Between 1849 and 1869 the annual number of deaths due to excessive drinking increased from 331 to 587, and that of suicides from the same cause from 240 to 664. Crimes against the person, committed under the influence of drink, have increased in like proportion. The unfavourable influence exercised by the habits of drink, not only in increasing the amount of disease, but in imparting a character of exceptional gravity to even slight surgical and internal affections, is proved by results which are causing more and more anxiety. Cases of insanity, too, of alcoholic origin, have been constantly on the increase during the last twenty years, and especially in the departments in which alcohol produced from beetroot and grain is consumed. In most of these such cases have been quintupled, attaining the fearful proportion of from 25 to 40 per cent. The Committee of Organisation consists of MM. Barth, Baillarger, Bergeron, Bouchardat, Chauffard, Déchambre, Fauvel, Hérard, Larrey, Roussél, and Luniér.

M. Guéniot, a candidate for membership of the Academy of Medicine in the Section of Accouchements, has communicated an example of that rare occurrence, the disappearance of an uterine fibroma by absorption. In his opinion, founded on M. C. Bernard's experiments on the pancreas, when a fibroma or myoma thus disappears it first undergoes fatty degeneration; and, therefore, those agents should be employed in their treatment which tend to produce fatty transformation of the tissues or organs. The principal of these are arsenic, phosphorus, and lead; and it is to such medicinal substances recourse should be add much rather than to mercury, iodine, bromine, and alkalies. The following are his conclusions:—1. The cure by absorption of certain fibroid tumours of the uterus, still sometimes disputed, may henceforth be regarded as a truth definitively proved. 2. These tumours may even undergo a rapid dissolution, some months sufficing in various cases for the complete disappearance of even large myomas. 3. In the cases hitherto observed, absorption has taken place during the period of activity of the genital affections; but the puerperal state has only quite exceptionally exercised an evident influence. 4. Uterine myoma may also disappear without Surgical operation by two other modes—*viz.*, spontaneous expulsion and gangrenous destruction or suppuration. But its disappearance by absorption being the only mode completely exempt from danger, and followed by cure, is that which should especially be sought to be induced. 5. Although the attempts made in this direction have almost constantly been unsuccessful or dubious in their results, some facts authorise us to believe that treatment is on the road of progress. 6. As far as can be judged by analogy, an uterine myoma, in order to become susceptible of absorption, must first undergo a fatty transformation of its mass. 7. The employment of steatogenic substances, such as arsenic, phosphorus, lead, etc., seems especially indicated in view of this result.

The *Gazette Médicale* of March 16 contains a case of uterine fibroid minutely detailed by M. Abeille, in which a very difficult and prolonged operation was performed for its removal with success.

MM. Labbé and Guyon recently read a paper at the Académie des Sciences, in which they gave an account of the results obtained in four cases in which they had tried the combined effect of hypodermic injection of morphia and the inhalation of chloroform. They were induced to enter on the investigation by having observed numerous experiments of M. Claude Bernard at the Collège de France, which demonstrated that, by such combination, very complete anæsthesia may be obtained by means of a much less quantity of chloroform than when this substance is employed alone. About the same time that M. Bernard was pursuing these researches, Professor Nussbaum, of Munich, with a view to the prevention of the pain consecutive to operations, injected in several cases the acetate of morphia while the patient was under the influence of chloroform. In all his cases pain continued suppressed, and sound sleep was prolonged for several hours after the operation.

While Professor Nussbaum, however, employed the morphia during the anæsthesia, MM. Labbé and Guyon injected it before this was produced, their object being also different—not the prevention of consecutive pain, but facilitating the production of anæsthesia and rendering it less dangerous by reason of the smaller quantity of chloroform employed. At present they have only resorted to the means in the four cases, abstracts of which they now lay before the Academy. In the first of these, twenty minutes before the performance of an amputation, two centigrammes of muriate of morphia were injected into the thigh, and then chloroform was administered. In seven minutes anæsthesia was complete, and was prolonged for a long time after the operation, which lasted seventeen minutes. The quantity of chloroform employed was twenty-

eight grammes. In a case of ovariectomy, occurring in a girl of 20, the chloroform was given twenty minutes after the injection, and complete anæsthesia was produced in six minutes. The operation lasted an hour and forty-five minutes, and the expenditure of chloroform during all this time was only forty-eight grammes. The patient continued in a state of complete resolution, and after the operation was entirely calm, having felt no pain whatever. Incomplete as are their researches at present, the authors feel entitled to conclude: first, we can in man—as M. Claude Bernard has shown can be done in animals—obtain anæsthesia much more rapidly by combining the action of chloroform and morphia; secondly, that this anæsthesia is of longer duration, and may be kept up by smaller doses of chloroform, the risks of fatal accidents being thereby considerably diminished. They suggest also that the quantity of morphia injected may be somewhat larger than that which they employed, and that the injection might be conveniently practised a longer time before the operation.

PARLIAMENTARY.—METROPOLIS WATER-SUPPLY—PUBLIC HEALTH BILL—NEW BURDEN ON THE RATES.

In the House of Commons on Thursday, March 14,

Mr. Kay-Shuttleworth asked the hon. and gallant member for Truro whether (under the eighth clause of the Metropolis Water Act of last session) the Metropolitan Board of Works had made, or were about to make, application to any of the water companies requiring them to give a constant supply of water in any districts of the metropolis, seeing that the six months named in the statute had now elapsed.

Colonel Hogg said, in answer to the question of the hon. member, he would permit him to remind him that before the companies could be compelled to provide a constant supply of water the regulations as to fittings, according to Section 10, were to be in operation. The companies issued their proposed regulations a few weeks since. These were at once considered by the Metropolitan Board, and placed before an engineer of great experience in such matters for his opinion as to their fitness; he had already made a preliminary report, which the Metropolitan Board had submitted to the Board of Trade, with a request that a full opportunity would be allowed for the complete and most careful examination of the regulations. The importance of such an examination would be obvious, as the question of these regulations went to the very root of the subject.

In answer to Lord R. Montagu,

Mr. Stansfeld said the port of London extended from Teddington to far beyond the Nore. As to the blank in the Public Health Bill, with reference to the port of London, he intended to fill it up by proposing that the Sanitary Board should be the sanitary authority for the port of London. As to the other ports, he proposed to take power to constitute the local sanitary authorities the sanitary authorities under the Bill, after inquiry had been made into the exigencies and conditions of those ports. As to the metropolis, it might probably be thought desirable that the sanitary authority should be fixed by the House, and not by the Local Government Board; and he had left a blank in the Bill in order that he might have an opportunity of ascertaining the opinion of London on that subject.

Sir Massey Lopes asked the President of the Local Government Board whether he was able to give any estimate of the average increased rate, in the pound which the provisions of the Public Health Bill would impose upon the ratepayers for the following objects, or any one of them:—Expenses of offices, officers, and other establishment charges; of sewerage works and prevention of nuisances; expenses relating to supply and purity of water; of disinfecting apparatus and conveyances for infected persons; for Hospital accommodation, dispensaries, Medicine, and Medical attendance for non-paupers; and whether he proposed, and, if so, by what means, to give effect to the recommendation of the Sanitary Commission that the expenditure for such sanitary objects should be aided by the State.

Mr. Stansfeld regretted that the hon. baronet did not consult him before putting the question, because he should have told him that some modification of it was necessary. It was impossible with reference to a Bill which had not yet passed the second reading to make any but the most hypothetical and untrustworthy statement as to its financial effects upon localities. As to the second part of the question, the recommendations of

the Sanitary Commissioners were at this moment under consideration, and he would not ask the House to agree to any proposal involving expenditure without being prepared to state the intentions of the Government upon this subject.

DR. QUAIN'S LUMLEIAN LECTURES, AT THE ROYAL COLLEGE OF PHYSICIANS,

ON THE

DISEASES OF THE MUSCULAR WALLS OF THE HEART.

LECTURE I.—MARCH 15.

DR. QUAIN commenced by observing that he had chosen the subject announced because he had shared with others the great interest attaching to the study of the heart and its diseases, and because of those diseases the affections of the valves had received a perhaps undue share of attention. By many, hypertrophy and dilatation were regarded as mere complications of the diseases of the valves, whereas a truer view to take of the subject was, that the diseases of the valves were occasionally a useful index to the presence and progress of the affection of the walls. The evidence in favour of this view of the subject Dr. Quain embodied in certain propositions based on clinical experience, each of which was illustrated by cases. 1st. All would admit, he said, that the really serious effects of heart disease were due to the hypertrophy and dilatation. 2nd. A person with valve disease alone might through life be unaware of its existence from the protective influence of the hypertrophy. 3rd. Not unfrequently valve disease, before unnoticed, suddenly caused much disturbance on the occurrence of damage to the walls. A patient of the lecturer's only began to suffer from a cardiac affection when he was told of its existence and restricted in his former habits, a return to which relieved him of all cardiac trouble at once and permanently. 4th. Additional hypertrophy will often compensate for additional valvular mischief. 5th. In such cases failure of cardiac walls is accompanied by progress in the disease. Lastly, dilatation of the heart may itself cause valvular incompetency.

The first diseased condition which Dr. Quain considered was enlargement. This, he said, was due to either hypertrophy or dilatation, commonly to both combined. After glancing at "concentric hypertrophy," as it used to be called—a state which had no real existence—he sketched briefly the history of hypertrophy, dwelling especially upon a description of it by Mayow, which was nearly that which might be given now. The changes which constitute hypertrophy were then described. Either of the three chief elements in the walls—muscular fibres, connective tissue, or fat—might be so abnormally abundant as to cause increase in size. The first form—simple muscular hypertrophy—was so familiar as hardly to need description. The second—hypertrophy of the connective tissue—was not yet recognised as a distinct disease, though such it undoubtedly was, and of great importance. Many cases during the last twenty years had come under Dr. Quain's notice. The state was alluded to by several writers on heart disease, though nowhere fully described. A heart so changed had its walls denser and firmer than normal, even of leathery consistence; its colour varied, and might not be greatly different from the colour of simple muscular hypertrophy. Under the microscope, connective tissue in all stages of development was seen between and compressing the muscular fibres. Its origin was a chronic inflammation or hyperplasia of the connective tissue. The third form—fatty hypertrophy—was distinct from fatty degeneration, though often confounded with it. The enlargement was due to increased growth of fat beneath the pericardium and between the muscular fibres.

Dilatation of the heart and its mode of origin were then described, especial stress being laid upon the occurrence of dilatation when the pressure of the circulation is normal, but the cardiac walls degenerated. Some instances of very large hearts were narrated, due to concomitant dilatation and hypertrophy. Bouillaud had described one weighing 34 oz., Lancisi one weighing 2 lbs., and Gibb and Bristowe each one weighing 46½ oz.

The lecturer then passed to the consideration of the causes of these forms of cardiac enlargement. Placed as the heart-

was, in the centre of the system of combined actions called life, it was liable to suffer from derangement of its own mechanism or of the other organs with which it is related. The morbid agencies acting upon it might be grouped in three classes:—First, influence of the nervous system shown in the effect of moral influence. Heart disease was considered to have been more frequent during the French Revolution than before; and the excited life of the present day seemed to be having a marked effect in increasing the amount of heart disease. Some statistics of Dr. Farre's showed that the percentage of deaths to the population living had risen by one-half during the last twenty years among men between 20 and 45 years of age, while in men under 20 and in women over 20 it had remained the same. The second class of causes comprehended the mechanical agencies. Habitual severe exertion was one of these—seen in the effect, often so injurious, of many laborious occupations, and of undue athletic exercise. This was no doubt the cause why hypertrophy of the heart is, as Vanderbyl showed, nearly twice as frequent in men as in women—a consideration worthy of the attention of those who were always trying to put women into the places of men. The chief mechanical causes, however, were those occurring in the course of the circulation in the heart, in the great vessels, or in the distal circulation. Two examples of the latter—that in Bright's disease, and pregnancy—were described at some length. A very interesting sketch was given of the history of the explanation of the hypertrophy of albuminuria, which refers it to obstruction to the flow through the small vessels, and has been chiefly connected with Bright and Johnson. Mr. James, of Exeter, was the first to propose it, in 1817. The fact of the enlargement in pregnancy was undoubted, but its explanation was less certain. It was probably due partly to the need for more blood for the uterus, and partly by the uterine pressure on the great vessels. Its relation to the albuminuria of pregnancy is still uncertain.

In conclusion, the influence of disordered nutritive functions on the heart was briefly alluded to. Such influence might be one acting on the whole system, as anæmia, etc., in which dilatation is the common form of morbid change. Of those acting on the heart alone, the most interesting was that connected with pericarditis and adhesion.

There had been much discussion as to the state of the heart in these cases. It was usually enlarged, but sometimes diminished. In each case the chief change was probably an increase in the connective tissue.

Finally, hearts were sometimes met with whose enlargement could not be referred to any of the above causes. Such were some of the enormous hearts on record. It might be that some of these were due to the form of connective-tissue hypertrophy. This opinion Dr. Quain said he had written a few days before almost as a prophet, for since writing it examination of one of these hearts, preserved at St. George's Hospital, had shown that a considerable part of the enlargement was due to connective tissue.

THE
REGISTRAR-GENERAL'S ANNUAL
SUMMARY OF BIRTHS, DEATHS, AND
CAUSES OF DEATH

IN LONDON AND OTHER LARGE CITIES IN 1871.

It will be well to print for reference the pithy statistical abstract with which the Registrar-General prefaces this Summary:—

“LONDON, 1871.—*Area*: The area of London (the registration division so called) is 78,080 acres, or 122 square miles, including 2718 acres of the Thames; this is equal to 31,597 hectares, or 316 square kilometres. *Houses*: At the recent Census there were within this area 417,767 inhabited houses, containing an average of 7·8 persons to a house—exactly corresponding with the proportion in 1861. *Annual Value of Property* (county-rate assessment of 1866) = £15,261,999. *Density*: 103 persons to a hectare; 42 persons to an acre; 26,674 to a square mile. *Elevation*: The population of London resides at a mean elevation of 11·9 metres (39 feet) above Trinity high-water mark—the elevation varying from 3·4 metres (11 feet) below high-water mark in Plumstead-marshes, to 131 metres (429 feet) above high-water mark in Hampstead.

“1871.—Population (enumerated April 3), males, 1,523,151; females, 1,731,109—total 3,254,260. Annual rate of increase of

population per cent., 1851-61, 1·73; 1861-71, 1·50. Births, males, 57,034; females, 55,501—total, 112,535. Annual rate of births per 1000, 34·5. Deaths, males, 40,685; females, 39,647—total, 80,332. Annual rate of mortality per 1000, males, 26·6; females, 22·8—total, 24·7.”

The Registrar speaks with satisfaction of the increasing “solidarity” of the civilised world, so that we are enabled to trace the first origin of an epidemic, even at Calcutta and New York; and he pertinently observes that if cholera, small-pox, or the plague can arise in some obscure corner of India, Arabia, or Egypt, and carry desolation all over the world, so now, at all events, “the discovery of the laws of public health, the determination of the conditions of cleanliness, manners, water-supply, food, exercise, isolation, medicine, most favourable to life in one city, in one country, is a boon to every city and to every country, for all can profit by the experience of one: a hygienic truth once established by facts becomes as general in its application as a truth in chemistry.”

The death-rate was very high in London last year, higher than in any year since 1866, when cholera was epidemic. It is satisfactory that “fever deaths are steadily declining, from 3689 in 1864 to 1746 in 1872.” This the Registrar accepts as a sign of the “improved sanitary condition of the metropolis.” But unluckily the 3894 deaths from diarrhoea exceed the number any year since 1859. But of the diarrhoea deaths five-sixths occurred during the heat of early autumn. Scarlet fever was low; small-pox was high—so one malignant star sets and another rises. Diphtheria presents a steadily declining range, and we hope may some day die out as an exotic in uncongenial soil.

The whole community owes the deepest debt of gratitude to the department which year after year shows us our sanitary condition, and enables us to gauge our state of physical purity. We must work on, and faint not; although conscious that if the animal emanations in our midst and the oxygen of the air are the two forces in opposition, the conditions of a large and increasing town daily place the friendly oxygen at a greater distance.

REVIEWS.

On the Symptomatic Treatment of Cholera, with especial reference to the Importance of the Intestinal Lesion. By Dr. FELIX VON NIEMEYER. Translated from the German by P. W. LATHAM, M.A., M.D. Cambridge: Deighton, Bell, and Co. 1872.

DR. LATHAM has done us a service in translating Niemeyer's remarks on the treatment of cholera. The author begins by disclaiming anything like a pretence to explain the intimate nature of the cholera-process, but asserts that, in the absence of known specifics, we must adopt a rational symptomatic treatment, which should be directed “against the symptoms arising from the intestinal lesion which in cholera is the starting-point of the disease.” The work, which is comprised in fifty-six pages, is divided into three parts—1, on the Significance of the Intestinal Lesion in Cholera; 2, on the Treatment; 3, on the Results.

We know not, says Dr. Niemeyer, the precise morbid agent in cholera, nor how it gains access to the system. [These are points, however (so the English think), on which we have great probability, if not actual certainty, of knowledge.] Neither, says Niemeyer, do we know what takes place between the reception of the poison and the outcome of consequences. In all cases that Dr. Niemeyer observed diarrhoea was the first symptom. In some cases, this, with more or less exhaustion, was the only one. In others, again, other symptoms followed, all to be explained without difficulty as arising from the condition of the intestines. There is no such thing as *cholera sicca*. Even if there be no vomiting or purging in fatal cases, the intestines are distended with fluid. Diarrhoea may be the only symptom, and between this and the most fully developed cholera there are gradations innumerable. The primary and essential condition is in the intestines, not in the blood nor in the ganglionic nervous system; for if it were, how could cholera be prevented or suppressed by extreme care in diet and by checking the diarrhoea? The likeness which some persons try to establish between cholera and typhoid is unreal; for no anti-diarrhoea treatment will check typhoid as it will cholera. There is no evidence of primary disease of the blood or nervous system. The altered condition of this fluid, and the cold, pulseless asphyxial symptoms follow the intestinal affection. The characteristic post-mortem appearances are—injection of blood,

occasional ecchymosis, and evidence of copious intestinal catarrh, with loss of epithelium, which is stripped off as from scalded skin. This local mischief gives rise to the thickening of the blood and the paralysis of the nervous system. Just so extensive burns of the skin, acute abdominal inflammations, and the action of corrosive poisons depress the heart's action and the animal heat. The blood, from its physical condition, circulates with difficulty, for the corpuscles are not diffused through an adequate amount of fluid; hence, also, in part, embarrassment of the circulation of the heart itself. Still, the rapid disappearance of the symptoms when the intestinal flux ceases, shows that it is the state of the bowels, not of the blood, which is the cardinal point. The so-called *typhoid* symptoms of the cholera and the consecutive inflammations do not always occur—hence are no essential part of the disease; and when they do occur are due to extreme exhaustion and anæmia of the brain, or to an inflammatory state of the intestinal mucous membrane, and to the consequences of venous stagnation and nervous paresis. This part of Dr. Niemeyer's book is fully worked out, but we could not explain it without transcribing the whole passage; but he believes that the hypothesis with which he starts explains not only the individual symptoms, but the morbid conditions which follow.

Now as to the treatment. Our author shows how some Physicians employ vapour-baths to warm the skin; others, venesection to relieve stasis in the internal organs; others, energetic counter-irritants against the paralysis. He does not believe in contagion; yet advises all persons to quit an infected house or place. He advises such a diet as shall counteract diarrhoea, with a moderate use of generous wine. Painless diarrhoea is the thing to guard against; and on the occurrence of such a symptom he advises his patients to go to bed, drink hot tea or coffee, and use hot bricks, etc., to keep the extremities warm. They must not leave their bed for any purpose.

If the motions, however frequent, remain "coloured and somewhat homogeneous," the patient may get good from "cholera medicines" of which the only essential ingredient is laudanum; but if rapid improvement does not take place from warm bed, warm drinks, and three or four ten-drop doses of laudanum at an hour's interval, then this remedy should be discontinued. And if the motions become serous or flaky, with thirst and anxiety, showing that the inflammatory stage is developed, Niemeyer gives a grain of calomel every hour or two, and envelops the body in cloths wrung out of ice-cold water, and renewed as often as they get warm. He does not believe that the biliary secretion is suppressed, only that the bile-colour is lost in the enormous liquid flow; so that he does not refer the good effects of the calomel to its action on the liver, but rather to its effects on the inflammatory and exudative process of the intestines. He relies more, however, on the cold, and speaks most highly of this agent in inflammatory affections in general. If vomiting continues, he leaves off the calomel, and gives merely little bits of ice and very small quantities of iced liquids, as white of egg in cold water—nothing hot. He also allows iced champagne or soda-water with a little ether in it. Meanwhile the extremities are kept warm with friction, hot bottles, and mustard liniment. Supposing the collapse to continue after the intestinal symptoms have been relieved, hot coffee, camphorated spirits, and sinapisms. Congestion of the head is combated with ice. Till twenty-fours have elapsed without evacuation, nothing is given but rusk and milk-and-water; the calomel is never continued so as to salivate, and the cold applications are continued so long as the patient expresses himself benefited. If the abdomen continues tender, with repeated purulent and greenish evacuations, just like the discharge from a blistered skin, mucilaginous drinks are given with the diet named above, and poultices to the stomach. Dr. Niemeyer, in conclusion, says that of all remedies the external cold is the most to be trusted, both for its immediate relief to the patient's distress and for its curative results.

As we said at starting, Dr. Latham has done a good deed in enabling the English Practitioner to see this terrible disease with Niemeyer's eyes, and to reinforce his remedies, if he pleases, with those which this great Physician recommends.

A Dictionary of Chemistry and the Allied Branches of other Sciences. By HENRY WATTS, B.A., F.R.S.; Assisted by Eminent Contributors. (Supplement.) London: Longmans. Pp. 1136.

THE present volume is designed by Mr. Watts to bring before the public the most important chemical facts attained since the publication of his large Dictionary. This Supplement

brings the whole work down to 1869, and in parts to 1870 and 1871. The contributors who have engaged to help Mr. Watts with this Supplement are—Professor Carey-Foster, who writes on Electricity and Heat; Dr. Michael Foster, who writes on Proteids; Dr. Benjamin Paul, who contributes articles on Beer and the Metallurgy of Iron; Dr. Roscoe, who is the author of what relates to Light and the Spectroscope; and, finally, Mr. Wanklyn, who contributes parts of what is written on Acetic Ether, Butyric Acid, and also on Butyl Alcohols, Ketones, etc.

The longer articles deal with the following subjects, viz.:—Acetic Acid, Acetylene, Organic Acids, Alcohols, Inorganic Analysis, Organic and Volumetric Analysis, Aniline Colours, Aromatic series, Arsenic, Atomicity, Benzine and its homologues, Benzoic Acid, Blood, Boron, Chemical Action, Alcoholic Cyanides, Electricity, Ethers, Fermentation, Absorption of Gases, Glycollic Acid, Heat, Hydrocarbons, Iodine, Iron, Light, Mellitic Acid, Naphthalene, Proteids, Quinine, Spectral Analysis, Sulphocyanic Ethers, and Sulphur. The others consist of short notices.

We need hardly say that the workmanship is good—worthy of the original work in every respect; and though a good deal of the volume relates to facts of pure science rather than to the applied Medical sciences, still we encounter a great many articles relating to our own particular compartment of the scientific field. If the book has a fault, it is that it is over-balanced, the earlier being by much the fuller portion; but it must be remembered that this is also the oldest portion of the large Dictionary.

NEW BOOKS, WITH SHORT CRITIQUES.

Medical Thermometry and Human Temperature. By C. A. WÜNDERLICH, Professor of Clinic (*sic*) at the University of Leipzig, etc.; and EDWARD SEGUIN, M.D. New York: W. Wood and Co. Pp. 280.

*** In this guise we fear Wunderlich would not be able to recognise himself. We have some abstracts of what Wunderlich has done, and then some work, let us say euphemistically, not quite so good by Dr. Seguin. The book, in point of fact, illustrates one of the phases of Americanism we particularly dislike. They will not only persist in republishing without authority works published here—a process generally known as pirating—but they will edit us. It is, of course, a grievance to be pirated, but nothing like that of being edited. We would beg of our American brethren to let us alone in the nakedness of our views or imperfections of our work. We should like to have an international copyright; but if we can't, let us be spared the misery of being edited.

The Pocket Formulary and Synopsis of the British and Foreign Pharmacopœias, etc. By HENRY BEASLEY. Ninth Edition. London: J. and A. Churchill. Pp. 546.

*** This is called a pocket formulary, but we suspect that it finds a more congenial home on the dispensary table than in the pocket. It will be found an exceedingly useful manual for preparing unusual remedies or suggesting forms for giving them when made. The references to foreign Pharmacopœias and prescriptions are particularly useful.

A Treatise on Human Physiology. Designed for the Use of Students and Practitioners of Medicine. By JOHN C. DALTON, M.D., Professor of Physiology and Hygiene in the College of Physicians and Surgeons, New York, etc. Fifth Edition. Philadelphia: Lea. London: Trübner. Pp. 728.

*** Dr. Dalton's treatise is well known, and by many highly esteemed in this country. It is, indeed, a good elementary treatise on the subject it professes to teach, and may safely be put into the hands of English students. It has one great merit—it is clear, and on the whole admirably illustrated. The part we have always esteemed most highly is that relating to Embryology. The diagrams given of the various stages of development give a clearer view of the subject than do those in general use in this country; and the text may be said to be upon the whole equally clear.

Plain Directions for Dealing with an Insane Patient. By J. M. WINN, M.D. Hardwicke.

*** A shilling's worth of most useful information on a subject practically interesting to almost every member of the Profession.

MR. PEASE has obtained leave to bring in a Bill to amend the Vaccination Acts by restoring the clauses limiting the penalties.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, March 19.

DEATH OF MICHEL LÉVY—THE LEGION OF HONOUR—SANITARY STATE OF PARIS.

You will learn with regret the death, which took place somewhat suddenly, of M. Michel Lévy, the eminent hygienist, and Principal Physician of Val-de-Grâce. It was only a few days ago that *lettres de faire part* (invitations) were issued by him for the marriage of his son, a distinguished engineer of mines, which was to have been celebrated this week; but, alas! these were replaced by funeral notices for his own obsequies. He died on the 13th inst., in his 63rd year, and was interred in a family vault in the Jewish quarter of the Père-la-Chaise, followed by a large concourse of friends and former pupils, but, according to his expressed wish, no discourse was pronounced over his grave.

M. Michel Lévy was a native of Strasburg, and born in 1809. He began his Medical career in the army in 1829, being then only 20 years old, and was appointed Assistant-Surgeon to the Moreau Ambulance. His career was a most brilliant one, and he contributed in a very great measure to the real progress of Medicine in France. His Medico-philosophical articles, which were published in the *Gazette Médicale*, will long be consulted by the present and future generations of the Faculty.

On the outbreak of the Crimean war, the Emperor Napoleon appointed him Principal Medical Officer of the Army in the East, and on his return from the war he was rewarded with the post of Director of the School of Military Medicine and Surgery. In 1850 he was elected Member of the Academy of Medicine, of which body he was also President; and in December, 1867, was promoted to the grade of Grand Officer of the Legion of Honour.

Among the recent nominations to the Legion of Honour, I may mention that of M. Collin, the worthy successor of M. Charrière, the famous surgical instrument maker, who was appointed Chevalier for the many improvements he had effected in that branch, and for the signal services rendered by him during the late war.

The sanitary condition of Paris is excellent. There is no epidemic at present, and the mortality for the past week is reported to be 788, which includes the deaths in Hospital and private practice.

HOLLAND.

ROTTERDAM, March 2.

DISPOSAL OF SEWAGE IN HOLLAND.

If the so-called water theory of cholera had no other merit than that of creating a wholesome horror of water contamination by excremental matter, everyone must confess that it would have done more good than a great many other theories which have been held in high esteem. In our country a reaction has arisen against the contamination of our rivers, canals, and the subsoil water by human evacuations; and it is to be expected that ere long a great amelioration will have taken place in this matter.

As I stated in my papers of May 1 and June 12, (a) 1869, in this journal, there is nowhere in our country, with a single exception, a distinct sewerage system, but everywhere all the excremental matters find their way directly into the canals and rivers, or, being collected in bottomless tuns, the greater part of them sink into the soil. The city of Gröningen only has long since introduced a system of *fosses mobiles*. The excrements are mixed with the city dust, ashes, dirt, etc., and sold to the farmers, and so successfully that after the deduction of all the costs there remained lately a net revenue of one shilling and eightpence per inhabitant. In Delft the same system was introduced last year with some ameliorations and with great success. The *fosses mobiles* consist of little tuns, very neatly kept, and a compost is made of the faecal matters in the same manner as in Gröningen. The farmers in the neighbourhood of Delft, to whom this system was quite new, have already taken a liking for the new compost, so that the demand increases daily, and also the price of it.

But what is still more interesting than this, with relation to

the removal of the excremental matters in a great town, is the introduction of Captain Liernur's pneumatic sewerage system into Leyden and Amsterdam which has taken place lately. In Leyden the Council of the town resolved to introduce the system in a part of the town populated with 1200 inhabitants, and the experiments have taken place publicly, and with success. The plan of introduction of the system was promoted by a private committee for the promotion of public health. In Amsterdam the Town Council resolved to give the system of Liernur a trial, when, in one of the poorest quarters of the town, a certain foul canal, into which all the sewage matters of the surrounding neighbourhood found their way, was to be filled up. After the system was introduced in that part (some weeks since), a public trial of it took place during a whole week by the liberality of the Town Council, so that the opportunity of seeing the system at work was given to everyone who interested himself in it, whilst all desirable explanations were given by the engineers in person, who were all present. (b) Hundreds of persons from all parts of the country, and even from Germany, have made use of this opportunity offered to them, and amongst them were a great many architects, engineers, and hygienists. The trial has met in general with great satisfaction. As a result of the working of the system, it will be introduced in many other parts of Amsterdam, and also in Leyden.

It is my opinion that we ought to be very glad of these endeavours for the removal of the human excrements. Firstly, with a view to the public health, by preventing the contamination of the water and soil; and, secondly, with a view to the conservation of a very precious manure. The prices of all comestibles are constantly rising; and, at the same time, a precious manure is not only wasted in enormous quantities, but suffered to corrupt the waters and the soil, and to be the cause of many sicknesses, which should not be so. Man in this case acts contrary to nature, where nothing is unnecessarily wasted.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

March 19.

SOME years ago an effort was originated by Dr. Trench, the very able Health Officer of this borough, to obtain the erection of a mortuary chapel in a part of the town densely populated by the poorer Irish, in which the bodies of their relatives could be deposited shortly after death, instead of being retained in close and overcrowded rooms for the purpose of being "waked." After much unavoidable delay, a building of the kind indicated has been completed, and on Sunday last (St. Patrick's Day) was formally opened by religious services from the Roman Catholic clergy. As if painfully to comment on the necessity that exists for such a building, a poor Irish woman lost her life through attending, on the very evening of the opening ceremonial, a wake on the body of a friend who had died of typhus fever just previously. This woman and three male companions were shut in a room in which the corpse lay. They were liberally supplied with whisky, and in the morning she was found in one corner dead, as the evidence at the inquest went to show, from suffocation resulting during intoxication. This is only one among very many cases that show the evils resulting from wakes, but it is specially striking from the time at which it has occurred. The Roman Catholic bishop and the clergy are earnest in their appeals to the people under their charge to avail themselves of the advantages offered to them by the chapel, so that it may fairly be hoped that after a few years one fertile source of the spread of disease—viz., the retention for days in close and crowded rooms of the bodies of relatives who had died from infectious disorders—will be done away. The mortuary can contain, without crowding, twenty-one coffins, and with the chapel has cost nearly £5000.

The subscriptions for the proposed alterations in the School of Medicine have already exceeded £2000, and as it is estimated that £3000 will cover the expenses, there can be no doubt that the work will be entered upon immediately, with the certainty of the remainder being in the hands of the treasurer, Dr. Waters, long before its completion.

A case of death through misadventure was investigated yesterday before the borough coroner, which should convey an

(a) "The Water-Supply of Holland and Cholera."

(b) Captain Liernur, Mr. de Bruyn Kops, Mr. Thoof, and Mr. P. Maes Geesteranus, agent for the Netherlands.

important caution both to those who send for and those who dispense medicines. Dill-water had been prescribed for the infant son of Mr. R. S. Iddeson, to relieve him of flatulency. The medicine was put into a bottle, which, although empty at the time, had, it seems, previously contained nepenthe, of which sufficient had remained adherent in a dried state to render the contents, after its solution, highly poisonous to an infant only 14 days old. Only a teaspoonful was given, but death ensued in the course of the day, with symptoms of narcotic poisoning.

At the last meeting of the Medical Institution, a petition to Parliament was drawn up, and signed by all the members present, praying for the adoption in the proposed Public Health Bill of clauses which shall insure the due independence of the Sanitary Officer, and provide for the consolidation of the sanitary departments of central administration; for the establishment of large local areas, and the consolidation of all functions within them; and for the recognition of a suitable local authority of a representative character.

GENERAL CORRESPONDENCE.

THE TICHBORNE CASE.

LETTER FROM DR. SAMUEL WILKS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your leader on the Tichborne case, together with the extracts from Professor Laycock's lectures, sufficiently show that the decision of such a claim as that preferred might possibly be left in the hands of a jury of physiologists. In reflecting upon the fact that a judgment was formed mainly by the ordinary legal tests of the Claimant's outward acts rather than upon what is called internal evidence, I cannot but feel that our Profession has not been equal to its obligations, in failing to have that knowledge in readiness which, after a due exposition of his physical, moral, and intellectual characteristics, would have settled speedily and satisfactorily the plaintiff's claim.

Man being the object of our study, we ought to have a more precise acquaintance with the varieties of the genus as seen in civilised life than we now possess: we ought to have a better knowledge of the temperaments, together with the physical and mental natures which belong to them. These, however, are studied by few, and the professors who have anything more than a superficial acquaintance with them in the three kingdoms must be regarded in the minority.

Natural philosophers are at the present day engaged in the great question of evolution, and are endeavouring to discover how, by a process of development, new species may arise and higher mental phenomena be evolved. They declare, however, that long periods of time are required for the change, and thus, for many generations, certain peculiarities of form remain permanent, by which the genus can be at once determined. Man is, therefore, profitably compared with the lower animals, and his varieties, again, have long been the subject of study; but, at the same time, as the doctrine of temperament shows, he is open to a still further analysis with respect to the modifications which he exhibits in civilised life, even in so small an island as ours. Although, no doubt, in man outward circumstances may through a lapse of time produce many of the peculiarities which we witness, yet these remain for generations perfectly distinct, and are transmitted through a long line of descent. We are thus able to distinguish the man of sanguineous temperament, with his physical strength and mental vigour, from the leucophlegmatic man, with his inactive body and sluggish mind. Such differences are, no doubt, appreciated by Medical men, and noted for practical purposes by a rule of thumb; but what we want is a more precise method whereby we could at once classify the individual, and never allow that he could belong to two temperaments at different periods of his life. We should not, then, be content with discussing so superficial a question as the possibility of a person growing fat or losing a tattoo mark, and similar outward and visible signs of identity. Nor, as regards his mental phenomena, would the question of identity turn on so trivial a matter as the capability of forgetting a language, but rather on the possession or loss of more essential mental characters. For example, a more important question would be, whether a generous and open-hearted youth could become a crafty, subtle, or lying man. The general opinion is, that peculiarities of body and mind remain unchanged, even to the twitching of a muscle; thence the importance attached to a trick of this kind. Novelists, in description of character, would assuredly take care to paint their hero

with some peculiarity of disposition which, striking in boyhood, should not be lost in old age.

It is difficult to believe that even now there are not those in our Profession who have so far studied their fellow-creatures in their several forms and modes of development as to be able to assert with much confidence that a youth with a certain configuration of head, chest, or limbs could not, by any possibility, assume in time the form of a man having, from their point of view, another temperament; or that there are those in all walks of life who have so studied character as to be able to speak positively of the impossibility of a certain mental or moral quality becoming extinguished and replaced by another. Although the subject has not been reduced to system, there have been those—and I myself was amongst the number—who, as soon as the Claimant entered the witness-box, had the very strongest conviction with respect to his personality.

So strongly am I convinced that a better knowledge of the varieties of social man, or of the temperaments, would have determined the question at issue, quite apart from any strictly legal procedure, that I feel assured that such a trial as we have lately witnessed would have been impossible in ancient Athens; for Praxiteles would have been there, with a much larger knowledge of the human form than we possess, and Hippocrates, with his discovery of temperaments (whose terms we use to this day), would have aided the artist by his ability to distinguish the varieties of the human type; and Plato, moreover, by his powers of analysis of the mind (made possible by the very forms of the Greek tenses), would have still further assisted by unravelling, in the subtlest manner, mental traits which at the present day might have been unobserved.

At some future time, when the Anthropological Society shall not only have studied man in relation to other animals, and have contrasted the various races of the species, but shall have also determined the lesser varieties, with their modes of development, another Tichborne trial will be, perhaps, impossible. I believe now there are men in our country (the name of one has already been designated) who could write an ingenious and instructive essay on the physical and mental types of social man as exemplified in the Tichborne case. I am, &c.,

Grosvenor-street, W., March 16.

SAMUEL WILKS.

SCARLET FEVER IN THE ORTHOPÆDIC HOSPITAL.

LETTER FROM DR. C. MURCHISON.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the account of the meeting of the Governors of the Royal Orthopædic Hospital which has appeared in your columns, it is stated that I advised the Committee as to certain sanitary measures called for by an outbreak of scarlatina in the Hospital, the Surgeons of the Hospital having declined responsibility in the matter. The statement is inaccurate, and conveys an erroneous impression. I was first asked by Mr. Adams, as a friend, to see a patient of his suffering from a severe attack of scarlatina; I did so to oblige him, and not at the request of the Committee, and I had repeated consultations with Mr. Adams on the case. Subsequently, at the request of Mr. Adams, and in consultation with him at my house, I drew up some instructions for the guidance of the Committee. And thirdly, on the written request of Mr. Tamplin, I gave advice as to the readmission into the Orthopædic Hospital of a child who had recently been discharged from the Fever Hospital. I have had no other dealings with the Orthopædic Hospital.

I may add that nothing would have induced me to interfere with the Medical affairs of the Orthopædic Hospital, except at the request of, and in consultation with, its Medical officers, or even then had they declined all responsibility in the matter on which they sought my advice.

I am, &c.,

C. MURCHISON, M.D.

79, Wimpole-street, London, W., March 19.

CHOLERA POISONS: DR. CHAPMAN'S THEORY.

LETTER FROM DR. CHAPMAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to thank you for your appreciative recognition of my pamphlet on "Diarrhœa and Cholera," reviewed in your issue of February 17. The thorough discrimination and judicial impartiality which distinguish your carefully expressed judgment of my little work awaken in me the liveliest feelings of gratitude, and at the same time assure me that you will be good enough to afford space for the following remarks on one

point in reference to which my meaning has not been quite correctly apprehended.

You rightly say: Dr. Chapman holds that the *chief* cause of cholera "is not a poison, by which he distinctly means that the cause is not a material particle or particles transmitted from sick to healthy persons." I have put the word "chief" in italics. You add, "The question, he says, is not one of the introduction of new matter, but of the states of the old matter; and among these states its temperature is, in his eyes, of chief importance." And afterwards you remark: "If Dr. Chapman denies that cholera depends in any way upon the introduction of a material poison from without, we hesitate to follow him. . . . The introduction of some specific material poison into the system from without seems to us almost indisputable. The observed course of cholera through Europe can scarcely be interpreted so favourably as Dr. Chapman seems to think. . . . Again, the well-known cases of well-poisoning, such as that of the fountain at Constantinople, and of the Broad-street pump, investigated by Snow, carry something like conviction with them."

These passages are likely, I think, to make your readers believe that I deny, as you say, "that cholera depends in any way upon the introduction of a material poison from without;" and inasmuch as, if they should believe so, they would misapprehend my meaning, I beg to re-state as precisely as I can my ideas on this important question. I have, I believe, adduced evidence sufficient to establish the doctrine that both diarrhoea and cholera, however induced, are essentially and invariably disorders of the nervous system, and that the *proximate* cause of all the phenomena of diarrhoea and cholera (before the stage of reaction) is hyperæmia, with consequent excessive action of the spinal cord and of the ganglionic or sympathetic nervous system. Now, it is easily credible that various agents, operating either separately or conjointly, may produce such hyperæmia in various degrees of intensity; that some may alone suffice to produce it in so high a degree as to give rise to the phenomena of cholera; and that some, acting on organisms the nervous centres of which have already been rendered hyperæmic to a considerable degree, but not sufficiently so to give rise to those phenomena, are then able to superinduce in them that intense degree of hyperæmia which is the "*conditio sine quâ non* of cholera and cholerae."

Solar heat may alone suffice, and I believe does alone suffice in thousands of instances, to induce even the most deadly forms of cholera; but I also believe that certain noxious effluvia, and water containing a large proportion of organic matter in solution, may each do the same; and, of course, if any one of these agents acting separately produces a certain degree of hyperæmia, but not sufficient to issue in cholera, it nevertheless engenders a predisposition to it, and then a second agent becoming operative on the nervous system in which that predisposition already exists may easily evoke the disease, whereas without such predisposition that agent would have been powerless to do so.

In fact, my doctrine of the genesis of cholera involves the recognition not merely of one cholera poison, but of several, the effectiveness of each poison in producing some or all the characteristic phenomena of cholera being dependent on the state of the nervous system of the patient when he becomes subject to its influence.

I freely confess that I am responsible for your misapprehension of my meaning; for, though in the pamphlet in question I expressly state that noxious *effluvia* and *impure* water are capable of becoming causes of cholera, I speak of them only as *exciting* causes, which may prove effective when the spinal cord and sympathetic ganglia have already become hyperæmic by the influence of great solar heat, but not sufficiently so to enable them to become self-originate of the disease.

This limitation of the potency of these causes is simply due to an inadvertence when I was intent on condensing the expression of my views within the compass of a few pages introductory to the reports of cases, which form the chief part of the pamphlet. But in my larger work,^(a) in which I discuss at length the pathology and etiology of cholera, there is no such limitation of the potency of those causes. I expressly recognise them as independently capable of originating cholera, and observing that, in respect to cholera at least, the distinction between *predisposing* and *exciting* causes cannot, strictly speaking, be maintained, I state "that what is a predisposing cause in one person may be an exciting cause in another, and

vice versa," but that whereas one only of the several causes of diarrhoea is very often productive of the disease, "the sources of cholera are more frequently complex, and thus effect, by their co-operation, results which, acting singly, they would be unable to produce." The section on *impure water* as a cause begins with these words: "That this is a cause of cholera has been proved by such an overwhelming amount of evidence, that no doubt on the subject can still be entertained by any competent judge," and I support this statement by citing two striking examples—that of the poisoning by the water from Broad-street pump, alluded to by yourself, being one of them.

What I do not believe in is the existence of the so-called specific "cholera-poison," by which, according to Parkes, Goodeve, Johnson, and other pathologists, a morbid change resulting in the phenomena of cholera is wrought in the blood of cholera patients, and which, being diffused in some mysterious way, causes those widespread and epidemic developments of the disease which we are all acquainted with. Neither do I believe in the existence of the so-called "cholera germs," which are alleged by Snow and Budd to be produced and disseminated in terrific abundance from the gastric and intestinal discharges of cholera patients. I do not believe in these hypothetical creations, because their existence has never been shown to be probable by any trustworthy evidence; because the hypotheses of their existence do not afford any satisfactory explanation of the mode of production of the several phenomena of cholera; because the genesis of every one of them is simply, rationally, and harmoniously explicable as a result of the operation of causes which are known to exist; and, finally, because experience proves that effective counteraction of the operation of those recognised causes, in cases of both diarrhoea and cholera, constitutes the most successful method yet known of treating those diseases.

I am, &c., JOHN CHAPMAN.

25, Somerset-street, London, W.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

LETTER FROM DR. JOSEPH ROGERS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to enclose the form of petition which I have forwarded for presentation to the House of Commons on Thursday, the 21st inst., and shall be obliged if you will publish it in your this week's issue. Would you also permit me to add, for the information of the Medical public, that all that will be necessary for those to do who agree with its tenor is to copy it out fairly on one side of a sheet of paper and sign their name; they can then send it on to their own member for presentation, or to me; if forwarded to me it will be put into the hands of a friendly member without delay. Whatever is done should be done quickly. I am, &c.,

33, Dean-street, Soho, March 21. JOSEPH ROGERS.

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The humble petition of the undersigned sheweth—

That whereas a Bill, called the Public Health Bill, has been brought before your honourable House, seeking to impose fresh burdens of work and responsibility upon Poor-law Medical Officers without providing for their proper remuneration for the same, the effect of which will be that the sanitary work entrusted to them will of necessity be ill-performed;

That whereas the position of the District Poor-law Medical Officer is not sufficiently independent of local influences to justify his incurring the odium and responsibility of directing what works should be executed to remove unsanitary conditions in his locality, the existence of which conditions he may have reported;

And whereas Clause 56 of the said Bill, which relates to the establishment of Poor-law Dispensaries, is permissive only as it leaves the question of their establishment or otherwise solely within the discretion of the Local Government Board;

And whereas to be truly of national benefit it is necessary that such Dispensaries should be more extensively distributed than is contemplated by the clause in question;

Your petitioner prays that no Bill be allowed to become law which does not provide for the proper remuneration of District Medical Officers who may be required to act as Deputy Health Officers, and that does not place the odium and responsibility of sanitary action in a Superior Health Officer, independent of private practice, and paid accordingly.

Your petitioner further prays that Clause 56 be amended so

(a) "Diarrhoea and Cholera: their Nature, Origin, and Treatment through the agency of the Nervous System." London: Trübner and Co. 1866.

that the establishment of Dispensaries may be made compulsory generally, instead of permissive only, as now contemplated.

And your petitioner will ever pray, etc.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH

Mr. HILTON, F.R.C.S., President, in the Chair.

THE Morbid Growth Committee reported on Dr. Gower's specimen of Enlarged Liver. It was stated that the growth was a medullary sarcoma.

Mr. McCARTHY exhibited a child, the subject of a Peculiar Cutaneous Growth on the left buttock. This growth, which was first seen when the child was three weeks old, corresponded to the distribution of the lower sciatic and external saphenous nerves.

The same gentleman showed a little girl, the subject of Keloid, which was improving. At one time she seemed likely to die. Her hands and feet had been hide-bound; they were now loose.

Mr. CARR JACKSON exhibited Parts of a Thigh-bone removed by amputation at the hip after excision of the head of the femur, and an Astragalus removed by excision.

Dr. GREENHOW exhibited specimens illustrating Embolism and Softening of the Anterior Cerebral Lobes. The patient was a woman, aged 27. At the age of 14 she had suffered from rheumatic fever. She was the mother of four children. In 1870 she had a kind of a fit, and in her fifth confinement she had more fits. She was admitted to Middlesex Hospital on January 1. She had then loss of sensation on the right side, but power had been regained after the fits. She could only make use of a few words, but was quite intelligent. She spoke slowly, but could repeat words which were spoken to her. There were signs of heart disease. On January 15 she had a fit, and after it there was loss of consciousness. When she improved, she could move her right limbs freely, but the left were paralysed. She gradually sank and died. The left frontal lobe of the brain was diminished in size, and a cavity was found in it, containing milky fluid, and its walls were pigmented, as from old clots. There were also softened patches and cavities in the right frontal lobes. The left anterior and right middle cerebral arteries were plugged, probably by fibrine from diseased aortic valves. The left side had been first affected, but had gradually improved till the right was affected.

Mr. GAY showed the Head of a Thigh-bone excised for long-standing disease. The boy had suffered much pain, and when he came to operate he found the capsule entire, and the neck of the bone tunnelled for the exit of pus, leaving a sequestrum. This was probably the cause of the pain. In one of two other specimens there had been no pain, but the capsule was entirely destroyed. He also thought that in this case pressure must in a fashion have flattened out the head of the bone. Disease of the acetabulum was, he thought, no objection to the operation.

Mr. T. SMITH was surprised to hear disease of the acetabulum so lightly treated. If it was of so little moment, why not leave the diseased femur too? If the acetabulum was diseased, he supposed Mr. Gay removed the diseased bone. Experience made him shy of such cases.

Mr. GAY's experience, on the contrary, was good. It was, he thought, almost a necessity to have some disease of the acetabulum. He of course took away bone if loose, but not if only denuded.

Dr. PYE-SMITH exhibited for Dr. Shepherd a Malformed Heart. The child was cyanotic, but had no clubbed fingers, and there was a systolic bruit at the base. It lived fourteen weeks. The lungs were condensed almost like the spleen. The heart gave off the aorta from its right side, and the pulmonary artery from its left side, and the right ventricle was thickened as the left ordinarily is. The venæ cavæ were normal, and the foramen ovale was cribriform. The ductus arteriosus was patent, and the septum ventriculorum complete. By this arrangement the head would receive the most impure blood, the lungs would receive the purest, and the lower extremities blood of an intermediate quality. He thought the condition might be accounted for by a twisting of the septum which

separates the aorta from the pulmonary artery in the foetus. There was no transposition of viscera.

In reply to Dr. C. T. Williams, Dr. PYE-SMITH said there was no time for any difference to be developed in the growth and nutrition of the parts supplied with blood of different qualities. The coronary arteries sprang from the aorta.

Dr. C. THEODORE WILLIAMS exhibited a specimen of Ulceration of the Vermiform Appendix caused by a lump of hardened faeces, and giving rise to peritonitis in the neighbourhood of the caecum. The patient had had two attacks of pleurisy, with effusion, from which he had recovered after tapping, and left the Hospital. A week later, after some constipation, he was seized with symptoms of severe peritonitis, and a tumour the size of an orange was felt in the right iliac fossa. Under treatment, the bowels became freely open. Several scybala were passed, the tumour disappeared, and the peritonitis subsided. Subsequently he died of pneumothorax. After death the caecum was found closely attached to the right iliac fossa and abdominal wall, except in the neighbourhood of the vermiform appendix, round which was a circumscribed abscess, containing the lump of hardened faeces, which had passed through an ulcerated opening in the appendix. No signs of peritonitis were observed elsewhere in the abdomen. Dr. Williams remarked that there must have remained some fluid in the right pleura before the peritonitis occurred, as the liver was pushed down and adherent to the caecum by inflammatory bands of lymph. The point of interest in this case was the localisation of the peritonitis and its conversion into a circumscribed abscess.

Mr. WAREN TAY exhibited a child of nine months, on whose right arm, close to the axilla and on its inner side, there had grown a Tumour the size of a fist. It was soft and pendulous. He removed it with most of the skin. It was whitish in texture, and seemed to consist of a soft connective tissue hypertrophied.

Mr. HAWARD exhibited a Fibrous Tumour of the Testicle, from a man aged 81. He had long suffered from enlargement of the right testicle. There was no pain, but it was heavy and dragged. The swelling was hard, nodulated, and elastic. There were no adhesions. It was removed, sloughing followed, and he died. The growth seemed to spring from the albuginea, and consisted of dense fibrous tissue. Such a structure was very rare. Mr. Heath's specimen grew from the cord.

Mr. HULKE asked if the histology was made out by examining one spot or more, and if cartilage cells were entirely absent.

Mr. HAWARD, in reply, stated that the tumour was examined at several spots, and no cartilage corpuscles were found.

Mr. ANDREW CLARK exhibited specimens of Disseminated Melanosis following melanosis of the eye. The nodules formed separate masses in the walls of the heart. The glands were not affected. There was a single nodule, almost free, in the abdomen. The liver, kidneys, and dura mater all contained nodules. There was little in the eye. No history was given.

Mr. T. SMITH exhibited a specimen of Axillary Aneurism, for which the subclavian had been tied. The patient (a male) had, nine months before his admission, noticed a tumour in his right axilla; but there was no pain. When seen, it was the size of a lemon. The arm was painful, and there was swelling in the hands. The fingers were clubbed, but after the arm had been raised the clubbing left. The operation lessened the pain and swelling, and the man did well for eight days. Then pneumonia and pyæmia set in, and he died in twenty days. The left lung was glued to the side. In the right were signs of recent pleurisy, but around the half-healed wound there was none. The wound was nearly healed; the tissues around it matted together. There was a small abscess near the ligature, and the veins were filled with coagula. The nerves had been stretched by the tumour. The aneurism was nearly solid. The aorta was enlarged and atheromatous, and there were three aneurisms in the sinuses of Valsalva. His occupation was that of a roundhand bowler. Pressure could not be borne by the tumour. There were abscesses in the left lung.

REGULAR MEDICAL SCHOOLS OF NEW YORK.—The *New York Medical Record* (February 15) states that the following are the only strictly regular Medical institutions empowered to grant diplomas for practice:—College of Physicians and Surgeons (1807), University of City of New York (1840), Bellevue Hospital Medical College (1861), Long Island College Hospital (1859), and the Woman's Medical College of the New York Infirmary (1868).

OBITUARY.

P. W. WILLIAMS, M.D., M.R.C.P., ETC.,

DIED on the 10th inst. at his residence in Foregate-street, Worcester, at a comparatively early age. He was the son of Sir John Bickerton Williams, who practised for many years as a Physician at Shrewsbury, and received the honour of knighthood in 1838. His widow only three weeks ago died at the advanced age of 85. Dr. P. W. Williams, who had for some years previously practised as a Physician in Worcester, was appointed one of the Physicians to the Worcester Infirmary in 1855 on the retirement of Dr. Nash; and on his recent resignation of the office, owing to severe indisposition, the governors, at their annual meeting on the 1st inst., adopted a resolution expressing great regret for the loss of his services, and conveying their thanks to him for the same, and also elected him an honorary Physician to the institution. Dr. Williams succeeded the late Rev. Robt. Sarjeant in the post of secretary to the Worcester Musical Festivals: this, too, ill-health had compelled him to resign. His gentlemanly demeanour, musical knowledge, and unvarying suavity rendered him a general favourite. He was married to a daughter of the late Robert Gillam, Esq., by whom he leaves several children. Dr. Williams was Consulting Physician to the Ophthalmic Institution, and Surgeon to the prison. He was the author of "Prize Essay on the Nature and Objects of Medical Science," and contributor to the *Provincial Medical Journal* of "Report on Cholera," "On Porrigo," and "Case of Granular Degeneration of Both Kidneys without Serous Effusion."

ROBERT OTTER BLYTHMAN, M.R.C.S.,

DIED at Swinton, on March 3, and will long be deeply mourned by all classes. During a residence of more than forty years at Swinton, he had gained a large practice both as a general Practitioner and consulting Surgeon, and his great experience and sound judgment will long be greatly missed. Mr. Blythman held the appointment of District Medical Officer to the Rotherham Board for thirty-seven years. He was also Certifying Factory Surgeon. Mr. Blythman was a student of Guy's and St. Thomas's Hospital, where he was a pupil of Sir Astley Cooper.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the examinations for the licence to practise Medicine, held on March 11 and 13, the following candidates were successful:—

Mayne, Nathaniel. | Ovenden, William Henry.
Pigott, John Charles C. Pemberton.

At the examinations for the Midwifery Diploma held on March 14, the following passed:—

Mayne, Nathaniel. | Ovenden, William Henry.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, March 14:—

Cartwright, Henry Gordon, Burton-on-Trent.
Cave, Alfred, Barking, Essex.
Clyma, Handsford Hosking, Truro, Cornwall.
Floyer, Blaise Bernard, Floore, Northamptonshire.
Julius, Stanley Alexander, Mortlake.
Stone, Charles Henry Augustus, Poole, Dorset.
Swan, William George, St. George's-road, Southwark.

The following gentlemen also on the same day passed their first Professional examination:—

Burton, John Randall, Guy's Hospital.
Pink, Thomas, Guy's Hospital.
Swan, Richard Jocelyn, Dublin.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

EDMONDS, SPENCER, M.R.C.S., L.A.C.—Medical Officer and Public Vaccinator to the Lullington District, Burton-on-Trent.

EVANS, ERNEST T. R., M.R.C.S., L.S.A.—House-Surgeon to the Salford and Pendleton Royal Hospital.

HEPBURN, ROBERT, jun.—Dental House-Surgeon to the Dental Hospital, London, vice Mr. Mordaunt Stevens, resigned.

LLOYD, THOMAS, of St. Mary's Hospital, Paddington—Dispenser to the West Ham Dispensary.

OWEN, D. C. LLOYD, M.R.C.S. Eng., L.S.A., M.B. Lond.—Honorary Surgeon to the Birmingham and Midland Eye Hospital, vice Charles Townsend, M.R.C.S. Eng., deceased.

PRIGG, FREDERICK, M.R.C.S., L.S.A.—Assistant House-Surgeon to the Birkenhead Borough Hospital, vice W. R. Hughes, resigned.

SHEARMAN, WILLIAM MILLAR, M.R.C.S.—District Surgeon to the Salford and Pendleton Royal Hospital.

STRANGE, Dr. A., of Colney Hatch Asylum—Medical Superintendent to the Salop and Montgomery Lunatic Asylum.

NAVAL AND MILITARY APPOINTMENTS.

TERRY, SEPTIMUS, has been promoted to the rank of Surgeon in her Majesty's Fleet, with seniority of August 18, 1871 (confirming a commission given by Vice-Admiral Sir Henry Kellott, K.C.B., late Commander-in-Chief of her Majesty's ships and vessels on the China station, vice M'Clement, deceased).

MEDICAL DEPARTMENT.—Staff Surgeon Donald Sinclair Smith, having completed twenty years' full-pay service, to be Staff Surgeon-Major, under Article 342 of the Royal Warrant of December 27, 1870; Staff Assistant-Surgeon Robert Arthur Elliott retires upon temporary half-pay; Assistant-Surgeon James Joseph M'Carthy, M.D., from the 5th Foot, to be Staff Assistant-Surgeon, vice Thomas White, M.B., appointed to the 5th Foot.

BIRTHS.

AUSTEN.—On March 15, at High-street, Ramsgate, the wife of Josiah Austen, Surgeon, of a son.

BARTON.—On March 16, at Hampton Court, Middlesex, the wife of Alfred B. Barton, M.D., of a daughter.

CARTER.—On March 12, at Lichfield, the wife of Graham Athérley Carter, M.D., of a son.

DUFFEY.—On February 13, at 30, Fitzwilliam-place, Dublin, the wife of George F. Duffey, M.D., of a son.

WEST.—On March 18, at Carlton House, Acock's-green, near Birmingham, the wife of James F. West, F.R.C.S., of a daughter.

MARRIAGES.

ANDERSON—COUDRON.—On March 13, at St. Peter's Church, Belsize-park, John Ford Anderson, M.D., to Gabrielle, only daughter of M. Louis Coudron, of Paris.

COTTON—CRANE.—On March 7, at Christ Church, Cheltenham, Dr. Cotton of Charges-street, Piccadilly, to Eliza, widow of the late Hon. William Crane, of Sackville, New Brunswick.

ROBERTS—PHILLIPS.—On March 1, at the Cathedral, by the Lord Bishop of Bangor, D. W. Roberts, M.D., son of the Rev. D. Roberts, Llanelidan Rectory, Ruthin, to Charlotte Elizabeth Hamilton, daughter of William Phillips, Esq., Cae Derwen, Bangor.

SKELTON—SMITH.—On March 12, at Cork, John Skelton, Esq., of Langton House, Cheltenham, to Susan Frances, eldest daughter of the late John Smith, Esq., M.D., Cappoquin, county Waterford.

SPENCER—HARVEY.—At Agra, India, on March 12, Lionel Dixon Spencer, M.D., Bengal Medical Staff, youngest son of William Spencer, Esq., of Newcastle-on-Tyne, to Elizabeth Gordon Lamond, eldest daughter of Alexander Harvey, M.D., Professor of Materia Medica in the University of Aberdeen. (By telegram.)

DEATHS.

ANDREWS, JANE C., widow of the late John Andrews, Esq., Surgeon, of Salisbury, at 2, Castlemaine-villas, Bournemouth, on March 13.

BLYTH, ROBERT OTTER, M.R.C.S.E., on March 3, at Swinton, Yorkshire, aged 69.

BREAKEY, ALICE JANE, second daughter of Dr. Breakey, R.N., at the Royal Naval Hospital, Plymouth, of scarlatina, on March 18, aged 5 years and 5 months.

CHAPPELL, JOHN C., M.R.C.S., L.S.A., on March 13, at 14, George-street, Hanover-square, aged 58.

CLIFFORD, JOSEPH, M.R.C.S., late of Clarence-crescent, Windsor, at High Wycombe, on March 17, aged 57.

DRUMMOND, MARIA SARAH, widow of the late Henry Drummond, M.D., at her residence, 15, Westbourne-terrace, Hyde-park, on March 16.

FURSE, ROBERT, Surgeon, on March 11, at South Molton, Devon, aged 74.

HORNER, THOMAS, M.D., son of the late William Horner, Esq., De Beauvoir-square, Kingsland, at 1, Bessborough-gardens, Pimlico, on March 16, aged 43.

JONES, THEODORE JOHNSTON, second son of Dr. J. Jones, of Notting-hill, on January 31, at Wickliffe, Victoria, Australia, aged 22.

LAMB, CHARLES STUART, third son of G. H. Lamb, Esq., and grandson of the late Dr. Lamb, formerly Physician-General, Bengal, at 11, Colville-gardens, Kensington-park, W., on March 16, aged 27.

MONRO, FREDERICK HUGH, fourth son of Henry Monro, M.D., at 13, Cavendish-square, March 17, aged 18.

STUART, JOHN, L.R.C.S.E., of Roxburgh House, Kelso, at 23, Porchester-square, Hyde-park, the residence of his son-in-law, after a lingering illness, on March 16, aged 80.

THOMPSON, JOSEPH, M.R.C.S., L.S.A., suddenly, at Oxford-street, Nottingham, on March 19, aged 63.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BECKETT HOSPITAL AND DISPENSARY, BARNSELY.—House-Surgeon and Secretary. Candidates must be duly qualified. Applications and testimonials, on or before April 8, to Messrs. Newman and Sons, Solicitors, Barnsley.

- BIRMINGHAM GENERAL DISPENSARY.**—Resident Surgeon. Candidates must be duly qualified. Applications and testimonials to Alexander Bottle, M.D., Secretary, on or before April 17.
- CAMBERWELL PROVIDENT DISPENSARY.**—Medical Officer. All particulars to be obtained from the Secretary, Dispensary House, Camberwell-park, S.E.
- CARMARTHEN COUNTY AND BOROUGH INFIRMARY.**—House-Surgeon. Must be M.R.C.S. and L.S.A. A knowledge of the Welsh language is necessary. Applications to Mr. H. Howell, King-street, Carmarthen, on or before April 10. Election on the 12th.
- HOSPITAL FOR CONSUMPTION, BROMPTON.**—Resident Clinical Assistant. Applications and testimonials to be sent on or before Saturday, March 30.
- RIPON DISPENSARY AND HOUSE OF RECOVERY.**—House-Surgeon and Dispenser. Testimonials to the Hon. Sec., on or before March 25.
- ROTHERHAM HOSPITAL AND DISPENSARY.**—House-Surgeon. Must be duly qualified. Applications and testimonials to the Honorary Secretary, on or before March 26.
- ROYAL SURREY COUNTY HOSPITAL.**—Assistant Honorary Medical Officer. Testimonials to be sent to the Hon. Sec., Rev. C. R. Dallas, Farncombe Rectory, Godalming, on or before April 16.
- ROYAL VETERINARY COLLEGE.**—Professorship of Physiology, Therapeutics, and Pharmacy. Candidates must be M.R.C.V.S. Applications and testimonials to the Principal of the College, on or before April 4.
- ST. MARYLEBONE GENERAL DISPENSARY.**—Surgeon. Candidates must be M.R.C.S. Eng., and must attend personally on Wednesday, April 3 next, at eleven o'clock in the forenoon, with a written application. No canvassing allowed.
- SALISBURY INFIRMARY.**—House-Surgeon. Candidates must be duly qualified. Applications and testimonials to be sent to the Secretary, on or before April 11.
- WALSINGHAM UNION.**—Medical Officer and Public Vaccinator. Candidates must be duly qualified in accordance with the General Orders of the Local Government Board. Applications with testimonials to be sent to Mr. J. Wright, Clerk, Bridge-street, Fakenham, on or before March 26.
- WESTMINSTER UNION.**—Medical Officer to the Workhouse Infirmary; also a Dispenser. Particulars may be obtained at the Clerk's office, Poland-street, where applications are to be sent, not later than Monday, April 1.
- WEST-SUSSEX, EAST HANTS, AND CHICHESTER INFIRMARY AND DISPENSARY.**—House-Surgeon. Candidates must be duly qualified. Testimonials, etc., to be sent to Mr. E. W. Barton, on or before April 1.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

East Ward Union.—Mr. Alexander Lindsay has resigned the Brough District.

Manchester Township.—Mr. George R. Brebner has resigned the office of Assistant Medical Officer at the Crumpsall Workhouse; salary £150 per annum and allowances.

Samford Union.—Mr. Charles Spurgin has resigned the Stratford District.

Sudbury Union.—Mr. W. E. S. Stanley has resigned the First District; area 12,651; population 3195; salary £55 per annum.

Tavistock Union.—Mr. J. H. Willis has resigned the Lew Trenchard District; area 12,710; population 1994; salary £25 per annum.

Weymouth Union.—Mr. T. Parker has resigned the Abbotsbury District; area 11,358; population 2034; salary £60 per annum.

APPOINTMENT.

Penistone Union.—George F. Leigh, L.S.A., to the Penistone District and Workhouse.

THE LEVÉE.—At the levée held on Thursday, March 14, at Buckingham Palace, the following presentations were made:—Dr. John Rose Cormack, on receiving the honour of knighthood, by the Secretary of State. Dr. Crothers, by Lieutenant-General Sir George Bell, K.C.B. Surgeon John Daniel Hill, by Lieutenant-General Sir Arthur Lawrence, K.C.B. Dr. Lowe, by General Sir W. Knollys, K.C.B. Dr. Edward Makaffy, C.B., Deputy Inspector-General of Hospitals, by Major-General Lucas. Deputy Inspector-General of Hospitals W. C. Maclean, on being made a C.B., by the Secretary of State. Sir James Paget, on being made a baronet, by the Lord Chamberlain. Dr. Paget, Regius Professor of Physic in the University of Cambridge, by the Right Hon. W. E. Gladstone. Dr. Maekenzie, C.B., C.S.I., Honorary Physician to the Queen, by Lieutenant-General Sir J. Hope Grant, G.C.B. Assistant-Surgeon Clement Cuthbert Walker, Kent Artillery Militia, by Viscount Sydney, G.C.B. The following gentlemen attended the levée:—Sirs James Alderson, W. Fergusson, H. Holland, William Jenner, Charles Locock, Henry Thompson, Thomas Watson. Deputy Inspector-General Jee, C.B., V.C. Drs. Acland, Emil Becher, Hinckes Bird, Brodie, Burrows, George Butler, Wm. Carr, T. B. Christie, Langdon-Down, Arthur Farre, Day-Goss, Hooker, Leonard Kidd, M.B. (Staff-Surgeon), Wickham Legg, Alexander Marsden, Mouat, Reginald Read. Messrs. W. Adams, Oscar Clayton, Alford Cooper, White Cooper, Du Pasquier, Cæsar Hawkins, Harry Leech, Leonard Sedgwick, John Simon, T. Spencer Wells. H. Cooper Rose, M.D.

MR. PARTRIDGE.—The friends of this gentleman will be glad to learn that he has so far recovered from his late serious illness as to be able to attend to his Professional and Collegiate duties, and on Wednesday last week was chairman at a meeting of the Dental Board of the Royal College of Surgeons.

DR. HUNT, one of the Medical Officers of St. George's (Hanover-square) Union, has been voted by the guardians £25 for extra services during the epidemic of small-pox.

WE learn from Malta that a spacious Hospital is being constructed near Zabbar-gate at a short distance from Verdala Barracks for the benefit of the troops stationed at the Cottonera district.

THE Wolverhampton Medical Officer of Health has resigned in consequence of the Town Council refusing to carry out the sanitary resolutions considered necessary by him.

THE LATE MR. WADE, F.R.C.S.—The exquisite collection of paintings by Hunt formed by the discriminating taste of the above esteemed member of our Profession (lately deceased) were sold on Saturday, the 9th inst., by Messrs. Christie, Manson, and Woods, and produced nearly £5000.

LECTURES AT CAMBRIDGE.—Dr. Bradbury, the Linacre Lecturer in Medicine at Cambridge, has given notice that he will lecture on Pathology in the Old Anatomical Schools on Tuesdays, Thursdays, and Saturdays, at 9 a.m., during the Easter term, commencing on Thursday, April 18. The fee for the course will be two guineas.

THE mortality per thousand, according to the annual report just issued for the last year of the Relief at Death Fund of the London Society of Compositors, is considerably in excess of the average rate; 50 per cent. of the deaths are due to chest affections.

YELLOW FEVER still exists in the ports of Pernambuco and Paraiba.

CHOLERA broke out on board H.M.S. *Daphne* before she left Calcutta for Saugor with the remains of the Viceroy, and a sub-lieutenant died. The captain, Assistant-Surgeon, and several men were seized, but the ship dropped down the river; and a telegram has been received stating that the captain's case was hopeful, and that the others were going on well.

DR. DECAISNE'S researches about the hygienic effects of the working of the sewing-machine on the health of the operative have been published. Putting aside some local influences of the pedal motion, the Doctor says that, when reasonably and temperately employed, and taking care not to overwork the female operative, as is frequently the case, the machinework is no more injurious than needlework. He, however, recommends a mechanical motor.

CAMBRIDGE PHILOSOPHICAL SOCIETY.—On Monday, February 26, Dr. Latham read a paper "On Teichopsia, a form of transient 'half-blindness'; its relation to nervous or sick headaches, with an explanation of the phenomena." The disturbance of vision referred to in this paper, Dr. Latham said, was a subject which had engaged the attention of Sir John Herschel, the Astronomer Royal, Dr. Hubert Airy, and many members of the Medical Profession. He should proceed to show that it was one stage of a complaint known under the name of nervous headache, bilious headache, or sick headache; the complaint not always accompanied by disturbed vision, but other disordered sensations being substituted for it, and on the other hand the disturbed vision not being always followed by headache; and he should then endeavour to explain the phenomena. He divided the complaint into two stages—first, the stage of disordered sensation, and, second, the stage of headache. After quoting the descriptions given by those whose names are mentioned above, as well as by persons who had come under his own observation, Dr. Latham referred to the causes and conditions under which the attacks were induced. It is to be observed, he said, that all these causes and causes like to them are of a depressing nature, exhausting the power, and therefore lowering the tone of the system, putting it out of tune, disturbing the harmony of the functions, and at the same time exalting the susceptibility of the nervous system. The result was that the power of the ganglia of the sympathetic nervous system to conduct, transfer, and radiate the effects of impressions was no longer controlled by the superior force in the cerebro-spinal centres, and instead of tranquil, even harmonious action in the various organs, as in perfect health, we had convulsive and painful movements. After referring to the effects of irritation and section of branches of the sympathetic, the next step in his argument was that, in the disorder under consideration, there was first of all contraction of the vessels of the brain (probably the middle cerebral artery), and so a diminished supply of blood produced by excited action of the sympathetic, and that the exhaustion of the sympathetic following on this excitement causes the dilatation of the vessels and the headache. This he supported by various cases and comparisons. He next discussed the question why the dis-

order might be sometimes unilateral and sometimes bilateral, and, lastly, why in some cases there is (1) disturbance of vision without headache following, (2) disturbance of vision followed by headache, and (3) headache preceded by disordered sensation, but not by disturbed vision, all of which he maintained were explicable by the theory which he had advanced.

CENSUS OF THE UNITED STATES FOR 1871.—The official Census returns the entire population at 38,923,210, distributed as to colour as follows:—White, 33,589,857; coloured, 4,886,387; Chinese, 63,254; and Indians, 383,712. Of these latter, some two-thirds are estimated as "nomadic."—*New York Medical Record*, January 15.

POMADE FOR BALDNESS.—M. Bouchut recommends the following:—Beef marrow, thirty parts; chloride of zinc, ten parts. The head is to be shaved, and friction made morning and evening until a purulent miliary eruption is produced. The pomade is then to be suspended until the scalp has returned to its normal condition, when it is to be resumed.—*Union Méd.*, March 5.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN FEBRUARY, 1872.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction . . .	20·61	0·135	0·124	0·005	14·3	4·0
West Middlesex . . .	19·11	0·049	0·121	0·002	14·0	3·6
Southwark & Vauxhall . . .	20·83	0·116	0·120	0·005	14·5	3·8
Chelsea . . .	21·03	0·134	0·121	0·004	14·8	4·0
Lambeth
<i>Other Companies.</i>						
Kent . . .	26·97	0·012	0·256	0·000	20·3	6·0
New River . . .	21·07	0·059	0·121	0·001	15·4	3·9
East London . . .	23·47	0·098	0·134	0·002	16·5	4·6

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—namely, in the case of the Grand Junction and the Chelsea Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 101,139,041 gallons; and the number of houses supplied was 492,231. This is at the rate of 31 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 27·7 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

NOTES, QUERIES, AND REPLIES.

Be that questioneth much shall learn much.—*Bacon.*

Ego.—In January, 1833.

Mr. Pratt, of Oxford-street, writes to warn the public that there are imitations of Stöhrer's batteries abroad which may not give the satisfaction the real articles generally do.

Bayswater.—Mr. Delamark Freeman is *not*, as stated on the prospectus of the Bayswater Mutual Medical Aid Society, a *Fellow* of the Royal College of Surgeons.

A Competitor.—Six essays were sent in for the Jacksonian Prize before Christmas-day last, hence the delay in making that announcement which you are so anxiously looking for, but which we understand will shortly appear.

CHANGE OF TYPE OF MODERN AMERICANS.

The marvellous advance of temperance among English-speaking people is a complex effect of vast and varying causes. It is to be attributed partly to the general improvement of the race under a Christian civilisation, which has made coarse vices of all kinds unpopular, partly to the very zealous efforts of temperance reformers, partly to the wide diffusion of knowledge of the nature and effects of stimulants and narcotics, and very largely to the enormous and rapidly increasing nervousness of our brain-working classes, which will not allow them to be the drunkards and gluttons that our ancestors were. Wisely has Bulwer remarked that it needs a strong constitution to be dissipated. The typical modern American, whose distant ancestor gorged himself like a boa constrictor, and in his character partook not a little of the hog, on whose meat he largely subsisted, now finds it difficult to eat enough to sustain life and labour, and can hardly take a glass of wine or smoke a pipe without at once paying the penalty by torturing headache, trembling nerves, and sad indigestion.—*Dr. G. Beard.*

Ears.—We do not know what Dr. Christie can be spoken of by the Plymouth paper as having first called attention to the ear as a distinctive feature in the "Claimant's" case. Professor Laycock's lectures were published in our columns in 1862, with the drawings of ears reproduced in our number of last week; and it is, we believe, to him that is due the credit of pointing out the relevancy of his researches to the present case of disputed identity.

A. B. C.—The error mentioned was of no consequence; the context was sufficient to show the meaning of the sentence. Mere "word-catchers" find fault when sensible people remain silent.

FALSE QUANTITY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the *Medical Times and Gazette*, p. 331, col. 1—in the verse "Principibus," etc.—if I remember rightly, the word is *ultima*,—certainly not *minima*, which will not scan. I am, &c., G.

Hastings.
[** Alas! the exigencies of life and work must be the excuse for such a slip.]

M. D.—Joseph Mazzini was the son of a Physician and Professor of Medicine in the University of Genoa. His father wished him to follow the same Profession, but he was determined on a political career.

Latin Prescriptions.—On a late trial of a chemist for manslaughter, in consequence of having dispensed muriate of morphia for solution of that compound, the defence was that the *solu.* looked like *salt*, and consequently the mistake did not amount to criminal carelessness or ignorance. The prisoner was acquitted. The counsel and judge made some strong remarks on the advisability of writing prescriptions in English instead of Latin. The mistake in a letter had been the cause of a death.

WHY IS THE TENCH CALLED THE PHYSICIAN OF FISHES?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I met, the other day, with a little scrap of some unknown book, published in Latin, in the sixteenth century, and referring to the manners and customs of the English. It says that the pike is a very common article of food in England, and that the fishwomen keep the pike alive in tanks, and fatten them on small eels and other fishes. It goes on to say that these women never hesitate to cut open the belly of a fish to show its internal fat and spawn for the attraction of purchasers, and that if the fish is not sold, they simply sew up the wound with needle and thread, and put it back into the tank. There are always tench in the tank, and the glutinous secretion of their skin is said to heal the wound in the pike's belly. I am, &c., A.

Thomas Bateman, M. D.—"Who was the author ('J. R.') of a Life of Thomas Bateman, M. D., F. L. S. (of Whitby), published by Longmans in 1826?—C. A. FEDERER, Bradford."—(*Notes and Queries*, February 24, 1872, p. 159.)—"The author of the Life of Dr. Bateman was his brother-in-law, Dr. James Rumsey, who practised for many years at Amersham, but spent the last years of his life at Clifton, Bristol. He received his M. D. degree from the Archbishop of Canterbury, and he well deserved it, for he was a skilful Practitioner and a truly good man.—J. D."—(*Notes and Queries*, March 16, 1872, p. 227.)—Are degrees in Medicine still conferred by the Archbishop of Canterbury?

THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your article on the Contagious Diseases Acts, published in your journal of February 17, you say that you "lay the chief blame of the *imbroglio* on those members of our own Profession who, in their laudable zeal for wiping out syphilis, began by introducing the thick end of the wedge first, and shaped their measures in such a way as to awaken the prejudices and alarm the moral sense of the community." And again you say—"We lay the blame, then, of the present inveterate opposition to the Acts on the way in which the matter was first handled; on the well-meaning attempt to make it an isolated question of disease—a mere Medical question. The results would have been far different if the moral side, which the advocates of the Acts are now fain to put forward, had been acted upon from the first."

Before proving from the published reports of the "Association for Promoting the Extension of the Contagious Diseases Acts" that the Committee of that Association were not unmindful from the first of the great moral benefits conferred by the Acts, allow me to congratulate the *Medical Times and Gazette* on its returning, after several years of opposition, to the advocacy of the Acts; but, at the same time, I regret that so respected a journal should cast blame on those who have laboured long in support of those Acts, and borne the chief burden of their defence against the fanatical attacks of their opponents.

The first report of the Association was published in 1868, and extended to fifty pages. One of the objects of the Association, as printed in the first page of the Report, is, that "it aims at the moral and social improvement of a numerous and degraded class;" and at page 14 the Report states that "the Association is opposed to the Continental system of licensing prostitutes and brothels, and is of opinion that nothing resembling a certificate of health should be given to the women themselves, either after their Medical examination or on their discharge from Hospital."

Section V. of the Report, consisting of two pages, is entitled "Moral and Social Effects of Prevention," and paragraph 41 in that section states that "the Association desires the suppression by police regulations of the open profligacy of the streets, which offers so great a temptation to the young and thoughtless. This has resulted from the operation of the Contagious Diseases Act at Plymouth." And in the Appendix the good moral effects of the Act are referred to repeatedly by reports from the subjected towns and in letters from the clergy and chaplains cognisant of the working of the Act.

I need not refer to the subsequent reports of the Association, suffice it to say that the fourth report has just been printed and circulated, and any one reading it will see that the moral side of the question has been fully treated in about sixteen pages out of fifty-six. The Committee of the

Association have the satisfaction of feeling that their labours have been appreciated by the political supporters of the Acts, but they have received scant justice from the Medical periodicals, from whence support was most expected.

I am, &c.,

J. BRENDON CURGENVEN, one of the Hon. Secretaries
to the Association.

March 6.

Bound in Human Skin.—A copy of the "Constitution of the French Republic of 1794," bound in human skin, is about to be sold in Paris. The binding, however, is said not to be unique. The public library in Bury St. Edmunds contains an octavo volume, consisting of a full report of the trial and execution of Corder—who, it may be remembered, murdered a young woman named Martin, at the Red Barn, in a neighbouring village, about forty years ago—together with an account of his life and other matter. This volume is bound in the murderer's skin, which was tanned for the purpose by a Surgeon in the town. The skeleton was prepared for the Suffolk General Hospital, and is still to be seen there. The human leather is darker and more mottled than vellum, of a rather coarse texture, with holes in it like those in a pig's skin, but smaller and more sparse. English books with this kind of binding are at the same time much less rare than is generally supposed. In the Bristol Law Library are several books bound in human skin, specially tanned for the purpose, and some curious details might be furnished of several local culprits executed in that city who were flayed after execution to furnish the leather for binding together some contemporary legal lore.

MR. MULTY LAL MITRA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your readers will be glad to learn that the Hindoo gentleman, Mr. Multy Lal Mitra (not Mr. Lal Mitra), L.R.C.S.E., mentioned in your last number as lying at the Lambeth Workhouse in a state of insanity, and incapable, from want of present means, of procuring a passage out to his own country, although said to be possessed of large wealth in India, is in a fair way of being properly cared for, and has already been removed from the workhouse.

On Friday last I had the happiness of calling the attention of a Hindoo gentleman, a member of the Inner Temple, to the case, who, with the utmost alacrity, at once proceeded to the workhouse, and on the following day informed me that every reasonable expense should be incurred in sending his unfortunate countryman home as soon as he was in a fit state for removal, and that in the meantime he should receive all proper attention; but that there were circumstances connected with the case, which he explained to me, that would not justify an expenditure beyond the necessities of the occasion.

The two Hindoo gentlemen are comparative strangers to one another, and I am, therefore, the more rejoiced to bear this testimony to the Christian-like conduct of one of our non-Christian fellow-subjects.

I am, &c.,

HUGH WEIGHTMAN.

1, Mitre-court, Temple, March 19.

Dr. Hill and St. Pancras.—The following letter addressed to the Board by Dr. Hill was read at their meeting last week:—

"In reference to an agreement which I was on Wednesday requested to sign at the meeting of the General Purposes Committee, I beg to inform you that I am quite willing to devote the whole of my time to the discharge of my duties as Medical Officer of this workhouse, and have held myself in readiness to do so since the 5th instant. My objection to sign the agreement is that, according to the construction placed upon it by the Committee, I should be bound to disobey the legal order of the coroner to make a post-mortem examination of the body of any person dying in the workhouse. I have the highest authority for stating that such disobedience on my part would render me liable to a penalty of £5 for each offence. I cannot, therefore, allow myself to be placed in such an unenviable position. But in order to show that my objection is based, not upon motives of pecuniary advantage to myself, but upon a desire of self-protection, I beg to state that if the Board will give me a bond, holding me free from the costs and payment of the before-mentioned penalties, and such as will be approved of by my advisers, I will not hesitate to sign the agreement."

The Chairman said the Board did not object to Dr. Hill attending inquests as a witness and taking his guinea fee, but there was a great objection to his making post-mortem examinations, and it was believed that Dr. Lankester could not compel him to make them if he had other business to attend to. Even if it were otherwise, what they wanted Dr. Hill to do was to carry out his agreement by giving up the fees. Mr. Joseph Salter said Dr. Hill had written to the coroner with reference to the law on the subject, and had received a reply stating that every Medical Officer was bound to obey the coroner's order to hold a post-mortem examination under a penalty of £5 in each case of failure. Presuming that to be correct, Dr. Hill could still refuse to take the fee, and that would secure the object of the Guardians. There was no objection to the fee of one guinea as a witness being taken. He would suggest that they should ask Dr. Hill to allow the Guardians to submit the coroner's letter to their solicitor. The Chairman thought the best thing they could do was not to confirm Dr. Hill's appointment, and to take no further notice of the matter, but leave Dr. Hill to come to himself. Shortly afterwards, a letter was handed to the Chairman from the Local Government Board, stating that they had no power to compel Dr. Hill to sign the proposed agreement with reference to taking fees for holding post-mortem examinations. It was then resolved—"That, Dr. Hill having declined to sign the agreement, the Board take steps to make other Medical arrangements for the house."

"AGE QUÆ JUSTA SUNT."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am a subscriber and regular reader of your invaluable journal, and shall feel obliged by your inserting the following remarks in your next issue:—

Judging from the many attempts made and suggestions given from time to time to improve the working of the present Medical Act, it would appear to a stranger that it does not give satisfaction to the members of the Profession at home; and, if this be the case, how much greater must the annoyance be to the members of the Profession who have been educated in the colonies, and have taken their degrees from regular chartered universities, whose professors are recognised as competent teachers by the different licensing boards throughout the United Kingdom. Those gentlemen are placed in the same category as the *vilest quacks* on putting their foot on the shores of Great Britain, no matter how high their Professional standing may be in the land of their birth. For example, as the Medical Act stands at present: Dr. A. is a regularly educated colonial Physician, and practising in the same neighbourhood is Dr. B., a member of a British university—the former gentleman meets the latter in consultation, and is in every way his equal in the colony; but let those two gentlemen meet in England, and how do they then stand? Why, Dr. B. is allowed to practise his Profession, and Dr. A. is not, although he thoroughly understands it, unless he is willing to go through again the routine of appearing in lecture-rooms, etc., for a year, and after submit to be examined by men whom he would perhaps have to meet the next day in consultation, and assist with his advice. The majority of the members of our Profession educated abroad would not submit to such a degradation, even to gain all the privileges obtained by their names appearing on the British Medical Register.

Assuredly a law that throws so great a slight on the members of an enlightened and educated class—our colonial Practitioners—is neither just nor generous; and I believe that the day is not far distant when an Act more in keeping with the spirit of the age in which we live will be introduced. If I am not already anticipated, I would suggest it should make provisions for the registration of the degrees of all foreign and colonial Practitioners, provided they can give satisfactory proof of their good standing in the country from which they have come, as well as evidence of having passed an examination for their degrees. Such information can be obtained from the registrars of the universities or colleges from which they were obtained.

I am quite aware that some over-cautious reader will say that, if such an Act became law, it would ruin the English colleges, and that the country would be inundated with foreigners; but I say to such "Fear not!"—for, if you will take the trouble of referring to the Medical Register, you will find that there were not many foreign degrees on the passing of the Medical Act in 1858. It must be remembered that before that date there was no law against even *unqualified* Practitioners, which clearly shows that foreign or colonial graduates, whose degrees would have been recognised then, did not think that the practice of their Profession would be more lucrative in England than in their own country.

You may say, then, What benefit accrues by our recognising them now, if they do not want to come here? I say the benefit is great; for, first, you would show that you were a liberal and enlightened body of men; and secondly, that you were willing to give the same privileges to foreigners as they have given and will give to graduates of British Medical schools; and lastly, by doing this it would prove that you consider that graduates of British colleges cannot be surpassed by those of any other—for I must say that the impression the present Act leaves on the minds of some is that British graduates in these days are not like their forefathers: they cannot defy competition.

Thanking you for the space occupied by these remarks in your columns, and hoping that they may be the means of gaining for members of the Medical Profession abroad all the rights and privileges which British Physicians receive and accept from foreigners,

February 27.

I am, &c.,

A VOICE FROM A COLONY.

FUNERAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—This morning a woman suffering from puerperal peritonitis lies ill in a miserable lodging, and in the same room a tiny coffin containing her infant attracts the attention and curiosity of neighbours—besides inviting typhus. Yesterday a lady, by no means of religious turn, quietly, peaceably closed her eyes, clinging to temporal existence less tenaciously than many a sister whose soul had been prepared, and ready for the dark future. Constantly reminded of death riding on every passing breeze, lurking in every flower, it is strange that we Medical men do not at all set our houses in order. Struggling for the laurels and the bays, have we no leisure to consider the elms, the yews, and the significant cypresses? Sir Astley Cooper, satiated with wealth and honour, often looked up at his tall trees half inclined to hang himself; Sir H. Holland, commencing practice at 27, able to travel all the world over, yet rapidly earned a large income. These instances of success are exceptional. The mitre, the woollen sack, and the ermine are for other professions. Even to put money in the purse is comparatively rare. There is a fable somewhere that the eagle promoted the cuckoo to the rank of the nightingale of the wood; but the other birds, hearing the harsh, shrill note, refused to recognise the sound, and flew away in terror or derision. The tide comes some time or another to every man, everything depending on his ability to be equal to the occasion. Alas! the trial in the scales of public opinion and private reflection may be unsatisfactory, very disappointing. In that unhappy frame of mind, easily recognised by the unsuccessful, broken-spirited middle-aged Practitioner, temporary mental relief is sought in scribbling, and to-night the disposal of the dead forms the subject—gloomy, but concerning all. When once the spirit has fled from the body, lately so lovable, so full of joyous health and activity, the cruel fingers of destructive decay leave us but a ghastly corpse, spreading perhaps pestilence in the house, and in the grave poisoning the atmosphere above and the water springs below. Trousseau relates that during the last century there was ordered the judicial exhumation of a person who had died of small-pox a long time before. The gravedigger and others contracted the disease, which spread rapidly in a village for years previously exempt. On reference to Parkes's "Hygiene," it appears that carbonic acid, ammonia, sulphuretted and carburetted hydrogen, nitrous and nitric acids, and various fetid gaseous products, result from burial; but should the body be burnt, carbonic acid, carbonic oxide, nitrogen, etc., are given off. The solitary cynic will say—Why not be placed in holes or caves, or hermetically sealed coffins, be embalmed at the expense of £200, be exposed to the vultures on the mountains, or in the Towers of Silence? Why not be preserved in a museum, be burnt, consigned to the waves, or become the prey of wolves, dogs, or crocodiles? What does it matter? *Que sais-je?* What do I know? *Ubiunque felix.*

From a sanitary point of view the question materially concerns the survivors; but, whether sulphate of zinc, carbolic acid, charcoal, or quicklime be sprinkled about the corpse or not, it is quite clear old English customs will remain intact—incineration will never be tolerated excepting

during a campaign, a panic, or an epidemic such as the plague at Eyam, where 267 out of 350 inhabitants died! Besides, this troublesome, expensive process carried on in large towns would constitute a nuisance, and in the country scarcely required. This afternoon, whilst driving from one anxious case to another (very sad at heart, and with sufficient reason), the intervals between the houses occupied reading Dr. Brehm's book, the subject appeared in such harmony with the train of thought that a quotation needs no apology. "When a bird dies a whole army of gravediggers take the little corpse under their care, hundreds of different beetles and other insects devour it; the grass soon covers its remains, mosses enclose the bleached skeleton; the feathers are scattered by the winds, the flesh has vanished, the bones are buried, and the leaves of the trees alone rustle and murmur long after the lovely being which lived, loved, and died under their gloomy shade has vanished from their midst."

In an obscure churchyard in the Scilly Islands rest wanderers returning from foreign climes; in invalids yearning for home and kindred pitifully die within sight of the blue hills of the dear old country, and are buried in this lonely spot.

The Moor has done his work; the Moor can go. Yes, many a worn-out Medical man, an exile whose sun is setting, wistfully longing for one last look at his native village, the ivy-covered church, the red-brick house, the trim garden, the clean streets, the quaint shops, the salmon river, and the green familiar lanes, would say with the poet—"There I should sleep softly; I would know that the things I loved so here below were about me still." I am, &c., A. W.

COMMUNICATIONS have been received from—

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.79 in. The highest was 30.15 in. on Sunday morning, and the lowest 29.27 in. on Thursday afternoon.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

CLINICAL LECTURES ON INTESTINAL OBSTRUCTION.

By THOMAS BRYANT, F.R.C.S.,
Surgeon to Guy's Hospital.

LECTURE II.

GENTLEMEN,—At our last meeting I took the opportunity of bringing under your notice the subject of constipation and intestinal obstruction, and of placing it before you from several points of view. We reviewed, too, the symptoms which these conditions give rise to in their different classes—namely, where the constipation or obstruction is due (1) to powerlessness of the bowel itself; (2) to tumours, bands, and other causes outside the bowel; and (3) to growths within the intestine. And, further, I went on to say that this latter kind of case led me on to the consideration of the subject of intussusception.

It is not my intention to describe fully and to differentiate the symptoms produced by each special cause of obstruction, but I may state in passing that these are distinct enough to allow of our diagnosing one kind of cause from the others. The symptoms provoked by the first class of cases are long-continued and gradually increasing constipation, leading up to complete obstruction, followed by pain, abdominal fulness, and ultimately, it may be, death. When the symptoms are due to the presence of bands they are of an acute character and paroxysmal—abdominal pain, vomiting, and constipation all occurring rapidly, and even suddenly. The acuteness of the symptoms and their paroxysmal nature are the two facts to be remembered.

Now, all these symptoms are common to a large variety of cases, and are due not only to the presence of bands. They are common to hernia—external hernia as well as internal hernia—for I would have you regard hernia as nothing more than constriction of the bowel; and if that occur suddenly, the symptoms are alike whether that constriction be situated outside or inside the peritoneal cavity. Anything, in short, that suddenly produces constriction of any part of the intestinal canal may give rise to these acute symptoms. But these differ widely from the more chronic symptoms we get in atony of the bowel, or when an extra-intestinal tumour encroaches upon the gut. We come next to the third class of cases—those, namely, in which the constipation and mechanical obstruction are due to some cause existing within the bowel itself. Intussusception is the first which presents itself to us.

Now, as to the signs of intussusception. It matters little whether the cause of the invagination is a polypus of a villous or fibrous character growing into the gut, or the presence of scybala; in each case nature's efforts to get rid of the foreign body is the direct agency in bringing about the intussusception. It is rare for the small intestine to be alone affected; more frequently the small passes through the ilco-cæcal valve into the large bowel, and sometimes the large bowel only is the seat of the disease, the bowel itself at times projecting externally through the anus. In all cases we get tenesmus—that is, violent pain with straining—and the passage of blood, mucus, and a little faeces. These symptoms we never find with the first set of cases, nor in obstruction due to bands or tumours; hence we see a great difference in the signs upon which our diagnosis is to be founded.

The importance of a correct diagnosis is great, for upon it our treatment must depend, and this differs in the different classes. In the first set colotomy is the means of relief we must resort to, but in the second class of cases, as where we suspect the presence of a band, abdominal section is the operation to perform. Desperate as this operation may seem, it is the right treatment to adopt, and if neglected death must inevitably follow. In strangulated hernia our rule is to operate; and why should it be different when the bowel is constricted within the abdomen by a band instead of at one of the rings of the abdominal wall? The old authors on Surgery were not well acquainted with the Surgery of the abdomen. It is a branch of our art which has of late years been developed. They knew nothing of ovariotomy, and would have discredited the possibility of many operations which are now performed with success—such, for instance, as a case of my own, which I intend bringing soon before one of the Societies, in which I removed the uterus with both ovaries. On this point, then, I feel strongly, and I affirm that we are not justified in standing by, waiting

for death, but should undauntedly perform abdominal section. As we do not hesitate to operate in ovarian disease and in hernia, neither should we here. As to the value of this operation in intussusception I will not so positively assert, but the experience I referred to of Mr. Hutchinson's is, perhaps, good enough to make us favourably entertain the operation even in these cases.

We will now pass on to consider some points connected with a subject distinct from, but still allied to, the above—I mean the subject of hernia. And in my remarks upon this disease I do not intend to dwell upon the characteristic features of hernia, for these, I take it, you are familiar with; but rather to point out some odd complications and results of hernia. In two of the cases I referred to in my last lecture hernia existed, although the symptoms were quite unconnected with it. In each of these cases a band of adhesion was the cause of the obstruction. Now, without attempting to explain why it is, I will state that bands are much more frequently found in persons the subjects of old hernia than in others; and I lay stress upon this fact because in such cases the seat of hernia must be first explored.

If you are called to a patient suffering from symptoms of intestinal obstruction, such as are produced by the presence of bands, and he is also the subject of hernia, you would obviously take the seat of hernia as the starting-point for your operation, and then, after exploring the hernia, you could proceed, if necessary, to open the abdominal cavity. In one of the cases I referred to at our last meeting, you may remember this course was followed, and the patient is alive now, eight years after; and in another, and a fatal case, I was only deterred from adopting the same treatment by the objections of the friends.

This, then, is one relation between hernia and intestinal obstruction, but the symptoms in these instances are not due to the hernia.

One class of cases in which the symptoms are due to hernia, but not to mere strangulation of the bowel, I have firmly impressed on my mind; it is where an adhesion has taken place between the bowel and the intestinal wall, or between the bowel and the sac of the hernia. A case of this sort, I well remember, occurred under the care of Mr. Cock. A patient who for a long time suffered from constipation got at last complete obstruction, followed by abdominal pain, vomiting, and death; and at the post-mortem the transverse colon was found adherent to the neck of the sac of an umbilical hernia. The hernia itself was reduced, but the colon was drawn up into a sharp flexure at the spot adherent, and the portion above the adhesion went on distending until rupture of the bowel occurred. A similar case in a patient the subject of femoral hernia was under the joint care of Mr. Birkett and myself. And a third case occurred in my own practice in a patient from whom I had removed an ovarian tumour. There were numerous adhesions, and one of these, attaching the tumour to the left loin, I ligatured. She got quite well, but some time afterwards symptoms of uncontrollable sickness set in, and she died from starvation. After death a portion of the small intestine, bent upon itself, was found adherent to the loin in the situation in which the ligature had been placed. This spot was marked by the presence of a small quantity of pus. This is no doubt a rare, but still an actual, cause of intestinal obstruction associated with hernia, and explains many cases in both Medical and Surgical practice. In these cases the operation of abdominal section is not to be thought of—it is altogether inapplicable.

A still rarer, if not an unique, case occurred to me in 1870, and consists in the subsequent contraction of the portion of intestine which had been strangulated in a femoral hernia, due to inflammation in the submucous and peritoneal coats of the intestine, and resulting in a stricture of the bowel.

I. H., aged 52, came under my care at Guy's Hospital on April 1, 1870, for a strangulated femoral hernia. She had been ruptured on the left side for four years, and had never worn a truss. The hernia had never given her any trouble till thirty hours before admission, when it came down, and was followed at once by vomiting and abdominal pain. When I saw her, a true femoral hernia existed; it was very painful, and an operation was proposed. Under chloroform, the taxis was applied, with no good effect. Herniotomy was consequently performed, the hernia being reduced without opening the sac. All the symptoms at once ceased; the bowels acted naturally within the week. The wound healed kindly, and the woman was only waiting for her truss to leave the Hospital, when some bowel trouble appeared. These were irregular in their action; at one time constipated, at another loose. Some griping abdominal pain appeared, and at the end of a week, after these

symptoms, vomiting—it being then seven weeks after the operation.

These symptoms persisted, and became worse. Her stomach became so irritable that all food was rejected, and she was kept alive only by nutrient enemata. She sank, however, exhausted on June 13, ten weeks and a half after the operation, and three after the appearance of the abdominal symptoms.

After death, about one inch and a half of small intestine was found contracted and thickened. The upper part was twice the diameter of the lower. No feces were found below the seat of stricture. It seemed as if the knuckle of intestine that had been strangulated had subsequently contracted and formed a stricture, for at this part the folds of mucous membrane had entirely disappeared, the surface appearing smooth. The folds of membrane above and below were natural. The thickening of the coats likewise points to the same conclusion.

Such a consequence of hernia I believe to be very rare. I am not aware that such has been recorded.

Rare, then, as such cases must be, still you may fairly suspect the presence of such a state of things if, after five or six weeks from the date of an operation for strangulated hernia, the symptoms of intestinal obstruction set in.

Thus far, then, we have seen (1) hernia co-existing with bands of adhesion, (2) hernia followed by the adhesion of some part of the intestinal canal to the old hernial sac, and (3) hernia followed by the contraction of the previously strangulated gut, engaged in the production of intestinal obstruction.

I shall now pass on to consider some other points connected with hernia, and the first I will allude to is the subject of displaced hernia.

No cases demand closer attention than these. When understood and appreciated, they are to be successfully treated; when misunderstood, they are sure to be overlooked. Thus, it may be accepted as a fact that a strangulated hernia with its sac may be bodily reduced within the abdominal ring and behind the abdominal parietes, the intestine being still held by the neck of the sac. This form was first described by the French writers as "*reduction en bloc*" or "*en masse*," and by Mr. Luke in this country (*Med. Chir. Trans.*, 1843).

This displacement of a hernia can probably only take place in the femoral form of rupture, and the whole sac and its contents are pushed up into the abdominal walls, without the contents being returned into the peritoneal cavity. A case of this sort occurred to me in November, 1871, and another similar to it in character has been described by Mr. Morris, of the Middlesex Hospital, in the twenty-second volume of the *Pathological Society's Transactions*. This preparation has been lent to me by Mr. Morris for your inspection, and you will see a large cavity formed behind the rectus muscle and the pubes, dipping deeply down into the pelvis in front of the displaced bladder, and limited posteriorly by the peritoneum and sub-peritoneal fascia, which had been detached from the abdominal and pelvic walls. My own case I will describe to you. It was as follows:—

On November 9, 1871, I was called by Mr. Berry, of Claremont-square, Pentonville, to see a Mrs. S., aged 64, the subject of strangulated femoral hernia.

She had had a hernia for years, and had worn a truss; it had never given her any trouble. On the present occasion it had been down a week, and for that time local pain, abdominal tenderness, constipation, and vomiting had existed—the vomiting having been stercoraceous for one day.

When I saw her she was very feeble; a hernia the size of a walnut existed in the right groin, clearly femoral. Chloroform was given and the taxis employed with great gentleness without success. Herniotomy was consequently proceeded with. Having exposed the sac, I divided the stricture externally, and, on employing the gentlest pressure, the whole hernia suddenly slipped up within the crural ring. By abdominal pressure it was made to reappear, and by digital pressure to the tumour to disappear a second time—indeed, to clear up some point, I reduced it again, after which some little difficulty was experienced in getting it down; but at last it reappeared for a third time. I opened the sac and exposed the intestine, readily reducing it without making any incision into the neck of the sac, which I took care to keep well down by means of forceps.

A morphia suppository was given, and a grain of opium by the mouth. The bowels acted six hours after the operation, and all pain and vomiting ceased, the wound healing by primary union. The patient, however, was too feeble to rally fully, and died on the tenth day.

No post-mortem could, unluckily, be obtained.

The facility with which the sac was separated from the sub-

adjacent tissues is a feature of importance, for had I used great force in the reduction, the whole tumour would have been reduced out of sight, the bowel remaining unrelieved and without the peritoneal cavity, although within the abdominal walls.

This case made me ask myself the question whether the same result might not have taken place had I attempted the reduction of the hernia without operation by forcible taxis.

The majority of cases reputed to be of this nature are probably caused by other lesions of the sac, and the credit of having made this out is due to Mr. Birkett, who, in an able paper read before the Medical and Chirurgical Society, 1859, gave the following explanation (the observations only apply to *inguinal hernia*):—

In the *first* form the neck of the sac becomes detached by force from the internal abdominal ring and pushed upwards beneath the abdominal walls, the intestine within the sac being strangulated by the orifice of the sac.

In the *second* form, "as the effect of forcible and long sustained compression of the hernial tumour, the delicate serous membrane of the sac is rent, burst, or torn, and the hernia makes it escape through the aperture into the subserous connective tissue. Its course outside the peritoneal sac is advanced by continued pressure; and, detaching the connexions of the neighbouring peritoneum, it forms for itself a pouch between that serous membrane and the internal abdominal fascia."

The posterior part of the neck of an inguinal hernia sac is the usual seat of the rupture, and the position of the artificial sac is downwards and outwards. The congenital form of hernia sac is also the more prone to the accident.

The indications of the accident having taken place are as follows—I give them in Birkett's words:—"The tumour becomes flaccid, and therefore smaller; the bulk of the tumour slowly diminishes as the pressure is continued, until at last, very little, if anything, can be felt; but the *Surgeon has failed to experience that sudden jerk so characteristic of the escape of the hernia* from the gripe of the mouth of the sac, as it enters the abdominal cavity. After the effects of the chloroform have passed away, *all the symptoms of strangulated bowel recur*, and perhaps with increased force; even the tumour itself may reappear and recede on the application of slight pressure. When this condition is found, there is but one form of practice to follow, and that is the exploration of the sac; at its neck two orifices will be found, one dipping down into the artificial sac, and the second into the abdominal cavity—from the latter the bowel will be seen to pass through the former into the artificial sac. The Surgeon must then draw out the bowel from the sac through its false orifice, and, having freely divided the true neck or abdominal orifice of the sac, replace the intestine; and "the exercise of great care and caution is needed to prevent the entrance of the hernia once more into the abnormal space outside the peritoneal cavity."

As a *third* form, an intermuscular, interstitial, or *intra-parietal* sac has also been described, being a kind of diverticulum from the inguinal sac. It is almost always found, according to Birkett, associated with the congenital form of hernia; and this sac may be found in the anterior abdominal walls—in an upward, outward, or inward direction—mostly behind the abdominal muscles, in front of the abdominal fascia, in some instances in front of the external oblique muscle beneath the skin. Birkett refers to a case recorded by Scarpa, and a second by Dr. Fano.

In a second class of cases, "the sac extends into the iliac fossa, and rests upon the iliacus muscle between the internal abdominal fascia and peritoneum; or, directing itself inwards, it passes behind the horizontal ramus of the pubes, and reaches the side and front of the urinary bladder."—Birkett.

At Guy's Hospital a preparation taken from a patient of my own confirms it. The disappearance of the tumour without the characteristic jerk, and the persistence of the symptoms, characterise all these three forms. The treatment in all is that described under the second form.

To Mr. Birkett, for his paper to which I have alluded, we owe a great deal. Not only is his description admirable from a literary and scientific point of view, but it is of great assistance to us at the bedside, and by its clearness and accuracy we are able to stand by and say to which class of these cases any individual instance belongs. Here is a case in which the diagnosis was rendered certain with the aid afforded by his investigations. It is an instance of the first class of cases:—

On January 6, 1872, Dr. Paul, of Camberwell House, called me to see an imbecile patient of his, aged 27, who had a congenital hernia, with all the symptoms of strangulated intestine. This patient had always worn a truss. Vomiting, abdominal

pain and tenderness in the seat of the hernia having existed for twenty-four hours.

I found the patient with the symptoms described, with the right testicle in the inguinal canal, and only a slight fulness at the internal ring; but above the ring, and occupying a space as high as the anterior superior spine of the ilium, and half-way between this process and the umbilicus, beneath the abdominal parietes, there was a marked, prominent, tense, elastic, and painful swelling. The swelling was pear-shaped, the end of the pear appearing at the internal ring.

Chloroform was given, and the inguinal canal opened, the testicle being exposed. The internal ring was then slightly enlarged, and directly this was done a knuckle of black congested intestine appeared. This knuckle was not in the abdominal cavity, but in a separate one continuous with the vaginal process of peritoneum that I had opened. I passed my finger freely into this cavity in search of the abdominal ring through which the hernia had descended, and I found the opening about the size of a sixpence—just enough to admit the tip of the finger at its upper and inner corner. Several inches of intestine existed in the sac. With the guarded herniotome I enlarged the opening of this ring, but found much difficulty in reducing the bowel, for I could only just reach the opening, and the walls of the cavity gave before the taxis. I then made forcible traction upon the testicle in the canal, and was pleased to find the cord ran upwards through the opening by which the bowel had descended. The intestine was then readily reduced. Opium was ordered, and the wound brought together.

On the next day the bowels acted, all symptoms having at once disappeared after the operation. Some suppuration followed in the sac, but no bad symptoms, the man convalescing.

Remarks.—This case was one of unusual interest, and was valuable, as it went far to prove the truth of Mr. Birkett's investigations into this form of hernia. When I first saw it, I was able to recognise its nature, and to know how to deal with it, simply from having made myself acquainted with Birkett's explanation of the masked hernia; for the case had all the clinical history and symptoms of a hernia into the vaginal process of the peritoneum, this process having been expanded towards the abdominal cavity, instead of externally—the constant wearing of a truss having probably done much towards producing this end. That the sac was really a dilated vaginal process, and not a new sac, I think was fairly proved when I found the cord passing into the abdominal cavity, out of which the intestine that had been strangulated had passed. The success of the case was better than I expected, for some inches of intestine were involved, and these were as black as jet from congestion. Possibly the feeble intellect had something to do with this absence of inflammatory action.

In the third class of cases, in which an intra-parietal sac exists, or that in which the neck of the sac becomes protruded, and the contents are forced into the dilated portion, the escape of its contents from the sac may take any direction, either downwards, inwards, upwards, or outwards. I will quote to you the following instance of this kind of case:—

On September 23, 1869, M. T. was admitted into Guy's Hospital under my care; he was a labourer, and 36 years old. He had been ruptured in the right scrotum for fifteen years, and had worn a truss. Whenever it came down it was easily reducible, except on two occasions when some difficulty was experienced. Two weeks before his admission it came down, and after its reduction he experienced pain, which kept him from work for three days. He remained well till two days before he came to Guy's, when the hernia came down into the scrotum. He pushed it up, however, by manipulation after a little trouble, but it did not go up as usual with a rush. After its reduction vomiting appeared and local pain; this continuing he came to Guy's. For the two days his bowels did not act.

When I saw him he had all the symptoms of strangulated bowel—vomiting, local abdominal pain, and constipation. There was no hernia down, but some fulness at the internal ring, and above this, towards the crest of the ilium, a tense, globular, painful swelling was to be felt. An exploratory operation was determined upon. Under chloroform I then laid open the inguinal canal, and I exposed the empty hernial sac with the testicle, showing that the hernia was of the congenital form. I then passed my finger into the internal ring and came against a tense piece of intestine. I enlarged the opening, and this intestine at once protruded; it was very dark from congestion, but glistening. On following up this intestine my finger passed downwards and outwards into a distinct cavity which was filled with bowel; but it was not the abdominal cavity—it was a

distinct cavity with a smooth surface, and about the size of an egg. At its upper surface it communicated with the hernial sac, and above this with the abdominal cavity. I then increased the size of the abdominal orifice, which was very small, drew out the strangulated bowel from its intraparietal sac, and returned it into the abdomen. The intraparietal sac was thin, and very distinctly felt; it was placed almost entirely below the ring, which was pressed upwards.

All symptoms ceased directly after the operation, and everything looked well, when peritonitis appeared, and death took place on the fourth day. The preparation I have shown you illustrates the existence of a distinct sac from which the hernia had been removed by the operation.

ORIGINAL COMMUNICATIONS.

CLINICAL REMARKS

ON THE SEVERAL FORMS OF PULMONARY PHTHISIS.

By R. DOUGLAS POWELL, M.D., M.R.C.P.,

Senior Assistant-Physician to the Hospital for Consumption and Diseases of the Chest, Brompton;
Assistant-Physician to the Charing-cross Hospital.

(Continued from page 152.)

Alveolar Catarrh before spoken of may set up local tuberculation; why disease tubercular, not simple chronic inflammation; seat; progress independent of pneumonia: How different from miliary tubercle; mode of extension by continuous growth; clinical differences—Chronic Tubercular Phthisis the best clinical name for this disease—Relationship of local tuberculation to local, miliary, and general tuberculosis one of degree or intensity as regards infective origin or specific constitutional nature—Distinctive characters of Chronic Tubercular Phthisis; prognosis—Sketch of a case of acute Tuberculo-pneumonic Phthisis; distinguishing characters from Acute Tuberculosis and Acute Pneumonic Phthisis—General rule as to prognosis; necessity of watching the signs of fever as well as physical signs—Table representing chief varieties of phthisis, with their distinguishing characters.

IN speaking of alveolar catarrh, it was remarked that, as in some cases it may proceed to catarrhal pneumonia of varying degrees of intensity, in which the pneumonic process, with its intra-alveolar products, gives the prevailing character to the disease, so in other cases the lymphatic or adenoid structures which so largely enter into the formation of the lung stroma may, under the same primary catarrhal irritation, take on the more prominent growth; and great thickening of the alveoli, grey induration, in which some individual granules of tubercle may or may not be distinguishable by the unaided eye, is the result—in fact, we have a local pulmonary tuberculation of slower and more insidiously destructive progress than caseous pneumonia, so far as the lung is concerned, but more obstinately and continuously progressive, more prone to be succeeded by early implication of the other lung, supposing both are not from the first implicated, more quickly followed (sometimes even preceded) by disease in other organs, particularly the larynx and intestines; and, in short, though a chronic or subacute disease, yet one of more early average termination than the corresponding pneumonic forms of phthisis.

It will no doubt be said by those who only admit the existence of tubercle in the discrete or disseminated grouped miliary forms that this local tuberculation is no tuberculation at all, that it is merely chronic inflammation. If so, it is an interstitial inflammation of a very special kind, that in typical cases spreads through the lung from apex to base, with a well-defined grey advancing margin, immediately beyond which the highly vascular but crepitant lung-tissue presents a striking contrast to it. On examining, however, more minutely with a lens, the alveolar walls are found considerably thickened to some little distance (perhaps half an inch) beyond the defined margin, though the alveolar spaces are not occupied with catarrhal cells—at least, not uniformly so, or to any material extent. I am not aware of any mere inflammation at all analogous to this in its invasive characters. It most resembles lupus of the cutaneous surface, which, I presume, no one would venture to describe or treat as merely inflammatory. On the other hand, this form of tubercle (as I think it must be considered) differs from miliary tuberculosis pathologically by its primarily attacking one portion of one or both lungs (almost always the apices), and spreading therefrom, not by the

dissemination of miliary tubercles far beyond the margin of advance, but by a continuous growth, involving destruction and subsequent excavation of the affected tissue. Clinically, the peculiarly insidious origin and progress of the disease with the gradually increasing *malaise* and anæmia, nocturnal cough, irregular fever, and the physical signs at first very obscure at one apex gradually increasing and developing at the other, are in accordance with its pathology, and distinguish it also from the still more severe miliary form of tubercle. "Chronic tubercular phthisis" seems the best clinical name for this variety, of which the pathological process is, as above stated, best represented by the term pulmonary tubercularisation. Miliary tuberculosis, though not differing essentially in anatomical characters from the infiltrated form of tubercle above spoken of under the terms pulmonary tubercularisation, grey induration, etc., appears to differ somewhat in its mode of origin, which has been proved by late experiments, and is now generally admitted to be *infective*. It may be, however, that we should better appreciate the relationship, so striking anatomically, which exists between these two forms of tubercle if we were to bear in mind that as there are two degrees of miliary tuberculosis—viz., first, that in which the tubercles are widely dispersed through many organs (infection through vessels?), second, that in which the granules are merely sprinkled around some old cheesy disease or induration (infection through lymphatics?)—so in a similar fashion a still less intense degree of infective power, amounting only to a specific irritation, may lead to the production of tubercle more limited still in extent, affecting only the parts contiguous to the infecting agent. Further, with a certain predisposition, it seems certain that both in animals and men miliary tuberculosis may arise from the mere irritation of a catarrh or local lesion, the specific quality being yielded by the constitutional peculiarity of the patient. And it may, correspondingly, be a question of degree of constitutional aptitude, whether the disease shall be as local as the irritation giving rise to it, or shall extend only by contiguity (it may be with gathering intensity) from the point of origin, or whether it shall at once take on the more virulent diffused miliary form. These observations are speculative in some degree, but they surely find some support in clinical experience, and more from recent anatomical inquiries.

That some constitutional aptitude, hereditary or acquired, is necessary for the occurrence of tuberculosis is proved by its so often failing to arise in cases of chronic phthisis and scrofulosis, in which for months and years inflammatory products in every stage of degeneration have existed as apparently efficient sources of infection; while in other cases the pathologist must with much diligence hunt the body through of one dead of tuberculosis to discover the required *cheesy mass*.

Returning now to the consideration of chronic tubercular phthisis, it is very difficult to depict a case with sufficient accuracy in writing to bring out those somewhat minute differences, the accumulations of which build up the distinction between the cases of catarrhal pneumonic phthisis already described, and those of chronic pulmonary tubercularisation, the pathology of which we have referred to. And indeed it has already been pointed out that alveolar catarrh is really the first stage of both these diseases—or, rather, it is the true first stage of the one (pneumonic phthisis), and the determining cause of the other (chronic tubercular phthisis).

It will, then, perhaps be most instructive to enumerate those symptoms and signs the presence of which will warrant us in regarding the case as one of tubercular phthisis—as one, at all events, in which tubercle is the prevailing lesion; for it has been before stated that chronic tubercle is rarely wholly unmingled with other inflammatory products.

So far as temperature is concerned, there is nothing at present known characteristic of chronic tubercle. It is at times elevated, during which periods there are fresh accessions of disease, and the non-febrile intervals are of varying duration. In this respect the disease presents no important difference, so far as I have been able to observe, from the chronic pneumonic forms of phthisis. The physical signs are more characteristic. The obscure signs of alveolar catarrh do not give place to the well-marked dulness and coarse crepitation or crackling of catarrhal pneumonia, but to continued weakness of respiratory murmur, with impaired expansion or actual flattening, while moist sounds may be altogether absent, or one or two dry crackles may be elicited on cough. The percussion-note becomes hardened, and we may suddenly be surprised by the development (having omitted to examine the patient for a week or two) of some feeble, blowing respiration, of hollow quality, still very dry, which increases in the same

obscure way until an unmistakable cavity is present. This formation of a cavity by a process of dry crumbling is very characteristic of the typical form of pulmonary tubercularisation.

Huskinness of voice, or actual aphonia, is a common first symptom in this variety of consumption, and is, I think, characteristic of tubercle. The huskinness may clear off, but the voice remains more or less altered permanently in quality. Too hasty a diagnosis must not, however, be made from this symptom, lest a grave prognosis be rested upon a simple laryngeal catarrh. The digestive organs are early affected; the tongue presents a scanty white fur on a very red ground, with prominent red papillæ, an appearance which is very significant, still more so if the fur clears off in patches, leaving raw-looking glazed surfaces. This tongue is almost always significant of intestinal lesion, the symptoms of which (alternating diarrhoea and constipation, with colicky pains, especially after food) soon appear.

As to prognosis, these cases admit of considerable temporary relief, and may appear to do well for the first few months. The physical signs progress, however, and I think the duration may be pretty safely reckoned as within two years of the first appearance of definite signs. The intestinal and laryngeal complications cause great distress towards the last, and hasten the fatal termination.

Patients the subject of this form of phthisis are usually of slender figures and good features. Among them are those more interesting examples of consumption or decline that novelists prefer to describe. This variety is, however, much more uncommon than the coarser pneumonic forms of phthisis.

The following sketch illustrates the phenomena characteristic of acute tuberculo-pneumonic phthisis—i.e., a case of pulmonary tuberculosis, in which the tubercular granulations and groups of granulations are attended with much pneumonia, which latter is the main element destructive to the lung; while the former appears to stamp the disease with its peculiar adynamic characters, its continued fever, and determined progress without check to a fatal termination.

A woman, aged 31, was admitted into Dr. Cotton's ward at the Brompton Hospital in October last, and seen by me in his temporary absence. She had had "inflammation of the lungs" (there was no sign of old pneumonia post-mortem) two years ago, but had suffered from more or less cough, with frothy expectoration, for three years. Four weeks ago, however, she had had slight hæmoptysis (two teaspoonfuls), which did not clear off for five days. She had since suffered from night-sweats, emaciation, cough, and pain in the side and between the shoulders, of which she complained on admission. The pulse was 112; the tongue furred; catamenia regular. She knew of no family predisposition to phthisis. The physical signs on admission were—harshness at the right apex, with subcrepitant rhonchus; at the left, jerking respiration and prolonged expiration. She lost rapidly in weight, however, losing 3½ lbs. between October 26 and November 14. On November 8 the physical signs were noted as unchanged. On the 21st she was much worse, with a red tremulous tongue, a rapid pulse, and great breathlessness, and much heat of skin. She was sitting up, though she could with difficulty stand from the trembling of her limbs and weakness. Subcrepitant rhonchus was found diffused throughout the right side behind, with some defect in resonance not amounting to dulness. At my request Mr. Garton, clinical assistant, took the temperature night and morning from this date. During this time—twenty-nine days (five days the temperature was not taken)—the maximum morning temperature was 103°, average 101.6°; maximum evening temperature 104°, average 102.3°; difference between the average morning and evening temperature .7°. On the frequent occasions when I saw the patient in the middle of the day the skin was uniformly hot, and the pulse very rapid—usually about 120. Meanwhile the pulmonary physical signs advanced, the crepitation became more abundant, and extended through both lungs. There were signs of breaking down at the right apex, though the presence of a cavity could not be ascertained. On December 19 there was present "diffused blowing respiration, with sonorous rhonchus and scattered crepitation more abundant at the bases, with some dulness; high temperature, and much dyspnoea." On December 15 the patient began to be troubled with diarrhoea, which continued more or less to the last. The emaciation and loss of power rapidly increased, the smooth red tongue became white with aphthous patches, and she gradually sank, having never evinced, however, any delirium or other morbid brain symptoms.

The continued fever, the great and early prostration, the diffused crepitation, with no defined dulness, rendered the diagnosis of pulmonary tuberculosis being the prevailing lesion

a tolerably certain one, while the absence of that degree of utter prostration, with occasional muttering delirium, and the early presence of decided pulmonary signs, prevented one from regarding the case as one of acute general tuberculosis. There was, however, but little satisfaction to be derived from this reflection, for the prognosis was, so far as present knowledge could decide, inevitably fatal.

Post-mortem the lungs were found studded with racemose groups of tubercle surrounded by ill-defined areas of soft catarrhal pneumonia, all in active process of formation and degenerative softening; the right apex was breaking up into small cavities. There was no miliary tubercle on the pleural surfaces.

It will be observed that in this case there was a history of "inflammation of the lungs" two years before her fatal attack, and of three years' slight occasional cough and frothy expectoration. More or less long-continued bronchial catarrh is the very common precursor of pulmonary tuberculosis. It has before been observed that catarrh long limited to the bronchial mucous membrane may extend to the alveoli, giving rise to simple alveolar catarrh, catarrhal pneumonia, or tuberculosis, as something we do not yet understand shall determine.

There are, it is true, certain cases of acute pneumonic phthisis (galloping phthisis) in which the broncho-pneumonia is so diffused as to render the diagnosis from acute tubercle very difficult; this matters little, however, for the prognosis is identical in the two kinds of cases. But the acute pneumonic phthisis, as a rule, proceeds by consolidation rapidly extending from one apex, or more rarely one base, with increasing dulness, and abundant metallic crepitan sounds, rapidly changing to gurgling. In such cases, at the moment when the condition of

the patient seems almost immediately hopeless, the extension of the disease may stop, the temperature (more intermittent than in tubercle) may fall, and the patient may again begin to pick up strength, while yet auscultation informs us that breaking down of the products of inflammation is still proceeding. Such cases point out what will generally be found a true guide to prognosis,—viz., that the more prominently the symptoms of acute phthisis are attended with *defined* auscultatory and percussion signs, the more hope is there that the active disease may subside and the patient recover from the attack with so much damaged lung; in fact, the more certainly is the disease to be acute *pneumonic*—and not acute *tuberculo-pneumonic*—phthisis, or acute tuberculosis. But it is imperative to watch closely, not the physical signs alone, for they will mislead us, but the signs of fever (temperature, tongue, and pulse), to learn the moment when the spread of the disease stops, and when tonic medicines, food, oil, etc., will have their due effect. Did we judge by the stethoscope alone, we should find softening and excavation signs increasing long after this period of true pause, because the products of the past inflammation must run through their normal stages of caseation, or liquefaction, and removal, and these mere physical processes largely contribute to the production of auscultatory signs. Nor is it easy by physical diagnosis alone to say when the limit of extension of the disease has been reached.

I may, perhaps, usefully conclude this series of papers by summarising in a tabular form the views advocated as to the distinguishing characters of the principal varieties of phthisis, which views have been acquired from the observation of a very large number of cases and the making and supervision of many post-mortem examinations

Table representing the chief Varieties of Phthisis, with their distinguishing Anatomical Characters.

Primary Lesion.	Pathological Nature and Tendencies.	Anatomical Characters.	Variety of Phthisis.
Alveolar catarrh ... Alveolar catarrhal pneumonia.	Terminates in recovery, or proceeds to catarrhal pneumonia. 1st degree terminates in resolution and recovery, or alveolar collapse. 2nd degree terminates in caseation, softening, excavation, or induration from thickening and agglutination of alveoli. 3rd degree terminates in simultaneous degeneration and softening of alveolar wall and contents; ulcerative destruction.	Large cells of epithelial type, more or less blocking alveoli; greater or less degree of implication of alveolar wall, and proliferation of its elements.	Catarrhal pneumonic ph. (<i>progress: acute, chronic, intermitting</i>).
Pulmonary capillary hæmorrhage.	(a) Copious hæmoptysis may be coincident with the commencement of, and may perhaps determine, <i>pneumonic phthisis</i> , giving rise at least to secondary pneumonia.	Coagulated blood blocking alveoli, with surrounding inflammatory changes.	(a) Hæmorrhagic ph.
Pulmonary tuberculosis.	Of primary irritative origin, or part of general tuberculosis, or supervening upon caseous pneumonia or chronic tubercle— 1. Pure, terminates in death without breaking down of lung. 2. When mixed with pneumonia, caseation softening and ulcerative destruction of tissue.	Nuclear growth of adenoid kind occurring as miliary grey granulations—(1) disseminated singly, or (2) in racemose groups, often associated with catarrhal pneumonia.	1. (a) 2. Acute tubercular or tuberculo-pneumonic ph. (<i>progress: acute, fatal</i>).
Pulmonary tuberculation.	3 (a). Irritative local grey induration, secondary to caseous pneumonia. (b) May be the primary disease progressively invading lung.	Coalescing granulations, proceeding to grey induration from fibro-nuclear development; degeneration.	3 (b) Chronic tubercular ph. (<i>progress: subacute or chronic, continuous</i>).
Pulmonary fibrosis	Present more or less in association with the chronic forms of the above varieties; <i>never primary</i> ; when so marked in unilateral cases as to give a special clinical character to the disease, is conveniently named separately.	Contractile fibroid cicatricial tissue, the result of proliferation of elements of fibrous stroma of lung, including vessel sheaths and lymphatic tissues, mingled with products of primary disease.	Fibroid ph. (<i>progress: very chronic; with sometimes long quiescence</i>).
Pulmonary arterial hæmorrhage.	(β) Copious hæmoptysis may be a marked and recurring symptom in the more chronic indurative forms of phthisis, attended with quiescent or slowly forming cavities.	Aneurismal dilatation, or erosion of vessels within cavities.	Ph. with recurrent hæmoptysis.

(a) Acute tuberculosis cannot be regarded as a variety of phthisis, though it frequently supervenes as a fatal complication of the disease.

NOTES ON THE PATHOLOGY OF MALIGNANT NEW GROWTHS.

By HENRY ARNOTT, F.R.C.S.,

Assistant-Surgeon to St. Thomas's Hospital, and Joint Lecturer on Morbid Anatomy in the School.

VII.

SARCOMA (*Concluded*)—LYMPHADENOMA.

Melanotic Sarcoma—Osteoid Sarcoma: Two varieties—Degenerative Changes common to these Tumours—Mixed Sarcomata—Lymphadenoma.

BEFORE quitting the subject of sarcoma, those varieties which depend upon degenerative changes or other modifications of nutrition must be briefly noted. This is the more necessary, because such variations have usually attracted far more attention than the changes in minute structure which have been

already referred to. The difference between a bone-like and a soft fleshy growth is far more marked than between two forms of fleshy tumour containing round or spindle-cells respectively, although clinically and anatomically the latter distinction may be by far the more important. The terms "melanosis," "osteoid cancer," and "colloid," show how much stress has been laid on these accidental conditions, and how necessary it is to study them in connexion with the subject.

MELANOTIC SARCOMA.—It was stated, when treating of carcinoma, that by far the greater number of pigmented tumours are really sarcomas, of either the round- or spindle-cell variety. In a case, to which reference has been already made, of a woman dying with innumerable melanotic tumours over the body, chiefly lying in the subcutaneous connective tissue, but also invading the lymphatic glands, breast, and one kidney, the cells were round or roundly oval, and those cells in which the pigment was contained were of considerable size. In this instance an old black wart was the seat of the primary manifestation, but in the melanotic sarcomata so

frequently met with springing from the choroid of the eye, the cells are more commonly of a spindle form. I once examined the head of a man dying with cerebral symptoms many months after an eye had been removed with such a growth, and I found several black masses of considerable size scattered through the brain, all of which were made up of beautifully delicate pigmented spindle-cells.

Whether the cells are round or oval the striking fact about these growths is that the pigment granules are contained in only a very small minority of the cells, although the tumours may be as black as ink; and it is to be further noted that although the rule is that all the secondary growths are also black, the amount of pigmentation may vary considerably, and some of the visceral masses may be quite pale—still, however, presenting the same cell-forms as the primary tumour. No organ is exempt from the liability to become the seat of these melanotic growths. By far most frequently encountered in the subcutaneous connective tissue, the muscular tissue of the heart itself may occasionally be infiltrated with nodules of the disease, and I have seen a case in which a melanotic sarcoma of the eye was followed by the development of similar black infiltrations in nearly every organ of the body.

The great clinical indication in all examples of melanosis is to cut out the primary tumour as speedily and as widely as possible, as the early and free dispersion of the germs soon renders the extirpation of the disease impracticable.

OSTEOID SARCOMA.—Bone-like sarcomata (commonly styled "osteoid cancer") may present very different structures. Springing usually from the periosteum, or from the medullary cavity of bones, the cells may be of either of the usual forms, and the peculiar character of the growths may depend upon either a growth of true bone ramifying through the tumour as an open spongy network, or an infiltration of the intercellular material with calcareous salts. In the latter case microscopic sections of the brittle chalky mass exhibit hardly any definite structure until a drop of dilute hydrochloric acid has been allowed to flow under the covering-glass. The observer, following the drop of acid, then perceives a copious effervescence, and, as the gas-bubbles float off the field, the confused granular network clears away, and reveals the delicate round or spindle-cells of which the tumour is constructed. No lacunæ nor canaliculi nor other bone elements are seen in such tumours, nor is there any cartilage or other structure suggestive of true ossification. The growth is simply an ordinary sarcomatous formation, in which the granular soft material between the cells is hardened by saturation with bone salts. Accordingly, although the secondary growths may be affected in the same way, it is not uncommon to meet with them quite soft or fleshy, and exhibiting only the cell structure of the primary tumour *minus* its calcareous infiltration.

True ossifying sarcoma is more rarely met with, and presents a very different appearance under the microscope. The bulk of the growth still consisting of round or spindle-cells, with soft intercellular material, a spongy network of bone pervades the cellular structure. The new bone varies in amount in different parts of the tumour, but almost everywhere lacunæ and rudimentary canaliculi are clearly recognisable, and at the margin of the growing bony spicules is commonly either a small-celled medulla-like structure, with perhaps some myeloid elements, or a cartilaginous tissue from which the bone is directly developed in the usual way. In this variety, as in the former, the rule is for the secondary formations to present a similar tendency to ossification; but here, also, the rule is frequently departed from, the remote growths often showing only the sarcomatous cell-structure of the unossified portions of the primary tumour.

It is clearly important to distinguish between the denser forms of these ossifying sarcomata and the simple osseous growths which they sometimes closely simulate; for the simple osseous tumours are probably never malignant, whilst the presence of any admixture of a soft fleshy substance having the microscopic characters of sarcoma is of grave prognostic significance, and, although by no means forbidding operation, necessitates the utmost care to insure the complete removal of the tumour. As in these cases the medullary canal of the bone is sometimes found to contain nodules of the disease at some distance from the neighbourhood of the large tumour, it would seem to be a sound rule to resect the affected bone entire, rather than to trust to sawing across it at an apparently safe distance from the morbid swelling, although, indeed, this last practice has the sanction of so high an authority as Mr. De Morgan.

Degenerative changes, due to fatty or mucous metamorphosis, or to the results of hæmorrhages, blocking of vessels, inflam-

mation, or gangrene, are all commonly met with in rapidly growing sarcomas—the mucous degeneration producing a colloid appearance of parts of the tumour which is specially striking, and to which reference has been already made when speaking of "Colloid Carcinoma."

MIXED SARCOMATOUS TUMOURS are sometimes so puzzling to students that they need a passing reference. When one remembers that a sarcoma is merely a tumour resulting from the reversion of healthy connective tissue to a foetal type, the cells of which continue to multiply without, as a rule, undergoing any special differentiation into a normal adult tissue, one is prepared to meet with a tendency to develop into different forms of connective tissue in various sarcomas, and even in several parts of the same tumour. Now, since the histological group of "connective tissues" includes mucous, areolar, fibrous, elastic, fatty, cartilaginous, and bony tissues, there need be nothing very surprising in meeting with a tumour presenting a combination of all these varieties more or less completely developed; and it does sometimes happen that nearly all these structures may be encountered in different parts of the same tumour. Where this is the case, the point of chief prognostic importance is the amount of primitive cell-structure showing no such development. Where this is great, the bulk of the tumour presenting a simple cellular structure, the presence of well-marked cartilage or bone here and there is no surety of the innocence of the tumour. Secondary formations, in which the spindle or other cell-forms predominate, may be expected; but where the greater portion of the tumour exhibits some one fairly developed adult tissue (and especially where this tissue is strictly homologous—as lipoma amongst fat, or fibroma in fascia), the prognosis is more favourable, provided that the tumour itself is thoroughly extirpated.

LYMPHADENOMA.—Amongst the various new formations to which Surgeons have in former times given the common name "encephaloid cancer," perhaps none is still so seldom recognised as that to which the name "lymphadenoma" has been given by modern pathologists, to signify the close correspondence between the microscopic structure of this growth and that of the follicular portion of a lymphatic gland, known as the "adenoid tissue of His." It is only quite recently that special attention has been called to this variety, in England more especially by Dr. Sanderson and Dr. Murchison, and in France by MM. Cornil and Ranvier. The disease may be shortly described here as one in which soft infiltrating tumours of various sizes are scattered through the several organs and tissues of the body in a manner precisely resembling many of the soft sarcomas and carcinomas already noticed, but made up of very different and sufficiently characteristic elements.

Usually commencing in an enlargement of lymphatic glands, and often limited to such hypertrophy, many glands being matted together to form one vast mass, the morbid structure is often met with invading the internal viscera—as the spleen, lungs, liver, and kidneys—and even the muscles and bones are not always exempt from the disease. The tumours are usually of a greyish or yellow-white colour, sometimes as distinctly encapsuled as a lymphatic gland, but in other cases passing gradually into the structure of the part in which they are seated, varying in size from a miliary granule to that of a cocoon, or larger, and in consistence from a creamy pulp to that of a cirrhotic liver, and yielding a more or less abundant milky juice. This juice, when examined microscopically, is almost sufficiently diagnostic, for it contains none of the cell-forms already described as occurring in carcinoma or the commoner varieties of sarcoma, but only small, spherical, faintly granular corpuscles, precisely resembling leucocytes or the white corpuscles of the blood. With these there may be free granules and a few somewhat larger distinctly nucleated cells. It is, however, only when thin sections are taken from bits of the tumour hardened in chromic acid solution that the true structure is seen.

Sections thus prepared show a fine homogeneous-looking network, enclosing in its meshes, either singly or in small clusters, the pale spherical corpuscles seen in the juice. In the early stages nuclei are to be distinguished in certain of the angles of this network just as in the stroma of a lymphatic gland; but in the later stages—those generally presented to the Surgeon—the network is formed of stouter fibrils, in which the nuclei are less apparent. The structure then closely resembles that of a lymphatic gland in a condition of irritative induration; and it is this structure, with the fibrillated stroma more or less largely developed, that forms the bulk of these tumours.

To see this stroma distinctly it is necessary to pencil out a very thin section under water. When the corpuscles which obscure the view have been thus mostly chased away, the irregular network is clearly visible. In the accompanying

sketch (Fig. 19) this has been done, and the thickened network shown is a fair sample of the usual structure of these tumours, although the absence of nuclei from the angles of the meshes

FIG. 19.

FIG. 19.—Very thin section of a lymphadenomatous tumour pencilled out under water, showing the delicate irregular network and a few remaining corpuscles. Magnified 220 times.

takes away the most characteristic element and that which specially distinguishes this growth from the small round-cell sarcoma. The latter, however, is so seldom accompanied by any notable fibrillation of its stroma, that a distinct small-meshed network is of itself sufficient to stamp the lymphadenomatous character of the growth presenting it. Whether these lymphoid formations originate in the proliferation of ordinary connective tissue, or whether they consist of hyperplasia of pre-existing adenoid tissue, is a question difficult to decide. In all their clinical features of rapid infiltrating growth, and implication of adjacent glands, as well as the formation of similar swellings in remote parts, they are probably as malignant as the most virulent carcinoma, and need the same treatment. The tumours differ from the similar masses present in leukaemia only in the absence of any obvious alteration in the blood. The histological structure is the same in both cases, but there is no notable excess of white corpuscles in the blood of a patient with lymphadenoma, as there is in so marked a degree in leukaemia.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. MARY'S HOSPITAL.

CLINICAL LECTURE ON A CASE OF ULCER OF THE STOMACH WITH PROFUSE HÆMATEMESIS.

DELIVERED JULY 8, 1871.

By W. H. BROADBENT, M.D., Physician to the Hospital.

GENTLEMEN,—The case I wish to bring before you to-day is that of a woman named Mary B., aged 29, a cook, whom we have just seen in the Victoria Ward. She was admitted June 16, in a state of extreme prostration from loss of blood, which she had been vomiting in large quantity during the preceding week. Four years ago she was in the Hospital on account of a similar attack, after recovering from which she remained quite well till fourteen days before her admission, when she began to have pain in the epigastrium. A week later the pain became more severe, and was felt in the right hypochondrium as well as in the epigastric region, and she now began to be sick, bringing up on two occasions a considerable amount of blood. Two days later the vomiting of blood recurred, and continued more or less up to the time of her

admission, the blood being always dark and clotted. The amount of blood vomited could not be ascertained, but it had been very great. The patient was extremely pale—as pale, indeed, as a living person can well be—the lips, mucous membrane of mouth, and conjunctiva white and bloodless. Pulse 140, weak and sharp; breath short; expression anxious and depressed; she complained of headache, faintness, and thirst; had no appetite, and vomited immediately if she took food of whatever kind.

There was no doubt or difficulty here as to the diagnosis; no room for question whether the blood might not have come from the lungs, and scarcely any ground for hesitation in forming the opinion that its source was an ulcer, and not capillary hæmorrhage from the mucous membrane of the stomach generally. Cases, however, are sometimes met with in which from disease of liver the portal circulation is obstructed to such a degree that blood exudes in large quantity from the gastro-intestinal mucous membrane, and is vomited or passed in the stools; this, moreover, though usually occurring in advanced life and in spirit-drinkers, may happen in comparatively young people. In February of this year I had under my care a well-nourished, muscular young man, of 23 or 24, who up to two months before death had been apparently quite well. He then began to vomit blood at intervals, and finally died from profuse hæmorrhage two days after his admission into the Hospital. Here the liver was small, the left lobe represented only by a thin layer of tough fibroid material, apparently consisting of the capsule from which all proper hepatic structure had disappeared, the rest of the organ irregular on its surface, and traversed by bands of fibroid tissue; the mucous membrane of the stomach was almost black, and had exuded blood from every part; the spleen was large, weighing four pounds, another consequence of the venous obstruction in the liver. The patient had been at work a few days before death, and the body was muscular and well nourished. The history of the case, however, we are now concerned with was clearly one of gastric ulcer, and all the more so from there having been a previous attack.

In ulcer of the stomach we have two sorts of history: one chronic, of habitual pain in the epigastrium, often shooting through to the left shoulder-blade, coming on usually soon after food; or sometimes the pain is worst when the stomach is empty, possibly from action upon the ulcerated surface of gastric juice poured out in consequence of the irritation due to its presence. With the pain there is tenderness on pressure in the epigastrium, the tender spot being frequently curiously circumscribed, and vomiting at various intervals after meals—sometimes severe, and all but incessant, at others occasional and capricious. Pyrosis is also common. Sooner or later blood will be seen in the vomited matters. If these symptoms continue long, as they are apt to do, and especially when they are severe, the patient necessarily becomes weak and emaciated, and may die from slow starvation and repeated loss of blood; or he (more frequently she) may be hurried off by severe hæmorrhage, or by perforation of the stomach. The two latter events are less common than might be expected from the size and depth of gastric ulcers as seen after death, in consequence of blocking-up of large vessels and adhesion of the wall of the stomach to neighbouring parts.

The other history of gastric ulcer is of an acute process; and in fact, a small ulcer rapidly drills its way through the coats of the stomach, or a small portion of the mucous membrane deprived of its blood-supply by stoppage of a minute artery is eroded by the gastric-juice, a large vessel is opened, and profuse hæmorrhage occurs; or the mucous, vascular, muscular, and serous layers are perforated, and the contents of the stomach escape into the peritoneal cavity. In the latter case, the only hope consists in the immediate administration of a large dose of opium. Unfortunately, severe pain in the region of the stomach, and a feeling of faintness, are suggestive of brandy and other stimulants, which, given before Medical advice is sought, seal the patient's fate.

But the emergency we had to contend with was hæmorrhage—the vomiting of blood, escaping probably from some large vein. In cases of this kind the medicines usually given for the arrest of hæmorrhage frequently fail; and you will easily see why. Let us suppose that our gallic or tannic and sulphuric acids or our perchloride of iron have, in the absence of food, reached the bleeding point, and blocked up the aperture in the vessel by a coagulum; let us suppose, also, that these or other

substances, such as salts of lead, have been absorbed into the blood, and have increased its coagulability, at the same time producing an astringent effect on the tissues; we may also have given ergot, or digitalis, or turpentine, with the object of aiding the other remedies by causing the minute arteries to contract and diminish the supply of blood. All goes well till food is taken. Then there will be a certain degree of distension of the stomach, which, however, as the amount of food allowed will be very small, may be disregarded. A more serious matter will be the physiological movements of the organ tending to displace the clot, and finally gastric juice will be poured out, which will tend to dissolve it. The gastric juice, as you know, does not respect even the coats of the stomach itself, but, unless they are protected by the circulation through them of alkaline blood, attacks and destroys them. It is not likely, therefore, to respect the clot any more than if it had been swallowed as food. At the same moment, moreover, that the coagulum is thus endangered, the afflux of blood which attends digestion takes place, and we cannot wonder that hæmorrhage recurs again and again.

What, then, is our resource under these circumstances? I reply by describing the treatment adopted in this case. When I sent her up into the ward I trusted simply to the care in feeding. She was to have nothing but iced milk in very small quantities at short intervals, and a little very weak iced brandy and water. She vomited twelve ounces of blood soon after admission, and eight ounces more during the night. Next day the Resident Medical Officer ordered her acetate of lead and opium in the form of a pill, and later a mixture containing tannic acid and sulphuric acid was substituted; but the stomach rejected both the one and the other, and twenty ounces more of blood were lost. She was completely blanched when she first came under observation, and yet she had vomited an amount of blood since which would have been considered outrageous and dangerous if taken by venesection. Her condition had become something more than critical. She had the languid, distressed look of perpetually impending syncope; and, indeed, an attempt on her part to raise her head would have induced a fatal fainting. The pulse was weak, short, and fluttering, and at one time had the peculiar sharp, excited character which is of such evil omen after great loss of blood.

I now ordered food by the mouth to be absolutely withheld for twenty-four hours. She was allowed only to sip iced water with a little brandy to allay the intolerable thirst experienced under these circumstances, and five minims of laudanum were given every four hours in a teaspoonful of iced water. In order to keep life in her an enema was to be administered every three hours, consisting of beef-tea ζ ij., brandy ζ ss., with laudanum $m\bar{v}$. Next day the enemata had been retained, and no vomiting had occurred, and a teaspoonful of milk was now given every half-hour; enemata continued. On the following day the quantity of milk was increased to two teaspoonfuls, and again next day to a tablespoonful every hour. We had not yet reached a stage at which sufficient food could be given by the mouth, as was shown by the fact that she had once vomited the milk, and now on the 22nd the enemata began to be expelled as soon as injected. Unless this could be obviated, we should have to feed our patient by the mouth at all risks, and our success might be compromised. I had, however, anticipated this complication, and at once ordered the lower bowel to be thoroughly washed out by means of a large injection of soap and water. When nutrient enemata are given frequently for a few days, insoluble matters accumulate on the mucous membrane of the rectum, and probably undergo decomposition. At any rate, irritation is set up and the injections are at once returned. The remedy is, of course, to remove the irritating substance and give the bowel a few hours' rest, when it again tolerates and absorbs the nutrient fluid. This was so in our case, and we were enabled to resume and continue the enemata till the 28th, when the soap and water had to be repeated. The amount of milk taken by the stomach was increased with great caution, as vomiting was sometimes threatened, and actually occurred on the 23rd, 28th, and 30th. The epigastric pain and tenderness disappeared, and there was great craving for food, but I did not venture to yield to the patient's urgent request till July 1, when I allowed her a little custard pudding. On the 3rd she ate a little fish, and on the fifth part of a chop, no vegetables being given till some days later. The recovery was from this time rapid and uninterrupted, the return of strength being aided by the administration of quinine and iron.

The lessons of this case are few and simple, but important; and they consist entirely in the application of physiological knowledge to the emergencies of Medical practice.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

INTERMITTENT GLAUCOMA—IRIDECTOMY IN BOTH EYES—GOOD RESULT.

(Under the care of Mr. GEORGE LAWSON.)

The following are the notes of a very interesting case of intermittent glaucoma which was under the care of Mr. Lawson. The intermissions were very marked and complete, the patient regaining sufficient sight to be able to read No. 1 of Jaeger's test-types (Brilliant type); whilst the recurrences of the glaucomatous attacks were so severe that at the time of the operation the patient was only just able to count fingers with either eye, and had to be led by an attendant to his ward in the Hospital.

William G., aged 60, applied to the Hospital on February 2 of this year. He complained that for the last six months he had suffered from repeated attacks of fogging of both eyes, which varied in degree from a mere dimness to such a loss of sight that he was unable to read ordinary printing. These attacks would frequently commence in the morning and pass off towards evening, and then his sight would be as good as usual; but sometimes they would last much longer. He also frequently observed rainbows around the candles and street-lamps. They were not, he said, constant, but he only noticed them when his sight was dim. He never suffered from any pain in his eyes.

On the day of his application to the Hospital his sight was worse than it had been before. He could only read Jaeger No. 16. The field of vision of each eye was contracted on the nasal side. The cornea of both eyes was dull and steamy in appearance; the pupils were rather dilated and sluggish; and the tension of the globes was increased to T 2. The patient was advised to come into the Hospital at once and have an iridectomy performed on each eye. To this, however, he positively refused, as he had not anticipated an operation, and could not make up his mind to submit to one. He therefore returned home, promising to come back to the Hospital if he did not shortly improve.

February 6.—The patient showed himself this morning in great glee, as all the glaucomatous symptoms had disappeared without an operation. The sight began to improve soon after he left the Hospital, four days previously, and he could now with either eye read Jaeger 1. The corneæ were quite clear, and there was no tension of the globes. An ophthalmoscopic examination was now made, and in each eye there was seen a deep glaucomatous cup. Under these circumstances Mr. Lawson still urged the patient to submit to iridectomy, as he felt sure that the glaucomatous symptoms would recur, and further that he was liable to an acute attack at any time which might destroy all sight in a few hours. The man promised to consider the matter and to return to the Hospital if the symptoms should recur.

13th.—The patient was admitted on the previous day suffering from an attack of subacute glaucoma. His sight was now so dim that he could only just count fingers, and he was obliged to have a guide to lead him up the stairs of the Hospital. Both corneæ were dull and steamy, and the tension of both eyes was T 2. Mr. Lawson performed iridectomy upwards in both eyes.

From this operation the patient soon recovered, and the sight of both eyes rapidly improved. At the end of a fortnight he could read Jaeger 2 with the left eye, and Jaeger 4 with the right, and there is reason to hope that in a few weeks he will be able again with proper glasses to read Jaeger 1.

MECHANICAL RESTRAINT OF THE INSANE.—A writer in the *Boston Journal* (January 11), reviewing an eulogium of Conolly by Dr. Lee, speaking of the opinion prevalent on the subject of restraint in the United States, says:—"In spite of former and existing abuses of mechanical restraint, it will be found to be the almost universal opinion of Hospital superintendents that it is often necessary and beneficial. The proportion of cases requiring it is small, no doubt. One per cent. is about the proportion at the Boston Hospital for the Insane. Here the *camisole* alone is used—a long-sleeved apron of drilling, which keeps the arms folded. This is used by some at night only, by some while at large in the wards, and by others who require confinement to bed for a time. To disuse restraint, or substitute seclusion, as is too often done in these cases, would be to overlook abuses, run risks, and lose chances of improvement. No number of attendants, no amount of free air and exercise, could take the place of it."

SATURDAY, MARCH 30, 1872.

THE LONDON WATER COMPANIES.

THESE Companies remind us of the persons sentenced to be executed in the reign of Louis XI., who were marched to the gallows between the executioners, Petit André and Trois Échelles—one jocose, one penitential—one charged with fun, the other singing psalms. On the one side we have Dr. Frankland reporting to the Registrar-General that "the daily supply to London is now about 107 millions of gallons. Of this twenty millions is 'good wholesome water from wells and springs in the chalk,' and eighty-seven millions is 'more or less impure water derived from polluted rivers.' The Chelsea and Lambeth Companies draw their supplies from the Thames after it has received the polluted Mole and the sewage of 600,000 people, including the filth of Oxford, Reading, and Windsor. The West Middlesex, Southwark, and Grand Junction Companies draw their water from the Thames above the junction with the Mole, but after it has received the sewage of the three above-mentioned towns, as well as of smaller places." There is no doubt that Dr. Frankland's tone is calculated to alarm the public mind, and to present the totals of impurity in figures of the most appalling magnitude. In Major Bolton (the Government Inspector of Filtration), Dr. A. S. Taylor, and Dr. Whitmore, our drinking water has much more lenient judges. Dr. A. S. Taylor even rebukes Dr. Whitmore for his use of the word "impurity":—"I object to the use of the word 'impurity' in Dr. Whitmore's analysis, because it has a tendency to mislead the public. He obviously employs this term to represent the solid or mineral constituents of the water—i.e., he applies it to substances such as carbonate of lime, common salt, etc., which are found more or less in all terrestrial waters, which are natural to these waters, and quite inseparable from them when they have once come in contact with the earth." "Living organisms" and "previous sewage contamination" have no terrors in Dr. Taylor's eye—so far, at least, as Dr. Frankland's evidence of the latter is concerned. Nevertheless, a little severity of judgment is not misplaced when applied to the qualities of so all-important a thing as our water-supply.

CRIMINAL RESPONSIBILITY IN CASES OF DELIRIUM TREMENS.

WITH reference to the case of William Frederick Hovey, mentioned in a recent number as having been tried at the late Lincoln Assizes for the murder of his wife—the question

involved in the inquiry being how far an attack of delirium tremens, from which the prisoner had been suffering, relieved him from the responsibility of his act—the authorities on this subject, as collected in Archbold's "Criminal Pleading" and Roscoe's "Evidence in Criminal Cases," are as follows, and are thus epitomised:—"The vice of drunkenness, which produces a perfect, though temporary, frenzy or insanity, usually denominated *dementia affectata*, or acquired madness, will not excuse the commission of any crime; and an offender under the influence of intoxication can derive no privilege from a madness voluntarily contracted, but is answerable to the law equally as if he had been in the full possession of his faculties at the time."—(1 Hale, 32; Co. Litt., 247; 1 Hawk., c. 1, s. 6.) "But if the primary cause of the frenzy be involuntary, or it have become habitual and confirmed, this species of insanity will excuse the offender equally as the former description of this malady. Thus, for instance, if a man, through the unskillfulness of his Physician or the contrivance of his enemies, take that which produces a temporary frenzy, he will not, whilst under the influence of the frenzy, be accountable for his actions. So neither will he be liable to be punished for any crime perpetrated under the influence of insanity which is habitual and fixed, though caused by frequent intoxication, and originally contracted by his own act."—(1 Hale, 32.) But to come nearer to our own times, Chief Justice Jervis, in 1852, in trying a woman for attempting to commit suicide, said to the jury—"If the prisoner was so drunk as not to know what she was about, how can you say she *intended* to destroy herself?"—(Regina v. Moore, 3 Carrington and Kirwan's Rep., p. 319.) So, in the charge of wounding with *intent*, etc., the drunkenness of the accused may negative the *intent*. In 3 Paris and Fonblanque's "Medical Jurisprudence," 140, a case of Rex v. Dey is reported, from which it appears that the prisoner, after a paroxysm of drunkenness, rose in the middle of the night and cut the throats of his father and mother, ravished the servant-maid in her sleep, and afterwards murdered her. It is superfluous to say that the prisoner was executed. He was doubtless suffering from a frenzy produced by drink, but not of a permanent character. There was no provocation to palliate his atrocity, and the paroxysm was brought on by his own voluntary act.

In Hovey's case in all probability the evidence did not go the length of showing that the unsoundness of mind, under which he might have been suffering when under an attack of delirium tremens, had become habitual and fixed, or that he was labouring under it when he shot his wife, so as to acquit him of premeditation, in which latter case, though the crime might thereby be reduced to manslaughter, he would not be held unaccountable for his actions unless, in addition, the long practice of intoxication had resulted in confirmed insanity. In no case would the mere fact of the accused suffering at the time from an attack of delirium tremens, voluntarily contracted, render him wholly unaccountable unless the insanity were also confirmed and permanent.

We ventured in our remarks on the case to "presume that a patient, suffering at the time from an undoubted attack of delirium tremens, although the result of drink, would not be held accountable for his acts." But it seems the law does not go this length. The extent to which the law does go is thus very clearly laid down by Mr. Baron Parke, in Rex v. Thomas (A.D. 1837):—"If a man makes himself voluntarily drunk, that is no excuse for any crime he may commit whilst he is so—he must take the consequence of his own voluntary act, or most crimes would otherwise be unpunished. But drunkenness may be taken into consideration in cases where the law deems sufficient provocation has been given; because the question is, in such cases, whether the fatal act is to be attributed to the passion of anger excited by the previous provocation—and that passion is more easily excitable in a person when in a state of intoxication than when he is sober; but if there is really a previous deter-

mination to resent a slight affront in a barbarous manner, the state of drunkenness in which the prisoner was ought not to be regarded, for it would furnish no excuse."—(7 Carrington and Payne's Rep., p. 820.)

Mr. Justice Quain, in disallowing the plea of Hovey, must therefore have meant that the law could only recognise permanent or confirmed unsoundness of mind from drink as a bar to responsibility; and that the prisoner, being actuated by jealousy, and not suffering from permanent mania, but from what the law calls *dementia affectata*, must abide the consequence of his own voluntary act, in thus exciting the passion of resentment without sufficient provocation to reduce the crime to manslaughter.

HARTNACK'S MICROSCOPES.

THE following observations may, we hope, tend to the benefit of the Medical world in more ways than one. Our object is, of course, to point out to our brethren the mode in which their money may be best spent; but if thereby British makers are stimulated to improvements which will also diminish price we shall be doubly repaid.

So many questions have been asked with regard to Hartnack's microscopes, that we propose once for all to tell what is to be told about them, and so allow people to judge for themselves. The two French makers whose names are best known in this country are Oberhaeuser and Nachet. The last microscopes we have seen made by Nachet did not quite come up to his ancient reputation; whereas those of Oberhaeuser, which, we think, were first introduced into British schools by Dr. Hughes Bennett, of Edinburgh, continued to become more and more popular until those of Hartnack, who is Oberhaeuser's successor, began to be known. What mainly commended these microscopes was their simplicity, their portability, and the excellence of their lenses. They were simple, and hence not likely to get out of order; and though it was somewhat more difficult to learn their manipulation, this once learned was not readily forgotten, and subsequently preferred.

These microscopes have no coarse adjustment—that must be managed by sliding the microscope-tube in the tube of the stand. A little care must be exercised as to keeping these surfaces neither too tight nor too loose; so that the microscope may move easily, but not too easily. They are readily portable, the box containing them being small in size. Moreover, they can be put away in it with lenses ready adjusted, so that the microscope has only to be removed from its box and placed in a proper light to be ready for use. Those acquainted with the trouble of getting some English microscopes ready would appreciate this. The modern Hartnack's microscopes are so short that no joint is required, though that is added to the better class of microscopes. The stage is thus flat, which is the position best suited for examining specimens such as fluid, which are apt to run. The slide need not be fixed in any way, and is free to be moved by the fingers in any direction. This seems a disadvantage at first, but experience shows that it is not. After the fingers are fairly educated, movement is so free, and may be made so rapid, as to excel all varieties of movable stage. This applies to ordinary powers; in working with very high powers a mechanical stage is an advantage.

The microscope having been placed in a suitable light, the heel of the body is to be seized with one hand, and, by a screwing motion, the objective brought to within a quarter of an inch or so (if for a 300-power) of the stage, a good light secured, and the object adjusted as nearly as possible by the naked eye; after which, by screwing round the body, the focus may be roughly caught, the exact focus being made out by the screw fine-adjustment. Not unfrequently it saves time to use a low power as a guide, and afterwards to screw on the higher power; but these are matters of detail into which it is not our province to enter.

In these microscopes, then, there is no coarse adjustment,

and no stage machinery beyond a pair of clamps to hold the slide *in situ*. But having learned how to work with them, there is no difficulty in working an English model of the ordinary powers. Such powers as Dr. Beale habitually uses are, however, a totally different thing; not many men can either work them or even make preparations fit for them.

There are three of Hartnack's models which we can confidently recommend from experience of their excellence; these are models 1, 3, and 8. No. 1 is the microscope we have had so often to commend for cheapness; it is very small, but very convenient. No. 3 has a larger stage and a more solid rest; it is bigger in every way. No. 8 is perhaps the best microscope Hartnack makes, though he himself places another not here mentioned before it. These numbers refer mainly to the framework of the microscope, for the lenses may be adapted to either. Hartnack's objectives are arranged, not like ours, according to focal length, such as half- and quarter-inches, but into systems 1, 2, 3, 4, etc.; so that a purchaser having fixed on his model may order what lenses he likes. Model No. 2 is very good, and is rather cheaper than No. 3. For our own part we should select either No. 1 or No. 3 for ordinary use—No. 8 if we could afford the money, for that is the next point.

Model No. 1, specially intended for clinical use, and having the objective combination No. 7 and ocular No. 3, gives a magnifying power of 300 diameters; this, with case and appurtenances complete, is to be obtained for the amazingly small sum of 65 fr.—*i.e.*, £2 14s. 2d.—and we repeat that no one need care to work with a better instrument up to that power, which is about equivalent to our English quarter. To enable this microscope to be employed with objects demanding a lower power, it is advisable to add to the contents of the case another objective—*viz.*, combination No. 4—which, with the ocular contained in it (No. 3), gives a magnifying power of about 65. With this addition, we can commend the instrument as a capital one for the Practitioner. The extra cost is 20 fr., bringing the whole up to a little over £3 10s.

Model No. 2, with powers from 50 to 600, costs 165 fr., or £6 17s. 6d.—surely marvellously cheap at the price. Model No. 3 costs 190 fr. To those, however, who could afford it, we should say—Buy No. 8, if you want a power over 600. The great feature of model 8 is the combination No. 9, which is adapted for immersion, and which, with ocular No. 4, gives a magnifying power of 1000 diameters. This model also possesses an ocular micrometer, and its price, according as it is furnished with a joint or no, is a little over or a little under £16.

For the purposes of the student or Practitioner we would recommend model No. 1, with ocular No. 3 and combinations Nos. 4 and 7; that costs £3 10s. 10d. For purposes of research with higher powers (the former are the best working powers) model No. 2, No. 3, or No. 8 may be selected, according to the capacity of the individual's pocket.

Hartnack has no London agent, so that it is necessary to write straight to his address, 21, Place Dauphine, Paris; and we may add that it will facilitate matters if, in accordance with Continental business fashions, a cheque, payable on a Paris house, be forwarded at the same time as the order; otherwise it will not be responded to.

THE WEEK.

TOPICS OF THE DAY.

AT an extraordinary meeting of the Fellows of the Royal College of Physicians, on Monday last, Dr. George Burrows, F.R.S., was again elected President of the College. It was proposed by Dr. Farre that the reports of the proceedings of the Comitia should for the future be sent to the Medical journals.

We have great pleasure in calling our readers' attention to the fact that the International Ophthalmological Congress

will be held in London during the first three days of next August. The Council of the Royal College of Physicians have placed the rooms of the College at the disposal of the Ophthalmologists for the purposes of their meeting. Mr. Critchett is the Chairman of the London Committee, and Professor Soelberg Wells the Secretary. Any inquiries for information as to the approaching Congress should be addressed to the latter gentleman at his residence, 16, Savile-row, W.

The appearance of the report of the Briton Life Assurance and of the statements lately circulated by the Clerical Medical and General Life Assurance Society, both offices being amongst those in which many members of our Profession are especially interested, calls our attention to the improved condition and prospects of life insurance generally in this country. The panic has now disappeared, confidence has been restored, and the general position of insurance companies has been bettered, inasmuch as in many instances those who, in consequence of the late panic, have abstained from making their annual payments, have left their accumulated interests for the benefit of others who have displayed greater confidence. To members of the Medical Profession life insurance offers the easiest and surest way of providing for a family and giving the fearlessness for the future which is one of the greatest helps to success. Few men know better than those who are engaged in watching the interests and progress of the Profession as Medical journalists the difficulty which every man who relies upon his Profession alone must find in leaving the most modest competence for wife and children. But the easiest way to accomplish it is to insure, and to insure when young.

We have received a letter from Lord Abinger on the subject of the recent occurrences at the Royal Orthopædic Hospital, which we append:—

“THE ROYAL ORTHOPÆDIC HOSPITAL.

“To the Editor of the *Medical Times and Gazette*.

SIR,—Though extremely unwilling to appear in print, I so fully concur in the justice of your remarks on the Royal Orthopædic Hospital as they appeared in your number of the 16th inst., that I cannot refrain from asking you to publish the following observations. I and my family before me have been connected with the Royal Orthopædic Hospital from its earliest foundation, and we have always taken a deep and abiding interest in its welfare.

“Into the personal differences which have arisen between the Committee of Management and their two Senior Surgeons, Messrs. Tamplin and Adams, as they have no reference to their Professional ability, I do not at this moment wish to enter.

“The broad view of the case is this—48,000 unhappy cripples have passed through the Hospital since its foundation. They have been cured by our Surgeons and not by the Committee, and it is by their eminent Professional skill and ability the Hospital now holds its position and the support which is accorded to it by the public.

“The two Senior Surgeons having placed their Professional honour in my hands, I am of opinion that it will be impossible for them to withdraw their resignations until the paragraphs reflecting on their conduct have been expunged from the annual report which was adopted at the Annual Court. In order to effect this object, I, in common with many other influential governors and earnest supporters of the institution, have summoned a Special Court, which will be held at the Royal Orthopædic Hospital on Monday, April 8, at 3 p.m. To this Special Court I earnestly invite the attendance of all governors, and they will then be able to judge for themselves as to the merits of the case from the facts which will be laid before the meeting.

“Since the holding of the Annual Court I have examined the Hospital books, and I find that on March 8 eight annual subscribers of £1 ls. were introduced, and that on March 12 (the day before the meeting) no less than twenty-two annual subscribers of £1 ls. were introduced—all these members being entitled to vote. I have it under the Secretary's own handwriting that the names of thirty of these members were given to him by one of the Assistant-Surgeons, who gave him his own cheque for £31 10s., and took thirty separate receipts for the same. I venture to think that the Assistant-Surgeon in question could hardly have failed to be aware that the adoption

of the report would necessitate the resignation of his two superior officers.

“At the same time there was a resolution on the notice paper of business to be transacted at the meeting, to the effect that after a certain number of years' service all Assistant-Surgeons should have the rank of full Surgeons. The adoption of the report and the passing of this resolution at once converted the Assistant-Surgeon in question into Senior Surgeon of the Hospital.

“I make no comment on this proceeding of the Assistant-Surgeon; but I should be glad to hear through the columns of your valuable journal whether it meets with the approval of the Medical Profession.

“The report of the Committee was carried by fifty votes against thirty-three. Deducting the thirty-two votes and those of the Committee and their more immediate friends, how many can remain to have passed the vote of censure on our Surgeons? I am, &c., ABINGER.

“Cromwell-road, South Kensington, March 25.”

It will be seen that Lord Abinger has called a special meeting of the Governors of the Hospital, and until that has taken place it would be perhaps premature to comment fully on the statements which his letter contains. We can only hope that Lord Abinger has been misinformed as to facts when he states that one of the Assistant-Surgeons of the Hospital has himself been instrumental in introducing persons to vote, paying their subscriptions by his own cheque, who came and outvoted the supporters of his colleagues. Such a policy, whether the report be correct or not, would deserve the censure of the entire Profession. Surely the Council of the Royal College of Surgeons should take cognisance of such a matter, supposing there be no mistake.

Several paragraphs have of late appeared in the papers under the heading “Drunk or Dying.” They refer to different occurrences, in all of which unfortunate persons have been taken to public Medical institutions, have been believed by the Medical men in attendance to be drunk, and it has afterwards proved that they were suffering from the fatal effects of accident or disease. Now, we do not criticise the opinion given by the Surgeons. We know the difficulty in many of the cases of arriving at a correct diagnosis, and we have not the full details before us; but these occurrences have a moral, and it is this—that whenever a person insensible is brought to a public Hospital, unless it is clearly proved that he is intoxicated, he should have the benefit of the doubt, and be put to bed. Twelve hours would clear the matter up, and these terrible cases would not occur.

The trial of Hannah Steele for the alleged murder of Mr. Harris, the Senior Surgeon of the Manchester Workhouse, took place at Manchester on March 21. Mr. Harris died suddenly with all the symptoms of poisoning by atropine. Circumstances threw suspicion on the prisoner, a nurse in the lunatic ward, who was supposed to have had a grudge against Mr. Harris for reporting her to the authorities for some neglect of duty. However, the jury thought there was no reliable evidence against her, and she was acquitted.

ROYAL MEDICAL SOCIETY, EDINBURGH, ON CONJOINT EXAMINING BOARDS.

PROFESSOR GAIRDNER, of Glasgow, at a meeting of this Society, held last week, delivered an address on “Medical Examinations and Conjoint Boards.” He said that “at various recent meetings of the General Medical Council it appeared that the Council were tending in a certain direction as regarded Medical examinations. It appeared perfectly plain to those who were in the secret that the Medical Council were acting under a sense, as it were, of constraint—that some individual members of it and some influences outside were, in fact, saying to the Council, if they did not do so, application would have to be made to Government for the institution of a system of Medical examinations wholly outside the control of the Profession itself. Although he appeared before the meeting as an oppo-

ment of this particular scheme of conjoint boards, he did not see any practical or theoretical objection to different examining boards acting in conjunction with each other, and giving common lessons. In fact, so far as the conjunction of examining boards might be effected in such a way as not to sap the feeling of independence belonging to each, and to accumulate examinations and toil and anxiety connected with examinations either upon examiners or students unnecessarily, he was entirely in favour of the conjoining of examining boards. He had no objection to conjoint examinations by the Colleges of Surgeons and Physicians, nor could he see any objection to conjoint examinations between the University and the Corporations of Physicians and Surgeons. As a teacher and Professor he had no jealousy whatever of the admission of other influences beyond those of teachers into examinations. He had no hope that any system could be established which would absolutely prevent incompetent persons getting into the Profession, but this new legislation was in danger of destroying incentives to improvement and all attempts to raise the character of Practitioners above that dead level indicated by the minimum. Dr. Gairdner concluded by adverting to the deteriorating effects which examinations by the conjoint boards would have upon the quality of teaching. An animated discussion followed, in which Dr. Martin (the President), Mr. Lewis Shapter, Professor Sanders, Dr. Gamgee, Professor Blackie, and others, took part. Ultimately the following resolution was unanimously adopted:—"That this meeting is of opinion—1st, that there is no sufficient reason or demand for 'uniformity of Medical qualification,' as attainable by one national board for each division of the kingdom; and, 2nd, that improvements in Medical education and examinations will be best carried into effect by the individual or voluntary conjoint action of the licensing boards."

HEALTH OF PARIS.

OUR Paris correspondent tells us that the mortuary report shows a slight increase in the number of deaths during the week ending March 22, which amounts to 844. Of this number there are 14 cases of measles, 19 of typhoid fever, 39 of bronchitis, 58 of pneumonia, 10 of sorethroat, 16 of croup, and 165 of phthisis, by which it will be seen that affections of the respiratory organs are the most prevalent; and this is not to be wondered at, as the sudden transitions from cold to heat, and *vice versa*, have been very great. The thermometer, after having risen to 60° Fahr. within-doors, suddenly came down nearly 15° about the middle of last week, when the thermometer out-of-doors marked freezing-point. On March 26 the mercury fluctuated between 45° and 50°, and there was a slight fall of snow in the afternoon. No comparison could be made with the corresponding week of last year, as there was no report published; but that for the preceding year gives a mortality of 1101. This, however, cannot be a proper criterion, as the present population of Paris, which must have been considerably reduced in consequence of the war and the subsequent disasters of last year, is not given in the weekly report just issued.

DR. HILL *v.* ST. PANCRAS.

AFTER a somewhat valiant show of resistance, Dr. Hill has absolutely, after all, signed the agreement with the Guardians which he contended was illegal and might subject him to penalties under the Medical Witnesses Act. It appears that last Thursday Dr. Hill addressed a letter to the Guardians, in which he regretted the difference which had occurred respecting his appointment, and offering to sign the agreement. On this letter being read to the meeting, the notice to rescind Dr. Hill's appointment was by consent withdrawn. Dr. Hill was then sent for, and signed the agreement, after it had been read over to him in the presence of the Guardians. It remains to be seen whether this illegal proceeding will or will not be interfered with by the Local Board and the County Coroner.

CHELMSFORD DISPENSARY AND INFIRMARY.

IT is stated that Dr. Nicholls and Mr. Carter, the Medical officers of the Dispensary and Infirmary, have been called upon by the Committee of that institution to resign. The circumstances which have led to this step are stated to be a painful want of harmony between these two gentlemen, having its climax in an angry correspondence. It appears that Mr. Carter has been recently appointed to the institution, and since then Dr. Nicholls had performed two amputations at the Infirmary without consulting with his colleague. His excuse is that Mr. Carter's appointment had not been officially made known to him. Hence a correspondence took place of an unpleasant character. The matter being brought before the Committee, they called upon both gentlemen to resign. Mr. Carter has acted on the hint. Dr. Nicholls has declined to resign.

SMALL-POX JOTTINGS.

SMALL-POX has been rapidly spreading in Crewe.—One death was reported in Mile-end Old Town last week from the disease.—Eight deaths occurred during the past fortnight from small-pox in the Hackney district.—In Aberdeen the past week's return shows—Total number of cases admitted to Hospital since opening, 137; new cases admitted on the 22nd, 2; number of patients in Hospital, 32; total discharged recovered, 84; total dead, 21.—In Halifax during the past fortnight two deaths occurred from small-pox, and five new cases were reported.—The new Small-pox Hospital at Stoney Royd is fast approaching completion, and will be ready for patients in a very short time.—Small-pox has broken out in Brighouse; already three deaths have occurred. Large numbers of persons are being revaccinated.—Upwards of 500 deaths from the disease have now taken place in Norwich; the disease is now abating, the weekly return showing only ten deaths, while the mortality at one time was thirty-seven in seven days.—Small-pox has disappeared at Newmarket and Cheveley.—The deaths from the disease in the eight principal towns of Scotland declined from 461 in January to 314 in February.—A householder at Brixton has been fined £3 at the Lambeth Police-court for having sent to his laundress a quantity of linen which had been exposed to infection from small-pox without having previously had the clothes disinfected.—Dr. Aldis, St. George's, Hanover-square, reported last week two cases of small-pox, both of which were sent to the Hospital.—Four deaths from small-pox had been registered last week in the Poplar Union, and twelve new cases brought under notice. In the same period seventy-seven persons were vaccinated at the public stations. There were five small-pox patients under treatment in North-street Infirmary.

MEDICAL SPIRITUALISM IN MELBOURNE.

MELBOURNE at the present time, according to the *Australian Medical Gazette*, is in a state of excitement similar to that which obtained in London during the O'Key *séances*. It appears that some of the principal Medical Practitioners in Melbourne have given in their adhesion to the spiritualist cause, and are in the habit of diagnosing and treating disease with the aid of a medium. The actors in this absurdity are not mentioned by name. One, however, is said to be a "Hospital Physician" connected with the Melbourne University, whose spiritual medium is an ex-grocer, now carrying on the business of Medical "medium" and biologist. This person professes to be able, by the aid of a lock of hair, piece of garter, or other adjunct of a sick person, without seeing the latter, to prescribe successfully for the most obscure and dangerous disease. A second Melbourne University Physician, attached to a Hospital, prefers a female medium, who is young and good-looking. The *Gazette* states that the "humbug" has many followers amongst all classes in the Profession, and justly denounces a system at once degrading, demoralising, and disgraceful, calculated to injure the Profession and bring it into ridicule.

MASTERS AND SERVANTS (WAGES) BILL AND DOCTORS' FEES.

THERE has been a meeting of the Scottish Western Medical Association in Glasgow to discuss the bearing of the Home Secretary's Bill relating to servants' wages. This Bill is intended to meet the terrible evils of the truck system, but it seems likely to interfere with the remuneration of Medical attendants in certain districts. We sincerely trust that no Bill will be passed which will interfere with the scanty incomes of Medical men; but, as we should also be glad to see the truck system abolished, we hope that some measure will be found for attaining the one end without compromising the other.

MEDICAL AFFAIRS IN DUBLIN.

OUR Dublin correspondent writes:—

"There is but little stir in the Medical world here at present, except the very injudicious newspaper excitement about the 'Irish Surgical Baronetcy.' If the list of 'eligible' names continues to be added to as rapidly as it has been of late, the 'Medical Directory' will soon be exhausted.

"The Conjoint Examining Board has, as you are aware, fallen through for the present.

"A very marked increase in small-pox has taken place. In the Cork-street Hospital the wards set apart for that disease are quite full, and the type is a very severe one. The health of Dublin in general is deplorably bad. Last week eleven deaths from fever were registered, in addition to fifty-four from small-pox. Of the latter, however, sixteen were of old date. The present severe weather will, I suppose, still further augment the mortality."

FROM ABROAD.—PRIZES AND PRIZE QUESTIONS AT THE ACADÉMIE DE MÉDECINE—THE LYONS MEDICAL CONGRESS.

THE anniversary at the Académie de Médecine has been held this year without any public ceremonial, M. Béclard, the Secretary, merely announcing the prizes that had been decreed and the prize subjects for the ensuing years:—1. The Academy Prize for 1870 (Intracranial Traumatic Effusions) has been awarded to M. Martial Robert, a military Surgeon. 2. For the Civrieux Prize (Diathetic Neuroses) no prize was adjudged, but the sum of 500 fr. has been awarded as an "encouragement" to M. Berthier, of the Bicêtre, and one of 300 fr. to M. Aribaud. 3. In like manner the Godard Prize (for the best work on Internal Pathology) has been divided between M. Carrière for his work on "Hydatid Alveolar Tumour" and M. Bertin for his "On Emboli." 4. The Orfila Prize (Digitalis) of 6000 fr. has been awarded to M. Nativelle for his essay on "Crystallised Digitaline" (*vide Medical Times and Gazette*, February 3, page 138), and a "recompense" of 1400 fr. has been given to MM. A. E. and S. G. Homolle. 5. The Itard Prize of 2000 fr. (for the best work on Practical Medicine and Therapeutics that had been published at least two years) was given to M. Lancereaux, for his "Treatise on Syphilis;" a recompense of 700 fr. being also adjudged to M. Guipon for his work on "Malignant Pustule." 6. The Civrieux Prize for 1871 (Bromide of Potassium in Nervous Diseases) was adjudged to M. Voisin, of the Salpêtrière. 7. The Barbier Prize for 1871, of 1500 fr., was given to M. Ehrmann, of Mulhouse, for his "Recherches sur la Staphylophie chez les Enfants." 8. The Capuron Prize for 1871, for the best memoir on Occipito-Posterior Positions, was not adjudged; but an encouragement of 1000 fr. was given to M. Sentex. 9. The Godard Prize for 1871, for the best work on External Pathology, was decreed to M. Berchon, a Naval Surgeon, for his "Histoire Médicale du Tatouage," an "honorable mention" being awarded to M. Rouge, of Lausanne, for his work on "Uranoplastie et les Divisions Congénitales du Palais." 10. The Amussat Prize for 1871, for the best work on Surgical Therapeutics, was given to M. Berenger-Féraud for his "Traité des Fractures non Consolidées ou Pseudarthroses." For the other prizes offered by the Academy there were no competitors, which is not to be wondered at, considering the troublous times they were offered in.

The following are the subjects of the prizes proposed for 1872 and 1873:—1. The Academy Prize of 1000 fr.—for 1872, "Malignant Jaundice" (*Jctère grave*); for 1873, "The Resection of Bones in their Continuity after Gunshot Wounds" (excluding articular resections). 2. Portal Prize of 2000 fr.—for 1872, for the "Best Memoir on a Question of Pathological Anatomy;" for 1873 (1000 fr.), "The Condition of the Bones and especially of the Vertebrae in Cancer of the Viscera." 3. The Civrieux Prize of 900 fr.—for 1872, "The Different Forms of Alcoholic Delirium and their Treatment;" for 1873, "The Transitory Mental Alienations which occur during the Convalescence of Acute Diseases." 4. The Barbier Prize of 2000 fr. for 1872, and 3000 fr. for 1873. This is to be given for the discovery of the means of cure of diseases recognised as usually incurable—as hydrophobia, cancer, epilepsy, scrofula, typhus, cholera, etc. "Encouragements" may be awarded to those who, without having attained the end in view, have made the nearest approach to it. 5. The Capuron Prize of 3000 fr.—for 1872, "The Precursory Phenomena and Concomitants of the Lactal Secretion;" for 1873, for the best unpublished memoir on any subject of Obstetrical Science. 6. The Godard Prize of 1000 fr. will be awarded in 1872 for the best work on Internal Pathology, and in 1873 for the best work on External Pathology. 7. The Orfila Prize of 2000 fr., for 1872, will be given to the author of the best work relating to any of the branches of Legal Medicine, except toxicology. 8. The Lefevre Prize of 2000 fr. for 1872, "De la Melancholie." 9. The Ruz de Lavison Prize for 1872—"Establish by means of precise and sufficiently numerous facts, observed in men and animals which pass from one climate to another, the modifications and alterations of functions and the organic lesions which may be attributed to acclimatisation." 10. The St. Lager Prize for 1872 is thus indicated by its founder:—"I offer to the Academy a sum of 1500 fr., in order to found a prize to recompense an experimenter who has induced a tumour of the thyroid as a consequence of the administration to animals of substances which have been extracted from the waters of localities where goître prevails as an endemic; the prize not to be awarded until the experiments have been successfully repeated by a committee of the Academy." 11. The Amussat Prize for 1873 of 1000 fr. "This prize will be decreed to the author of the work or of researches, simultaneously based on anatomy and experimentation, which shall have realised or prepared the most important progress in Surgical Therapeutics." 12. The Itard Prize for 1873 of 2700 fr. "This triennial prize is to be accorded to the author of the best book or memoir on Practical Medicine or Applied Therapeutics. In order that such works may have stood the test of time, it is obligatory that they shall have been published for at least two years." 13. The Marquis d'Ourche's Prize for 1873. The following are the conditions imposed by the testator:—"I desire to found two prizes—(1) A prize of 20,000 fr. for the discovery of a simple and vulgar means of recognising in a certain and indubitable manner the signs of real death. An express condition of this prize is that such means may be put into force by even poor and ignorant peasants. (2) A prize of 5000 fr. for the discovery of the certain means of recognising real death by the agency of electricity, galvanism, or any other procedure requiring either the intervention of a Professional man or the application of knowledge and the employment of instruments or substances beyond the knowledge of ordinary persons. If after five years from the date of the acceptance of this offer, either or neither of these prizes have been gained, the sums allotted to this foundation shall revert to the estate." All the essays, written in French or Latin, must be sent to the Academy by August 1 of the respective years.

The Committee of the Fourth Session of the French Medical Congress, to be held at Lyons during the International Exposition, has just issued its regulations and programme, signed by its President, M. Diday.

According to these the Congress will be opened on the 18th of September, and will hold its session during nine days (Sundays excepted). All Professional men who do not belong to the Lyons Medical Body, on signifying their adhesion to the Secrétaire-Général, M. le Dr. Dron, 5, Rue Pizay, Lyons, will be acknowledged as members without payment. Those of them who may wish to address communications to the Congress, either upon the subjects specified in the programme or on others not embraced in it, are requested to send them to M. Dron at latest by September 10. The Committee will decide upon the propriety of bringing them before the Congress. They should be as short as possible, as the time allowed for reading them will be limited, and all memoirs read will remain the property of the Congress, and will be published by the Committee.

The following are the eight questions which, according to the programme of the Committee, are to be brought before the Congress:—1. *Epidemic Small-pox*: It has appeared to the Committee that, in face of the vast epidemic which has spread over so large a part of Europe, it is "important to centralise the observations that have been made on the different regions visited by this scourge." It especially draws attention to certain points relating to vaccination, such as the comparative value of the different varieties of this, animal vaccination, and the measures of sanitary police calculated to favour and assure the practice of vaccination. 2. *Gunshot Wounds*: The Committee calls attention to the following points:—(1) The primary and consecutive effects of the new projectiles on the tissues, discussing also the question of explosive balls; (2) the respective indications for expectation, amputation, and excision in fractures of the diaphyses and joints; (3) the modes of dressing wounds most suitable for the prevention of complications, and allowing the transport of the wounded to great distances. 3. *Ambulances during War*, the chief points to be considered being the comparative examination of their organisation in different countries, the relations of the *chef d'ambulance* with the military officer in command, and the relations of the regular military Medical service with volunteer ambulances. 4. *Cattle Plague*: Under this head it will be of importance to consider the amount of loss from the last epizootic, which still prevails in some part of France; its comparison with other virulent epidemics or epizootics; its various modes of propagation; the best means of arresting its progress and preventing its return; and the nature of the legislation adopted in respect to it in various countries. 5. *The Causes of the Depopulation in France, and the means of Remedying it*: (1) The causes of the diminishing number of births—such as paucity or want of fecundity of marriages, large military levies, luxury, debauchery, alcoholism, etc.—will form one chief point for consideration; (2) the other will be the causes of the excessive mortality of young children. 6. *Treatment of Syphilis*: Here the whole question of the mercurial and non-mercurial treatment will have to be considered, as also the agency of local treatment. Other points will be—the efficacy and adaptability of the subcutaneous mercurial treatment; the comparative efficacy of mercury and iodine; and the utility of sulphurous mineral waters in certain forms of syphilis. 7. *The Reorganisation of the Teaching of Medicine and Pharmacy in France*. 8. *The Means calculated to Ameliorate the Condition of the Medical Practitioner*, so as to bring him into harmony with the importance of the part which he has to fulfil in society.

M. De Rause, criticising the above programme in the *Gazette Médicale*, expresses his opinion that nine days is too long a period for the Congress to last, and that it should not extend beyond the week. He also believes that the Committee has brought forward too many topics for discussion, as it is far preferable to have a few important subjects well examined than a great variety superficially dealt with. Thus, he suggests the suppression of Nos. 1, 4, 5, and 6. The subject of variola

has been recently and universally discussed. The cattle plague is an economic question, possessing little direct interest for the Medical Profession. The causes of depopulation, too, is a vast social question, which would alone occupy all the meetings the Congress contemplates. The discussion of the treatment of syphilis is much more suited for Medical societies and journals than for a Congress. On the other hand, Nos. 2, 3, 7, and 8 are subjects of great importance and actual interest.

PARLIAMENTARY.—AMENDMENT OF THE MEDICAL ACT—CONTAGIOUS DISEASES BILL—PUBLIC HEALTH BILL.

In the House of Commons, on Thursday, March 21,

Dr. Lush asked the Vice-President of the Council whether it was his intention during the present Session to introduce a Bill for the amendment of the Medical Act, 1858.

Mr. W. E. Forster: Lord Ripon and I have conferred on the question of my hon. friend. We are informed that most of the Examining Medical Bodies in England have already combined by voluntary action. We are therefore of opinion that it is unadvisable to bring in this session a Bill to amend the Medical Act of 1858. Next year we shall know how this combination in England is working, and to what extent similar action has been taken in Ireland and Scotland.

On Monday,

Mr. W. Fowler asked the Home Secretary whether he could name a day after Easter on which he would move the second reading of the Bill for the Prevention of Contagious Diseases.

Mr. Bruce: I regret to state that I cannot with any certainty fix a day for the second reading of the Bill.

Mr. Gladstone stated that the second reading of the Public Health Bill should be placed before the Parks Bill on Thursday, April 4.

THE NEW EDITION OF VIRCHOW'S
"CELLULAR PATHOLOGY."(a)

FOURTEEN years have elapsed since the "Cellular Pathology" of Professor Virchow made its appearance, raising stormy discussions throughout Germany and strong opposition everywhere, and nine years lay between the previous edition and this last one. This long interval is chiefly due to the author's political life, upon which he spent all his energy during that period, and which furnished to his malicious detractors and enemies a most welcome pretext for hideous comments. It will be fair, therefore, to remark that his endeavours in politics rank equally high with his various merits regarding science. After the traditional fashion of the noble Prussian aristocracy, Bismarck, at the beginning of his glorious career, was very much given to violating and overlooking of constitutional rights, and only by the party of which Professor Virchow for some years was one of the chief leaders was the violent Minister brought about to take a different course. Thus Professor Virchow has his good share in the historical events of the last year. Lately he has returned to his work, and he has done so with his wonted vigour, the summary of which is laid down in the present volume.

Professor Virchow firmly holds up his system in all its essential parts. "The new discoveries," he says (p. 391) "do nought but confirm my theory—*omnis cellula e cellula*" (p. 24). All tissues consisting of simple cells—that is, such as are not distinguished by some peculiar quality, as is the case with muscles and nerves, with an intercellular substance interposed between them—are united into one large species: the connective tissue. Its cells, if they enter into communication with each other, which they very often do by the way of threadlike elongations they send forth, then form the corpuscles of the connective tissue. These anastomoses form a system of channels for the transmission of the nourishing juice to those cells which are not within the immediate reach of the capillary bloodvessels, thus representing a substitute for the *vasa serosa antiquorum*, which do not exist. That is the way the cornea, the cartilage, bones, and all the parts are provided for, where the bloodvessels are relatively scarce (p. 48, 119 *et seq.*). The connective-tissue corpuscles act not only a most important part in the nutrition of the part to which they belong; they partake, moreover, to a great extent in the process of inflam-

(a) "Cellular Pathology." By Professor R. Virchow. Fourth edition, revised and enlarged. Berlin, 1871. Pp. 574. Hirschwald.

mation. To a certain limit they produce the normal, as well as the anomalous, cellular products in their region. "It will be difficult to decide which part of an inflammatory product is due to white blood-corpuscles emigrated from the capillaries and to their division, as observed by Stricker, and which to the activity of the irritated cells. Cells, however, are not originated by the free fibrine, but again by other cells."—P. 479. "It has been said that I have built my doctrine of the origin of the new formations upon the activity of the connective tissue. I never had such an idea. I have always acknowledged the formative power of the epithelia."—P. 392. His views as to the origin of dyscrasies are still the same: the blood is constantly supplied with the noxious matter, be it from some outside source, as in different chronic intoxications, or by some locality in the body which always produces the venom afresh (p. 270).

It is impossible to give in a small space a proper account of the book, whose leading principles are still the same already known. The present edition is considerably enlarged, with several additional engravings. All the principal recent discoveries which have any bearing are duly registered and brought to harmonise with the whole system. With all its strange conjectures, the "Cellular Pathology" of Professor Virchow is highly interesting, and well worthy the attention of the Profession, and its able translator ought to put himself to work again.

SIR HENRY HOLLAND, BART., M.D.,
F.R.S., D.C.L.(a)

No. II.

HOLLAND commenced practice in 1816 in Mount-street, Grosvenor-square, and four years after removed to the house he now occupies in Brook-street—a house possessing, as he mentions, a charm for him, as Burke was in the habit of breakfasting there when he came up to town from Beaconsfield. But was not Burke staying at this very house at the time of his famous speech against Warren Hastings? For four successive years after his commencement of practice, Holland was in the habit of visiting Spa professionally. This brought him into contact with Wellington, Londonderry, the Duc de Richelieu, the Emperor Alexander, the Prince and Princess of Orange, the Duke and Duchess of Cumberland, and other notabilities. We gladly quote what Sir Henry says of a man as "well abused" as any public man has been in our times. Whatever were the faults of "Lord Castlereagh," something—nay, a good deal—must be allowed for them in the character of the times in which he lived. "I had a good deal of intercourse with Lord Londonderry at Spa, accompanying him in several excursions over the surrounding country. There was a certain nobility of presence and demeanour about him agreeable to the eye. Nor was this belied by his conversation—always, in my recollection of it, acute and intelligent, and in manner calmly courteous. This estimate, I am aware, is not commonly received. The sarcasms of Moore's poetry,^(b) and one or two Parliamentary anecdotes, have clung to him with epigrammatic force. I may add I never met a man for whom I should less have predicted the unhappy way in which his life was closed. Within a short period of time three of his contemporaries—all men of note in public life—came to their end in a similar way." Two of these men were as much opposed in character to Lord Londonderry as could possibly be conceived—one, his fierce political opponent, was consistent and able (Samuel Whitbread); the other, the good, affectionate, and melancholy Romilly. Whilst on the subject of personal sketches, we may refer to what Sir Henry says about the "great Lord Erskine." Here are his words:—"In singular contrast to Sir S. Romilly came Lord Erskine, of whom, indeed, I saw much less, and at a time when his faculties had undergone a decay more obvious to others than to himself. He was still eager and eloquent in speech, but with a certain

restless irritability, augmented, as I believe, by narrow worldly circumstances, and what he deemed the neglect of his former political friends. His mind, too, when I knew him, was clouded by little foibles and superstitions. I well recollect a dinner at Sir S. Romilly's where his agitation was curiously shown in his reluctance to sit down as one of thirteen at table, and by the relief he experienced when the fourteenth came in. His life had been one of *meteoric* kind throughout, vanishing in mist, as such lives are prone to do." Now, we emphatically protest against what we regard as this unjust "sketch" of Lord Erskine. We might with as much reason draw our conclusions respecting Marlborough or Swift from the distich of Pope—

"From Marlborough's eyes the tears of dotage flow,
And Swift expires a driveller and a show."

Every one knows that in his later years Erskine had become addicted to the use of opium in large doses; that he became irritable, vain, and querulous. He had much cause to complain of the neglect of his former friends, notably of the Prince Regent. But it would be as unjust to Erskine to forget his former life—his services to the cause of liberty of the press, his great speeches on trial by jury—as it would be unjust to Marlborough to forget the battle of Blenheim, or to Swift that he was the author of "Gulliver's Travels" and the "Tale of a Tub," and, at the time, the more celebrated "Drapier's Letters." To recur to the "Recollections"—in Paris in 1818, Holland dined at the house of the Countess Rumford, widow of Lavoisier. Here is the list of the illustrious guests: Laplace, Cuvier, Berthollet, Gay-Lussac, and Prony; Madame Laplace, Madame Berthollet, and Mrs. Marcet; Berzelius came in in the evening. Holland adds this melancholy line, "I am now the only one of these alive." In another memorable visit to Paris, just thirty years afterwards, he came into contact with Arago, Leverrier, Dumas, and Elie de Beaumont. Sir Henry's work is so discursive that it is impossible that we can be otherwise in our review of it. Early in practice he had some idea of becoming one of the Physicians of St. George's Hospital; but, no vacancy occurring until he was in considerable practice, he abandoned the intention. He seems to have been well satisfied that he did not become attached to the institution, as it afforded him more leisure for travel and for the indulgence of those literary and scientific pursuits so dear to him. We may here state that Sir Henry's practice continued large and lucrative for many years, and that he is now gradually and quietly retiring from it—not altogether, as employment is essential to him, but in consonance with his determination to do so. He was appointed Physician Extraordinary to the Queen in 1837; Physician-in-Ordinary in 1852. He was created a Baronet in 1853, the offer having been previously made by Lord Melbourne, but declined, on account of his anxiety for providing liberally for his eldest son. He became F.R.S. in 1816,^(c) being introduced to that august body the same evening as Lord Byron. In 1847 the title of LL.D. was conferred on him by the University of Cambridge, Massachusetts; in 1856 he received the D.C.L. of Oxford, and somewhat later was elected one of the five Honorary Members of the Royal Academy. Amongst the more interesting of Sir Henry's sketches is the description of the meetings held by Sir Joseph Banks of the Fellows of the Royal Society in Soho-square. Here is an amusing sketch of the man who formed so prominent a figure in some of the best satires of Dr. Wolcott—"Peter Pindar":—"Sir Joseph Banks himself was necessarily a very conspicuous personage in these parties at his house. Seated and wheeled about in his arm-chair, his limbs helplessly knotted with gouty tumours, speaking no other language than English, and carrying his scientific knowledge little beyond the domain of natural history, he nevertheless looked the governing power of the Royal Society, and was such in reality. I had frequent occasion to notice the strong impression his aspect and demeanour made upon foreigners—men of science and others—who came over to England at this period of renewed Continental intercourse. It is less paradoxical than it may seem to say that this impression was strengthened by the very fact of his not speaking any foreign language. Silence often carries more weight with it than speech, and especially when the latter is enumbered with the effort to find words for its object. The intellect here becomes the slave of the instrument, and thought and argument are lost in the struggle to give them right expression. Sir Joseph Banks, silent in his chair, was more imposing than he would have been exchanging imperfect

(a) "Recollections of a Life." By Sir H. Holland, M.D., etc. Longmans.
(b) Sir Henry might have added, the savage epigrams of Byron.

(c) By the death of Dr. Granville, recorded in our last, Sir Henry became the oldest Fellow of the Royal Society.

phrases, whether of science or courtesy, with the strangers who came to visit him." These meetings were held on Sunday evenings, and here are the names of some of those who attended them most constantly:—Cavendish, Wollaston, Young, Davy, Chenevix, Davies Gilbert, Pond, Prout, Robert Brown, Tenant, Hatchett, and Warburton. Sir W. Herschell and Dalton occasionally attended. The following quotation relates to three of the most remarkable of this group, and is of great interest:—

"Two striking figures at these meetings were Cavendish and Wollaston—the former the shyest and most taciturn of men; listening intently when discussion was going on, but never taking part in it, and shrinking out of sight if reference were made to himself or his own researches—Wollaston, sternly logical and sceptical, listening to others as if ever ready to refute or rebuke; and generally doing so by pungent questions to which few could venture to reply. I have often known a plausible theory, uttered by someone unconscious of Wollaston's presence, suddenly upset by two or three of these abrupt questions or comments. To the mere pretence of science he showed no mercy. The habitual scepticism of his mind was, however, a hindrance to his own scientific career. This was strikingly shown in the circumstances attending his discovery of the metal palladium; and at a later time in his relation to the greater discovery of the electro-magnetic rotation. Though the first to denote the dark lines in the solar spectrum, the germ of so many later researches, he did not himself carry the observation further. That aid which hypothesis, duly limited, renders to experimental inquiry, he unduly disdained and put aside. He would have accomplished more had he doubted less.

"At these parties in Soho-square, the youthful and more elastic genius of Davy came in striking contrast to the inflexibility of Wollaston and the *umbratilis vita* and hereditary taciturnity of Cavendish. His early successes in science had emboldened a mind naturally ardent and speculative; and I well remember the eagerness with which men elustered around him to listen to his eloquent anticipations of future progress, many of these now more than fulfilled. His lectures at the Royal Institution, novel and earnest in manner, and invigorated by the succession of discoveries they recorded, brought crowds of admiring hearers. Admiration, indeed, derived from other sources than those of science was one of several concurrent influences on Davy's natural character, altering it disadvantageously in several respects. I knew him intimately throughout the greater part of his career; and with melancholy interest through those stages of decline sequent on his first paralytic attack. I saw him under this seizure a few hours after its occurrence, and when he was hardly yet aware of its nature or import. The peculiarities of his mind, his genius and irritability, were strikingly marked when the consciousness of the event came fully upon him.

"So in a different way were those of Wollaston, under another form of cerebral disease, which, though less sudden in its beginning, ended more speedily in death. Watching over his latter days with Sir B. Brodie, it was matter of deep interest to us to observe his philosophical mind taking calm but careful note of its own decay—the higher faculties, which were little if at all impaired, occupied in testing, by daily experiments of his own suggestion, the changes gradually taking place in the functions of the senses, the memory, and the voluntary power. Diagrams and figures drawn on a board before him were among the methods he thus employed. He had manifestly much interest, if not indeed a certain pleasure, in detecting the changes going on and in describing them to us. He would admit no interpretation of them save in reference to that final change which he constantly and calmly kept in view. It was a self-analysis of mind carried on to the last moments of life.

"Dr. Young, again, stood in singular contrast to each of the remarkable men just mentioned. His profound and very various knowledge was concealed under a certain spruceness of dress, demeanour, and voice, which strangely contradicted his Quaker origin, and perplexed those who had known him only from his scientific fame. I have seen the discoverer of some of the grandest and most occult laws of light loitering with ladies in a fashionable shop in Bond-street, helping them in the choice of ribbons and other millinery. But what might hastily be deemed affectation was in Dr. Young not really such, but genuine courtesy and kindness of heart. My attachment to him gave me much interest in the valuable memoir of his life by the late Dean of Ely, than whom no man was better able to appreciate his scientific achievements. These had been obscured for many years by an article of Lord Brougham's on his discoveries in the *Edinburgh Review*—an article to which

the term *erroneous* is the mildest that can be applied. They were eventually restored to their proper place in the annals of science, by French philosophers succeeding in the same line of research. While interwoven with every part of the theory of light, they collaterally illustrate many others of the great physical problems of the universe."

Sir H. Holland refers with satisfaction to "The Club," the creation of more than a century ago, of Johnson, Burke, Sir Joshua Reynolds, Goldsmith, Garrick, etc. This club, at its centenary in 1864, numbered thirty-five, twenty-six of whom sat down to the dinner. Holland was elected a member in 1840, since which time many have been removed by death. Amongst these may be mentioned Lord Lansdowne, Macaulay, Hallam, Lord Aberdeen, Lord Holland, Lord Clarendon, Bishop Blomfield, Bishop Coplestone, Sydney Smith, Sir G. C. Lewis, Whewell, Lord Kingsdown, Dean Milman, Senior, Eastlake, Hawtrey, etc. Holland remarks—"When looking round our dinner-table, I cannot but feel at times how much the individualities are changed since I first sat there. With the exception of Lord Stanhope I am now the oldest member."

The concluding chapters of Sir Henry Holland's book refer more particularly to himself and his writings. He makes some valuable remarks on the influence of habits on health and on longevity. According to his experience, want of occupation is a very frequent cause of premature decay. He says—"Retirement from business and quietude of life are happy provisions, taken at the right time and in the right degree; but they may be adopted too soon, and too largely indulged in, and the vitality both of mind and body be unduly impaired by the very means employed to preserve it. Easy arm-chairs and other appliances of luxurious comfort are an invitation to indolence and to the disuse of faculties which need employment for their preservation." (d) So he considers the exercise of the intellectual faculties of the highest importance, and whatever the intellectual habit, these should be pursued, no long interval being allowed of abstention, or the habit would become irksome or lost. He managed, even in his busiest time, to snatch if only a few minutes for some "diversion of thought" from his Professional pursuits. With respect to books, he has never been a "book collector," and is rather in favour of *weeding* his library than adding to it. He refers to his contributions to literature, the earliest of which was published in 1810, the latest in 1871. He wrote both for the *Quarterly* and the *Edinburgh Reviews*. He states that on no occasion did he enter into any political discussion, and appears to be pleased with the fact that only on one occasion did a review of his offend the author of the book reviewed. The two great reviews with which his name is honourably associated would never have attained their great reputation if all the writers for them had pursued so Fabian a policy. His work entitled "Medical Notes and Reflections" has passed through three editions—the first was published in 1839, the last in 1855. The "Notes" consists of a series of papers of the most interesting character, chiefly concerning pathology or practice, and is too well known to require any lengthened notice here. It is certainly one of the most interesting and charming volumes ever written, and though by some regarded as "too sceptical on some points both of Medical doctrine and practice," every page is pregnant with thought and most valuable suggestions.

Hitherto we have spoken in terms of warm commendation of Sir H. Holland's "Recollections," and it is fully deserving of that praise; but it is impossible to rise from its perusal without a feeling of disappointment at his omission of almost every Medical celebrity of his day. He must have come into contact, Professionally and otherwise, with many men of whom we should

(d) We well remember the last consultation we had with Sir Astley Cooper, after his return to practice in Conduit-street. He spoke of the irksomeness of his retirement, of the almost intolerable *ennui* he endured. "Ah," he said, "never retire, as they call it; depend upon it there is no rest where there is no work." Many of our readers will recollect James Milman Coley, who was a frequent visitor and speaker at the societies about twenty-five years ago. We used to call him the "Old boy." Though about 75 years of age, he had the manner and vivacity of a youth. He came to London when upwards of 70 to make a practice, and was Physician for some time to Pimlico Dispensary. He did not succeed in London, and having obtained the appointment of Physician to the Embassy at Brussels, removed to that city. I was astonished at the ease with which he mounted the stairs of the Hotel de Ville, and said, "Why, Coley, you are younger than I am." "Oh," he said, "we are a long-lived family; I attribute this to our active and regular habits. My father succumbed to idleness—he retired when he was 90; took to indolence, smoking, etc., and did not live long afterwards. I shall not follow his example." Poor Coley! he suffered from reverses, got into ill-health, became paralysed, and died a few years since. He was a man of varied acquirements, and of considerable intellectual power. When engaged in a most extensive practice in Shropshire he managed to write regularly for Dr. Johnson's *Medico-Chirurgical Review*. His remuneration consisted of the books he received for review.

be glad to have heard something more about. It is true that Sir Henry more than once informs us that he has purposely avoided reference to Professional anecdotes, and, of course, we must suppose Professional men of his own calling. At all events, he mentions the names of one Physician and one Surgeon only with whom he was acquainted during his long career. The latter he merely mentions by name; the former he dismisses thus curtly and unsatisfactorily. Speaking of Joanna Baillie and her sister Agnes, he says: "Their brother, Dr. Baillie, exhausted by years of Professional toil when youth was already gone by, and reaching repose only when it was too late to be of avail, died when but 64. He was the Physician with whom I was most intimate in my early Professional life—a man of simple and generous nature, in no way sullied by his large intercourse with the world." We are sure we shall be joined in our expressions of regret by many, very many, of Sir Henry Holland's Medical readers that he has not given us more anecdotes of his Professional life and more sketches of his Professional brethren. Anecdotes told in his striking way, and sketches drawn with his graphic power, would have been most acceptable. An extra chapter of his "Recollections" devoted to such anecdotes and sketches would have made his work of surpassing interest to the Profession. Is it too much to hope that he may yet favour us with that chapter? With what interest should we read his account of such men as the second Warren, Nevinson, Maton, Charles Clarke, Gooch, Halford, Jenner, Paris, and Chambers, of some of whom we know little or nothing—of the Surgeons with whom he probably came into contact, and who would form subjects for his pen: the first Hawkins, Gunning, Astley Cooper, Brodie, the first Keate, Cline, Abernethy, and Lawrence? Of Cline we know literally nothing; and yet he was one of the most considerable men of his time in various respects. He was, unquestionably, a Surgeon of the very first class, and was an accomplished gentleman. He had political views of an extreme character, but he was bold, honest, and single-minded.

In speaking of his earlier career, Sir Henry states that he ventured to disregard the admonitions tendered to him by persons of large experience in London practice. It was told him, and told very truly as a general fact, that there was danger to a young Physician in gaining other repute than that belonging strictly to his Profession; that the suspicion of literary tastes, or even of devotion to other parts of physical science, was taken as of evil augury for his Medical ability. "More than one instance, indeed," says Sir Henry, "had occurred to my own knowledge of failure owing presumably to this course, when all other circumstances promised success. The question bore directly on my own case, since with my fondness for travel I blended the inclination to certain other pursuits which I had taken up in early life, and was unwilling to relinquish." In a note on this subject, the following amusing anecdote is related:—"A man of high political rank, being remonstrated with by his family for employing a particular Physician, pleaded in reply that Dr. — was so ignorant of everything else, that he could not be otherwise than profound in Medicine." There can be no doubt that if a reputation is acquired by a Physician for anything not strictly Medical, it may interfere with his Professional progress. But this is confined mainly to those cases in which the *real* work of life has been neglected for the *ideal*. Men who combine with what Baillie said—"A moderate amount of information, with good common sense"—earnestness and industry, will not find "accomplishments" interfere with their success as Medical Practitioners. The classical attainments of Sydenham, Mead, and Halford, the study of natural history by Jenner(e) and Wells, of physics by Paris and Arnott, did not interfere with their success or reputation as Physicians. When men fail from any such "acquirements," it certainly depends on some cause independent in a great measure of them. The law, our kindred profession, is open to the same objection; yet Blackstone, Denman, and Talfourd wrote poetry, were scholars, and were withal great lawyers. However, Sir Henry Holland is himself a remarkable illustration of a man rising to the highest distinction as a Physician, not because he had not other claims to distinction, but apparently because he had. His life appears to have been one singularly calm and unconstrained—methodical to a degree which shows an amount of self-command and determination which is rare indeed. But he had been from the first in easy circumstances, had good health, and no severe family afflictions. A wonderful constitution it must be indeed, physically and mentally, that enables a man in his 84th year to write a book like this, run along the streets

(e) Jenner, moreover, wrote poetry of a character which stamps him as being imbued with true poetic genius.

like a boy, and enjoy the comforts, if not the luxuries, of life. There is much in the closing chapter which we should have been glad to quote, but our space is exhausted, and we must refer the reader to the book itself, promising him a rich intellectual treat from its perusal.

One of the most interesting chapters in the "Recollections" is that which refers to a "generation now nearly gone by," and a parallel the author draws between that and the present. He puts the question to himself whether the present is better or worse—morally, intellectually, and socially—than the generation gone before it. The question, he admits, is one difficult to answer; but he treats it in the spirit of an impartial and liberal observer. He is not, like some old men, infatuated with the past and dissatisfied with the present, but he compares the two, so as to do justice to both. What he describes as the *deterioration* of society he attributes to *overcrowding*. The cause of this is "a more miscellaneous intermingling of the different elements of society—the lower gaining, I fear it must be admitted, in their proportion to the higher." There is a little cynicism in the following, but there is some justice in the remark:—"The crowded dinner-tables of the present day, and still more those evening assemblages, under whatever fanciful name convoked—stifling breath as well as conversation—have largely swelled society, but not improved it. The practical definition of a crowd, of whatever rank it is composed, approaches closely to that of a mob; the intellect and happier refinements of society alike suffer from it. The men of genius, literature, and wit are doubtless as numerous in London as heretofore; but they are less marked individually in the multitude, and many of them partially concealed by their connexion with the anonymous periodical writings of the day." Recollections of the dinner parties and the evening gatherings at Holland House and elsewhere no doubt had their effect in producing the above sentences. The following is so much in accord with what we have repeatedly urged in this journal that we quote it entire. No observer of the times can fail to acknowledge the truth of these observations, particularly so far as they refer to Medical institutions:—

"I might enumerate, from my experience, other and more important influences, moral as well as physical, of this overcrowded life, were these things not alien to the purpose of my narrative. There is, however, one particular result on which I would say a few words, inasmuch as its effects upon society are patent to daily experience, and call strongly for correction. This is the present extravagant multiplication of societies and institutions of every kind, dividing and subdividing all the concerns of human life—charities, literature, science, art, the professions, trades, and social intercourse in all its shapes. Scheme follows scheme in rapid succession, and the devising and prosecution of these schemes has become itself a profession to many. With every allowance for increasing population and wealth, life and estate in London are grievously over-ridden by the multitude of the exactions thus imposed; often wholly fruitless for the objects assigned, and consuming in their method of use the means that have been evoked for more laudable purposes. Of the endless institutions thus created by public charity, fashion, or credulity, many speedily become mendicant; while those of higher and better purpose are starved in the struggle of competition. To annul some of these institutions altogether, and to concentrate others into co-operation, may be a work of difficulty, but is well deserving a vigorous effort to accomplish it. Those belonging to charitable objects especially need revision and reformation. I cannot doubt, from what I have myself seen, that the pauperism of London is augmented rather than relieved by their multiplicity and maladministration."

Sir Henry pays a graceful compliment to the press, and acknowledges its great influence, the vast ability employed upon it, and characterises it as "happily tempered by knowledge, good taste, and right temper in most instances, but capable of being mischievously used—and too frequently so used—among those with whom these qualities have little or no value."

Sir Henry has been struck with two results of the progress and diffusion of physical knowledge. One is the "boldness of modern hypotheses in regard to the highest problems of the universe and of man"; "the other is the more general and rigid demand for *evidence* on every subject of inquiry resulting from these methods of research, and not limited to physical science only, but extending to other and very dissimilar questions, in which truth is the object sought for." He fully appreciates the value of this change. He then discusses the influence which London clubs have exerted on society, and thinks that they have tended to refine it. He considers that society has

been very much modified in the present day by the closer intermingling of the higher and middle classes of society, due to many causes: the increase of wealth amongst the latter, the altered constitution of the House of Commons, modern modes of travelling, etc. Life, too, is faster in every way—people walk faster and live faster than they did. Religious thought and action have come into full force, in place of “quietude” or “stagnation.” The chapter finishes with some admirable remarks on the “wits” of the past and present generations; but for these we must refer the reader to the book itself.

In concluding this somewhat desultory notice, we may say that Sir Henry Holland has mixed little with his Professional brethren. We have never seen him in a Medical society, nor, with one or two exceptions, at the gatherings of either of the Royal Colleges; but he was nearly a constant attendant at the Friday evening meetings at the Royal Institution, of which he was Vice-President, and is now President. We think this isolation of himself is to be regretted—not, perhaps, as regards himself, but his brethren. It was perhaps too much to expect of him that he should attend these meetings; he had great and irresistible attractions in other quarters. The man who could pass his evenings in conversations with Madame de Staël and Macintosh, in “coaching up” Lord Palmerston on the spectrum analysis, chatting with Lord Aberdeen, breakfasting with Cobden, dining with Rogers, or at Holland House, in company with “all the talents” of the time, as well as—

“Chiefs out of war and statesmen out of place,”

might be forgiven for neglecting the somewhat dull and prosaic *réunions* of the brethren of his own craft. Certainly his sympathies appear to have been with “great and distinguished persons” rather than with those less great and distinguished persons who were merely “Doctors.” Finally, however, we may say of Holland as Sir Robert Peel said of Lord Palmerston—“We are all proud of him.” J. F. C.

REVIEWS.

Treatment of Fractures of the Limbs. By S. GAMGEE, Fellow of the Royal Society of Edinburgh, Surgeon to the Queen's Hospital, Birmingham. London: J. and A. Churchill. 1871.

THIS monograph neither is, nor pretends to be, a complete treatise on the subject of which it treats. It is put forth rather with the intention of defending and advocating one particular kind of treatment of fractures, and, as the author declares, with the hope that it may “contribute to the establishment of sound first principles, . . . and to the transference of one of the most important departments of Surgical practice, from the stage of contradictory teaching to scientific generalisation.”

The volume consists of an appendix and eight lectures. Seven of the lectures have been delivered at various times since 1862 to the students at the Queen's Hospital; the eighth is a condensation and revision of several addresses to students and papers to Medical societies. The appendix explains by descriptions and illustrations how the principles of treatment contended for in the lectures are to be put into practice.

The points upon which conflicting opinions have been, and still are, held by Surgeons and Surgical teachers of eminence, and which Mr. Gamgee discusses, are numerous, the most prominent being the advisability of setting fractures at once, or after two or three days have been allowed for the subsidence of swelling; whether all fractures are or are not accompanied or followed by swelling at the seat of injury; whether the displacing force acting upon the ends of a fractured bone is entirely vital—*i.e.*, muscular—or whether it is partly vital and partly physical, and sometimes wholly the latter.

The treatment which the author contends for is one which has been long employed by him, and that, too, continuously, since he first put it into practice in University College Hospital in 1852. He states that he has again and again proved the advantage of it over other methods. He quotes many cases in support of it, and urges its claims upon physiological grounds. Its characteristics are, in his own words, “Firstly, immediate reduction, regardless of spasm, blebs, extravasation of blood, or inflammatory swelling; secondly, circular compression; thirdly, immobilisation.” He emphatically denies that the great feature of the treatment is a *starched bandage*, which he considers as little more than an efficient substitute for the pins ordinarily employed in bandaging. He, too, justly

condemns the confusion of a *compressing* with a *constricting* apparatus.

The author advocates his subject in language which is sometimes exaggerated and extravagant, generally high-flown, and always expressive of the completest self-confidence. Still, he has the merit of being clear and unequivocal, if dogmatic, and when argumentative his conclusions are, to our thinking, correct.

The work carries the impress of being the outcome of much earnest study and thought, and the result of long and wide experience, and we give credence to the author's assertion that, like Byron, when asked to perpetuate his curses to tyranny, he has taken care “to chew the cud before writing a line.”

Though not exactly a work of easy reference for busy Practitioners, still to all who are concerned in the treatment of fractures it offers a large supply of material for thought, and the method of treatment it defends deserves a much wider trial and a much more dispassionate consideration from Surgeons than it has hitherto received.

NEW BOOKS, WITH SHORT CRITIQUES.

Photographic Clinique of the British Hospital for Diseases of the Skin. Edited by BALMANNO SQUIRE, M.B., Surgeon to the Hospital. No. I. Oval or True Keloid.

* * * We have received the first number of this publication, and feel bound to say that it is a photograph of unusual excellence. Attention may be also drawn to the exceptional size of the photograph and the nevertheless unimpaired sharp definition of detail. Persons engaged in photography well understand the difficulty of combining so much distinctness with such size of detail, and an expert in photography would be able to see that the photograph is obtained *direct*, without intermediate process of any kind—a great advantage as regards the important matter of clearness of definition. The size achieved has not been attained, as it usually is, by the process of enlargement from a smaller photograph, nor has the photograph been “touched” either on the negative or the positive by any hand except that of the colourist. The photograph is superior to any photographs of skin diseases as yet published, inasmuch as the detail is much larger and the definition, nevertheless, clearer than in the series previously published by Mr. Balmano Squire. The subscription-list still remains open for the current year at a slight increase of rate—*viz.*, 22s. prepaid—the subscription-list of 21s. being restricted to those who paid their subscription before the commencement of the year. All communications should be addressed to the Secretary, at the Hospital, Great Marlborough-street.

Il Barth, Gazzetta di Medicina e Scienze Naturali. No. 6. Del Dr. GAVINO GULIA. Malta. March 9, 1872.

* * * The only fault of “Il Barth” is its small size. It contains Medico-legal notes on the assertion hazarded by some Maltese Physicians, that it was possible to distinguish the dried stains of human blood from those of animals. The Editor's verdict is supplemented by that of Dr. J. Denis Macdonald, R.N., F.R.S. There is a case of diabetes treated by lactic acid and nitrogenous food by Dr. Carmelo Borg; a good account of *Coca*, reprinted from Dr. Scrivener's papers in the *Medical Times and Gazette*; and some interesting notes on the botany of the island.

TREATMENT OF DYSENTERY.—Dr. Dale reports that the following formula has been for many years employed by the Practitioners of Kentucky with great success:—Sulphate of soda, ʒj.; sulphate of morphia, 1 grain; water, ʒvi. A tablespoonful every two hours until free watery evacuations are produced. The interval is then to be increased to four hours, continuing the mixture until the dysenteric symptoms cease. Thus administered in the early stages of spasmodic dysentery, it seldom fails to control the disease in two or three days.—*N. Y. Med. Record*, Feb. 15.

REMOVAL OF PLASTER-OF-PARIS BANDAGES.—Dr. Carsten states that this is very easily accomplished by employing a concentrated solution of chloride of sodium. If the bandage be moistened with this, it becomes so yielding in a few minutes that a sharp knife finds little resistance. In the cut thus made some more of the solution should be poured, and after repeating this three or four times the bandage can be easily removed. The same solution is also very useful in cleansing the hands and nails of the operator.—*New York Medical Record*, February.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, March 26.

STUDENTS' ROW AT THE FACULTY OF MEDICINE; LIST OF PROFESSORS, LECTURES, AND HOURS; M. DOLBEAU, ALLEGED CAUSES OF HIS UNPOPULARITY—ALCOHOLISM—M. LITTRÉ—NEW SOCIETY OF POSITIVE SOCIOLOGY—SOCIÉTÉ PROTECTRICE DE L'ENFANCE.

THE opening of the summer session of the different Faculties took place during the course of the week, but that of one of the Professors of the School of Medicine was marked by scenes of a most scandalous nature. Allow me, first of all, to give you a programme of the course of lectures for this session, which I give in French, in order that your younger readers may familiarise themselves with the names and subjects of the leading members of the Profession in Paris before they visit Paris:—

FACULTÉ DE MÉDECINE.

Les Cours d'Été de la Faculté auront lieu dans l'ordre suivant.

- Histoire naturelle médicale—M. Baillon, Lundi, Mercur., Vend., à 11 heures.
 Physiologie—M. Bécлар, Lundi, Mercur., Vend., à midi.
 Pathologie chirurgicale—M. Dolbeau, Lundi, Mercur., Vend., à 3 heures.
 Médecine légale—M. Tardieu, Lundi, Mercur., Vend., à 3 heures (petit amphithéâtre).
 Pharmacologie—M. Regnaud, Mardi, Jeudi, Samedi, à 11 heures.
 Accouchements, Mal. des Femmes et des Enfants—M. Pajot, Mardi, Jeudi, Samedi, à midi.
 Anatomie pathologique—M. Vulpian, Mardi, Jeudi, Samedi, à 2 heures.
 Pathologie médicale—M. Hardy, Mardi, Jeudi, Samedi, à 3 heures.
 Hygiène—M. Bouchardat, Mardi, Jeudi, Samedi, à 4 heures.
 Thérapeutique et Matière Med.—M. Gubler, Mardi, Jeudi, Samedi, à 5 heures.
 Clinique médicale—M. Bouillaud (supplée par M. Blacher, agrégé), à la Charité; M. G. Sée, à la Charité; M. Behier, à l'Hôtel-Dieu; M. Lasègue, à la Pitié—tous les jours le matin, de 8 à 10 heures.
 Clinique chirurgicale—M. Richet, à l'Hôtel-Dieu; M. Gosselin, à la Charité; M. Duplay, agrégé, à la Pitié—tous les jours le matin, de 8 à 10 heures.
 Clinique d'Accouchement—MM. Broca et Depaul, à l'Hôp. des Cliniq. et de la Faculté, tous les jours le matin, de 8 à 10 heures.

Cours Cliniques Complémentaires.

- Maladies des Enfants—M. H. Roger, à l'Hôp. des Enfants, Lundi, Jeudi, Samedi, à 8½ heures.
 Ophthalmologie—M. Trélat, à la Charité, Jeudi (leçon clinique) à 4 heures; Samedi (exerc. ophthalmolog.) à 4 heures.
 Maladies syphilitiques—M. Fournier, à l'Hôp. de Lourcine, le Jeudi, à 9 heures.

Cours Complémentaire.

- Chimie—M. Gautier, Lundi, Mercur., Vend., à midi, petit amphithéâtre.

On Wednesday, the 20th inst., M. Dolbeau, Professor of Surgical Pathology, was at his post at the appointed hour, but long before that time the students began to assemble in the court, and when the doors were open about 2000 entered and took their seats in the amphitheatre. At three o'clock M. Dolbeau made his entry, preceded by the beadle, and was received by a salvo of cheers, soon overpowered by a storm of hisses. For about five or six minutes after this vociferous demonstration there was a comparative dead silence, during which M. Dolbeau remained impassible. Some of the rebellious students finding that the Professor did not seem disposed to break the silence, redoubled their hisses, which were this time mingled with cries of "A la porte le dénonciateur! Qu'il donne sa démission! M. Dolbeau, expliquez-vous!" This cry became more general; soon after which one of the students approached the demonstration board, and with a piece of chalk renewed the demand for an explanation of the Professor's conduct in an affair which will be noticed hereafter, while at the same time slips of paper to the same purport were being circulated in the amphitheatre. To this the friends of M. Dolbeau responded that the Professor had no explanation to give them. At these

words the clamours and hisses increased; the most insulting epithets were showered on the Professor, accompanied by volleys of paper balls and coin, the latter being conspicuous by the absence of gold and silver. One reporter even took the trouble of collecting the money, which is stated to have amounted to about fifty sous! These M. Dolbeau received with silent contempt. Then followed a general move, and the rival parties seemed to be on the point of coming to blows; but the fistic mode of deciding quarrels being unknown in France, this part of the scene ended in clouds of dust. During all this time the Professor remained seated in his chair in a dignified attitude, while the rebel students were determined not to allow him to utter a word.

This uproarious state of things continued for nearly an hour, when M. Wurtz, the Dean of the Faculty, made his appearance; and, although very popular, he was powerless to appease the wrath of the students. He was, however, cheered by them, which he gracefully acknowledged; and then, going up to M. Dolbeau, shook him by the hand, and after exchanging some words with him offered him his arm, and conducted him out of the theatre. M. Wurtz soon after returned, when he was again received with hearty cheers, and he caused the following to be written on the board:—"Que les manifestants quittent les gradins, et envoient leurs réclamations par l'organe d'un délégué?" None of the students had the courage to respond to this. So, after having rebuked them for their scandalous demeanour, the Dean said that such conduct, which occurred almost every year, would not only give the public an unfavourable opinion of the discipline of the School, but that they were thwarting their own interests in interrupting their studies, which were already so long suspended by the painful circumstances to which all had been more or less subjected, and from which the country had scarcely recovered itself, and he finished his discourse in the following terms:—

"Messieurs, vous abusez véritablement de la résolution que j'ai prise d'éviter à l'École la présence des agents de la force publique. Mais sachez que de telles manifestations ne sauraient rester impunies, et que je suis plus que jamais résolu à y mettre fin. Quant aux faits reprochés à M. Dolbeau, ils sont tout à fait en dehors du Professeur."

This latter theory of separating the man from his official capacity, and of reviving the theory of two distinct moral agents existing in the same individual, did not seem to satisfy the radicals.

After this short allocution, M. Wurtz left the amphitheatre, and recommended the students to do the same. This was done in the greatest order.

Stringent measures were taken to prevent a recurrence of the disorder, and the following resolution, signed by the Dean, was pasted up in different parts of the School and principal Hospitals:—"En raison des désordres graves qui se sont produits dans la journée du 20 Mars, la Faculté a pris la décision suivante à l'unanimité:—1. Les élèves en médecine seuls pourront entrer dans l'École, sur la présentation de leur feuille d'inscription. 2. Si les désordres se renouvellent les cours seront suspendus." And the following injunction was noticed on the demonstration board in the amphitheatre:—"La suspension des cours et des examens ne pouvant que nuire à beaucoup d'étudiants, ne serait-il pas sage de s'abstenir de faire une seconde démonstration?"

Notwithstanding this, much the same disgraceful scenes took place on Friday. M. Dolbeau was obliged to leave the theatre. M. Wurtz was equally unsuccessful, and he therefore announced the closing of the School, which resolution was pasted on the principal entrance of the School in the following terms:—"Les cours et les examens de la Faculté sont suspendus. Une affiche ultérieure fera connaître la date de la réouverture;" which produced great consternation among all concerned, innocent as well as guilty, as this will not only interfere with their studies, but may be the means of blasting their prospects in life.

Now as to the cause of these disturbances. You will of course be prepared to have different versions of the whole affair. M. Dolbeau is accused of having denounced two "Federates" who were under his care in the Hôpital Beaujon when the Versailles troops entered Paris in May last year, one of whom was set at liberty, and the other shot on the spot. It turns out, from authentic information, that this is totally incorrect, and the real facts have been most shamefully misrepresented. The truth is, M. Dolbeau is very unpopular among the students, as he is said to be unnecessarily severe at the examinations and in his Hospital discipline. He is perhaps the ablest Surgeon in Paris, but so reserved and little communicative as to be considered surly and conceited. Moreover, when

called in consultation by some of his *confrères*, he is said to speak disparagingly of them—and in their presence, too—to patients; which, if true, would justify his *confrères* in shunning him as they would a viper. It will be remembered that these “manifestations” have taken place from time to time; some of them may have had a political significance, but the greater part have occurred with Professors who are unusually severe at the examinations, and this goes to prove the inexpediency of having the offices of teacher and examiner filled by the same person. I shall, with your permission, write more on this latter subject on a future occasion.

The School of Medicine will be closed during the Easter holidays, which last for a week, commencing from to-morrow. It is to be hoped that the “*mutins*,” as the rebel students are called in French, will have had sufficient time for calm reflection, and return to their benches wiser and better men than when they left them.

In your editorial of last week I find you notice the formation in Paris of an “Association against the Abuse of Alcoholic Drinks,” and you very justly express your surprise that such an association had not been organised before now in France. The French are a very sensitive people, and they look upon all innovations with suspicion. When anything new is mooted, they are tardy in accepting it, as they are always afraid of an attempt on their liberty—a thing so greatly cherished by the French, and yet so ill-used, as we on this side of the Channel know to our cost. There already exists in Paris an Association against the Abuse of Tobacco. Alcoholism is increasing to an alarming extent in France. Among the principal causes of suicide habitual drunkenness ranks as one of the first, and M. Legoyt, the official statistician to Government, has made the alarming statement that, owing to this cause, to every woman who commits suicide there are seven men.

A meeting of the Medical members of the National Assembly has just taken place at Versailles, under the presidency of the illustrious M. Littré, to examine and report upon the subject for submission to the Chamber of Deputies. A warm discussion took place on the minute proposed by M. Theophile Roussel, which is to the effect that if any individual who, under the influence of alcoholism, commits a crime is acquitted on the plea of irresponsibility, he ought to be condemned for drunkenness and punished very severely. This proposition was negatived, and no other resolution has for the present been adopted. In St. Petersburg and other large cities of Russia drunkenness is considered a crime, for which the culprit is flogged in public; and if this were adopted in our more civilised towns, we should see fewer of those degrading scenes that are occasionally witnessed in the streets.

Apropos of M. Littré, I may mention that the great lexicographer and Academician is organising a Society in Paris entitled the “*Société de Sociologie*”; and from its programme I learn that the object of the Society is “the scientific study of social and political problems.” Its fundamental principles are those of positivism, and the Committee of Management for the present year consists of M. E. Littré, President; MM. Ch. Robin and G. Wyruboff; MM. T. E. Cathelineau and Antonin-Dubost, Secretaries; and M. Caubet, Treasurer and Archivist. There are already twenty-five members, and these are styled “*membres fondateurs*.” There are as yet but two corresponding or honorary members named, the celebrated J. Stuart Mill, of England, and M. de Roberty, of Russia.

One of the most useful Societies in France is, beyond doubt, the *Société Protectrice de l'Enfance*, which, as its name implies, is intended for the protection of infants, particularly those brought up by wet-nurses or by the hand, and prizes, consisting of bronze medals, accompanied with a certain sum of money, are annually distributed to those nurses who exhibit the healthiest babies. This boon has just been extended to mothers, in order to encourage them to nurse their own children. At the last annual meeting of this Society, which was held only lately, a woman, the wife of an artisan, exhibited a triplet a few weeks old. They seemed well developed, but I am afraid they will not live long, as the mother, not being sufficiently strong to nurse them, is obliged to bring them up by the hand. She received a small donation as an act of charity, and I suppose by way of encouragement, as the Society is justly alarmed at the gradual degradation and depopulation of France. Besides these prizes, others, in the form of medals, are awarded to the most meritorious inspectors, whose functions are to have a surveillance over the children in the provinces; and, lastly, prizes are annually offered to the best authors on subjects proposed by the Society. That for the present year is “*Des Causes du Rachitisme*,” and the prize offered is £20,

with or without a gold medal, according to the option of the Prize Committee. The subject is open to public competition, and even foreigners are admitted. The manuscripts, written in French, are to be forwarded, post paid, to the Secretary, Dr. Alex. Mayer, 17, Rue Béranger, and should reach his office before November 1, 1872. The manuscripts are not to be signed by the authors, but a motto is to be affixed instead, which will correspond with a similar one on a sealed envelope enclosing the real name and address of the author. Papers rejected will not be returned. I may here mention that the Society is composed of members of both sexes, lay as well as Medical, its present President being M. Bédard, Member of the Academy of Medicine and of the Council of General Salubrity. An urgent appeal is made to all interested in the work; and this, I should say, would be the proper field for the gentler sex.

PROVINCIAL CORRESPONDENCE.

BIRMINGHAM.

March 20.

SMALL-POX still continues to prevail extensively in this town. The number, as reported by the sanitary inspector for the borough, for the week ending March 16, shows a decrease of twelve cases on the number reported in the previous week. The total number of cases reported up to the present time is 1062—Number of new cases 44, number vaccinated 39, not known 1, number not vaccinated 4, cases at workhouse infirmary 74, cases at Queen's Hospital 9, cases recovered 34, deaths 6, number of cases remaining 119. The accommodation provided for the reception of cases is none too great. At the workhouse a building has been erected by the guardians for pauper and other patients, and a special Medical officer has been appointed to take charge of them. We are informed that this Medical officer does not, however, possess the Professional qualifications required by the Poor-law Board. Whether or not this be correct, the reports which he has from time to time issued show him to be a man not deficient in skill and judgment.

The Parish Dispensary gives complete satisfaction to all parties. To the guardians it has proved a valuable auxiliary to parochial dispensation by reducing the amount of pauperism; the Doctors are quite satisfied with it, inasmuch as, among other reasons, their private residences now are private, the patients are better disciplined and physicked; and the public is at last satisfied that the poor are properly attended, and get good medicines. Even the patients themselves express gratitude for the new and improved order of things. The sanitary question, so far as it will affect Poor-law Medical Officers, is the question with us here. From what we can gather, our parish Doctors are not indisposed to act in the capacity of sanitary inspectors—in fact, they would regard the appointment with favour, providing that suitable stipends be attached to them. They do not in this respect agree with the views of their *confrères* at Cardiff. Some little time since the guardians, owing to the outbreak of small-pox, took the “contagion” alarm, and made a tremendous outcry about the number of patients who were in the habit of assembling in the waiting-hall. They imagined that a focus of disease would be created, and that even themselves would become victims of pestilential disorders. This not altogether unreasonable fear ended in good results, for, on inspection of the premises, the chief nuisance was discovered—not in the assemblage of patients, but in an indescribable quantity of noisome rubbish lying *perdu*, consisting of bygone cleanings, and which emitted the rankest odours. This being removed, together with a thorough cleansing, the place became so sweet as to defy the most sensitive nostril. The end of it all is that the Dispensary is pronounced by friends and foes alike to be a perfect success. At the outset the Medical officers thought that the system would entail too much clerical labour, but this belief has vanished under the test of experience.

The Committee of the Queen's Hospital has paid the working men a graceful compliment as an acknowledgment of their labours on behalf of the Extension Fund. From amongst their number twenty have been appointed life governors of the Hospital. This infusion of the real working element will, it is hoped, stimulate the artisan classes to take a more active share in the sustentation of the charities which are mainly erected for their benefit than they have hitherto done. The working men have certainly accomplished a great deal

for this institution; still, to make amends for past shortcomings, much more is due from them.

At the branch meeting of the British Association a few days ago a most unseemly uproar occurred. It arose out of the "Club question." Some half a dozen gentlemen of good Professional standing (holding anti-Club opinions) having been proposed as members, were unanimously blackballed. This, of course, gave great offence to their proposers and partisans. What the result of the row may be we will not be rash enough to predict.

SCOTLAND.

EDINBURGH, March 25.

To all who desire to see the distracting question of female medical education finally disposed of, the position which that question has now assumed will be a matter of congratulation. At the instance of the lady-students, a Court of Session summons has been served on the Senatus Academicus and Chancellor of Edinburgh University, with the view of having it declared that the University is bound to provide for and complete the Medical education (including graduation) of lady-students. The pleas in law advanced by them are as follows:

"1. According to the law and constitution of the University of Edinburgh, women are entitled, on payment of matriculation and Professors' fees, to attend the classes of any Professor as students, and are entitled to demand instruction from such Professor, which he is bound to give to them.

"2. According to the law and constitution of the University of Edinburgh, women are entitled to obtain degrees in Medicine, on proving that they are qualified in point of attainments and knowledge for that distinction. And the Senatus Academicus, whose province it is to regulate the teaching and discipline of the University, are bound to provide instruction to them, to admit them to examination as candidates for Medical degrees, and, on being found qualified, to recommend them to the Chancellor, in order that he may confer such degrees upon them.

"3. The pursuers having paid their matriculation fees, some for one, some for two, some for three years, on the faith of being permitted to continue their course of study with a view to a profession, and having gone on with this course of study by attendance on the classes of Professors, and this with the knowledge of the Senatus Academicus, the latter are now barred from pleading that women are not entitled to receive instruction at the University, or to obtain Medical degrees.

"4. According to the laws by which Universities are governed, and apart from any special circumstances connected with the University of Edinburgh, women were entitled to demand and receive instruction from the Professors in their ordinary classes, and also were entitled to graduate; and the University of Edinburgh being modelled on the constitution of such other Universities, and being subject to the same laws, women are entitled to all such privileges from the University of Edinburgh."

Certainly, it is painful to see the Senatus Academicus and Chancellor of the University summoned into a court of law by a handful of wilful women who will have their own way. It would unquestionably have been much better had these venerable parties, with the forethought which might have been expected from them, looked before they leaped; and it is difficult to find palliation for their offence. To some of the ladies' most headstrong and headlong supporters out of the University doors, the excuse might be granted that "love is blind"; but there can be no such excuse for the unwarrantable and unkind dalliance of the University potentates.

It does, however, seem as though even they have been these few years spell-bound, and that they are only now finding the pleasing and easily pleased fairies of their dream suddenly transformed into veritable nightmares, whose talons are on their throats, and who threaten to take the wind out of them.

It is a popular belief that a nightmare ends either in awaking or in death. We would still indulge the hope that, to the University authorities, the end of theirs will be awaking, and that soon this incubus will be a dream of the past.

The decision of the legal point involved in the question of the admission of females into the University, which ought to have formed the starting-point of the whole matter, is now attempted to be made the hinge on which a door already constructed is to turn. It does not follow, however, that it will be so easy to close, or to avoid throwing wider open a door which has been made, as it would have been to have refrained from making it at all. Had the legal question been settled at first, the right of females to study Medicine would have been

decided on the simple merits of the case. Now, however, it has become almost inseparably connected with, and weighted by, blunders of omission and commission on the part of the University authorities, which may go far to turn the balance in favour of the ladies.

It is almost self-evident that if we admit the right of ladies to become matriculated students of the University, we must allow that they are entitled to all the privileges of students of the University.

But if it is a question whether the University authorities, after having granted the ladies permission to become matriculated students, are not bound to grant them degrees, it is also a question whether, in allowing them to matriculate at all, they have not exceeded their powers.

This matter can never be satisfactorily settled on the strength of steps already taken, the legality of which is questionable; and although the University authorities by their past conduct may have greatly weakened their present case, and have taken the arguments out of their own mouths, in a court of law the public expect, and have a right to expect, that the points at issue will be tried apart from, and unprejudiced by, past inconsistencies and blunders on the one side or on the other.

GENERAL CORRESPONDENCE.

MORPHIA PLUS CHLOROFORM.

LETTER FROM MR. FREDERICK JOS. MAVOR.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have the pleasure to inform you that I have for some years used morphia in conjunction with chloroform in cases of enteritis in the horse. My mode of proceeding has been to administer subcutaneously a full dose of morphia, and if the severe and violent pain was not relieved in a few hours, to cast the horse and administer chloroform by inhalation, when I have produced by one ounce of chloroform a profound and unbroken sleep for seven or eight hours, my patient waking convalescent. I may add that I am at the present time experimenting with the vegetable alkaloids in conjunction with chloroform, and, should I have anything worth recording, will again communicate with you. I am, &c.,

FREDK. JOS. MAVOR, M.R.C.V.S.

91, Park-street, Grosvenor-square, S.W., March 25.

RUPTURE OF THE HEART.

LETTER FROM DR. THOMAS B. DIPLOCK.

[To the Editor of the Medical Times and Gazette.]

SIR,—There are many, probably, to whom a statistical report of the comparative frequency of death from rupture of the heart will prove of interest sufficient to justify the insertion of the following report. The saying, "He died of a broken heart," may, indeed, be more frequently true in its absolute than in its metaphorical sense.

The preventive care of nature was proved by one case in which the apex of the left ventricle had become extremely thin; but rupture was prevented by the apex having become adherent at that part to the pericardium. Overcrowded or ill-ventilated dwellings will induce a tumultuous action of the heart, or even spasm that may cause death, and of course if any part of the heart is attenuated it may then give way.

Verdicts of Rupture of the Heart.

	Date.	Name.	Parish.	Age.	Sex.	Ruptured at
1	1868: April 3	S. D.	Chelsea	68	F	...
2	1869: Jan. 6	A. M. J.	Kensington	81	F	Apex of left ventricle
3	Feb. 6	W. G.	Feltham	57	M	Ditto
4	Oct. 4	H. F.	Fulham	26	M	Ditto
5	1870: June 13	M. A.	Hammersmith	51	F	Ditto

Verdicts of Disease of Heart other than Rupture.

1868.	1869.	1870.	1871.	1872 (to Feb. 29).
50	69	68	79	11

I find from a committee report presented to the magistrates of this county in February, 1862, that the area of the Western Division is stated to be 109,000 acres (about 171 square miles) and the population 285,537—this latter by the census of 1871 is 416,547; therefore, taking the average population as 375,000, it appears that the average number of deaths from rupture of the heart is one annually for 90,000 persons. The average number of sudden deaths from other diseases of the heart would be one annually for every 6000 persons.

The return for 1868 is for ten months only, dating from my selection at the end of February in that year.

I am, &c., THOS. B. DIPLOCK,

Coroner for the Western Division of Middlesex.
Coroner's Office, Ranelagh House, Fulham, March 5.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 12.

T. B. CURLING, F.R.S., President, in the Chair.

MR. WM. MACCORMAC read an account of a case of Resection of the Shoulder- and Elbow-joints in the same Arm, for Gunshot Injuries. This paper detailed the history of a French soldier who had been wounded at the battle of Sedan. The right arm, in the region of the shoulder- and elbow-joints, was extensively injured, the soft parts being much lacerated and the bones extensively comminuted by a shell explosion. The question arose whether it was at all possible to save the limb. Rather, however, than perform disarticulation at the shoulder-joint, Mr. MacCormac determined to excise both the shoulder- and elbow-joints—an operation hitherto, he believed, unique. The patient narrowly escaped death from pyæmia, but he afterwards made a satisfactory recovery; and the interest of the case centres in the amount of usefulness subsequently enjoyed by the limb. Some portions of necrosed humerus have yet to come away, and in the deltoid region a sinus still remains. The elbow is soundly healed, and regeneration of the excised bones has taken place. The operation was performed subperiosteally; and in the after-treatment the limb was supported on carefully adjusted cushions—a method Mr. MacCormac prefers in most cases to the employment of splints. The shoulder can now, after an interval of eighteen months, be moved freely backwards and forwards, but not raised from the side, the deltoid muscle having been almost completely destroyed by the original injury. Flexion, extension, and rotation are very perfect in the elbow, and the usefulness of the hand is nearly as good as before. Four inches of the upper end of the humerus, very greatly comminuted, was removed; and a long piece of ulna, in addition to the head of the radius and the articulating condyloid surface of the humerus, required removal. Mr. MacCormac considers that he may fairly claim this case as one of successful double resection of the two principal joints in the same upper extremity.

The PRESIDENT remarked that this case was probably unique, and as such very interesting.

MR. CROFT thought that splints were worse than useless in cases of resection in the upper extremity; had always used sand-bags with very good effect; and asked the author what special means were adopted to keep the limb quiet.

MR. TIMOTHY HOLMES thought that all excisions might be treated without splints; but he preferred in elbow cases to use a very light splint, which really did no harm, and was specially adapted for children. He quoted a case in which no splints were used, a result being that the ends of the bone eventually projected from the wound. He asked for Mr. MacCormac's experiences as to subperiosteal operations; believed that the amount of bone saved was often hurtful rather than beneficial; instanced a case in point; and remarked that in successful excisions of the head of the humerus the arm can always be moved some way from the trunk, though the want of power in this case may have been caused by the great amount of injury done to the deltoid muscle.

MR. JOHN WOOD had discarded splints for some time; and ten days after the operation, commenced and continued to alter the position of the limb once every twenty-four hours, believing

that with careful and frequent manipulation a very fair olecranon may be produced. He presumed that the question of splints or no splints entirely depended upon whether a movable or an ankylosed joint was required.

MR. SPENCER WELLS quoted a case that had occurred to a Continental Surgeon at Metz, in which a subperiosteal section of the entire humerus was successfully made. He believed that in active service splints were necessary, and that plaster-of-Paris bandages answered exceedingly well.

MR. THOMAS SMITH failed to comprehend how splints could be safely or properly dispensed with, and averred that with children they were absolutely necessary.

MR. MAUNDER thought that the question of splints wholly depended upon the sort of joint desired. He rarely used splints at all for the elbow, except in cases of children, and then only during the first week, but always applied them in knee cases, though he considered it an open question in excisions of the hip.

MR. CALLENDER was surprised that no reference had been made to the very capital anterior splint used in America, and asked Mr. MacCormac why no effort was made to save the limb in its entirety.

A VISITOR (an American Surgeon) said that the bent wire splint was much used in the United States, and believed that, in subperiosteal operations, mischief was sometimes caused by the subsequent growth of awkward spicula, which might, and indeed sometimes did, endanger arteries.

MR. SAVORY commented sarcastically on the varied experiences and the various facts that they had heard in the course of the discussion. Believing it to be an axiom in Surgery that repose was necessary to repair, he was surprised to hear Surgeons advocating a "perpetual motion" sort of practice with reference to excised joints. He also took exception to the title of the paper, inasmuch as about four inches of the humerus and a large mass of the ulna were removed by the operation.

MR. MACCORMAC, in replying, answered this last objection by remarking that the fragments alluded to were detached, lying in the wound bathed in pus; so that there was no option as to their removal.

MR. T. HOLMES read a paper "On the Surgical Treatment of Suppurating Ovarian Cysts, and on Pelvic Adhesions in Ovariectomy." A case is related in which chronic suppuration occurred in an ovarian tumour, after paracentesis had been performed for the first time. Ovariectomy was postponed for some months on account of the patient's condition. When it was performed the cyst was found extensively adherent in other directions, and so tightly wedged into the pelvis that it was impossible to reach its pedicle. It contained about a gallon and a half of fluid, of which about half was pure pus. The remains of the emptied cyst was dragged out of the abdomen, a clamp was applied to its neck (at a distance above the pedicle which could not be accurately ascertained), and the wound was closed. The patient recovered, and after her recovery no sinus was left, nor was any tumour to be felt. The symptoms of acute and chronic suppuration in ovarian cysts are discussed, and it is attempted to be shown that if the general condition admits of it the suspicion of suppuration is a reason for performing the operation instead of delaying it. The case is also used to show that, in some instances, the results of ovariectomy may be perfectly favourable, though pelvic adhesions have prevented the complete delivery of the tumour. If the neck of the cyst admits of being embraced in a clamp, the lower portion of it may be obliterated during the healing of the wound. The superiority of this method, when feasible, to the other courses which may be pursued in dealing with pelvic adhesions, is shown.

MR. BRYANT remarked that the accurate diagnosis of a suppurating ovarian cyst was most important; that wasting, a hot skin, a permanently high temperature, bad appetite, local pain and tenderness on pressure, all indicated suppuration. If any doubt as to the diagnosis exists, he would be still more induced to interfere quickly, to remove the cyst if possible, or to take away as much as could be removed. He quoted a case to show the desirability of not leaving ligatures, and one also that showed the useful peculiarities of catgut.

MR. SPENCER WELLS said that the diagnosis between an inflamed or suppurating ovarian cyst and peritonitis was generally easy, the chief point being that with a suppurating cyst there was considerable elevation in the temperature of the body, especially at night. In the morning it would range from 99° to 101°, and in the evening rise to 103° or 105°. In peritonitis, on the contrary—unless it were of the septic type—there was either no rise of temperature, or it might even fall

to about 97°. But practice would be the same in either case. Whether the patient's life is in danger from a suppurating cyst, or from peritonitis set up by the presence of the cyst, or from escape of ovarian fluid into the peritoneal cavity, the cyst and fluid should be removed. He had learned this lesson from Sir Thomas Watson. Operating with Dr. Farre on a lady whose peritoneum was acutely inflamed from the bursting of an ovarian cyst, they were very fearful of an aggravation of the peritonitis; but Sir Thomas Watson, with the rare clinical sagacity which was his great characteristic, said, "Now the irritating cause is removed we may hope the irritation will subside." And it did so in this case and in several others since. In one step of the operation he thought Mr. Holmes might have adopted a safer plan than separating the adhesions before emptying the cyst. These adhesions prevented any purulent or fetid fluid in the cyst from entering the peritoneal cavity, and in most cases it was generally better to completely empty the cyst before separating any adhesions. In cases where the cyst could not be removed a cure might sometimes be obtained by draining the cyst through a tube and daily injections of iodine or carbolic acid.

Mr. HOLMES, in replying, doubted if the diagnostic signs spoken of by Mr. Wells were positive as well as negative, because in some cases high temperature exists without suppuration, and in some cases of peritonitis the temperature has been persistently high.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 19.

Mr. HILTON, F.R.C.S., President, in the Chair.

Mr. SEBASTIAN WILKINSON exhibited a patient from the Central London Ophthalmic Hospital, the subject of Congenital Disease. This consisted of a kind of conjunctiva covering the whole of the eyes, or nearly so. It was vascular in its nature, but the outer part seemed thicker than the central portion. It was loosely attached. He had removed part of it, and the condition had slightly improved.

Mr. HUTCHINSON exhibited a Meningocele from the back of the head of a child 10 months old. The tumour was congenital, and cystic. It seemed tempting for removal, but experience had warned him against this, and he opposed it. He tried the tumour in various ways; it did not fill with the child's crying, and it had a very distinct pedicle. Its parents were very anxious to have it removed, and at last he consented to do so, under protest. The child did well. The specimen showed a communication with the interior of the skull, and there was a vein in the pedicle which bled freely when the child cried. The cyst did not communicate with the meningeal cavity. He acknowledged that in operating he had offended against the rule.

Mr. HULKE mentioned two cases showing the undesirability of interference. One tumour was situated at the root of the nose; removal was declined; but another Surgeon took it in hand, removed it carelessly, and death followed. He had seen another at the back of the head, where there seemed to be no communication with the cerebro-spinal cavity. It was dissected out, and its root could be traced to the cord. Inflammation followed, and death. No tubular communication with the meningeal cavity could be made out.

Mr. T. SMITH confirmed this opinion. One which had been ligatured was brought to him. This ligature was rather loose, though it had eaten into the flesh, so he recommended another rather tighter. This was applied, and death followed.

The PRESIDENT remembered one on the top of a child's head on which Mr. Aston Key operated. After death he found a cord going down by the corpus callosum to beneath the lateral ventricles.

Mr. HULKE said several cases of tubular communication with the ventricles had been recorded by Billoth. One had been tapped, and iodine employed.

Mr. HUTCHINSON exhibited certain specimens illustrative of one form of Chronic Arthritis characterised by no outgrowths, but great destruction of cartilage. He thought this distinct from the ordinary kind. He first saw the patient after a return from Bath, where he had been treated for rheumatism. He had been its subject for years, and the attacks simulated those of acute gout, but never passed entirely off. He suffered from erysipelas in the leg, but got well from that, though the leg remained crippled. All the joints in his body grated more or less. After this he had a sudden relapse in his knee, which

had not previously suffered much. He expected this would subside as the other attacks had done; but it did not, and by-and-by there were signs of pus being present, so Mr. Hutchinson removed the limb. The knee was in a state of acute inflammation, and there was no eburnation. The ankle-joint, which exhibited no trace of swelling, had its cartilage thinned, and was extremely congested. Every joint examined was like this, and he thought every joint in the man's body was similar. The patient was a steady man, and there was no reason given for the onset of the disease. His brothers were like him in condition; his sisters complained of rheumatic pains only. The condition did not appear to be hereditary.

Mr. HUTCHINSON also exhibited certain other specimens illustrative of the same condition in a subject sent from the workhouse. The subject had been sent for operation, and was a man aged 61, a Spaniard by birth, who had been in the house eight years. The joints of one hand did not seem to be affected, yet they crepitated. The other hand was contracted. Other parts were in a similar condition. The knee cartilages were almost entirely removed, and there was great blood-staining.

In reply to Mr. Croft, Mr. HUTCHINSON said that the urine of the former individual had been examined and only lithates found. He had much improved in health since the operation.

Mr. W. ADAMS considered that in the whole group of cases there was an absence of tendency to pus or ankylosis, though the knee-joint was full of grumous pus. There was no resemblance to the nodular form of rheumatic arthritis. In some there was a tendency to favour ankylosis.

Mr. HUTCHINSON said that even in the ordinary cases there were exceptions as to ankylosis and suppuration.

Dr. EDWARDS-CRISP, referring to the fact that the patient was a steady man, said the worst cases he had seen were in teetotalers.

Mr. HUTCHINSON said one of the affected brothers had been a hard drinker all his life.

Mr. DURHAM exhibited a portion of a Hydatid Tumour removed from the thigh of a woman, aged 41. Six years ago a swelling began in the left thigh, which after a time was fixed, though movable at first, and gradually increased in size. A kind of second swelling after a time became amalgamated with the former, and united to constitute an enormous mass, which was red, hard, and tender. Two small openings appeared, but no pus came away, only a kind of membrane, which was detected as a portion of a hydatid cyst. He tried to operate, but found the mass intimately connected with the vessels. He removed a portion, scooped away others, and left the rest. There had been much inflammation, but no true suppuration.

Mr. COOPER FORSTER exhibited Two Breasts removed that day from women aged 54 and 58 respectively. They had been supposed to be malignant, but, though of enormous size, he was not quite certain of that now till more carefully examined. There was no gland enlargement, and no indurated skin. (Referred to Morbid Growth Committee.)

Mr. SAUNDERS exhibited for Mr. Stewart a specimen of Recurrent Sarcoma of the Breast, following an old mammary abscess. The tumour, which was cystic; was tapped, and afterwards removed. There was no gland infiltration. It returned again and again, finally assuming the characters of cancer. Exhaustion followed, and death. There was no post-mortem examination. (Referred to Morbid Growth Committee.)

Dr. WHIPHAM showed a Kidney which, when recent, was studded over with small blood-red conical tumours. The patient had bronchitis, and died of that. The uterus and kidney seemed studded with small minute bloody extravasations, which were afterwards found to be cellular structures, but too late to examine the uterus. The tubules of the kidney were partly blocked with the growth, which seemed like that of lymphadenoma. In some parts the tube epithelium was gone, and the tubes and glomeruli compressed. Blood was extravasated into the new growth.

Mr. ARNOTT exhibited a portion of a Congenitally Enlarged Tongue. The child was 14 months old when seen; at that time the tongue was large, swollen, and red, the saliva dribbling from the mouth. It protruded about half an inch at birth, and at the time when first seen about an inch. It was very thick, and could not be retracted. Mr. Simon removed some parts of the tongue, but the child died. There were now a good many similar cases recorded. The extra growth was rarely muscular hypertrophy. It either depended on enlargement of the vessels, interstitial proliferation, or lymphatic enlargement. All were present here. The teeth were not well through, so they did not grasp the tongue. (Specimen referred.)

Mr. HULKE said Mr. Lawson had such a case.

Mr. FAIRLIE CLARKE narrated the case of an infant 4 months old, who was born with its tongue at the tip of its chin. It diminished for a day or two, and then remained unchanged. Strapping was useless, as it would not stop on; so he removed a portion by the *écraseur*. It had sucked well. The operation interfered with sucking, but the child took food well and recovered. The tongue was now slightly clubbed and thickened at the end, but otherwise natural. All the tissues seemed hypertrophied.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 8.

JOHN COOPER FORSTER, Esq., Vice-President, in the Chair.

Dr. BUZZARD showed a case of Unilateral Face-Atrophy, dating from an attack of chorea. A female, aged 25, applied to him at the National Hospital for Paralysis on account of fits, epileptic in character, which had troubled her for eleven years. She had been attacked with chorea when 6 years old, and again at 13; and, after this second attack, the right side of her face was observed to grow thin. The atrophy involved chiefly the frontal, malar, and inferior maxillary bones, together with the alar cartilage, the buccinator, masseter, and, in a less degree, the temporal muscles. The tongue was greatly wasted on the same side, and the palate was also involved. Cutaneous sensibility was unaffected. She was liable to attacks of hemicrania affecting the right side of the head, which had commenced between the first and second attacks of chorea. There was some mental deficiency. A systolic mitral bruit was present. Dr. Buzzard was inclined to refer this rare and obscure case to the category of those described by Eulenberg under the title "progressive facial hemiatrophia," and suggested the possibility of embolism of a nerve-centre accounting for the peculiar disturbance of nutrition.

Mr. G. LAWSON exhibited a little girl aged 15 months, with congenital hypertrophy of the tongue. The child was so stunted and ill-developed as to give the appearance of an infant about three months old. The fontanelles were as wide open as at birth. She showed no signs of any teeth, nor had she indicated any marks of intelligence. The tongue was a large fleshy mass, which not only filled the mouth, but a large portion lolled outwards between the lips. With pressure with the finger, the child would withdraw the tongue into the mouth; but it was almost immediately afterwards again protruded. Notwithstanding the size of the tongue, the child could suck well, and take the required amount of nourishment by the bottle. The father and mother were healthy, and had two other children, both of whom were healthy and intelligent. The child was born at the full period of utero-gestation. The mother attributed the defect to a strong impression she received when visiting the Crystal Palace, when in about the third month of pregnancy. She said she was terribly shocked by the appearance of some African figures with large protuberant lips.

Dr. LANGDON DOWN thought the child of the cretinous type. He had seen such with large tongues and swellings in the neck.

Mr. ARNOTT referred to the case of a child with a large tongue which lived eighteen months. The new growth was mainly connective tissue.

Dr. SANDESON mentioned a similar case, where the lymphatics were enlarged.

Mr. ARNOTT could not satisfy himself of this in his case.

Dr. HERMANN WEBER read a paper on a "Case of Hyperpyrexia in Rheumatic Fever," successfully treated by cool baths and affusions. The patient was a youth aged 16, who had rheumatic fever (first attack) in August, 1871. The affection of the joints was well marked, but not excessive. The temperature of the body varied between the ninth and twelfth days of the disease from 101.6° to 102.2° Fahr.; the pulse between 98 and 118; the respirations between 20 and 24. The lungs were free, and there was only the slightest indication of a murmur with the first sound near the apex. The medicinal treatment consisted of three grains of quinine three times a day. On the morning of the thirteenth day great restlessness, vomiting, excessive micturition, involuntary motions, delirium, tendency to coma, and lividity of face supervened, simultaneously with a rise of temperature from 101.6° on the previous evening to 108.2°, of the frequency of pulse from 118 to 148, and that of respiration from 22 to 56. The patient was then placed in a bath of 71° Fahr.; and affusions of water of the same tempe-

rate were made. The mental condition and the appearance of the patient rapidly improved already during the first ten minutes, and at the termination of thirty minutes, when he was removed from the bath, the temperature in the cavity of the mouth was only 101.8°, and further sank during the next half-hour to 98.8°; while the patient fell asleep, and began to perspire freely. In the course of the same afternoon, the temperature again began to rise rapidly—*i.e.*, from 100.8° at 3 p.m. to 105.8° at 6.40 p.m. Pulse 148; respirations 38; slight delirium. The patient had then another bath with affusion, as in the morning, when the temperature further rose during the first five minutes of the bath to 106.2°, but afterwards fell rapidly, the mercury receding within twenty-five minutes (the duration of the bath) to 101°, and during the following hours to 98°. After the second bath, without any further medicinal or hydrotherapeutic treatment, the disease took the course of a usual mild form of rheumatic fever, leading to perfect recovery, leaving only a rather too long first sound. Dr. Weber repeated the view stated in a former communication to the Society: that the nature of these attacks was the same as in common heat-stroke or *insolatio*; and thought that the term hyperpyrexia, as employed by Dr. Wilson Fox, more appropriate than heat-stroke, which conveyed the idea of causation by external heat. Acknowledging that hyperpyrexia was an accident which could occur in all febrile diseases, he maintained that it occurred infinitely more often in rheumatic fever than in any other disease; and, regarding the peculiarities of rheumatic fever, was inclined to ascribe it to the tendency to endocarditis and fibrinous deposits existing in this disease. He suggested that it might have a similar origin as chorea, and might possibly be due to minute embolism or to plugging of some small vessels in a certain portion of the nervous system, as the hypothetical centre of animal heat and chemical changes. As to prognosis and treatment, he pointed out that all cases formerly had a fatal termination when once the temperature had reached 108° Fahr.; but that the hydrotherapeutic plan, if early and energetically pursued, and with watchfulness as to the possibility of several attacks, gave great promise of a speedy cure, as shown by the two complicated and yet successful cases published by Dr. Wilson Fox, the one by Dr. Meding, and the one by the author. Dr. Hermann Weber alluded also to a difference in the action of the cold bath in this class of cases (hyperpyrexia) and in the pyrexia of typhoid or enteric fever, typhus, and other fevers of longer duration. While in the latter the baths, when given during the height of the disease, produce only a transitory reduction of temperature, which is followed sooner or later by a fresh rise, so that three, four, or even five baths may be required on each of several successive days, in the hyperpyrexias one or two baths may be sufficient entirely and finally to remove the complex of symptoms within less than twenty-four hours. He thought that this difference in the action of the plan in question pointed to a difference in the underlying pathological causes.

Dr. GREENHOW gave the particulars of a case which ended unfavourably. The patient, a male, was admitted on the fourth day of an attack of rheumatic fever, his temperature being 101°. On the seventh day the patient was drowsy; temperature 105.2°; when he tried packing. Later the temperature was 109°. He brought the temperature down to 101.5°, when the man fell asleep. He awoke with a temperature of 107°. Unfortunately the treatment was not renewed, and he died in the morning.

Dr. ANDREW asked what treatment had been followed before the rise in temperature. In some cases quinine did good, in some the reverse.

Dr. GREENHOW thought alkalies were used, but was not sure.

Dr. WILSON FOX said hyperpyrexia occurred independently of any treatment, and the value of cold in such cases was verified by facts. In diseases running a course they did not use it; but certain phenomena demanded it, and they really must have recourse to it or let the patient die. All who reached a certain temperature died before this was used; almost all have recovered with its use, but they must watch the case for days. Hyperpyrexia might occur in any disease with ordinary pyrexia. The sooner the public knew this and the good effects of cooling the better.

Dr. ANSTIE related a case where hyperpyrexia occurred in a patient suffering from delirium tremens. The temperature was 109°, and the pulse irregular in every direction. There was nothing remarkable in any other way.

Dr. SOUTHEY thought stasis in the cerebrum might be the cause of high temperature. The arrest of cutaneous circulation might favour the removal of this.

Dr. A. P. STEWART remembered one of these cases in which

the blood was completely fluid after death. They differed remarkably in this as in other respects from ordinary cases of rheumatic fever, being from the beginning of a typhoid type. Had he been giving alkalies, he would have attributed the condition to that. He thought the treatment correct.

Dr. C. J. B. WILLIAMS thought such terminations due to some condition of the nervous system. A temperature over 104° killed leucocytes; above that temperature, therefore, no function can be carried on. He had a doubt as to the application of such a treatment in these cases, though it was useful in other fevers; but in rheumatic fever inflammation might be transferred by it from without to within. In University College Hospital there were only two fatal cases of rheumatic fever whilst he was there. He thought the iron treatment had something to do with their frequency.

Dr. WILSON FOX said that at University College they were looking out for the condition, and were trying iron in all the cases.

Dr. WEBER said his treatment varied; he would not treat every case so, but only to remove an amount of heat which would otherwise prove fatal. He thought the fever shortened by it, and the deaths reduced in number.

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, FEBRUARY 14.

Mr. JAMES F. WEST, President, in the Chair.

Dr. CARTER, of Wolverhampton, was elected a Fellow.

Mr. WEST brought forward an example of Stricture of the Urethra and its Sequelæ. The bladder was immensely thickened, the ureters were greatly dilated, and the kidneys were enlarged, containing several abscesses, and their pelves were distended with pus.

Dr. UNDERHILL exhibited a specimen of Chronic Ulcer of the Stomach. The history of the case was quite characteristic; death occurred from hæmorrhage. The base of the ulcer had become adherent to the pancreas, and the ulcerative process had opened up a large branch of the pancreatic artery, the open mouth of which could be seen.

Mr. FURNEAUX JORDAN read a paper entitled "A Couple of Operating Days." At the Queen's Hospital, on two recent occasions, he had performed the following operations:—Excision of the tongue, excision of the hip, operation for anal fistula, ligature of hæmorrhoids, application of the actual cautery in hip disease, removal of scirrhus tumour of the breast, reduction of an old sub-coracoid dislocation, removal of a sequestrum from the radius, employment of the "aspirator" in a large abscess of the abdomen. Mr. Jordan removed the tongue by a method somewhat different from those in ordinary use. He first divided the cheek, as advocated by Professor McLeod, then, seizing the root of the tongue, he passed a "handled" needle, carrying four pieces of ligature, twice under it. These drew back the chains of two écraseurs, one after the other; one was arranged to divide the tongue in front of the larynx, the other to separate it from the floor of the mouth. The instruments were worked together, and a clean bloodless surface was left. Through the uncut mouth the tongue cannot be efficiently removed; through an incision in front of the hyoid bone the tissues at the floor of the mouth are removed too freely. In 150 cases of hip-disease, treated by rest, pulley-extension, and the actual cautery, only three had required excision. A running commentary on the other operations concluded the paper.

NEW PREPARATIONS.

EXPRESSED MEAT-JUICE.

WE have received from The Laboratory, No. 1, Great Winchester-street-buildings, a specimen of meat-juice extracted by pressure and solidified by gentle evaporation. It contains the juice of the muscular tissue plus much albuminous matter. Hence, when the extract is submitted to the action of boiling water, the albuminous matter coagulates, leaving the meat-juice in the form of a beautifully clear light-amber soup, from which the coagulated albumen can be strained off, if desired. The soup is remarkably clean-tasting, and of fine aroma, free from the stickiness which is the bane of much "concentrated soup," and of any burnt taste such as disfigures some extracts.

We long for the introduction of meat-juice in this guise from Australia. It satisfies the eye and palate of the consumer, and the judgment of the dietetic and chemical philosopher.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, March 21:—

Bowkett, William David, 243, East India-road, E.
Clouting, John Revett, Shipdham, Norfolk.
Evans, John, Canton, Cardiff.
Utting, James, Hockering, Norfolk.
Welch, Samuel, 377, Hackney-road, E.

As an Assistant in Compounding and Dispensing Medicines—
Dear, James Edward, Huntingdon.

The following gentlemen also on the same day passed their first Professional examination:—

Greet, William Amdrose, University College.
Roberts, William, St. Bartholomew's Hospital.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

DAVIES, ENOCH, M.R.C.S., L.S.A.—Medical Officer to the Llansamlet-District of Neath Union.

DAVIES, HENRY, M.R.C.S., L.S.A.—Medical Officer to the Llansamlet-District of Neath Union.

JACK, CHARLES, M.D., C.M.—Surgeon to the Leeds Reformatory.

KAY, THOMAS VALENTINE, L.R.C.P., L.R.C.S., L.M., &c.—Medical Officer to the Alton Collieries.

MYLES, THOMAS WILLIAMS, L.A.H. Ireland—Apothecary to the House of Industry Hospitals, Dublin.

RICKARDS, ALFRED, L.R.C.P.L., M.R.C.S.L.—Medical Officer to the Armley Workhouse, Brandley.

SIMPSON, THOMAS PEMBERTON, M.D.—Medical Officer to the Portsea Island Union.

VICKENY, GEORGE, M.D., M.C. Queen's University Ireland, L.M., L.A.H.I.—Medical Officer to the Kinsale Union.

NAVAL AND MILITARY APPOINTMENTS.

Surgeon W. J. Hamilton, M.D., has joined the *Tamar* on appointment, vice Staff Surgeon George Fletcher Banks, appointed to the *Duke of Wellington*, flagship, in Portsmouth Harbour, of Admiral Sir George Rodney Mundy, K.C.B.

ASHTON, WILLIAM, M.B., Assistant-Surgeon, from the Royal Artillery, to be Staff Surgeon, vice Staff Surgeon-Major Thomas Parr, who retires upon half-pay.

BIRTHS.

FOX.—On March 21, at 14, Harley-street, Cavendish-square, the wife of Tilbury Fox, M.D., of a son.

GRAVES.—On March 21, at 14, Chichester-road, Westbourne-square, W., the wife of F. G. Graves, M.D., of a son.

LOWE.—On March 17, at St. Mark's, Lincoln, the wife of Dr. G. M. Lowe, of a son.

NEWTON.—On March 20, at Alconbury-hill, Huntingdon, the wife of Lancelot Newton, M.R.C.S.E., of a daughter.

ORTON.—On March 12, at Crouch-end, Hornsey, N., the wife of Dr. F. Orton, of a daughter.

ROBINSON.—On March 19, at 47, Lupus-street, St. George's-square, S.W., the wife of Frederick Robinson, M.D., Scots Fusilier Guards, of a daughter.

WOODGATES.—On March 18, at 44, Southernhay, Exeter, the wife of Henry Woodgates, M.D., of a son.

MARRIAGES.

AMBROSE—McMURDO.—On December 5, 1871, at the church of St. James's, Delhi, J. D. Ambrose, M.D., Assistant-Surgeon 58th Regiment, to Kathrine Emily, eldest daughter of Major-General W. M. S. McMurdo, C.B., commanding the Rawul Pindee Division.

BENTLEY—WHYTEHEAD.—On March 18, at Bilton, near Hull, John Eugene, only son of T. Amand Bentley, of The Schools, Shrewsbury, to Caroline, youngest daughter of Henry Yates Whytehead, M.D., late of Crayke, in the North Riding of Yorkshire.

BLACKMORE—FARR.—On January 3, at St. Peter's College Chapel, Adelaide, South Australia, Edwin Gordon Blackmore, Esq., Clerk Assistant and Serjeant-at-Arms, House of Assembly, fourth surviving son of the late Edward Blackmore, M.D., of Bath, to Eleanora Elizabeth, eldest daughter of Canon Farr, M.A., of Pembroke College, Cambridge, Head Master of the Collegiate School, Adelaide.

HILL—PRIOR.—On March 16, at St. Mark's, Cheltenham, Dallas Hill, B.A., eldest son of the late Rev. Alfred Bligh Hill, M.A., incumbent of St. Paul's, Tiverton, to Bessie, only daughter of the late Frederick James Prior, L.R.C.P., of North House, Tewkesbury.

DUKES—BELL.—On March 20, at Upper Norwood Chapel, Major Charles Dukes, M.D., of Wellesley-road, Croydon, to Maria, second daughter of James Bell, of Penybryn, Upper Norwood.

MACPHERSON—THOMSON.—On March 25, at 17, Alva-street, Edinburgh, Norman Macpherson, LL.D., Advocate, Professor of Scots Law in the University of Edinburgh, to Georgina Gordon, youngest daughter of the late William Thomson, M.D., Professor of the Practice of Medicine in the University of Glasgow.

SKIMMING—BOWRING.—On March 21, at St. Paul's Church, East Molesey, Robert Skimming, M.D., of Bridge House, East Molesey, to Fanny Charlotte, elder daughter of Edward Bowring, Esq., of Mole-bank, East Molesey.

SMITH—WEEKS.—On March 19, at St. Peter's, Maidstone, Frederick Walter Smith, L.R.C.P., of Blackman-street, to Ruth, youngest daughter of the late Wm. Weeks, Esq., of Maidstone.

DEATHS.

CHAPMAN, JANE, youngest daughter of Frederick Chapman, M.R.C.S., at Old Friars, Richmond-green, Surrey, on March 22, aged 5.

COLEMAN, THOMAS, F.R.C.S., at Eastbrook-place, Dover, on March 18, aged 81.

GERMAN, JOSEPH, M.D., at the Manor House, Borrowash, Derby, on March 18, aged 45.

PATERSON, ROBERT HALDANE, L.R.C.S. Edin., L.S.A., of Brigg, Lincolnshire, at Buxton, suddenly, on March 22, in his 68th year.

PRICHARD, WILLIAM, M.D., at Partick, near Glasgow, on March 23, aged 51.

SHEEHY.—At Claremont-square, Pentonville, N., the beloved wife of Dr. W. H. Sheehy, after many months of suffering, on March 21.

SMITH, W. HENRY, M.D., eldest son of the late W. Henry Smith, D.C.L., barrister-at-law, at his residence, 15, Lancaster-road, Westbourne-park, W., on March 24, aged 32.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BECKETT HOSPITAL AND DISPENSARY, BARNSELY.—House-Surgeon and Secretary. Candidates must be duly qualified. Applications and testimonials, on or before April 8, to Messrs. Newman and Sons, Solicitors, Barnsley.

BETHLEM HOSPITAL.—Two Resident Medical Students, who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the Hospital for a term generally not exceeding six months. Applications and testimonials to be forwarded to Bridewell Hospital, Blackfriars, E.C., addressed to A. M. Jeaffreson, Esq., on or before April 6.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Candidates must be duly qualified. Applications and testimonials to Alexander Bottle, M.D., Secretary, on or before April 17.

CARMARTHEN COUNTY AND BOROUGH INFIRMARY.—House-Surgeon. Must be M.R.C.S. and L.S.A. A knowledge of the Welsh language is necessary. Applications to Mr. H. Howell, King-street, Carmarthen, on or before April 10. Election on the 12th.

CENTRAL LONDON OPHTHALMIC HOSPITAL, GRAY'S-INN-ROAD, W.C.—Assistant-Surgeon. Candidates must be M.R.C.S., and must have attended the practice of some Ophthalmic Institution for at least six months. Testimonials, etc., to be sent to the Secretary, on or before April 6.

ECHT, ABERDEENSHIRE.—Medical Officer to the Parish of Echt.

HOSPITAL FOR CONSUMPTION, BROMPTON.—Resident Clinical Assistant. Applications and testimonials to be sent on or before Saturday, March 30.

ROYAL SURREY COUNTY HOSPITAL.—Assistant Honorary Medical Officer. Testimonials to be sent to the Hon. Sec., Rev. C. R. Dallas, Farncombe Rectory, Godalming, on or before April 16.

ROYAL VETERINARY COLLEGE.—Professorship of Physiology, Therapeutics, and Pharmacy. Candidates must be M.R.C.V.S. Applications and testimonials to the Principal of the College, on or before April 4.

ST. MARYLEBONE GENERAL DISPENSARY.—Surgeon. Candidates must be M.R.C.S. Eng., and must attend personally on Wednesday, April 3 next, at eleven o'clock in the forenoon, with a written application. No canvassing allowed.

SALISBURY INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications and testimonials to be sent to the Secretary, on or before April 11.

STAFFORDSHIRE GENERAL INFIRMARY.—House-Surgeon and Secretary. Candidates must be M.R.C.S. of London, Dublin, or Edinburgh, and possess a qualification in Medicine which will entitle to register. Candidates must attend the Infirmary on Monday, April 22, at one o'clock.

WESTMINSTER UNION.—Medical Officer to the Workhouse Infirmary; also a Dispenser. Particulars may be obtained at the Clerk's office, Poland-street, where applications are to be sent, not later than Monday, April 1.

WEST SUSSEX, EAST HANTS, AND CHICHESTER INFIRMARY AND DISPENSARY.—House-Surgeon. Candidates must be duly qualified. Testimonials etc. to be sent to Mr. E. W. Barton, on or before April 1.

DR. J. BURNEY YEO has been appointed Honorary Physician to the Westminster Memorial Refuge at Streatham.

An International Medical Congress will be held at Vienna in 1873.

The health of Paris is said to be very bad. The latest returns show that deaths from low fever and typhoid have greatly increased.

An important meeting has been held at King's Lynn to found a convalescent home at Hunstanton, within a few miles of the Norfolk residence of the Prince and Princess of Wales.

CONVALESCENT homes at Mount Pleasant, near Norwich, and at Kessingland, near Lowestoft, have been established for the special benefit of patients leaving the Norfolk and Norwich Hospital.

STAFF SURGEON J. L. MUNDY, in Medical charge of the Indus Rest Camp, Meean Meer, was on the morning of the 24th ult. waylaid and assaulted by three privates of the 37th, one of whom was drunk. He lies at present in a very precarious state, having nearly lost his life from a succession of fainting fits, which came on after his bruised and bleeding body had been dragged through the camp and then deposited at his own door.

DEATH OF M. PICTET, OF GENEVA.—At the meeting of the Académie des Sciences on the 18th inst., M. Dumas announced the death of this eminent *savant*, who was elected a Corresponding Member in 1867. For the last twenty years he has especially been engaged in palæontological researches, and his "Traité de Palæontologie" is known far and wide. Possessed of a large fortune, he has always been munificent in his patronage of scientific enterprises, and his death has taken place just on the eve of the inauguration of a museum of natural history in the University of Geneva, erected at great cost, and the initiation of which is due to him.

MR. I. B. BROWN.—The following gentlemen have kindly come forward as contributors to a fund about being raised in behalf of Mr. Isaac Baker Brown, who is at this time suffering from severe bodily illness (paralysis) and great pecuniary distress. The hon. treasurers are Dr. Forbes Winslow and Dr. Charles Cogswell. Subscribers—Sir Wm. Fergusson, £3 3s.; Sir Wm. Gull, £2 2s.; Sir Ranald Martin, £2 2s.; Sir Henry Thompson, £5; Dr. Quain, £2 2s.; Mr. Erasmus Wilson, £2 2s.; Dr. Forbes Winslow, £5 5s.; Mr. Henry Smith, £2 2s.; Mr. Erichsen, £2 2s.; Dr. Sieveking, £2 2s.; Dr. Gream, £3 3s.; A Friend, £2 2s.; Dr. Routh, £3 3s.; Dr. Richardson, £2 2s.; Mr. Ernest Hart, £2 2s.; Dr. Semple, £1 1s.; Mr. Gascoven, £2 2s.; Mr. Henry Spencer Smith, £2 2s.; Mr. E. B. Hicks, 10s. 6d.; Dr. Murchison, £1 1s.; Dr. C. Cogswell, £5; Mr. T. H. Hills, £2 2s.; Dr. James Wakley, £5 5s.; Mr. Thomas Wakley, £5 5s.; Dr. Waller Lewis, £1 1s.; Mr. J. F. Clarke, £2 2s.; Mr. Edwin Saunders, £1 1s.; Anonymous, £1 1s.; Mr. Critchett, £1 1s.; Dr. Tilbury Fox, £1 1s.; Mr. George Busk, £1 1s.; Sir James Paget, £2 2s.; Dr. Druitt, £1.

CHLORAL IN TRAUMATIC TETANUS.—Dr. Lavo relates three cases of severe traumatic tetanus which were successfully treated by means of chloral aided by the employment of the cold bath. The quantity of chloral used during the course of the first case amounted to 240 grammes, with twenty-five baths; in the second to 147 grammes, with fifteen baths; and in the third to 140 grammes, with eleven baths.—*Annali Universali di Med.*, February.

PRESERVATION OF BODIES BY CARBOLIC ACID.—Professor Guillery has submitted to the Belgian Academy of Medicine his simple and efficacious procedure for the preservation of bodies. Having taken a body from the Hospital, and placed it on one of the dissecting-room tables, he completely wrapped it in a cloth impregnated with a solution of 2 per cent. of carbolic acid. After an interval of four or five days he poured some of the solution on the body. All cadaveric smell was prevented, and, examined from time to time, the body was found to retain nearly the appearance it had at the time of death, the walls of the abdomen having retracted gradually. Six months after the experiment was commenced the body continued in the same state.—*Presse Belge*, March 10.

MALINGERING IN THE FRENCH ARMY.—M. Beaunis, narrating the fatal campaign of the East in the late war, after describing the dreadful suffering of the wounded during one of the retreats near Belfort, transported by tired-out mules on a bitter winter's night, adds—"Besides these unfortunates, there were others whom one cannot too severely stigmatise. These were cowardly wretches, who mutilated themselves to gain admission into the ambulance, and blew off a finger in order to escape the perils of the battle-field. These shameful manoeuvres assumed such proportions that on January 17, of twenty-four wounded whom I dressed myself, nine were in this position. There could be no doubt on the matter, and I am certain that, of about 150 wounded received on that day, full forty of them were wretches of this description.—*Gaz. Méd.*, March 16.

CARBOLIC ACID CERATE.—Dr. Boehme recommends the following as an excellent formula:—R. Adipis, ʒx., ceræ alb. ʒv., terebinth. Canad., acid. carbolicæ, aā. ʒj. Melt the lard and wax together, add the Canada balsam, and when the mass begins to cool stir in the carbolic acid. The addition of the balsam corrects the disagreeable odour of the acid and renders it slightly adhesive.—*New York Med. Record*, January 15.

A NEW AND PAINLESS MODE OF CIRCUMCISION FOR THE JEWS.—A member of the Philadelphia Obstetrical Society, having witnessed the circumcision of a Jewish child, described the operation to his wife, who was in the early period of her pregnancy. A strong impression was made on her mind, and the event was the subject of constant thought for several days. Seven months afterwards she gave birth to a child whose glans penis was found exposed, while the retracted prepuce actually showed the yet granulating cicatrix of what looked like a very recent circumcision. This extraordinary circumstance, which is related in a first-class journal, under the head of "Birth-mark from Maternal Impressions," suggests a ready method by which our fellow-citizens of the Israelitish faith may do away with the sanguinary mode of performing circumcision in common use.—*Boston Journal*, from *Pacific Medical Journal*.

NOTES, QUERIES, AND REPLIES

He that questioneth much shall learn much.—*Bacon*.

Our report of Dr. Quain's second Lumleian Lecture is unavoidably postponed until next week.

L. A.—The former query shall be answered next week. Buttermilk is not at all in fashion in England for babies' food, because it is not an article of ordinary commerce, and not easy to procure in towns. In the country it is given to the pigs.

Inquirer.—Yes; Dr. Carnochan was the Health Officer of the port of New York, but was removed by the Governor, who has appointed in his place Dr. Vanderpoel, a leading Physician.

C. E.—We could not think of recommending any book for the purpose. If you are ill, consult some respectable Practitioner in whom you have confidence; if not so ill as to require that, endeavour to lead a healthy, regular life—mentally as well as physically. Abandon reading books on fancied ailments, and dosing yourself with inappropriate remedies.

PUBLIC HEALTH BILL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to the first paragraph in Dr. Rogers' memorial as printed in your last, it seems to me that the existing salaries of Medical Officers form the most simple basis for estimating the remuneration derivable from their new duties as Health Officers. For instance, the Bill might contain a clause to the effect that under the Public Health Bill the Medical Officers, acting also in their new capacity, should receive a minimum remuneration equivalent to two-thirds of their former salary in consideration of the new and onerous duties undertaken. Thus a simple standard would be created, and the public ought not to grudge, for the protection of the whole community—from the "upper ten" down to the street Arab—a sum less by a third than the very inadequate remuneration now paid to Poor-law Surgeons for combating the diseases and mitigating the sufferings of our poor. I am, &c., A PROVINCIAL M. O.

Burton-on-Trent, March 25.

TO VACCINATION OFFICERS.

Dr. Joyce presents his compliments to the Editor of the *Medical Times and Gazette*, and requests that the attention of vaccinators be drawn to the enclosed circular. It is hoped the form of the vaccination marks will lead to the discovery of the child's name, etc. Similar copies have been sent to the *Lancet* and *British Medical Journal*.

Rolvenden, March 25, 1872.

"Police-office, Tunbridge Wells, March 16, 1872.

"Child Desertion.

"Whereas some person who is unknown did, about seven o'clock in the evening of March 7, 1872, leave a female child, about 2 or 3 months old, on a doorstep of a house in Cambridge-street, Prospect-place, Tunbridge Wells, whereby it became chargeable to the Tunbridge Union. The child appears to be a little wasted, pale complexion, dark eyes, and rather long brown hair, and was wearing an old calico gown, embroidered front, with frills at neck and arms, two pieces of flannel, and wrapped in a piece of old green serge. The child appears to have been vaccinated on March 1, with five

marks *** on left arm, as on the 8th inst., the day after it was found,

other children were vaccinated from it. Surgeons are kindly requested to communicate with Superintendent Embery respecting children vaccinated about that time, and not since brought for inspection. Registrars are also requested to search their vaccination returns.

"Two Pounds Reward will be given by the Guardians of the Tunbridge Union to any person giving such information to Superintendent Embery, Tunbridge Wells, as shall lead to the detection of the guilty party."

DALE v. CONSTABLE.

In his speech for the plaintiff in this case, Mr. Digby Seymour quoted the following doggerel verses from Mr. Constable's pamphlet. The devil, it is supposed, visits a prison in which a man is incarcerated for not vaccinating his child:—

"From his brimstone bed at dawn of day,
From his bed the devil is risen—
Risen, and dressed in his Sunday best,
To inspect a model prison.

"There were two or three persons swearing hard,
And he caught the word 'damnation';
The devil was bored, yet he sneered a sneer
Of lazy approbation.

"Oh, oh!" said the devil, as he rubbed his paws,
'This is nuts, this is nuts,' said he;
'A poor man crushed by the strong hand
Of legal tyranny.'

"The devil laughed; he was far too pleased
To return to his place below;
He stayed and chuckled, and waved his tail
Gently to and fro."

Mr. Seymour then recited the following, said to be *impromptu*:—

"A beautiful child in Scarborough town
On her pillow of sickness lay,
And the shadows of death seemed settling down,
While her young life ebbed away.

"Then a Doctor stood by the infant's bed,
And in healing faith he spoke;
And the "Rose" that was drooping upraised its head,
And the clouds into sunshine broke.

"And did the child's father compensate,
Then, the good man's Medical art?
No; he blackened his name with a slanderous pen,
Till he almost broke his heart.

"And oh! how the devil was filled with glee,
How his imps into laughter burst;
For of all the devilish sights that be,
Ingratitude is the worst!"

"Εἰς τὸν Πέτρον.

To a popular official.—A grateful effusion from the pen of Mr. Thomas Gushington, who, having been — times plucked, is now M.R.C.S.E., etc., etc.

Who, when I was distress'd in mind
Consoled me, and was wondrous kind,
And said in him a friend I'd find?
Good Πέτρος.

Who, when from work I felt oppress'd,
To cheer me always did his best,
And like a father me caress'd?
Good Πέτρος.

Who, when I'd had my "little go,"
Said, "If you do your final so,
You need not fear but you'll go through" ?
Good Πέτρος.

Who, when I lost my "second run,"
Sincerely grieved that I was "spun,"
And did not at me poke his fun?
Good Πέτρος.

Who, when I had made up my mind
To try again, was passing kind,
And gave me many a friendly "grind" ?
Good Πέτρος.

Who oft, when my hard "grinds" were o'er
And my poor mind was troubled sore,
Would down my throat his sherry pour?
Good Πέτρος.

Who, when my dread "exam." was near,
And I did sadly quake and fear,
Gave me some "fizz" my heart to cheer?
Good Πέτρος.

Who, when I thought the prize was mine,
Called out my number—"forty-nine,"
Which made cold chills run down my spine ?
Bad Πέτρος. (a).

Who, when I hung my lower lip,
And fear'd I'd made another slip,
Gave me a true Masonic grip ?
Good Πέτρος.

Who, when my heart began to thump,
And in my throat I felt a lump,
Assured me I with joy might jump ?
Good Πέτρος.

Who wished I would L.R.C.P.
Add to my name, that I might be
To kill and slay considered free ?
Good Πέτρος.

*** This is genuine enough as a psychological study of a student under examination. We hope the distress some men suffer will be made up to them somehow. A little of the oil of human kindness in officials goes a great way in preventing mental friction.

SKIN DISEASES IN HOSPITAL PRACTICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reference to my letter, which recently appeared in the columns of your journal, respecting the statistics of Hospital patients affected with skin disease, I may direct attention to a pamphlet which I have to-day received from Dr. Louis A. Duhring, of Philadelphia, U.S., in which some attempt is made in the same direction. The pamphlet is the Report of the Dispensary for Skin Diseases in Philadelphia, and the fact established by it to which I attach the chief importance is that skin disease appears to be in America, as I have myself found it to be in this country, more common with males than with females. I think I am correct in stating that the contrary impression prevails with most persons, and, if the fact is one that will be supported by the general verdict of clinical observers, it is of some importance in the etiology of cutaneous disease. Thus, according to the Report before me, the number of patients treated during the year was 425; of these, 248 were males, and 177 females. Distributed in uncertain

(a) Hearing a great disturbance in the room, and suspecting Mr. Gushington as the cause, Πέτρος called out his number, which led him and others to suppose he was "spun."

(because unstated) proportion between the males and females were 64 children. Now, the statistics I framed of the patients attending at the Great Marlborough-street Hospital for Diseases of the Skin furnished a somewhat similar result. Thus, in the year 1870, of 2577 patients, 1172 were males, 958 were females, and 447 were children under 12 years of age. The year 1871 furnished a similar result; thus, of 3719 patients, 1696 were males, 1343 were females, and 680 were children under 12 years of age. It may be noticed that in each of the three separate results above given, although they severally are derived from quantities of very different magnitudes, there is but very little variation of the ratio, which may be simply put as four males to three females. Now, when we add to this the fact that females in this country at least, if not also in America, are more numerous than males, it becomes pretty obvious that skin disease is considerably commoner with the male than the female. Whether this difference be due to the greater exposure of the male to noxious influences I will not pretend to say. Lest anyone, however, might suppose that it is to be accounted for by the greater prevalence of syphilis among the males, it may, perhaps, be not altogether gratuitous for me to refer to a communication which I made some time since to the *British Medical Journal*, in which I stated, as the result of a careful tabulation of 1000 consecutive cases of cutaneous disease that had been treated by me, I had found only 4.5 (four decimal five) cases per cent. of cutaneous syphilis.

As regards the statistics of the occupations of patients furnished me by my American correspondent, I regret to say that, in my opinion, they are utterly valueless, inasmuch as they are not placed side by side with a census of the number of persons engaged in the several occupations as ascertained for the locality in which his dispensary is situated. I am, &c.,
9, Weymouth-street, Portland-place, March 19. BALMANNO SQUIRE.

COMMUNICATIONS have been received from—

Mr. LAWSON TAIT; Mr. J. H. BRUNTON; C. E.; Dr. NEILD; Dr. CONRAD; Dr. MURCHISON; Dr. ALDIS; Dr. W. H. BROADBENT; Mr. H. ARNOTT; Mr. J. CHATTO; A PROVINCIAL M. O.; Mr. MAJOR; Mr. METCALFE JOHNSON; Dr. H. OSBORN; Dr. DOUGALL; Mr. J. W. HULKE; Dr. WINSLOW; Dr. JOYCE; Mr. HANNAY; Dr. PLAYFAIR; Mr. ELDER; Mr. REEVES; Dr. BRAKENRIDGE; L. A.; Dr. MOFFATT; Mr. MAHOMED; Dr. JOHN WARD COUSINS; Dr. JOHN W. OGLE; Mr. GEORGE LAWSON.

BOOKS RECEIVED—

On the Myoidema of Phthisis, by Lawson Tait, F.R.C.S.—Report of the Stafford County Lunatic Asylum—On the Physiology of Syphilitic Infection, by F. N. Otis, M.D.—Thomas on the Diseases of Women—Dauchell on Sewage—Statistical Abstract of the Health of the Navy.

PERIODICALS AND NEWSPAPERS RECEIVED—

Essex Herald, March 19—Edinburgh Courant, March 23—Melbourne Argus, January 26—Australian Medical Gazette, December—Australian Medical Journal, January—The Clinic—Yorkshire Gazette, March 23—Scarborough Express—American Journal of Insanity—Dublin Medical Journal, March—Glasgow Herald—The Scotsman—Bethnal-green Times—Family Friend—Children's Friend—Kelso Chronicle.

APPOINTMENTS FOR THE WEEK.

March 30. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

April 1. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON. No Meeting.
ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

2. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Dr. King, "Malformation of the Heart." Mr. Thomas Smith, "Aneurism of the Sinuses of Valsalva; Clubbed Fingers." Dr. Thorowgood, "Stricture of the Oesophagus." Dr. L. Down, "Abscess of the Liver, with Ulceration of the Colon." Mr. Sydney Jones, "Tumour weighing 4 lbs. removed from the Parotid Region." Dr. Crisp, "Abscesses in the Heart-wall of a Child 4 years of age;" "A New Form of Intestinal Obstruction." Mr. Croft, "Two Cases of Colloid Cancer of the Breast." Dr. Bristowe, "Effusion into the Corpus Striatum, and Gangrene of the Lower Extremities from Obstruction of the Aorta by a Clot;" "Carcinoma of the Descending Colon, causing Fatal Obstruction."

3. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

OBSTETRICAL SOCIETY, 8 p.m. Dr. Newman, "On a Case of Delivery per Vias Naturales in which the Cæsarian Section had formerly been performed." Dr. Barnes, "On Dysmenorrhœa, illustrated by Retention of Menstrual Fluid." And other Papers.

ROYAL MICROSCOPICAL SOCIETY, 8 p.m. Meeting.
SOCIETY OF ARTS, 8 p.m. Meeting.

4. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Mr. Victor de Méric, "On Discharges from the Male Urethra."

5. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, March 23, 1872.

BIRTHS.

Births of Boys, 1070; Girls, 1033; Total, 2103.
Average of 10 corresponding weeks, 1862-71, 2160.9.

DEATHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.66 in. The highest was 29.91 in. on Sunday morning, and the lowest 29.50 in. on Thursday at noon.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

CONCERNING THE
PROPRIETY OF PRESCRIBING ALCOHOL
FOR THE SICK,

AND ON THE MEDICAL DECLARATION RESPECTING ALCOHOL.

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

DURING a febrile attack, and many other forms of illness, some persons do well without any alcohol at all. Others *must* take it, whether ill or well; but the principle long acted upon, of withholding stimulants *because* a patient has fever, or is suffering from some form of inflammation, cannot be sustained. This view is founded, not upon fact, but upon erroneous data and theoretical assumptions. It is not in accordance with the observations of intelligent persons upon themselves, nor with the experience of Medical Practitioners. It is distinctly contrary to the teaching which results from accurate observation of patients suffering from various forms of fever and inflammation.

But there is the strangest prejudice against giving wine, brandy, or other forms of alcohol in cases in which there is any tendency to bronchitis or acute affection of the lungs. The hypothesis that alcohol increases inflammation of the respiratory organs is still erroneously acted upon by some Practitioners. This, like many other speculations concerning the action of remedies, has been shown over and over again to be fallacious. The reasoning upon which the objections have been based, as well as the data relied upon, have been shown to be erroneous. Patients suffering from these affections often find the greatest relief from alcohol, and some are cured, and in a very short time, by this remedy only. Not a few have found out its usefulness for themselves; and some have unwisely and without advice resorted to too large and too frequent doses. Alcohol has been given with excellent results in cases of lung disease in cattle and many of the lower animals. Many veterinary Surgeons are fully conversant with the use of stimulants in the treatment of acute febrile pulmonary diseases in our domestic animals.

If the Practitioner withholds alcohol in the case of a person suffering from a febrile or inflammatory affection, who when in health takes habitually a liberal allowance of stimulant, he may do very serious harm. He may cause a slight attack of fever or internal inflammation to become a severe one. He will be acting upon a thoroughly incorrect theory, and may even, in certain cases, by such treatment increase the morbid process he desires to check.

In the management of acute disease it is therefore very necessary to inquire into the ordinary habits of the patient as regards taking alcohol; and although it is our duty to warn innocent persons, who are ignorant of the action of wine and spirits they have unconsciously been led to take, against the injurious effects of habitual indulgence in alcohol, a serious illness is not the proper time to attempt to induce them to try the experiment of completely abandoning the bad habit they have acquired.

Very much has been said and written concerning the impropriety of our prescribing alcohol to the sick, lest a taste for the remedy given during illness should be acquired and indulged after recovery has taken place. Some have gone so far as to assert that not in any case ought we to give alcohol, because by so doing we encourage the vice of spirit-drinking. But those who enunciate such a doctrine as this either maintain, contrary to the teaching of experience, that alcohol is of no use in illness, or they have never fairly considered the position the Medical Practitioner holds as the adviser of the sick, and his responsibility in discharging his Professional duties. Unless it can be proved that alcohol is absolutely useless in the treatment of disease—that is, unless the conclusions arrived at by thousands of intelligent persons, Medical and non-Medical, can be shown to be utterly groundless prejudices—it is simply the duty of the Practitioner to prescribe it; and if upon purely theoretical or upon moral grounds he refuses to order alcohol, he fails to discharge the duties of his office.

It will not be contested that, as Practitioners, our first consideration ought to be simply how to save or prolong life, without any reference whatever to the habits or morals of our patient, bad though they may be. Surely we should look upon him simply as a sick man; and, be his habits

bad or good, it is equally our duty to place him under the circumstances most favourable to his recovery. Even if the measures we may consider it necessary to take for his present advantage should be ever so strongly condemned by the ardent advocates of temperance and abstinence, they must nevertheless be carried out. Though it is our *duty*, as it is the duty of every rational being, be his calling what it may, to do what we can to encourage virtue and correct vicious habits, it must never be forgotten that our first *duty* as persons having care of the sick—that which takes precedence of every other duty whatever, whether attaching to us as citizens, philanthropists, or moralists—is to save, if we can do so, the life of our patient. To this object every other consideration, every other thought, must yield. And I hold that, if in any particular instance the duty of the Doctor seems to clash with his duty as a citizen, the first of his duties must be honestly discharged to the minutest detail, though to do this the last may have to be neglected altogether. For is not the number of earnest citizens and the number of moralists and philanthropists so very great in comparison with the number of Doctors as to render it certain that the interests of the citizen will be efficiently discharged, though many of us may be unable to attend to them?—while if our own special duties were to be neglected the health of the people might suffer, and in this way the vigour of the commonwealth might be undermined. If many Doctors were to devote themselves wholly and solely to their Profession, it is doubtful if the State would deteriorate, while it is not improbable that by such a course the public health would be improved, and, therefore, the happiness of the people enhanced.

To abolish vice from the world, to convert drunken into temperate members of society, are laudable objects for any man to endeavour to achieve; but, when treating the sick, our whole attention, our whole interest, our whole thought, must be concentrated upon their complaints and the adoption of means for relieving their sufferings. To us, in the earnest practice of our Profession, great social problems, it seems to me, should be as nothing—the individual sick man all in all. His mortal interests are for the moment paramount; his life is to be preserved if possible, but if this cannot be, he is to be kept alive to the last moment, though the means employed should be condemned by the most influential and most powerful of all associations that have ever been formed in modern times. We have been told that though we are Doctors we are not to forget that we are citizens; but is it not of the first importance for the interests of the sick that we should remember that we have the care, not of the people, but of individual organisms out of health? Our responsibility, though extending, it may be, but to a few individuals, is immense; and however important measures for promoting the welfare of the people may be, they are to us as nothing in comparison with the thorough performance of our Medical duties.

Further, I venture to offer the suggestion that in our collective capacity as a Profession we ought to discourage and condemn all attempts made by associations and societies to use Medical opinions for political purposes. The progress of science, of Medicine, of hygiene, will not be promoted by political alliances or political agitation. These subjects clearly are, and ought to be, by general consent removed from the sphere of party strife. It is an outrage that such questions as drunkenness, drainage, the supply of good water, the spread of fevers and contagious diseases, should be regarded in any sense as questions for political contention. The most advanced Liberal, surely, might do all in his power to aid the most thorough-going Conservative in doing everything to promote the people's health, without, in any sense, losing political caste. It is unfortunate that questions of Medicine and police should be dragged into the political arena at all. Legislation upon such matters, one would think, might be easily conducted, independently of party feeling. But at this very time we have the miserable spectacle of seats being threatened because a representative may have been led to form a certain opinion concerning the manner in which a loathsome disease may be most effectually prevented.

Such considerations, it seems to me, may, without impropriety, be adverted to even by a Doctor at a time like the present, when men's minds are not unexercised by the discussion of Utopian impossibilities and philosophical abstractions. The imagination of some seems to be at this moment absorbed in the contemplation of the happiness and contentment that *might* belong to a society in which the pernicious influences of alcohol were prevented by law. The weakness and impracticable character of a proposition which has been cleverly forced into undue notoriety are not unfrequently indicated by the

extravagant efforts and dexterous manoeuvres made by warm partisans to obtain apparent support to their cause by getting the names of a number of persons occupying high Professional positions appended to a petition or a declaration. It is remarkable how, by a little ingenuity, an impossible, unpractical doctrine may be made to appear as if it had the sanction and very warm support of numerous persons who, individually, perhaps do not sympathise with it. So difficult is it for some to refuse to append a signature to a document already signed by many friends for whom the highest respect is entertained, that not a few sign simply because they see the names of others. Signing is contagious, and, if well managed, spreads rapidly. An enthusiastic advocate, who displays a little tact, will soon get multitudes of names to support his cause, though it be the compulsory regeneration of mankind, in spite of their determination not to be regenerated, or the proposal to purchase happiness and contentment for multitudes who have no desire whatever to profit by the generous designs of those who desire to make them good by restrictive laws.

Towards the close of the year 1871 a "Declaration respecting Alcohol" received the signatures of upwards of 250 members of the Medical Profession. Among those who signed were the Presidents of the Royal Colleges of Physicians and Surgeons, and most of those who stand at the head of our Profession at this time. This Declaration declares that "the *inconsiderate* prescription of large quantities of alcoholic liquids by Medical men for their patients has given rise in many instances to the formation of intemperate habits." It implies that the directions given by some Doctors to their patients regarding alcohol are so loose as to have been "interpreted as a sanction for excess," and concludes by the statement that those who signed "would gladly support any *wise legislation* which would tend to restrict within proper limits the use of alcoholic beverages, and gradually introduce habits of temperance."

Do the promoters of this Declaration really believe that drunkards are to be converted into temperate persons by laws, and that the people of England will be persuaded that habits of temperance or any other virtues are to be propagated by mere legal enactments? What is meant by the term "proper limits"? and who is to determine the quantity of alcohol each particular man, woman, and child is to take? The wording of the Declaration is vague and ill-considered, except as regards the statement about the *inconsiderate* prescription of alcohol by some of our own body, which is clear and precise to a fault. That members of a liberal Profession should make such an accusation against other members of the same Profession is extraordinary, and the only apology that could be offered by those who signed would be the knowledge on the part of each one of them of several instances of the *inconsiderate* prescription of alcohol by Medical men with whom they were actually acquainted. But in this case surely a private letter to the *inconsiderate* prescriber would have been more considerate as well as more efficacious than the circulation of a general charge and a vague condemnation, preferred by a number of distinguished men against a number of others, of whom some are not less distinguished, and, though proscribed by their brethren, are upon an equal footing. Is it conceivable that the course that has been actually adopted could have been taken by the members of any other profession in the world? Faucy the judges and most distinguished members of the bar signing a declaration informing the public that there were many *inconsiderate* legal practitioners; or a number of members of the House of Commons signing a document directing public attention to the *inconsiderate* acts of certain politicians who had obstructed wise legislation and had used *inconsiderate* expressions, which had been interpreted as a sanction for the performance of treasonable acts! Yet such declarations would surely not be more useless and absurd, or more thoroughly wrong in principle, than this unfortunate attack upon certain imaginary *inconsiderate* Doctors, who are supposed to have prescribed alcohol *inconsiderately*, to have sanctioned excess, and supported or excited habits of intemperance.

That so many highly respected members of our body should have been induced to come forward publicly to support the dicta of a league is to be lamented. It is one of many indications that in these days liberal minds and well-meaning persons sometimes *inconsiderately* lend themselves to the spread of tyrannical ideas and the diffusion of views with which they do not entirely sympathise, and which as individuals they would not support. How many of those who signed that Declaration could declare individually that they knew members of their own Profession who prescribed large quantities of alcohol *inconsiderately*, and that in their opinion this *inconsiderate* Medical prescription had given rise in many instances to the formation of intemperate

habits? and yet everyone who signed ought not to hesitate in doing so.

This Declaration, with all those influential names attached, has been freely circulated with a pamphlet published for the National Temperance League, in which the following sentences and phrases occur upon one single page (page 7).—"Hence the support which the Church, or, at least, professing Christians give to the liquor traffic;" "The drinking customs of society;" "And with shame be it said, that this powerful and all-important stronghold, behind which the whole army of liquordom shelters itself, has been built, armed, and manned by the noble Profession of Medicine!" "The error that alcohol is a necessary medicine, a useful beverage, and at any rate a harmless luxury, is the great delusion for which the Profession is accountable, and which is filling our land with lamentation, and weeping, and great mourning;" "What reply can our honourable Profession make to the awful impeachment brought against it by every intelligent student of the temperance question, that its members as a body are the very mainstay of that traffic, and of those customs which have brought misery and ruin to so many households, and which constitute a perpetual 'carnival of sensuality, crime, and death'?"

Is this the sort of language for the members of a Profession like that of Medicine to encourage? Is it likely in any way to assist those who have to legislate? How many of us agree with it? How many of those who signed the Declaration really sanction such expressions or would use them? Nevertheless, the Declaration and the pamphlet have been widely circulated together, and both can be obtained of the "National Temperance League." (a)

LECTURES ON THE COMPARATIVE ANATOMY OF THE ORGANS OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE III.

(Continued from page 337.)

THE next animal for consideration is the large man-like ape from the islands of Borneo and Sumatra, commonly known as the orang-utan, or *Simia satyrus*, of which, however, it appears that there are two species or varieties, differing chiefly in size. As the diagnostic characters of these are not well ascertained, especially in the immature specimens which have mostly come under the anatomist's scalpel, it is not always certain to which of them the following remarks apply.

The visceral anatomy of the orang has been described from a young specimen by Camper, (a) and in an adult by Sandifort, (b) and also briefly by Owen (c) and by Huxley. (d) Preparations of all the more important parts are to be found in the College museum.

The mouth is more prognathous than that of the chimpanzee, though its opening is not so wide. The edges of the lips can be projected forwards in a remarkable manner, the lower lip having no frænum tying it to the gum, and the upper lip very little indication of one. There are no cheek-pouches.

The tongue is long and narrow, the sides being nearly parallel throughout. It is more pointed anteriorly than in the chim-

(a) "Truly the great two hundred and fifty against alcohol, themselves even, leave some room for question as to their meaning when they proclaim that 'it is believed that the *inconsiderate* prescription of large quantities of alcoholic liquids by Medical men for their patients has given rise in many instances to the formation of intemperate habits.' Believed by and of whom? By the two hundred and fifty Doctors, of their Profession at large, or by society in general of it, including them? One would like to know who the believers are in order to be enabled to appraise the belief, and it would also please one to be informed whether or no the belief includes a confession, which the two hundred and fifty make for themselves. Did you, gentle reader, in the course of your experience, ever happen to meet with a victim of the bottle who dated his intemperance from taking port wine or brandy prescribed for him when convalescent, for example, from typhus fever?"—*Punch*, Feb. 3, 1872.

(a) "Naturgeschichte des Orang-utang," etc. German edition, 1791.

(b) "Ontleerkundige Beschryving van een volwassen Orang-cetan." (*Verhand. Natuur. Gesch. d. Nederl. overzeesch Bezittingen.*) 1810.

(c) *Proceedings Zool. Soc.*, November 9, 1830.

(d) Report of lectures in the *Medical Times and Gazette*, 1864. As has been already stated, the animals described as "orangs" by Tyson and by Traill belong to the species to which the name "chimpanzee" is now applied.

panzee, but not so much as in man. The hinder part is thick, and the dorsum much arched from side to side. The fossa between the tongue and epiglottis is deep, with a well-marked median frænum. In a specimen about half-grown, the entire length of the tongue is three inches and three-quarters; its greatest breadth, which is nearly equal throughout, one inch and a half; the frænum is attached one inch and a quarter behind the tip. The papillæ much resemble those of the human tongue, especially the circumvallate, which are about ten in number, and arranged rather irregularly in the form of a letter V, with the apex turned backwards.

It is commonly said that the orang has no uvula, but this statement requires qualification. There is, in reality, a very thick muscular uvula, forming a distinct prominence on both surfaces of the soft palate, but the margin of the velum is prolonged as a thin membrane beyond it, so that its free edge is evenly arched. The tonsils resemble those of man and the other allied forms. The ducts of the submaxillary glands open on distinct prominences on each side of the frænum of the tongue, a quarter of an inch apart, much as in man.

The stomach has much the same form as that of the chimpanzee, but the pyloric antrum is more dilated. Sandifort figures this part in the adult animal as separated from the main cavity by a narrow constriction, and as having very thick muscular walls. The same anatomist describes valvulæ conniventes in the jejunum, (e) but in no specimen which has been dissected in this country have they been found, and Camper expressly mentions their absence. (f)

The colon is proportionally larger and longer and more loosely attached than in man, and consequently more convoluted. It commences by a cæcum in the usual situation on the right iliac region, then ascends to the under surface of the liver, passes obliquely to the left across the lower border of the stomach; but before descending into the pelvis it makes a very large bend upwards, which lies superficial to the small intestines—an exaggeration, in fact, of the human sigmoid flexure. This disposition is figured by Sandifort in the adult animal. It resembles that of the human foetus shortly before birth, and is similar to that generally found in the lower Old World monkeys.

What appears at first sight to be the globular apex of the cæcum is, as in man and the chimpanzee, really a dilatation or sacculus of the external tract of the colon. The real apex is drawn up very close to and behind the entrance of the ileum, and prolonged into a vermiform appendix of great length—about seven inches in a nearly adult specimen—which is coiled by its peritoneal attachment into a spiral of three turns. The transition from the dilated part of the cæcum into the constricted appendix is more gradual than in man and the chimpanzee, the opening of the latter into the former being infundiliform. It thus resembles a transient condition of the human cæcum at an earlier stage than does that of the chimpanzee.

The livers of different individuals of this species vary considerably. Fortunately, I have been able to examine a good series, otherwise it would be easy to fall into error in making a general description from only one or two specimens.

FIG. 10.

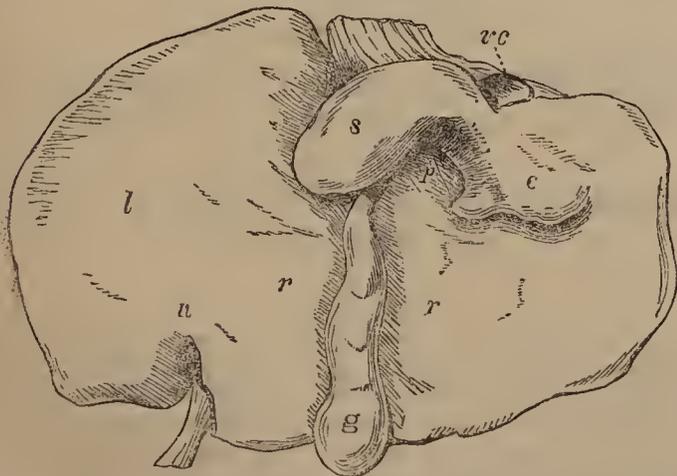

FIG. 10.—Under surface of liver of orang-utan: u umbilical fissure, p portal fissure, vc vena cava, l left lobe, r right lobe, s Spigelian lobe, c caudate lobe, g gall-bladder.

(e) "Het intestinum jejunum was onafgebroken beget met dwarse plooijen (valvulæ conniventes)."

(f) "In dem Zwölffinger und im Leerdarme waren gar keine Querfalten auch im übrigen dunnen Gedarme kein Runzeln, so dass der Orang hierin sehr vom Menschen verschieden ist. Doch die Zotten (villi) waren sehr sichtbar."—Loc. cit., p. 166.

The one figured (Fig. 10) appears of the average form. As in the human liver, it is divided only into two principal lobes by the umbilical vein, and shows no trace of lateral fissures. The left lobe is expanded and flat, and very thin at the free edge, which is nearly semicircular; the right lobe is thicker in substance, and of an oblong form, with rounded corners. On the inferior surface the umbilical fissure is converted into a tunnel by the continuity of the hepatic substance of the left and right segments, a notch at the free border only remaining. The fossa of the vena cava completely separates the Spigelian from the right lobe, the vein being quite superficial. The Spigelian lobe has a tongue-shaped flattened prolongation, which in the natural position overhangs the portal fissure. The caudate lobe is a well-marked projection on the under surface of the right lobe, reaching to nearly half an inch of its free border, but not detached from it even at its apex, although its anterior border is indicated by a deep sinuous fissure, extending from the right end of the portal fissure. Posteriorly it subsides indistinguishably into the hinder edge of the right lobe. On its anterior or free border it has two well-marked projections.

In an adult female orang's liver, in the Museum (No. 804B), the caudate lobe is still more distinct, being marked from the right lobe by a fissure which extends all round it, except the base or left end, but which does not cut it completely free, except quite at the apex. Its anterior edge is nearly straight. On the other hand, in two other orang's livers in the Museum stores, this lobe is quite obsolete, or certainly not more marked than in the human liver.

The other differences observed in these livers consist in the greater or less prolongation of the Spigelian lobe, and the extent of the bridge over the umbilical fissure. In all the vena cava is quite superficial.

The gall-bladder is long and narrow, and its fundus projects considerably beyond the edge of the liver, as in the chimpanzee. Sandifort noticed and figured the termination of the common bile-duct and the pancreatic ducts by distinct orifices upon one papilla in the duodenum.

Genus *Hylobates* (Illiger).—This group of animals comprises the gibbons, or long-armed apes of the Indo-Malayan region, and includes several distinct species, which, as far as is at present known, closely resemble each other in anatomical characters. It must be remarked, however, that very few individuals of this most interesting group have yet been dissected with the care necessary for satisfactory comparison with allied forms. The Museum contains preparations of the viscera of more than one species, and Hunter has left records of the dissection of two monkeys of the genus. Daubenton (Buffon, tome xiv., 1766) and Camper have also given observations and figures of some parts of the visceral anatomy of the gibbons.

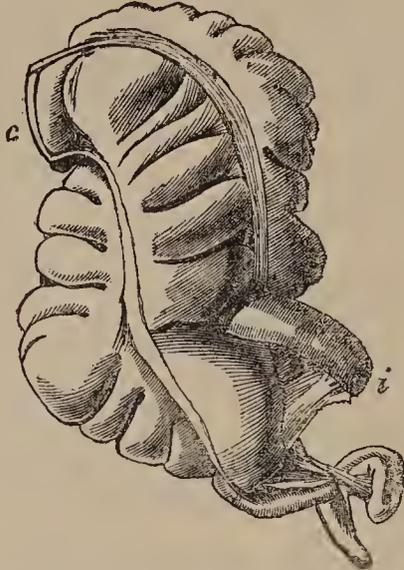

The description of the mouth and tongue I take from a specimen of *Hylobates agilis* in the Museum. The lips appear less extensile than in the preceding species, and there is a rudimentary frænum below; there are no traces of cheek-pouches. The anterior half of the palate has a series of crescentic ridges on each side, with the concavity turned back, and with uneven notched edges, about eight in number, but not very regularly arranged. As noted by Hunter, there is a perfectly distinct uvula. The tongue narrows slightly from the base towards the apex, which is obtusely rounded. The circumvallate papillæ are small and very irregularly disposed, but, on the whole, assuming the ordinary V-shaped pattern; the fungiform papillæ are large and distinct, and pretty evenly distributed; the filiform papillæ are short and thick—they increase in size at the back part of the tongue, where they insensibly pass into a group of very large soft papillæ, with pointed apices on each side of the dorsal surface, quite at the root of the organ. The group of perpendicular linear fissures in the lateral edge of the tongue, immediately in front of the attachment of the palato-glossal fold, already noticed in the human tongue, is very distinct. Rather below the middle of the anterior edge of the frænum is a triangular fold of membrane, projecting freely forwards and terminating in a bifid apex. This is the sublingual process, which becomes so largely developed in some of the lower monkeys, and is formed by the union of the papillæ on which Wharton's ducts terminate in the chimpanzee, and, though in a more rudimentary condition, in man. In *Hylobates lar* the process is free for the space of a quarter of an inch, and it is about that width at the base. Its lateral edges are continued backwards into the ridge of mucous membrane which lies over the sublingual gland.

Hunter notes that "the stomach is similar to the human, but rather more globular." The specimen in the Museum (*Hylobates lar*, No. 535Bh), prepared from an animal which

died in the Zoological Society's Gardens in 1870, is rather narrow in proportion to its length. The pyloric portion is less tubular than in the chimpanzee, and therefore approaching nearer to the form of the human stomach. The whole organ in its distended state is curved in its long diameter, being convex in front and concave behind.

As noted by Hunter, there are no *valvulae conniventes* in the small intestines. "The caecum is situated and adheres as in the human. The appendix is about three inches long, and

FIG. 11.

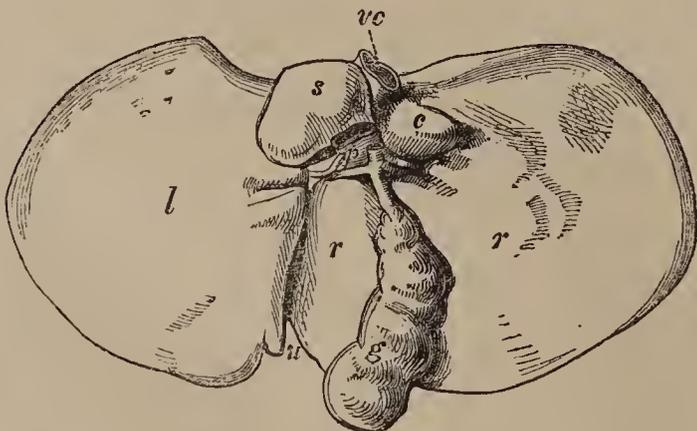

FIG. 11.—Caecum of white-handed gibbon (*Hylobates lar*). *i* ileum, *c* colon.

half an inch in diameter." In the specimen No. 725Ea in the Museum, from the same individual as the stomach above described, the appendix is somewhat longer and coiled upon itself. Though it commences very abruptly, there is an important difference in its situation from the forms previously described, for it springs from the extremity of a short conical caecum. The whole retains more nearly the primitive form, the true apex not being drawn up to the neighbourhood of the ileo-caecal valve. It thus represents a still earlier condition of the human embryonic caecum than the orang, but hardly justifies Vrolik's expression that the "vermiform appendix is very small and almost rudimental in the gibbons." (g) One specimen, however, which I have examined of the "silvery gibbon" has the appendix only an inch and a half long and proportionately thick. In the animal examined by Daubenton it was five inches long and two and a half lines in diameter. It seems, therefore, that there are considerable differences in the structure of this part.

The colon is greatly sacculated, the usual three muscular bands being strongly marked. The descending colon, completely surrounded by peritoneum, and attached by a distinct mesocolon, is very different from that of the orang, being nearly straight, with scarcely any sigmoid flexure—at least in two specimens I have examined (*H. leuciscus* and *H. agilis*). Hunter notices the absence of sigmoid flexure in one specimen and its presence in another.

The great omentum is attached to the whole of the transverse colon.

FIG. 12.

FIG. 12.—Under surface of liver of white-handed gibbon (*Hylobates lar*). The letters as before.

(g) Article "Quadrupana," "Cyclop. Anat. and Phys."

I only know the liver of the white-handed gibbon (*Hylobates lar*), of which the Museum contains two specimens. In general form and proportions of the principal parts they both show a great resemblance to the human liver—perhaps more than any of the preceding forms. The umbilical fissure is strongly marked at the free edge, and in both specimens is not bridged over on the inferior surface. There is no trace of lateral fissures. In one specimen the free edge is notched where the elongated narrow gall-bladder lies, but in the other it is not. The vena cava is superficial in both. In both the Spigelian lobe is prominent and rounded, much resembling its ordinary form in the human liver. In one there is scarcely a trace of a caudate lobe; in the other (Fig. 12) this forms a distinct but short conical prominence, about the size of a hazel-nut, with a free apex projecting to the right.

Before leaving the interesting family of *Simiidae*, it will be well to take a short review of the more important points noted in the anatomy of their digestive organs, especially in relation to their resemblance to man. The gorilla unfortunately must be omitted in most parts of the summary. In all the tongue is much longer in proportion to its width; in the gibbons alone are the salivary papillae united to form a distinct sublingual process, as in all lower apes, though in the chimpanzee the papillae are much elongated though distinct, while in the orang they more nearly resemble the same parts in man. The uvula, with its azygous muscle, is developed in all, though in the orang it is masked by the production of the membranous edge of the velum palati. The stomach in all differs from that of man only in a greater elongation of the portion next to the pylorus and its more marked separation by a constriction from the rest of the cavity—a point on which there is, however, great individual variation in the human subject. They all differ markedly from man in the absence of *valvulae conniventes* in the small intestines, unless the statements of Vrolik in the chimpanzee and of Sandifort in the orang (which have not been verified by subsequent observers) can be trusted. The colon is proportionately longer than in man (perhaps *Hylobates* excepted). They all agree with man, and differ from the lower apes in having the terminal portion of the caecum constricted and lengthened into a vermiform appendage, and this appendage in the chimpanzee and the orang is, as in man, drawn up to the neighbourhood of the ileo-caecal valve, though not so in the gibbons. The great omentum is attached by its posterior layer to the whole of the transverse colon, as in man, but in none of the lower monkeys. Finally, the liver, in all except the gorilla, resembles that of man, and differs from that of all the lower apes in having no lateral fissures subdividing the right and left segments; but it differs from that of man in the possession of a small caudate lobe, which, however, has been found to be wanting in some specimens of oranges, and also in some gibbons.

The abnormal form of the liver of the gorilla is one of the most interesting facts that has been brought to light by recent researches into this subject. It shows either that the modifications of the liver are not very characteristic in natural and related groups of animals, or that the gorilla ought not to occupy that position in the system which has hitherto generally been accorded to it.

DR. QUAIN'S LUMLEIAN LECTURES, AT THE ROYAL COLLEGE OF PHYSICIANS,

ON THE

DISEASES OF THE MUSCULAR WALLS OF THE HEART.

LECTURE II.

HAVING discussed in his first lecture the nature and causes of enlargement of the heart, Dr. Quain next proceeded to consider the effects, the diagnosis, and the treatment of this condition.

Of the familiar effects of enlargement of the heart locally—on the organ itself and on the surrounding viscera—it was unnecessary to dwell; the general effects of enlargement, on the other hand, were deserving of careful study. These the lecturer accordingly described at considerable length, contrasting the effects of the four varieties which he had enumerated in his previous lecture—viz., enlargement from increased development of muscle, connective tissue, and fat respectively, and enlargement by dilatation. The general effects of *uncomplicated muscular hypertrophy* of the heart are in the first place beneficial—there is an increase of power created to meet an

increase of resistance, and from the even balance of these nothing but benefit to the system can result. Yet at times the hypertrophy seems to be excessive in its effects. Thus, in aortic valvular disease, when the left ventricular walls have become sufficiently thickened to overcome the obstruction, the aortic tension is normal and the circulation perfect; but in a case of contraction of the minute and distant vessels, as in Bright's disease, where no obstruction in the large arteries intervenes to break the force of the hypertrophied left ventricle, the column of blood between the heart and the capillaries exerts an undue lateral pressure; and if this, from any local cause, is excessive, the well-known symptoms of hypertrophy of the heart result, such as flushings, sensations of fulness and throbbing in the head, glandular congestions, and exudation of serum and of blood. It is in this case also that, should a small intermediate vessel be diseased, it is especially liable to give way, and hæmorrhage results, as in the brain. Again, the increase of power may be misdirected so far in a retrograde direction, as in hypertrophy of the left ventricle from mitral regurgitation, where an increased quantity of blood must be driven back at each systole on the left auricle and lungs.

True hypertrophy may also be injurious from being imperfect, and the temporary occurrence of failure in this direction is not unusual; either from accident, emotion, or a passing local disorder of circulation the balance is suddenly disturbed, and care and time alone will restore it.

The effects of a heart enlarged by an increased development of connective tissue are those of an organ of increased action but diminished power, the muscular element, although it is also in greater volume, being restricted in function by the new connective tissue by which it is surrounded. Such a heart, however powerful it may seem, is in its results weak; yet it is perhaps less likely to dilate than the degenerated heart.

The heart, with the course of its muscular fibres distorted by interstitial fatty growth, produces effects on the system which might be briefly described as those of circulatory weakness, to which might be added a tendency to angina pectoris and sudden death. These three forms of hypertrophy of the heart occur much less frequently alone than combined with each other and with the condition of dilatation—a complication which results in blood stasis in the small vessels, and passive congestion, with its consequences, varying with the side of the heart affected, and constituting the long line of symptoms so distressingly present in chronic cardiac disease.

Such are briefly the general effects of enlargement of the heart: its *special* relations were next considered to certain diseased conditions of the brain, the lungs, and the kidneys.

The question of the connexion between hypertrophy of the heart and the occurrence of *cerebral hæmorrhage* has long been a source of difference of opinion among pathologists. After giving a brief *résumé* of the history of the discussion at various times between Lancisi, Baglivi, Corvisart, Andral, and Cruveilhier in favour of the connexion, and Kellie, Abercrombie, and Rochoux against it, Dr. Quain quoted the valuable conclusions of Dr. Burrows of the very close relation between apoplexy and diseases of the heart, and adduced abundant statistical facts of his own in support of it. Analysing sixty-five cases of sanguineous apoplexy which he had himself collected, and in which the condition of the heart was carefully noted, Dr. Quain found that in these the heart was enlarged forty-three times—thirty-one times without and twelve times with valvular disease. The particular cavity affected, and the presence or absence of disease of the cerebral vessels, were also carefully observed in every case; and from the results thus obtained Dr. Quain was enabled to arrive at the following, amongst other important conclusions:—That, in the sixty-five cases of cerebral hæmorrhage, the left ventricle of the heart was hypertrophied thirty-nine times, more frequently without than with valvular disease, and that enlarged heart more frequently accompanies cerebral hæmorrhage than does disease of the vessels of the brain.

With regard to the condition of the heart in *phthisis*, Dr. Quain made another series of important investigations, and found, by an analysis of the records of 171 fatal cases of *phthisis* in which the heart was accurately weighed, that the heart in this disease is small in more than half the number of cases, especially in females, and enlarged in 25 per cent. of males, and in but 7 per cent. of females; that hypertrophy of the heart tends to prolong life in *phthisis*, especially in the first and third years of the complaint; and that hypertrophy of the heart seems to have no effect in promoting hæmoptysis. In this series of cases there occurred two extraordinarily small hearts, weighing but 2 oz., and 1 oz. 14 dr. respectively.

Lastly, the effect of an enlarged heart in producing disease

of the *kidneys* was considered, and the opinions of Dr. Chambers and of Professor Traube alluded to. In respect to the view adopted by the latter, that the condition of the kidneys under these circumstances is one of congestion only, Dr. Quain showed that he had himself expressed an exactly similar opinion in a paper which he wrote nearly five-and-twenty years ago; while in regard to the further teaching of Traube, that it is rare to find true chronic Bright's disease developed out of this congested renal condition, Dr. Quain maintained, as he did at that early date, that protracted renal congestion gives rise to renal alterations, both tubular and intertubular, and is thus a direct cause of chronic disease of the kidney.

Passing on next to the *diagnosis* of enlargement of the heart, Dr. Quain pointed out that, assuming the existence of increased size of the organ, the two important points to be determined were the exact nature of the enlargement and the capability or non-capability of the heart to perform its functions. In determining the exact nature of the enlargement, the textural condition of hypertrophy of the walls and the physical condition of dilatation of the cavities are—the lecturer said—to be kept distinctly apart in the diagnosis, although they are so intimately blended, for on each of these factors there depend corresponding signs and symptoms. First, there is no difficulty in diagnosing simple cardiac hypertrophy. Of the existence of the second variety, in which there is an increase of connective tissue, we cannot in any particular case be so certain—at least, as yet—for our clinical experience cannot here be said to be on a level with our pathological knowledge which has been so recently acquired. Energetic restricted action, with feeble and inefficient results, would however, as had been already shown, characterise this form of hypertrophy—*i.e.*, as peculiar physical signs, a strong heaving impulse and dulness of the first sound, and, in the system generally, abundant symptoms of circulatory weakness. Of this character were the phenomena in a case of Dr. Hyde Salter's which seems to belong to this category. "And when," said Dr. Quain, "in addition to this peculiar combination of symptoms, we meet with a history of some previous rheumatic or inflammatory affection of the heart, with the absence of signs of pericarditis and endocarditis, or with a history showing that the patient has, as Niemeyer puts it, 'led the life of a glutton,' in such a case we should consider whether we have not to deal with connective-tissue hypertrophy of the heart." The third form of cardiac hypertrophy being an hypertrophy with weakness, is at once diagnosed from the two previously described by its local phenomena, which are striking expressions of that condition. The diagnosis of this form, therefore, requires no further consideration. It is otherwise with dilatation. This, as a mere physical condition of the heart, is to be diagnosed by a few physical signs—namely, a peculiar shape of percussion dulness, and short, clear, and sharp cardiac sounds, with, in some cases, a systolic murmur.

Dilatation is, however, in nearly every instance combined with degeneration of the walls; and so (said Dr. Quain) the physical signs of dilatation come to be confounded with those of cardiac weakness, and not only the local signs but the symptoms also, such as congestions and dropsy, which, although called symptoms of dilatation, are really the effects and symptoms of degenerated walls. With these considerations steadily in view, we are able to appreciate the importance of making out distinctly the second point in the diagnosis—of determining the textural soundness of the cardiac walls rather than the simple signs of their physical condition. Dr. Quain then discussed the various means of obtaining this information, and he especially directed the attention of his audience to the importance of the sphygmograph and cardiograph as instruments of research in this direction.

In introducing the subject of *treatment* of enlargement of the heart, the lecturer made some pointed remarks on treatment in general, and especially on the application of therapeutical agents to the treatment of cardiac diseases. Reviewing the plan followed by Valsalva, and that of more modern Physicians with whom stimulation is a favourite weapon, Dr. Quain remarked how readily one might complain of want of philosophy in a science which could countenance the entertainment of opinions so extremely diverse. Yet, he proceeded to show, this is but the result of our ignorance of pathology on the one hand, and of the action of medicine on the other; and, as this ignorance becomes replaced by knowledge (for example, of the nature of *phthisis* and heart disease, and the action of digitalis), our faith in the value of therapeutical treatment would, as it certainly does, steadily increase. "For myself," said Dr. Quain, "my lack of faith is not in physis, but in my own want of discrimination in its use. I find the uncertainty,

not in the action of medicines, but in the propriety of their application." So in the case of enlargement of the heart; as we arrive at an exact notion of the several varieties of the condition, we become more and more convinced that while the system of Valsalva is the treatment most suitable for one, a system of the very opposite character would be best adopted in another. Coming to consider more particularly the treatment of the individual forms of enlargement of the heart, Dr. Quain pointed out that in the first form, where there is a simple increase of contractile tissue, the primary object of treatment is on the one hand to subdue abnormally excited action, and on the other to prevent decay and degeneration of the cardiac walls. The causes of the condition are to be removed, as far as possible, whether physical or moral, and aconite and allied drugs, which seem to have a controlling effect on the heart, intelligently administered. The connective-tissue form of hypertrophy, on the other hand, is most likely to be benefited by alteratives and counter-irritants, such as mercury, iodide of potassium, alkalies, and cupping. Of the medicinal and dietetic treatment of a heart enlarged by accumulation of fat on and within it, it is unnecessary to speak. The various conditions included under the term "dilatation" will demand (said Dr. Quain) each its own treatment. First, there is a dilated cavity, an increased amount of blood, and passive oppression of the muscular walls; for the relief of these the most evident means is the abstraction of fluid directly by bleeding (which is sometimes almost essential), and less directly by withholding liquids as much as possible, and by purging and stimulating the secretions (a plan which is always practicable and of enormous remedial value). This step in the treatment also counteracts the second condition in dilatation—namely, diseased blood. The third condition may then be remedied—the textural change, degeneration in the cardiac walls—and that by the so-called cardiac tonics, whether these means are hygienic, dietetic, or medicinal. Dr. Quain here entered at some length into the action of iron and digitalis, of both of which it might be said that, while they are of enormous value, they are by no means easily managed. Above all, they are never to be given to strengthen the cardiac walls until the heart has been relieved by some means of part of its oppressive and distending contents by one of the plans just mentioned. Of the value of this advice Dr. Quain adduced more than one example from his own practice.

In conclusion, two practical points were noted as worthy of being kept in mind by the Physician attending a case of heart disease. One was the great relief to be given by acupuncture of anasarca parts, and the other the importance of never failing to examine the urine regularly and with extreme care for the presence of albumen.

ORIGINAL COMMUNICATIONS.

ON THE

RADICAL CURE OF INGUINAL HERNIA.

By J. FAYRER, M.D., C.S.I.,

Professor of Surgery, and Senior Surgeon, Medical College Hospital, Calcutta.

SINCE my last report on this subject I have recorded fifty cases of operation for the radical cure of hernia, an abstract of which is appended. I have no reason, after further observations and experience, to doubt the efficacy of this operation; and though I have not had many opportunities of noting its results after a period of years, yet in a few I have been glad to find that success continued permanent. In some, where it failed, it evidently did so from want of the simplest care or the observance of the most ordinary precautions on the part of the patient in protecting a part which must, at the best, be regarded as weaker than natural. At present I know of two cases operated on years ago, who, I have reason to believe, remain free from the protrusion.

The simplicity of the operation, if properly performed, and the comparatively small amount of suffering it entails, are matters of importance, and it certainly, also, is comparatively free from danger. In no case have I known it prove directly fatal, as from peritonitis. Two deaths are recorded among the fifty cases—one from erysipelas, the other from tetanus. These were just as liable to have followed any other Surgical operation, and cannot be regarded as peculiarly the consequence of this.

I would remark that the object of the operation is not merely to bring the margins of the inguinal canal into apposition, but to close or occlude the internal abdominal ring, thus restraining the contents of the abdomen altogether within that cavity. This is effected by the inflammatory products and tissue-changes induced by the presence of a plug pressed tightly, by the tension of the ligatures, against the apex of the canal and the internal ring. Unless this is effected, the hernia will again protrude—if not immediately, as soon as absorption of the new products has taken place—should they not, in cicatrising, have closed the opening; and even if perfect closure should not occur, the opening may be so much limited as to greatly diminish the tendency to hernia. And if not perfect, at all events considerable relief may be obtained, and the protrusion rendered more controllable. I had an excellent opportunity of seeing that the internal opening may be thus completely closed, in the case of a young French sailor who had been operated on, and who was killed some time after by a fall from a house. The preparation is now in the Medical College Museum, and it well illustrates the complete closure of the internal ring.

Of the fifty cases here recorded, 31 were of Americans, Eurasians, or Europeans; 19 of natives. The following results were obtained:—Europeans: Doubtful, 1; relieved, 2; failed, 4 (one being direct inguinal hernia, one being femoral hernia); died of tetanus, 1—total, 8. In one operated on in 1866 the hernia came down again in 1869. Of the natives 15 were successful, 3 unsuccessful; one died of erysipelas. It is to be noted that in four cases the operation for strangulated hernia had to be performed before that of the radical cure. One case of femoral hernia which proved unsuccessful, and one of direct hernia which was doubtful, might both fairly be excluded, for I do not think the operation well adapted for these forms of hernia. In one case of direct hernia, in an American, the operation failed. In some cases the operation having failed, was repeated, and with success.

Case 1.—M., an English sailor, aged 35, was admitted on April 12, 1865, with left oblique inguinal hernia. Operated on for radical cure on April 17. The plug was removed on the 19th, and he was discharged cured on June 11, 1865.

Case 2.—B. F., an English seaman, aged 45, was admitted on March 27, 1865, with left direct inguinal hernia. He was operated on for radical cure on May 10, 1865. The plug was removed on the 14th, and he was discharged cured on June 16, 1865. The hernia was large, and the rings probably dragged together—not anatomically direct hernia. The permanency of the cure in this case is very doubtful.

Case 3.—D. L., aged 35, a Maltese, admitted on May 16, 1865, with right oblique inguino-scrotal hernia. He was operated on for the radical cure on May 22. The plug was removed on the 26th, and he was discharged cured on July 24, 1865.

Case 4.—Ballacksing, a Hindoo, aged 50, was admitted on July 12, 1865, with right oblique inguino-scrotal hernia. Came in with symptoms of strangulation, which were relieved by ice and taxis. He was afterwards operated on for radical cure on the 18th. The plug was removed on the 21st, and he was discharged cured on August 28, 1865.

Case 5.—Nujeeboolah, a Mahomedan kholapee, aged 32, was admitted on September 15, 1865, with right oblique inguino-scrotal hernia of five years' standing. Operated on for radical cure on the 20th. The plug was removed on the 23rd, and he was discharged cured on October 18, 1865.

Case 6.—Soroop Chunder, a Hindoo coolie, aged 40, was admitted on October 11, 1865, with right oblique inguino-scrotal hernia of three months' standing. Operated on for the radical cure on October 16. The plug was removed on the 20th. The operation proved unsuccessful, and he was discharged on November 6, 1865.

Case 7.—E. B., an English sailor, aged 33, was admitted on October 30, 1865, with left oblique inguino-scrotal hernia. Came in with symptoms of strangulation, which were relieved by ice and taxis, and then operated on for the radical cure on November 16. The plug was removed on the 20th, and he was discharged only partially cured (the hernia protruded, but was much more controllable than before the operation) on January 27, 1866.

Case 8.—B. J., a French sailor, aged 20, was admitted on December 28, 1865, with right oblique inguino-scrotal hernia. Operated on for radical cure on January 1, 1866. The plug was removed four days after the operation, and he was discharged cured on January 21, 1866. Four months after, he came in with dislocation of right femur and injury of the head, from which he died. On post-mortem examination the

internal ring was found to be entirely occluded, but the invagination had descended.

Case 9.—Gopál, Hindoo water-bearer, aged 36, was admitted on January 5, 1866, with right oblique inguino-scrotal hernia. Operated on for radical cure on January 6, 1866. The plug was removed on January 9, and he was discharged on March 16, 1866; but the operation proved unsuccessful.

Case 10.—Deerjotolla, a Mahomedan, aged 40, was admitted on January 8, 1866, with right oblique inguino-scrotal hernia. Operated on for radical cure on January 14. The plug was removed on January 18, and he was discharged cured on February 14, 1866.

Case 11.—Nagir Mahomed, a Mahomedan, was admitted on April 20, 1866, with right oblique inguinal hernia of several months' standing. He was operated on for strangulated hernia on April 20. The constriction was found at the external ring. The sac was not opened. A month later, when the wound was completely healed, the operation for radical cure was performed (on May 10, 1866). The plug was removed on the 14th, and he was discharged cured on July 25, 1866.

Case 12.—Bashooly Mookujee, a Hindoo sircar, aged 28, was admitted on June 17, 1865, with right oblique inguino-scrotal hernia of four years' duration. Operation for strangulation on the 17th. The sac was not opened; the constriction was found at the external ring. After the wound had healed he was operated on for radical cure on July 2. The plug was removed on the 6th, and he was discharged cured on July 29, 1865.

Case 13.—C. R., an East Indian, aged 23, was admitted on July 17, 1866, with left oblique inguino-scrotal hernia. Operated on for radical cure on July 22. The plug was removed on the 26th, and he was discharged cured on August 14, 1866.

Case 14.—J. D., an English engineer, aged 32, was admitted on August 8, 1866, with left oblique inguino-scrotal hernia. He had been operated on for strangulation in 1859. The sac was not opened. The operation for radical cure was performed on August 24, and the plug was removed on the 27th. The operation failed, and the patient was discharged on December 27, 1866.

Case 15.—Dwarkaunouth, a Hindoo oilman, aged 28, was admitted on February 22, 1867, with right oblique inguino-scrotal hernia. Operated on for radical cure on the 25th, and the plug was removed on the 28th. The operation proved unsuccessful, and he was discharged on April 14, 1867.

Case 16.—Ram Coomar, a Hindoo servant, aged 30, was admitted on February 27, 1867, with left oblique inguino-scrotal hernia. Operated on for radical cure on March 5, 1867. The plug was removed on the 8th, and he died from erysipelas of the body generally on March 28, 1867.

Case 17.—M. G., an English sailor, aged 41, was admitted on March 4, 1867, with right oblique inguinal hernia. Operation for radical cure on March 15, and the plug removed on the 19th. The operation proved unsuccessful, and he was discharged on April 14, 1867.

Case 18.—H. C., an English sailor, was admitted on May 14, 1867, with left oblique inguino-scrotal hernia. Operated on for radical cure on May 15. The plug was removed on the 19th, and he was discharged cured on April 22, 1867.

Case 19.—Gour Keramanil, a Hindoo weaver, aged 41, was admitted on June 2, 1867, with right oblique inguino-scrotal hernia. He was operated on before for radical cure on December 29, 1866, which proved unsuccessful. He then underwent a second operation on June 15. The plug was removed on the 19th, and he was discharged cured on July 14, 1867.

Case 20.—W. S., an English sailor, aged 32, was admitted on January 16, 1867, with right oblique inguinal hernia. He was operated on for radical cure on January 21. The plug was removed on the 25th, and he was discharged cured on July 4. In 1869 the hernia returned after great physical exertion. During the intervening time he had led an active life as a railway employé.

Case 21.—Mahomed Apoodollah, a Mahomedan steward, aged 22, was admitted on September 1, 1867, for right oblique inguinal hernia, and was operated on for radical cure on September 3, 1867. The plug was removed on September 7, and he was discharged cured on October 24, 1867.

Case 22.—D. C., an Englishman, aged 32, was admitted on September 2, 1867, for right oblique inguino-scrotal hernia, and was operated on for the radical cure on November 23, 1867. The plug was removed on November 26, and he was discharged cured February 7, 1868.

Case 23.—W. W., a Scotch sailor, aged 52, was admitted on January 24, 1868, with right oblique inguinal hernia. He was operated on for radical cure on January 27. The plug

was removed on the 31st, and he was discharged cured on March 23, 1868.

Case 24.—T. P. an American, aged 22, was admitted on January 22, 1868, for left direct inguinal hernia, and was operated on for radical cure on February 18, 1868. The plug was removed on February 22, and he was discharged on April 16, 1868; but the operation proved unsuccessful.

Case 25.—J. W., an English sailor, aged 48, was admitted on February 14, 1868, with left oblique inguinal hernia. He was operated on for radical cure on February 25. The plug was removed on the 29th, and he was discharged cured on April 6, 1868.

Case 26.—J. C., an English fireman, aged 32, was admitted on February 14, 1868, with right oblique inguino-scrotal hernia. He was operated on for radical cure on March 18. The plug was removed on the 23rd, and he was discharged cured on May 23, 1868.

Case 27.—H. M., an English sailor, aged 20, was admitted on March 18, with right oblique inguino-scrotal hernia. He was operated on for radical cure on May 13. The plug was removed on the 16th, and he was discharged cured on June 22, 1868. He had been operated on once before in the General Hospital.

Case 28.—J. P. N., an Irish clerk, aged 40, was admitted on April 18, 1868, with right femoral hernia. He was operated on for radical cure on May 21, and the plug was removed on the 26th. The operation proved unsuccessful, and he was discharged on July 18, 1868.

Case 29.—H. W., an English cook, aged 28, was admitted on May 29, 1868, with left inguino-scrotal hernia, and was operated on for radical cure on the 30th. The plug was removed on June 4, and he was discharged cured on August 23, 1868.

Case 30.—J. M., a Scotch seaman, aged 39, was admitted on May 29, with left oblique inguino-scrotal hernia. He was operated on for the radical cure on May 30. The plug was removed on June 4, and he was discharged cured on July 2, 1868.

Case 31.—W. D., a Scotch carpenter, was admitted on June 24, 1868, with right oblique inguinal hernia. He was operated on for radical cure on July 14. The plug was removed on the 18th, and he was discharged relieved on August 3, 1868.

Case 32.—Nobo Krishun, a Hindoo priest, aged 34, was admitted on July 29, 1868, with left oblique inguino-scrotal hernia. He was operated on for the radical cure on July 29. The plug was removed on August 2, and he was discharged on September 14, 1868.

Case 33.—Assodoolah, a Mahomedan moonshee, was admitted on July 19, 1868, with left oblique inguino-scrotal hernia. He was operated on for radical cure on August 25. The plug was removed on the 29th, and he was discharged cured on November 29. He had been operated on for strangulated hernia immediately after admission. The sac was not opened. The stricture was found at the external ring.

Case 34.—C. S., a Dutchman, aged 43, was admitted on August 29, 1868, with left oblique inguinal hernia. He was operated on for radical cure on October 2. The plug was removed on the 6th, and he died of traumatic tetanus on October 12, 1868.

Case 35.—J. B., a Scotch clerk, aged 33, was admitted on January 2, 1869, with right oblique inguino-scrotal hernia. He was operated on for radical cure on March 22. The plug was removed on March 26, and he was discharged cured on April 29, 1869.

Case 36.—Dinonath, a Hindoo farmer, aged 17, was admitted on March 20, 1869, with left oblique inguinal hernia. He was operated on for radical cure on the 22nd, and the plug was removed on the 26th. He was discharged cured April 29, 1869.

Case 37.—J. F., an English cook, was admitted on August 15, 1869, with right oblique inguino-scrotal hernia. He had been operated on before by Wutzer's method, which failed. He was then operated on for the radical cure on August 19. The plug was removed on the ninth day, and he was discharged cured on September 2, 1869.

Case 38.—E. J. G., an English seaman, aged 40, was admitted on August 25, 1869, with right oblique inguino-scrotal hernia. He said he had been operated on before. The operation for the radical cure was performed for the third time on August 25. The plug was removed on August 29, and he was discharged cured on November 16, 1869.

Case 39.—Scenath, a Hindoo, aged 45, was admitted on September 20, 1869, with right oblique inguino-scrotal hernia. He was operated on for radical cure on September 24. The plug was removed on September 29, and he was discharged cured on October 26, 1869.

Case 40.—E. C., an English sailor, was admitted on

September 29, 1869, with left oblique inguino-scrotal hernia. He was operated on for radical cure on October 4. The plug was removed on the 8th, and he was discharged cured on October 27, 1869.

Case 41.—J. C., an English sailor, aged 25, was admitted on December 10, 1869, with right oblique inguinal hernia. He was operated on for radical cure on the 16th, and the plug was removed on the 20th. He was discharged cured on March 15, 1869.

Case 42.—J. D., an English sailor, aged 32, was admitted on December 18, 1869, with right oblique inguinal hernia. He was operated on for radical cure on January 15, 1870. The plug was removed on January 20, and he was discharged cured on February 22, 1870.

Case 43.—Koylas, a Hindoo shopkeeper, aged 24, was admitted on January 21, 1870, with left oblique inguino-scrotal hernia. He was operated on for radical cure on February 3. The plug was removed on February 8, and he was discharged cured on March 15, 1870.

Case 44.—W. S., an East Indian clerk, aged 28, was admitted on February 15, 1870, with right oblique inguinal hernia. He was operated on for radical cure on February 15, 1870, and the plug was removed on the 18th. He was discharged cured on March 20, 1870.

Case 45.—J. T., an Englishman, aged 27, was admitted on February 16, 1870, with right oblique inguinal hernia. He had been operated on with the plug once before. Wood's operation was performed on February 17. The wires were removed on February 24, and he was discharged cured on April 29, 1870.

Case 46.—C. K., an American guard, aged 30, was admitted on November 11, 1870, with right oblique inguino-scrotal hernia, and was operated on for radical cure on November 15, 1870. The plug was removed on November 19, and he was discharged cured on December 18, 1870.

Case 47.—Nobo, a Hindoo farmer, aged 20, was admitted on October 14, 1870, with left oblique inguino-scrotal hernia. He was operated on for strangulated hernia on October 15. The sac was not opened, and the constriction was found at the external ring. After the wound had healed he was operated on for radical cure on November 15, 1870. The plug was removed on November 19, and he was discharged cured on December 14, 1870.

Case 48.—Sue Nauth, a Hindoo, aged 40, was admitted on January 12, 1871, with right oblique inguino-scrotal hernia. He was operated on for radical cure on the 21st. The plug was removed on the 14th, and he was discharged cured on February 22, 1871.

Case 49.—E. B., a Welsh sailor, aged 27, was admitted on July 15, 1871, with right oblique inguinal hernia. He was operated on for radical cure on July 15, 1871. The plug was removed on July 20, and he was discharged cured on August 12, 1871.

Case 50.—Hajee Mahomed Ally, a Moullah, was admitted on August 9, 1871, with right oblique inguino-scrotal hernia. He was operated on for radical cure on the 18th. The plug was removed on the 22nd. He was discharged cured in September.

Calcutta.

AMAUROSIS SUCCESSFULLY TREATED WITH HYPODERMIC INJECTIONS OF STRYCHNIA.

By A. S. G. JAYAKAR, M.R.C.S.E., Etc.

P. H., A RAJPOOT, aged about 35, was admitted into Hutteesingh's Hospital on March 21, 1871, with total amaurosis of both eyes. He had an amaurotic look, and his vision was very dim, being perfectly unable to distinguish light from darkness. He constantly turned the eyeballs upwards, almost under the upper lids, evidently for the purpose of attempting to bring the remaining small portion of the retina in axis with the object seen.

History.—The history of the case was rather unsatisfactory, the patient being far from intelligent. The only account he could give of his blindness was that it first commenced thirteen months ago with a sensation of burning in both the eyes, followed by a gradual loss of sight. He then suffered from fever for about ten months, and had suffered from total amaurosis for nine months before his admission.

Ophthalmoscopic Examination.—Right eye: Image natural;

media dull; disc anæmic; no venous congestion; shape of bloodvessels undefined; arteries atrophied; retina pale and anæmic. Left eye: Image natural; media dull; disc and retina anæmic, the same as in the other eye; arteries atrophied.

There was no photophobia or pain of any kind in either eye.

On March 31 one twenty-fourth of a grain of strychnia was injected into the back of the neck.

April 1.—The patient expressed himself slightly relieved. He could count fingers and distinguish colours with the left eye. With the right he could only distinguish light from darkness.

4th.—There was some more improvement in the right eye. He could count fingers and tell different colours with it; but there was no progress with the left eye. He was ordered to again have one twenty-fourth of a grain of strychnia injected.

5th.—Left eye considerably improved; so also the right, to a certain extent. Could tell the shapes of different objects and count dots.

9th.—One twenty-fourth of a grain of strychnia was again injected.

10th.—There was a marked and decided improvement in the left eye, the right also having improved to some extent. With the left he could tell minute objects.

18th.—Another injection administered.

19th.—The patient could count dots No. II. (arranged on Snellen's test-type scale). With the right he could only count No. XX.

May 21.—An ophthalmoscopic examination revealed an improved state of both the disc and retina in the left eye; whilst the same structures in the right eye were in much about the same condition as on his admission.

7th.—Hypodermic injection of strychnia was given in the right temple.

12th.—The injection in right temple was repeated.

22nd.—No change having been noticed in the right eye since the last note, the injection was again repeated, with this beneficial effect: that he could see No. VI. easily with the right eye, the sight in the left eye remaining stationary.

By June 6 (the day on which he was discharged from the Hospital, being very anxious to return home) the physical condition of both the disc and retina in the right eye had greatly improved; and, instead of atrophic arteries, there were well-defined bloodvessels in both the eyes. Vision of right eye could count No. VI.; with left eye could count No. II.

Remarks.—This was evidently a case of asthenia of the retina and discs, accompanied with exhaustion of the optic nervous apparatus, and a case, therefore, best suited for treatment with hypodermic injections of strychnia, so strongly advocated in these cases by Professor Nagel, of Tübingen. The patient had altogether seven injections between March 31 and May 22, the quantity of strychnia used being about one-third of a grain; and, on the whole, the progress of the case has been satisfactory. Perhaps, had a larger quantity been injected each time, a more rapid improvement might have been noticed; and, if the line of treatment had been persevered with for a few weeks more, I have no doubt but that his right eye would have eventually come to the same state as the left, so as to be able to count No. II., and even some further improvement may have been reasonably expected in the left.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

EDINBURGH ROYAL INFIRMARY.

CASE OF ADHESIVE PERIMETRITIS.

(Under the care of Dr. MATTHEWS DUNCAN.)

[Reported by Dr. J. R. HARDIE.]

B. C., AGED 21, who is married, and has three children, was admitted to Ward 16, January 9, 1872, complaining of a weight in the left side of the belly. Her last child was born two months ago, and it was a month subsequent to this occurrence that she first felt the symptom complained of. She was knocked down two days after delivery, and although she experienced no pain at the time, attributes her complaint to this accident.

a clean start, but this cannot be done in a day; and meanwhile we should be very foolish to reject new sharp instruments because there is a confused multiplicity of cabinets in which they are kept.

Then, again, as to the authorities who are to put the laws into force. Most towns at present, which possess anything like municipal government, have in that governing body a "local authority" to put sanitary laws into force. Mr. Stansfeld proposes to continue them under the name of *Urban*, and to erect extra-urban districts under the name of *Rural* sanitary districts; besides which, *Ports* are to have a special sanitary authority of their own.

In the next place, there are the officers who shall inform the local authorities (*i.e.*, Medical Officers of Health), and those who shall execute the laws, serve processes, etc. (*i.e.*, Inspectors of Nuisances). The existing Medical Officers of Unions may be elected Medical Officers of Health.

There is, lastly, the machinery requisite for harmonising and combining the powers of the various local authorities, and for superintending the due execution of the whole. This is reserved for the Local Government Board, with its Medical Officer and its Inspectors—Medical, engineering, and legal—with a responsible Cabinet Minister and Member of Parliament at the head.

This is the gist of Mr. Stansfeld's Bill. Now, it is perfectly unavoidable that it must be subjected to the sharpest criticism at every stage. Most important it is that our brethren who have invested their capital—*i.e.*, their lives—in acquiring practice in rural districts, and who have borne the burden of parochial work, should not be disturbed by regulations which might inflict on them new duties for which they have neither time nor taste. At the same time we would urge them not to listen to the fretful friends who are perpetually plying them with dismal prophecies. Increase of pay, of authority, and of position will always tell; and we do not believe that a man who is honoured and trusted for his Medical skill will be damaged by being called upon to use it as Medical Officer of Health. Public opinion demands preventive as well as curative treatment, and they will be wise in swimming with the flood. If a man is afraid of acting as Medical Officer of Health, he will also be afraid of acting as Deputy or Assistant. As for the question of sanitary areas, so many interests are involved that we may be certain this will be decided on other than theoretical grounds. Country people, if we know them, will repudiate the possibility of paying for town improvements. Monopoly in analysis or in work must be repudiated. Between inspectors from a central Government office and those from intermediate centres, in these days of railways and telegraphs, there may not be much practical difference. If there is any difference, so far as despatch of business is concerned, commend us to a central power. Too much stress should not be laid on the idea that men who act as sanitary officers should give up private practice; every case should be decided on its own merits; and there are many provincial Physicians who could afford to devote some time to sanitary work. Meanwhile, we would urge our readers to get what they can, without waiting for the realisation of impossible dreams. In this view, Dr. Barclay's late criticisms will be accepted as those of a practical man well acquainted with the subject he treats of.

THE WARWICKSHIRE STRIKE.

The Warwickshire Strike is a movement which is of some Medical interest. We do not mean in its political aspect, but in its sanitary. The English agricultural labourer is entirely a different man in habits and mode of life from the English town labourer, whether mechanic or manufacturing hand. He is taller, bigger, and stronger, but not so acute and restless; slower, and less energetic. He does not consume one-tenth of the animal food that the town operative devours, but he does

not drink one-twentieth of the quantity of alcohol. He may occasionally get a little muddled on muddy ale or sour cider, but he is never incapable for three days in the week. He lives in the open air, and is exposed to all weathers; his clothing is, as a rule, not insufficient, but his food is chiefly bread, potatoes, suet dumpling, and vegetables, with a little pork or cheese, but very rarely fresh butcher's meat. He sleeps probably over a dungheap or near a cesspool, with his wife and half a dozen children in the same room, and is very fortunate if he escape an attack of continued fever once in his life. But his great enemy when he is over 50 is rheumatism, and this consigns him to the care of the parish during the last decade. Still his existence has its bright side. He rarely knows what a headache is. His labour is of the slow, enduring kind which does not exhaust; and, if he escape death from continued fever or accident, he lives beyond three-score years and ten. His children are healthy, they are not syphilitic or strumous, and his wife does not suffer from "nerves." The town operative, who earns twice as much money, and who could earn three times as much if he worked all the working days of the week, dies at 50, and rarely passes a year without being an out-patient at a Hospital or getting some medicine from his club Doctor. One of his children has hip-joint disease, and another is blind with one eye from keratitis. His wife spends nine hours a week waiting for the Doctor in the out-patient room of a Hospital. He was a clever, intelligent lad, with a smattering of education, but after 30 he got heavier and more stupid, and has long given up all idea of climbing to a higher round in the social ladder.

Now, supposing that the Warwickshire Strike spreads, and that it results in giving the agricultural labourer higher wages, what will be its result? Will the agricultural labourer become a higher, better-developed, more intellectual, and not less physically healthy man than he is? or will he, with increased means, adopt any of the causes of deterioration which are at work among our town populations? We perfectly agree with the defenders of the present combination, that the agricultural labourer's condition might be and ought to be bettered. He ought to have a better dwelling, and he ought to have a somewhat more animalised diet; but, except in these two particulars, we believe his lot in life is infinitely preferable to that of the town operative, who works on from day to day amongst the noise, the comparative darkness and smells of a factory, and retires from the public-house (the only bright place that he knows of) to his room, with his ailing wife and sick children in a town alley. If the farm labourer can be taught to make some provision for old age, and to give his children a better education, and to spend part of his increased pay on a somewhat more nutritious diet, a higher rate of wages will make him a happier and a more energetic man. But if the greater amount of money current amongst a rural population, and the shorter hours of work, convert the village ale-house into a gin-palace and bring into the country the vices of the town, it will only necessitate an increase of Cottage Hospitals and County Infirmaries.

ANTISEPTIC TREATMENT OF SMALL-POX.

DR. ARTHUR WYNNE FOOT, of the Meath Hospital, has recently communicated to the Medical Society of the College of Physicians, Dublin, during their discussion of the subject of small-pox, a paper which we deem worthy of being made as widely known as possible. A full report of the proceedings of this Society appears in the current number of the *Dublin Monthly Journal*, to which our readers may refer, should they desire greater detail. The subject is the "Antiseptic Treatment of Small-pox," and is the more important inasmuch as it introduces a principle into the chaotic varieties of treatment generally adopted. The ordinary plan of dealing with small-pox, as with most other diseases which run a course, is to let it alone, to treat symptoms as they arise, and to ward off evil effects should they

make their appearance. In the ordinary sense of the word this is not treatment at all, and we are by no means sure that it is sound in principle. At all events, Dr. Foot has attempted, with a certain degree of success, to apply a system which has been attended with good results in Surgery to a loathsome disorder, and one of extreme severity. We are happy to make his ideas and his system more widely known than they now are, and we hope that others will test both, so that we may know their true value.

The total number of patients treated was fifty-nine; but these were so carefully studied that their value is much greater than a multitude less closely observed. Of the fifty-nine, twenty-four were confluent and six semi-confluent, and out of these eleven died—a mortality of more than one-third. But it must be remembered that confluent small-pox in a severe epidemic is an extremely fatal malady, its fatality amounting to quite 50 per cent.; moreover, the cases treated were in badly fed patients, brought late to Hospital, some unvaccinated—in short, a most unpromising series. Dr. Foot says—

“The way in which I endeavoured to carry out the antiseptic treatment was by giving carbolic acid internally in the shape of the sulpho-carbolate of sodium, and when more suitable the sulpho-carbolate of iron, giving the sulphurous acid of the Pharmacopœia, diluted with water, as the usual drink, using gargles of sulphurous acid, spraying the larynx with it, washing the nares and upper surface of the soft palate with solutions of sulphurous or of carbolic acid, keeping carbolic oil to the face, washing the body with solutions of sulphurous acid or vinegar and water, throwing pure sulphurous acid about the bed and bedclothes of the patient, and burning sulphur in the room, so that the sick might breathe for some portion at least of the day an atmosphere charged with some sulphurous acid gas in it.

“After much consideration of the subject I have adopted the opinion that the secondary fever of confluent and semi-confluent cases is due to the presence in the body of products of decomposition, which commence to be formed as soon as the lymph contents of the hitherto vesicles become purulent, rather than that it results from the dermatitis which springs into existence at that period, and which I consider to be the necessary consequence of the irritation of the now numerous sub-epidermic abscesses; and believing that in carbolic acid, used both externally and internally, there is an agent capable, when it can get fair play, of checking the decomposition of the pus, or of paralysing the effects of the products of its decomposition, I considered the first thing was to ascertain the best mode of its administration.

“I have given the sulpho-carbolate of sodium in thirty-four cases of small-pox, in doses of from seven grains occasionally, to sixty grains every third hour; it is very soluble, and can be taken in plain water, or if its earthy-saline taste must be disguised, it can be given with some infusion of orange-peel or of cascarilla. During its administration carbolic acid is eliminated by the lungs, its odour being very perceptible in the breath, and the sulphuric acid and soda pass off by the kidneys. I have not observed it to cause any sickness of the stomach or unpleasant feeling in the head, even in very large doses; children have no objection to it. I have also verified the observations of Dr. Sanson, that subsequent to its administration the fetor of the evacuations from the bowels is greatly lessened, the urine is unusually slow to decompose, and the flesh resists putrefaction. I had opportunities of remarking the latter fact in making post-mortem examinations. I never found anyone to complain of the usually nauseous variolous odour of the skin.

“At the same time, in all confluent and semi-confluent cases I use sulphurous acid in every form and way in which it can be applied.

“One of the simplest and most effective ways of exhibiting sulphurous acid is in the gaseous form; flowers of sulphur dropped on a heated shovel and carried about the room with its pale blue flame, forms by its combustion sulphurous acid gas, which, diluted with the nitrogen of the atmosphere, can pass into the lungs of the patients; and I consider that there is reason to believe that this practice three or four times a day is beneficial to the attendants and other inhabitants of the house as a prophylactic. Irritation of the bronchial membrane soon gives notice when there is as much sulphurous acid gas in the atmosphere of the room as is consistent with health; it specially and soonest affects anyone with bronchitis, and I should say it

ought to be used very carefully if the variolous patient were labouring under that affection. One of the nurses at the Hospital who suffered from chronic bronchitis used to be greatly affected by the daily fumigations if in the rooms when it was being done, and used to feel its effects long before and long after any of the patients or other attendants. Some persons in health also have by idiosyncrasy a condition of the lining membrane of the air-passages which makes them peculiarly sensitive to this gas, even in a very much diluted form, and in such a reflex cough is very quickly excited. It is not to be supposed that the principal object in burning sulphur is to disinfect the room—this is an after-consideration, and would require an amount of sulphurous acid gas dangerous if not fatal to life; but it is to develop as much of this antiseptic agent as may be safely inspired, with the view of checking the multiplication of the small-pox poison in the person of the patient, very minute quantities of sulphurous acid being capable of arresting fermentation.

“The sulphurous acid of the Pharmacopœia undiluted I frequently apply in an atomised vapour to the nares and pharynx, through vulcanite tubes, curved or straight as may be required, in the manner recommended by Dr. Dewar, of Fifeshire. I have found that patients like it, and eagerly ask to have the operation repeated. It removes disagreeable tastes from the mouth, keeps the nose free from obstruction by accumulated crusts, and much of it must reach the lungs. A few whiffs open the nose when it is stuffed, or when, as hospital patients say, the head is stopped; the spray has not the suffocating odour of the bottled acid.

“I give them the acid internally several times in the day, or for a drink both day and night when there is much thirst, in drachm or two-drachm doses at a time, diluted with water. One drachm of the acid in two wineglassfuls of iced water is a very pleasant drink. Less water may be used—a drachm may be taken in a wineglassful of water; but if the acid has been freshly prepared, or very well kept, the drinking such a solution may catch the breath. If the person drinking the acid in the strength of one drachm to two ounces of water will avoid inspiring through the nose when the glass is brought to the lips, and swallow the liquid in gulps, the vapour cannot irritate the air-passages. I always have the acid added to the water which the confluent and semi-confluent cases drink, and they like its acidity very much. I frequently take it myself as an agreeable and wholesome beverage, and advise the students to do so, as a prophylactic. I prefer the sulphurous acid to the sulphites or bisulphites, because they are so unstable in solution—the form in which they must be given—rapidly absorbing oxygen, and passing to the state of sulphates. Neither have they much to recommend them in preference to sulphurous acid on the score of cheapness, purity, or flavour.”

Of the complications which may arise in confluent small-pox, and which add so much to its danger, Dr. Foot enumerates four—laryngitis, delirium, hæmorrhage, and albuminuria. Of the first he says—

“Laryngitis in some degree is an almost inevitable event in confluent variola, and is, perhaps, usually the most frequent immediate cause of death. I have endeavoured in all severe cases of variola to anticipate this event—this I think is the way to combat it; but if the case is not got in time, of course this plan is out of the question. When I have had an opportunity of treating a case from the commencement, or from an early period, upon the very first complaint of any kind about the throat—and sometimes the answer to the constant inquiry will be only a ‘queer feeling’ in the neck—I surround the neck with cotton-wool, spray the larynx and pharynx with a saturated solution of tannic acid, give ice, and mop the throat with glycerine of tannin. I afterwards, when necessary, apply leeches freely to the neighbourhood of the thyroid cartilage, followed by poultices and hot sponges. I also use sprays of solution of carbolic acid, five minims to the ounce, solution of sulphite of soda, sixty grains to the ounce, or the sulphurous acid B.P. undiluted. Of any single remedy ice has certainly given the most relief in laryngeal complications, and has been in almost constant use night and day, in the small-pox wards; the swallowing of the melted ice also relieves the salivation and dysphagia resulting from the irritated mouth and pharynx, and next to ice the patients seemed to like, from its immediate, though often only temporary relief, the spray of carbolic acid, especially when sent through the nose, and followed by a stream of water.”

Delirium, Dr. Foot thinks, is mainly due to habits of previous intemperance, and so allied to one form of delirium

traumaticum commonly called delirium tremens. In these stimulants were the most useful remedies; chloral and opium did no good.

There was only one case of hæmorrhagic small-pox, and of this the patient died. Albuminuria occurred in three, and these died.

As regards the face, Dr. Foot thinks the treatment given above as important as local applications, but he takes advantage of these, too, by keeping carbolic oil on it from the first in varying strength, from one to three or one to seven of oil, hiding the smell, if objected to, by origanum. This he thinks does good.

Dr. Foot notes that with the sulpho-carbolates the urine is commonly blackened; but this, he says, is not due to the presence of blood. Furthermore, he remarks that he has always given sulphurous acid along with the sulpho-carbolates, his object being to cure his patient, not to experiment with drugs.

The use of antiseptic remedies in such a disease cannot be made out by one series of experiments, but in the hands of Dr. Foot they have at least proved so useful as to amply merit further trial. Dr. Hudson's experience has also been highly favourable.

THE BRIGHTON REVIEW.

THE battle of Easter Monday has been this year even more bloodless than usual. A case supposed to have been an epileptic fit, and two or three of faintness from fatigue, have been all that came into the Doctors' hands. About 25,000 Volunteers have come to Brighton, gone through the day's work, and returned, with no greater list of casualties than this. Less could scarcely have befallen them if they had stayed at home; more would almost surely have befallen them if they had walked about the streets of London all day. But, however satisfactory this result may be, it is by no means one that can be reckoned upon in such cases, and the precautions taken by the Medical Staff, under the direction of Brigade-Surgeon J. Cordy Burrows, with the assistance of Dr. Mayo, Assistant-Surgeon Inns of Court R.V., cannot be considered excessive. An accidental explosion, the upsetting of a gun or waggon, a stampede among the horses, or a score of other mishaps, might seriously change the aspect of the day. To be ready for any such occurrence, Field Hospitals were established as follows:—

1. A large marquee on the top of Newmarket-hill, with twelve beds, in charge of Surgeon J. Heckstall Smith, 1st Sussex Artillery Volunteers, assisted by Dr. Paul, Surgeon 8th Surrey R.V.

2. Some rooms at the Warren Farm, with six beds, in charge of Surgeon G. F. Hodgson, 1st Sussex R.V.

3. A room at the Race-stand, with six beds, in charge of Assistant-Surgeon H. Helsham, 19th Surrey R.V.

4. A flying Hospital, consisting of a bell tent carried in an ambulance waggon, of which Dr. Mayo took charge.

The last-named very compendious establishment was first set up on the left of the 4th Division—the left wing of the Lewes force—at a point indicated by the commander, Major-General Armstrong, and afterwards moved up to a position near the centre of that force; but the brevity of the battle, which lasted only an hour and a half, prevented its quality of mobility from being put to the test. It was necessary to have an outlying Hospital of some kind, because the three stations before mentioned were all towards the Brighton end of the ground. To one looking at the Volunteers not from a purely military point of view, but simply as "Kanonen-futter," or food for powder, the improvement which has taken place in the last few years is very apparent. A better average physical standard and a steadier deportment distinguish the Brighton Volunteer of to-day from the raw shopboy, whose idea of the mode of enjoyment of those whom he supposed to be his betters led him in former years to make many nights hideous, and from the

hero of that Windsor review—a day to Volunteers always *carbone notandus*—when a not-much-enduring Inspector-General was mobbed at a fatal bridge. But all this, let us hope, is buried in the past. At all events, it is certain that no general in the world need wish for better average material, or for men more willing to learn, than those five-and-twenty thousand partly trained soldiers who went out on Monday; and it is no less certain that, whether under the name of Volunteers or, what would be far better, as battalions of Militia, the class which furnishes those men has taken, and will take, its place in the defensive force of the country, whether it please office-holders and other privileged persons or not.

At the service held on Sunday in the dome of the Pavilion, the upturned faces of 3000 men afforded an interesting study. The great majority were, of course, of one class—the well-fed, well-clothed, well-housed, well-to-do class. There were 3000 crania, noses, and mouths, and as many pairs of eyes and ears from which to generalise—all, or nearly all, belonging to natives of the southern part of this island. The noses did not justify the pictures of the typical Englishman of our Continental neighbours' satirists, for the great majority, instead of being hooked, were more or less straight, or concave. The ææ were, perhaps, wider and fuller than the Teutonic type, and decidedly more overhanging than the Celtic type. The open mouth and projecting upper incisors represented by the same artists were scarcely to be seen. They belong, indeed, usually—with other instances of defective development—to the women of the idle and overbred class in this island. As to colour of hair and eyes, the Teutonic tints decidedly predominated. Of downright carrotty heads there were very few. The crania were, it must be admitted, not very much to boast of. They were, however, of a fair average shape, capable of improvement; and if education in this country is brought up to anything like the level of other civilised countries, the heads carried by the grandsons of these 3000 will show a marked advance. There was a fringe of elegance apart from the general throng, where the narrow skeleton, small brachycephalic cranium, and projecting nasal bones gave not much promise of improvement. Among so many faces all kinds of character were, of course, to be read; the ambitious man, perhaps, came most to the front. The patience with which all endured an overdose of carbonic acid and clerical oratory, until human nature would stand it no longer, was highly praiseworthy.

The Ambulance Service was somewhat more efficient than on former occasions. Four very well-horsed waggons were sent, in charge of Lieutenant Irving, of the Control Department, two of which, under Dr. Mayo's direction, accompanied the Lewes force, while the other two were stationed between the Brighton force and the fixed Hospitals. Fortunately, their duties were almost limited to a "walk over"; but if accidents had occurred, four waggons would have been found none too many for ten square miles of ground. A new pattern of ambulance waggon was completed a year ago at the Arsenal at Woolwich, but has not yet made its appearance among the Volunteers. That there is room for improvement in the old ones may be inferred from the perhaps too-highly-coloured statement of a Regular officer on the field on Monday, that, if he were badly wounded, he would elect to be taken out and shot at once rather than travel across country in one of them.

Medicine has had more to do with this review than appears on the surface; for did she not, in the person of our worthy brother, Mr. J. Cordy Burrows, now for the third time Mayor of Brighton, rally the fainting spirits of the citizens when the eoked-hatted interest was adverse—nay, more, beard the lion in his den, the official on his stool in Pall-mall, and when the point was carried, and the review after all came to Brighton, entertain the commanding officers and the Doctors at breakfast at the Pavilion, and crown the day with a capital subscription-ball there, got up in forty-eight hours, at which Prince Arthur and Prince Edward of Saxe-Weimar, a great part of the staff,

and about 500 others right willingly assisted? Long may this most public-minded citizen retain the power of acting as a Pericles to his fellow-townsmen; and when his active career is closed by a green old age, let no man, moved by that irreverent spirit of jesting against our Profession which is so common among ignorant people, deny him the right to use the famous boast of that great man when his work was ended.

Mr. Burrowes's fellow-townsmen have shown their appreciation of his readiness to devote himself to their interest on all occasions by presenting him, shortly before his third election as Mayor, with a handsome carriage and pair, and £300 worth of plate—a gift as creditable to them as honourable to him.

The march past at the Grand Stand was all that could be desired; and as the two contending armies joined in brotherly accord on the race-course, their day's work could be briefly summed up as a short engagement, ending in a happy union.

THE WEEK.

TOPICS OF THE DAY.

Saunders's News-Letter of April 1 contains an able letter, signed "Dispensarius," on the Poor-law Medical Service of Ireland, which well deserves the consideration of Parliament and the General Medical Council. Ireland is just now suffering from a severe epidemic of small-pox. In Dublin alone the deaths already amount to 750, a number which would be represented by about 7500 deaths in London, and the disease will undoubtedly spread over the country as it has in England. The Poor-law Medical Officers in Ireland number about 1000, and they include half the Medical men in the country. In the country districts the majority of the Medical men are Poor-law Medical Officers, and in many—as Cavan, Fermanagh, Kildare, Longford, Queen's County, Roscommon, and Sligo—they are nearly all so. Four-fifths of the inhabitants of Ireland form the rural population, and number over 4,000,000 souls, who in sickness are treated by 1000 Medical men, or about 1 to every 4000. There are at present about 2000 Medical men in Ireland, but of these 1000 practise in towns, and the meagre salaries of the Irish Dispensary System are not sufficient to induce them to go into the country districts. Moreover the supply of Medical men is lessening. This is proved incontestably by the diminishing receipts of the General Medical Council for Registration, and the reasons are not difficult to find. In the first place, the portal into the Medical Profession is becoming yearly more narrow and difficult of access, and the difficulty will be greatly increased by a Conjoint Board with a thirty or thirty-five guinea diploma; in the second, Medical fees have not risen in proportion to the general diminution in the value of money; in the third, trade and manufactures offer, in consequence of the levelling-up process that has been going on for a long time, an equally good station in society and in public estimation, and far greater facilities for becoming rich. In the face of these things how are the sick poor population of Ireland and (in course of time) of England and Scotland to be Medically tended? Small-pox, as we have said, is increasing in Ireland, and will very probably be followed by typhus, which is never entirely absent, and at present there is one Medical man to 4000 of a sparsely scattered population! There are three remedies for the present state of things. First and foremost, an increase of pay to the Dispensary Medical Officers sufficient to attract men to enter the Profession. Secondly, a division of the Dispensary districts into smaller areas. Thirdly, the competitive system, which would do away, in Ireland, with the miserable religious feuds which make it impossible for a Roman Catholic Doctor to obtain an appointment in one district, or a Protestant in another.

The Rectorship of St. Andrews has been accepted by Lord

Neaves, who, in the election, obtained three more votes than Professor Huxley.

Mr. R. Strickland Hannay, the House-Surgeon to the Westminster Hospital, in reference to one of the cases headed "Drunk or Dying," which appeared in the papers, has written to the *Times* a letter in explanation of his conduct, which appears to have been greatly misrepresented at the inquest. He writes:—

"I examined the man carefully, and questioned the two men who were with him, and the information which they gave me was quite different from what they are reported to have sworn. They did not tell me he had vomited blood, nor had he any marks of having done so, and they did not lead me to suppose that he had fallen anything like sixteen or eighteen feet; but one of the men told me that he had given Ford two half-quoters of brandy after he fell.

"I did not order him away from the Hospital then; but, though there were not the slightest symptoms of either concussion or compression, I said, 'Better let him lie down for half an hour, and I shall see him again.' About three-quarters of an hour after this I again went into the surgery, where I found the man sitting on the couch whistling, quite conscious and rather violent. I said I did not think it a case for admission, and advised him to go home.

"Now, Sir, for the statement that I refused to attend the inquest. That is entirely wrong. I saw the coroner's officer and nodded to him two hours before the inquest was held, and he said not one word to me about such an inquest being held, or that it would be held in our Hospital. Had he done so, I should have been only too glad to have attended without a subpoena, for the sake of clearing my own character and that of the Hospital; but I was not in the Hospital nor within some miles of it when the inquest was held, I being off duty at that time.

"I must solemnly and emphatically state that at the time I saw the man he had not one symptom of either concussion or compression of the brain, nor any sign by which any Surgeon in the world could have diagnosed the nature of the injury sustained; and others, besides myself, examined the man, and can bear me out in this statement."

Mr. E. Charlesworth, F.G.S., believes he has discovered traces of man in the Suffolk crag (older Pliocene). He has found teeth of an extinct shark, apparently perforated by human agency. The specimens will be exhibited and described at the Anthropological Institute on April 8. If his inference is correct, this would make man in England a congener of the mastodon, and put him back far earlier than the earliest flint implement yet discovered.

PROCEEDINGS OF THE ROYAL COLLEGE OF SURGEONS.

The following is an abstract of the unconfirmed minutes of the last Council of the Royal College of Surgeons, held on the 26th ultimo:—The President reported that communications had been received from the Home Office and from Marlborough House, conveying the gracious acknowledgments of her Majesty and of her Royal Highness the Princess of Wales of the addresses from this Council congratulating them on the recovery of his Royal Highness the Prince of Wales. The following resolution of the General Medical Council, forwarded by Dr. Paget, the President, was read: "That the Council approve of and sanction the Conjoint Scheme of Examination submitted by the Royal College of Physicians of London and the Royal College of Surgeons of England, to which the Universities of Oxford, Cambridge, and Durham have given their adhesion. The Council has at the same time to express its desire that means may be found by which the University of London and the Apothecaries' Society may be enabled to join in the scheme, so as to render it a complete scheme for a Conjoint Board for England."

Mr. Quain, as representative of the College in the General Medical Council, then made a statement in reference to the proceedings of that Council, when the following resolution of the Committees of the Colleges of Physicians and Surgeons with respect to the resolution of the General Medical Council

on the Conjoint Scheme was read, viz.:—"That this Committee, though not officially acquainted with the resolution of the General Medical Council on the subject of the scheme for an Examining Board adopted by the Royal College of Physicians and the Royal College of Surgeons, consider that the terms of the resolution warrant their recommending to the representative Colleges that they should proceed, so far as in them lies, to carry out the adopted scheme." Whereupon, it was moved by Mr. Charles Hawkins, and seconded by Mr. Hilton—"That the Committee on the Conjoint Scheme be authorised to proceed, so far as in them lies, to carry out the scheme as sanctioned by the General Medical Council;" and the votes of the Council having been taken on the motion, the same was carried *nem. con.* When Mr. Quain moved, and Mr. South seconded, the following:—"That having reference to the resolution of the General Medical Council respecting the scheme for Conjoint Examination, the Council thinks it desirable that means should be taken by the conjoint Committee of the Royal Colleges of Physicians and Surgeons to carry out the wishes of the General Medical Council, so as to render the scheme complete;" and the votes of the Council having been taken, a majority was against the same.

The Council elected a Committee to consider and report upon the conditions upon which members of twenty years should be elected to the Fellowship under Section 5 of the Charter of 1852. The Council also elected a Committee to consider and report on any alterations required in the by-laws and standing rules.

A report from the Dental Board was read, and the recommendation in reference to the non-recognition of the Dental Hospital, Russell-street, Liverpool, was adopted; but with regard to the recognition of the Dental Department of St. Thomas's Hospital, the Council was of opinion that the same should be recognised.

Owing to his absence, the consideration of Mr. Erichsen's motion was postponed.

A letter was read from Mr. Quain, resigning his appointment as a member of the Committee on the Conjoint Examining Board.

ACTIONS RELATING TO MEDICAL MEN.

THE recent Spring Circuits have been somewhat rife in actions by and against Medical men. They have been either for negligence on the one hand, or for defamation on the other. On the whole, the Medical Profession has come off with as little damage as the glorious uncertainty of the law generally assures, and has vindicated its honour and reputation as fully as such a large and somewhat heterogeneous body could expect. But what about the costs? In one case the judge cannot satisfy himself whether a contract was entered into with a father or with a son under age, and the court above must solve the knotty point. This means ruinous costs. In another, an apology with payment of costs terminated the action; but this means a balance of extra costs to be defrayed by the successful suitor, there being no damages to cover them—a compliment from the Bench being considered more than an equivalent. In a third case, £5 damages for a deliberate libel, though carrying costs, leaves a large margin disallowed by the taxing master. The spirit thus evinced by the individual members of the Profession to protect their honour or their reputation is, however, only the more creditable. Mistakes will occasionally occur, but they are not necessarily proofs of negligence or ignorance, and the Medical Practitioner cannot be expected quietly to acknowledge them as such. On the other hand, to submit patiently to slander would be only too readily accepted by the public as an acquiescence in its truth. Thus are Medical men, perhaps above all other members of the community, placed in positions which affect both their reputation and their pockets; and in the vindication of the former they must, it seems, generally make up their minds to suffer in the latter. There is one case of

peculiar hardship that has happened on the Home Circuit. A Medical man at Islington sued a gentleman living at Stoke Newington for £88, the balance of an account for Medical attendance for some years past. The defendant resorted to the ungracious plea of the Statute of Limitations. This, however, related only to £24, and there was a doubt whether even this sum was so barred. There was no defence to the remainder of the claim. A bill of exceptions was tendered to the judge's ruling; but as the judge perceived and observed that the only object was to gain time, and that the defendant could not prosecute the bill without finding substantial security, he suggested that that object would be attained by his giving such security upon the execution being stayed for a year; to which both parties agreed. The plaintiff is thus saved any further expense, but the ungrateful defendant obtains a further delay of twelve months.

AÉROTHÉRAPIE BY BATHS OF COMPRESSED AIR.

Is there amongst our readers a Doctor "out at grass" who is looking for some speciality to waft him into practice? If so, let him look through an article on compressed air baths by M. le Docteur Raoul Le Roy, in the number of the *Bulletin Général de Thérapeutique* for March 13. All useful inventions, says the author, are the product of France. Baths of compressed air were first proposed by Tabarié in 1838, and taken up by Pravaz, Junot, and Bertin, of Montpellier. Nevertheless, the idea was neglected at home, and wandered abroad, where it pined "dans la funeste adoption des idées Allemandes"—in the hands of persons incompetent to deal with it; now, however, it is again brought into notice in its native soil with some chance of scientific appreciation. It is chiefly as a remedy for the *cachexie urbaine* that M. Le Roy suggests it; and surely there are few more terrible sufferers from this than some of the inhabitants of the house-covered province which we call London. Want of sunshine, of proper food, and of proper exercise all conduce to the anæmia of crowded cities, but more especially such circumstances as conduce to the defective elimination of carbonic acid and admission of oxygen, which latter is required to complete the conversion of the white leucocytes into red globules. Hence M. Le Roy justly claims for mountain air the function of liberating the excremental carbonic acid, and thus as acting as a better hæmatic remedy than any drug or diet. By a singular transition, he passes from the virtues of air that is expanded to those of air which is compressed. The bath of compressed air has been used at various therapeutical establishments in this country for the opposite conditions of phthisis and pulmonary emphysema, but we are not aware that it has been used for the urban cachexy; but M. Le Roy propounds the theory that it has the same expansive power on the pigeon-breasted townsman that the elevation has on a mountaineer. It is not a high degree of compression which is needed—from four- to eight-tenths of an inch is enough; this is attained by forcing air into a neatly fitted metallic chamber, large enough to hold two persons, who may read, chat, and sleep whilst their air-cells are expanding and their tissues gaining strength under the dose of compressed oxygen. What this treatment may do in pulmonary disease we cannot say, but for inactive respiration we should say to the Londoner—Try Margate.

THE CHELMSFORD DISPENSARY AND INFIRMARY.

It is seldom that matters relating to our Profession are understood by the public, and more seldom still that they are commented upon by the general press in a spirit of justice and moderation. As a rule, we are regarded as always in the wrong. We are justified, therefore, in drawing attention to an able leading article in the last number of the *Chelmsford Chronicle*, respecting the dispute at present going on at the Chelmsford Dispensary and Infirmary. It appears that the Infirmary was established, as it were, on the Dispensary, Mr.

Gilson and Dr. Nicholls being Surgeons to the joint institution. It was customary to present each of these gentlemen with an annual gratuity of twenty guineas. Mr. Gilson always returned the gratuity as a donation to the funds of the institution. This gentleman withdrew from his appointment at the end of last year. The committee thereupon issued a circular to the Medical gentlemen of the town, intimating that it was their wish "to obtain gratuitous Medical advice for both institutions." One gentleman, and one only, accepted the offer, and this gentleman, Mr. Carter, was accordingly elected. It was scarcely likely that a paid and an unpaid officer should cordially agree, and hence the disagreement to which we referred in the last number of this journal. The *Chelmsford Chronicle* regrets this disagreement, and sees results from it perilous to the welfare of the institution. The writer remarks, with much justice and force, that such a condition of the Medical staff could not have been produced had the Medical gentlemen of the town been true to their own interests and to the interests of the Profession. A meeting should have been called of the Profession in Chelmsford, and a vote taken as to the advisability or otherwise of accepting the offer of the committee. Upon the vote so taken the Medical gentlemen would have acted, and hence no cause of disagreement could have occurred. The *Chronicle* makes some judicious remarks on the entire question of paid and unpaid Medical services to charities, and is in favour of the services being paid for. It condemns, but in qualified language, the entire proceedings of the committee, and thinks that they were not fair to either of the Medical gentlemen involved in the transaction. It suggests the calling of a public meeting of the governors of the institution to discuss the entire question.

A GOOD EXAMPLE.

THE Hackney Board of Guardians have set a good example with reference to vaccination. They have, with the consent of the Local Government Board, given gratuities varying in amount from five to ten guineas to four of the District Medical Officers of the Union, who are not public vaccinators, for the extra duties performed by them during the prevalence of the late epidemic.

CERTIFICATES OF DEATH.

IT is the bounden duty of a Medical Practitioner, before giving a certificate of the death of any person who has died under his care, to satisfy himself of the correctness of the facts to which he certifies. This is not only necessary to insure correct returns to the Registrar-General, but as a preventive of crime. We fear these facts are not regarded in their important bearings as they should be in very many instances. A certificate of death is frequently given as a "mere matter of form," and nothing more. Such a practice cannot, we think, be too strongly condemned. The following case in illustration is worthy of record:—At an inquest held on Monday by Dr. Lankester, at the Marylebone Workhouse, on the body of a boy aged 16 months, son of a tradesman in Gilbert-street, Clare-market, the evidence showed that, owing to some family misunderstanding, the mother took deceased away from home on March 24, and the next day placed him out to nurse. On Thursday he was taken by his grandmother to Dr. Clapp, who examined him and found he was dead. The friends then went to a Medical gentleman, the Physician to a charitable institution, who, although he had not seen deceased for five days, gave a certificate to the effect that he expired from hooping-cough, bronchitis, and dropsy. Dr. Clapp said he had made a post-mortem examination. The body was poorly nourished, the brain was congested, and the cause of death was inflammation of the pericardium. The Coroner remarked that no Medical gentleman who had not seen a patient for five days ought to give a certificate. In this case the party did not appear to know even the sex of the deceased. The practice, if carried out, would give rise to grave errors, if not

something worse. It was very fortunate that some of the registrars were sharp enough to detect these irregular certificates, and in the interest of the public he hoped a stop would be put to them. The jury thanked the coroner for his remarks, and returned the following verdict: "Death in the streets from inflammation of the pericardium through want of proper Medical treatment."

THE SMALL-POX EPIDEMIC IN DUBLIN.

AT the invitation of his Grace the Archbishop of Dublin, an influential gathering of some of the leading Physicians and citizens of that city assembled at the Palace, Stephen's-green, on Monday last, to consider the alarming extent and severity of the present epidemic, and the best means of attempting to arrest its further progress. Among those present were Drs. Stokes, Fleming, Ivory Kennedy, Cruise, Hayden, Banks, Head, Aquilla Smith, the President of the College of Surgeons (Dr. Wharton), the Vice-President of the College of Physicians (Dr. Gordon), William Moore, Grimshaw, Churchill, Speedy, and J. Hamilton.

Most of the Physicians present made important statements with regard to the nature and severity of the epidemic now raging, and laid special stress on the inadequate arrangements as yet made, amounting to almost absolute want of accommodation for convalescent patients. It was unanimously agreed that no effectual means can be devised for checking the disease which do not include the separation of the infected from the healthy until the period at which they become incapable of communicating infection has arrived. That there is thus an imperative necessity for the immediate establishment of a convalescent home. It was also resolved that the attention of the public should be directed to the necessity of removing families and individuals out of infected dwellings and rooms to a sanitarium or healthy lodging until the means of disinfection shall have been used. A requisition was presented by those present to the Lord Mayor, requesting him to convene a public meeting of the citizens of Dublin as soon as possible, in order to take these important matters into earnest consideration. We understand that the Lord Mayor promptly acceded to this request, and that a public meeting of the citizens was convened for Friday, the 5th inst. A subscription-list was opened for the purpose of raising a convalescent fund. The Archbishop has also asked those present last Monday to meet again at the Palace on to-day (Saturday). It is a matter for hearty congratulation that the citizens of our sister metropolis have at length been thoroughly aroused to a sense of the inefficiency of the existing sanitary arrangements of their city, and of the inadequacy of the accommodation for the victims of small-pox in their midst. There is no period of illness during which patients require more care and attention than that of convalescence; for, leaving out of view the risk to which those not yet attacked by an epidemic are exposed while associating with convalescents, the latter are themselves only too likely to fall victims to typhus fever in their enfeebled and frequently helpless state.

SMALL-POX JOTTINGS.

SMALL-POX is very prevalent at Dudley; one District Medical Officer alone has seventeen cases under his treatment.—Small-pox in Surrey at last shows signs of abatement in its virulence. In many of the rural districts which were affected with the disease there are no recent cases, but in the suburban and thickly populated localities the disease still lingers. In country districts, where temporary Hospitals were erected for destitute patients, the buildings are now abandoned, and hopes are entertained that the epidemic has been at its worst in the county of Surrey, and is gradually subsiding.—In Rome small-pox has almost disappeared; the few cases still registered are chiefly imported from Naples.—Last week in Islington one case of small-pox was reported, as against two in the previous week.

There had been two deaths from the disease.—Dr. Lankester, St. James's, Westminster, reports that during the past fortnight only one case of small-pox had been brought under notice since the last report, making in all 276 cases and 35 deaths since the beginning of the epidemic.—Small-pox has broken out in Peterhead.—The disease has appeared at Fraserburgh; stringent measures are being adopted to prevent the spread of the disease.—The return for the Mounthooly Small-pox Hospital, Aberdeen, last week shows:—Total number of cases admitted since opening, 148; new cases admitted March 28, 2; number of patients in Hospital, 28; total discharged recovered, 97; total dead, 23.—The Doncaster Board of Guardians recently ordered 250 members of the West Yorkshire Militia assembled at Doncaster to be vaccinated. The cost was £7 10s., and the Board asked the War Office to pay the money; the War Office declined.—In Berlin, in the week ending the 21st ult., 45 fatal cases of small-pox were recorded.—In Vienna, during the week ending the 16th ult., 49 deaths occurred from small-pox.—Forty fatal cases of small-pox were registered in Bombay during the week ending February 27; thirty of these occurred among the Hindoo population.—Thirteen deaths from small-pox took place last week in the borough of Sheffield—the lowest weekly number since the middle of October last; of these, six occurred in Brightside, three in Ecclesall Bierlow, and two each in Park and Attercliffe sub-districts.—There were nine cases of small-pox in the Halifax Workhouse Hospital last week. The new borough Hospital for the reception of small-pox patients will, it is anticipated, be completed and ready in the course of the next fortnight.—At the meeting of the Colchester Guardians last week it was reported that there were no fresh cases of small-pox in the workhouse, and that they now had a clean bill of health. It was also stated that there were no fresh cases of small-pox in the town.—Mr. Edward Foster, chemist and druggist, of Preston, was fined at the Preston Police-court, on Monday, 20s. and costs for refusing to get one of his children vaccinated. He had previously been summoned thirteen times for the same offence, and has invariably been fined for his negligence.—Sixty-seven deaths occurred last week in Dublin from small-pox; in the two previous weeks they had been 54 and 32.—In the metropolis last week the deaths from the disease rose to 55 as against 42 and 48 in the two previous weeks. In the four Small-pox Hospitals at Hampstead, Islington, Homerton, and Stockwell 19 fatal cases occurred, against 12 and 14 in the two preceding weeks.—Among 1616 patients (says Dr. Trench, in his report on the health of Liverpool for 1871) treated for small-pox, the deaths of the unvaccinated and of those on whom vaccination was doubtful were at the fearful rate of 56.4 per cent.; the deaths where one cicatrix was visible, on the other hand, were only 14.9 per cent.; where two cicatrices were visible they fell to 9.8 per cent.; while where three cicatrices were visible they were as low as 7 per cent. Dr. Trench adds, that he traces the importation of the disease to two Spanish sailors, who died of small-pox in Hospital in Liverpool in August, 1870. These two cases were followed by an epidemic which, commencing in the immediate neighbourhood of the Hospital, extended to almost every district of the town, and carried off 2093 persons.

SNAKE-BITES.—HALFORD'S TREATMENT.

Two cases of snake-bite (says the *Melbourne Argus* of February 15) which were successfully treated according to Professor Halford's plan are reported in the country papers. The *Ballarat Star* has an account of a young girl who was bitten just above the ankle by a snake five feet long. She was treated two hours afterwards with doses of ammonia by the mouth; but this mode of administration being insufficient, Halford's method was employed, and the patient was in about eight hours pronounced out of danger. In

the other instance, reported by the *Bendigo Advertiser*, a boy was bitten by a whip snake. He lost no time in getting home, and was kept up by strong doses of brandy. On the arrival of Dr. Thom the boy was growing drowsy and vomited violently. Caustic was applied to the wound, and brandy was administered; but, as the patient appeared to be growing comatose, Dr. Thom injected ammonia into one of the leading veins of the arm. The treatment took visible effect, and in a short time the boy was out of danger.

FROM ABROAD.—M. ALPHONSE GUÉRIN'S PANSEMENT OUATÉ—CASE OF IMPALEMENT—TREPHINING IN EPILEPSY FROM INJURIES OF THE HEAD.

M. FIAUX, in an interesting article in the *Gazette des Hôpitaux* (Nos. 22 and 25) calls attention to the eminent applicability of M. Alphonse Guérin's wadding dressing (*pansement ouaté*) in Military Surgery. The experience at the St. Louis during the War of the Commune, carried on under very unfavourable circumstances, exhibited its great superiority in a remarkable manner. Success attended this treatment of the most complicated as well as the most simple wounds, prevention of purulent infection by the filtering action of the wadding being a chief cause of this. The simplicity, facility, and rapidity of this mode of dressing constitute its chief feature, several sheets of wadding and five or six strong rollers being all the apparatus required. The dressing is always applied or renewed elsewhere than in the impure air of the wards. After having washed the stump or wound with tepid water, to which carbolic acid or camphorated spirit has been added, M. Guérin cuts all the ligatures save the principal one close, and fills up the depths with small masses of cotton level with the surrounding parts. Wadding is then applied in sheets or rollers until the part is surrounded by a thick and voluminous cylindrical cuirass, which extends far beyond the limits of the wound. The limb and applied wadding being held by the assistants, the Surgeon next applies a strong resisting bandage, twelve metres in length, in such a manner that after securing the proper adjustment of the wadding by its aid, he employs all the force he is master of in producing compression. However energetic or laborious this may be (never executing it with violence or jerks, however), the elasticity of the wadding renders it painless to the patient, and its being so is the test that a sufficiency of wadding has been applied. M. Guérin regards this "elastic compression" as one of the best elements in the treatment, preventing, as it does, abscess, purulent sinuses, induration, œdema, and other accidents. Under this compression, and in spite of the mass of wadding and bandage which surrounds it, the skin in the vicinity of the wound retains all its elasticity, suppleness, and physiological properties. The dressing once applied, whatever may be the seat, extent, or gravity of the wound, *all pain is immediately suppressed*; and thus, protected by so substantial a covering, the patient can be carried or can walk back to the ward without any inconvenience.

Another peculiarity of this mode of dressing is the rarity of its renewal, this only taking place at periods varying from twenty-five to forty days. At the end of two or three days there is usually some loosening of the bandage, which has to be remedied by the application of a new one, this usually rendering the whole solid enough until the time arrives for its removal. When any of the secretion oozes through the bandage, or air gains admission at its upper part, additional layers of wadding and a new bandage have to be applied. This is a rare occurrence, and is usually due to insufficient wadding having been employed, the bandage not being tight enough, or the meddling of the patient. The dressing is never removed before the twentieth day, and M. Guérin has always regretted when he has yielded to the impatience of the patient, only to find the wound proceeding rapidly towards a cicatrization that ought not to have been interrupted. No fetid odour attends the non-

renewal of the dressing, and the slight smell of "old linen" which is sometimes present yields to the application of camphor or carbolic acid water. The removal of the dressing is performed out of the ward, and is speedily accomplished until arriving near the wound itself. Here gentleness is required, owing to a more or less firm adhesion that has become established between the cotton and the skin. Abundant washing in tepid water, to which camphorated spirit has been added, may then be required, or even immersion of the part. When the wound is exposed it is found to be granulating, the process of healing having been more rapid than under ordinary dressing. The amount of almost inodorous pus is usually small, even in extensive wounds, while in those of little extent it is usually absent. There are usually no traces to be found of the ligatures.

"Such," says M. Fiaux, "is the dressing of M. A. Guérin. Of simple and rapid application, clean, solid, suppressing pain, and convenient for the patient—whose movements are by it rendered easy and without inconvenience—light, inodorous, and cheap, it requires after its application only intelligent surveillance unattended with fatigue. Then there is its seldomsness, thus saving at the same time fatigue and suffering to the patient as well as to the Surgeon, who, as in the late events, may often be overworked and at last exhausted by his labours. Finally, it is a shelter from purulent infection and the perils resulting from the overcrowding and vitiated air of a Hospital. What other mode of dressing will allow of our no longer fearing this overcrowding so sadly inevitable in Hospitals as they are now constructed? What other dressing would allow of our transporting to a distance with more facility and less anxiety and danger patients suffering from dangerous wounds?" He goes on to show how such advantages great as they are in civil practice, are of tenfold importance in Military Surgery.

Dr. Sargent communicated recently to the Boston Society for Medical Improvement (*Boston Journal*, February 22) an interesting account of a post-mortem examination in a case of impalement which he had described twenty years before. A woman, 37 years of age, sliding down some hay from a loft (August 7, 1851), became impaled on the handle of a pitchfork, which entered the body through the vagina to a distance of twenty-two inches, where it was arrested by the upper left rib, which it broke, and by the woman's feet reaching the floor. There was no injury to the bladder, uterus, or intestine. Blood flowed from the vagina, and there was pain near the injured rib followed by emphysema, and eventually a prominent callus. The pitchfork handle, with its abrupt bloody line twenty-two inches from its rounded end, was deposited in the museum of the Society. The account of her condition until her death on December 29, 1871, is imperfect, and chiefly derived from hearsay statements. It seems, however, that she suffered greatly and for many years with oppression and flatulence and constipation, and sometimes with nausea. She could not lie on her right side or back, and was so tired of lying on the left side that she had sat up at night mostly for nine or ten years. Her last illness attracted the less attention, because her whole life had been one of suffering.

At the post-mortem examination the cavity of the left side of the chest was found to be entirely filled with abdominal viscera—viz., the stomach, the transverse colon, with a few inches of the descending colon, and a considerable portion of small intestine. All these had passed through an opening in the diaphragm, at the left of the median line. This opening was an irregular oval, with rounded edges, and occupied a large part of the left half of the diaphragm, being about four inches in diameter. The stomach and intestines in the chest, and the small intestine in the abdomen, were distended with flatus, while the descending colon and the sigmoid flexure were scarcely larger than the finger, and were filled with scybala.

One fold of the small intestine in the chest was agglutinated by a red, rough thickening of its peritoneum, so as to present a mass which was at first mistaken for the spleen, which organ was afterwards found in its normal position. The peritoneal coat of the intestines was generally reddened. There were adhesions midway up the left costal pleura, between it and the omentum. The transverse colon and a fold of the small intestine were crowded against the clavicle and the first rib. The callus of the fracture of this was quite conspicuous. The left lung was compressed to the thickness of the hand, and was permeable to air only at its anterior surface and lower lobe—in all for a space of perhaps five inches by one. It had also contracted adhesions to the stomach. The heart was crowded to the right of the sternum, and was entirely healthy, as was the right lung. On removing the contents of the abdomen, a large irregular cicatrix was quite obvious in the peritoneum of the left uterine cul-de-sac.

"The case is interesting," Dr. Sargent observes, "as being, perhaps, unique. The treatment was only by enforced rest, the chest being supported firmly by a broad bandage; and the system was saturated by morphia—three grains, in one grain doses, having been given within six hours from the time of the injury. . . . Her death seems to have been from peritonitis, which, strange to say, was in the left thorax."

In a paper entitled "Trephining in Epilepsy," Dr. Boutelle, of Boston, endeavours to lay down some rules of practice in a small and interesting class of cases. These are instances, twelve in number (which have occurred in the Massachusetts General Hospital since its foundation), of the trephine having been employed for the relief of epilepsy ensuing on fracture of the skull with depression. The clinical histories of these have been very similar—viz., a blow on the head, producing fracture with depression; recovery from the immediate effects of the accident; then, after an interval of health, varying from a few weeks to many years, epileptic or epileptiform seizures begin or continue, with longer or shorter intervals, but generally increasing gradually in frequency and violence. Of the twelve operations performed during 1832-70, seven failed, while four were followed by cure and one by relief. In most of the fatal cases death took place shortly after the operation from acute meningeal and cerebral inflammation, accompanied by abscess of the brain or sloughing of the membranes. In four cases the operation was followed by a rapid succession of fits, succeeded by hemiplegia and coma. In three cases the dura mater was so adherent that it was unavoidably torn. It is to be observed, also, that of the four reported cures the histories of three of the patients continued only for a few weeks after the operation. The following are Dr. Boutelle's conclusions, so far as this scanty material allows of any such being drawn:—1. The operation promises a fair chance of success, and, unless contra-indicated by an excessively feeble state of the patient, ought always to be performed. 2. It requires dexterity and the greatest caution on the part of the operator, owing to the fact that the membranes are frequently adherent to the depressed bone, and that the slightest laceration greatly increases the chance of death. There is also much uncertainty, before making the incision, as to the extent of the depression and condition of the parts. 3. The depression must be entirely removed, as any projection remaining would nullify the benefit expected. 4. The wound should be kept open to allow the freest possible discharge of pus. 5. The knowledge of the possibility of epilepsy in after life, in consequence of injury to the cranium, should make the Surgeon especially careful, in cases of recent fracture of the skull, to elevate every existing depression, and remove all fragments and spicula.

FROM the Cape we learn that reports from the diamond-fields state that the rains have set in, and that sickness prevails extensively and very often fatally.

PHYSIOLOGY AT THE ROYAL INSTITUTION.

IN his fourth and fifth lectures on the Circulatory System, Dr. Rutherford explained the innervation of the heart. To show that the heart contains within itself all the machinery necessary for its motions, the heart was removed from a frog and laid upon a slip of glass. The motions of the heart were demonstrated upon a screen by means of the electric light. To show that all the machinery is not found in every part of the heart, the apex of the heart was cut off. The apex was then seen to lie motionless, while the base went on beating rhythmically as before. The motionless condition of the apex was ascribed to the apex having been cut off from the influence of the ganglia, which are at the base of the heart, and which are essential for the heart's action. The heart's rhythmical motions may be regarded as probably due to the periodical discharge of nerve force within the nerve-cells of the heart. It appears most probable that nerve force is being continually evolved within the intracardiac nerve-cells, and that this force excites the nerve-fibres at intervals, probably because ere it can do this it must attain to a certain degree of tension. The influence of various circumstances upon the rapidity of the heart's action was considered. The action of a frog's heart was accelerated by the addition, and retarded by the withdrawal, of heat. This experiment (Cyon's) was shown upon a screen. The influence of the cardiac branches of the sympathetic and of the vagus was discussed. The inhibitory influence of the inferior cardiac branch of the vagus was demonstrated. The heart of a frog was exposed, and a lever in connexion with a movable mirror rested upon it. A beam of light thrown upon the mirror rendered evident to all the heart's motions. The lower end of the vagus was galvanised, and the heart brought for a time completely to a state of rest. After alluding to the various influences which stimulate the inhibitory and the accelerating nerves of the heart, and to the condition of fainting, the lecturer demonstrated the action of the valves of the heart, the phenomena of the pulse and the blood-pressure, by means of several models invented by him with a view to facilitate the study of these subjects. The method of estimating the blood-pressure by means of the hæmodynamometer was demonstrated. The fact that the blood-pressure is greater in the arteries than in the veins was shown by experiment to be due to the unequal distribution of the blood. The arteries are more distended with blood than the veins. The blood is heaped up in the arteries because the small arteries resist its exit. It was shown that the amount of the arterial pressure depends chiefly upon the rapidity with which the blood is sent into the arteries by the heart, and the rapidity with which it escapes into the veins. The faster it flows into the arteries, and the slower it flows out of them, the higher does the pressure within them rise. The variations of the pressure in various parts of the body, due to alteration of position, were demonstrated. It was shown by means of a model how the blood-pressure in the head rises when the feet are raised or the head lowered, etc. The cause of the pulse was explained. It was shown that when a fluid is jerked at intervals through a bent elastic tube the tube tends to straighten itself at every projection of the fluid. That this takes place within the body was demonstrated by means of the following experiment:—A man was placed upon a chair in a sitting posture, and his legs crossed in the usual fashion. In such a case the foot of the pendent leg is jerked forwards at every beat of the heart. This fact was exhibited to all by resting a lever with a mirror upon the foot. A ray of light was reflected from the mirror upon a screen, and the motions of the foot were thereby greatly exaggerated, and so rendered evident. It was explained that the motion of the limb in this case is due to the sudden rush of blood through the popliteal artery, causing it to unbend to some extent, and so drive the foot forwards. Sphygmographic tracings were taken from elastic tubes and from the radial artery. The tracings, taken on smoked glass, were then thrown upon a screen by the electric light. The fact that the pulse-wave takes a certain time to travel through an artery was also demonstrated. Two sphygmographic levers were rested upon a tube filled with water driven through it by means of an elastic pump to imitate the heart. One lever was placed close to the pump, the other at a considerable distance from it. Both levers registered their movement upon a plate of smoked glass, the one lever being placed above the other so that the writing

point of the one was precisely vertical to the writing point of the other. The tracings obtained in this way were projected upon a screen, and the retardation of the pulse demonstrated. Ludwig's "stromuhr" or hæmometer was shown and explained. This instrument is for the purpose of measuring the quantity of blood which flows through a bloodvessel in a given time. It is a valuable instrument for enabling us to ascertain the alterations of the circulation through an organ—*e.g.*, the kidney—which may result from stimulating its nerves, the administration of various medicinal or toxic agents, etc. If, in addition to the quantity of blood in a given time, the calibre of the bloodvessel be measured, the velocity of the blood-current may be ascertained by means of this apparatus.

The innervation of bloodvessels was discussed, and the effect upon the bloodvessels of the ear produced by division of the cervical sympathetic was demonstrated in a rabbit.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

[To the Editor of the Medical Times and Gazette.]

SIR,—At a meeting of the Council of this Association held this evening, the following resolutions were unanimously adopted; and I have been requested to ask you to be good enough to publish them in your this week's issue.

I am, &c., J. WICKHAM BARNES.

12, George-street, Mansion House, April 2.

1. That the system of Poor-law Medical relief in England and Wales is in the highest degree unsatisfactory, and urgently requires amendment.

2. That, as the provision of drugs by the Medical officer frequently places him in a delicate and false position by provoking a conflict between his interest and his duty, the extension of the Dispensary system to all country towns and practicable rural areas would be most desirable; and that, as the excess of area in many rural districts and of population in urban districts is very disadvantageous to the sick poor by precluding even the possibility of efficient Medical attendance, such excessive districts should be reduced, and in no case allowed to extend beyond the limits already determined by the Poor-law Board—*viz.*, an acreage of 15,000 in rural districts, and a population of 15,000 in urban districts.

3. That it is desirable that the salaries of Poor-law Medical Officers should be placed on a uniform basis, and revised triennially, so that the salaries may be estimated according to the average number of cases annually attended (due regard being paid to area); and that, as the duties of Medical officers are essentially imperial, it is expedient that the whole of such salaries should be paid out of the Consolidated Fund, instead of part only, as at present, or that one-half should be paid from the Consolidated Fund and the other half from a rate distributed over a whole county.

4. That, as the position of the Poor-law Medical Officer is not sufficiently independent of local influences to justify his appointment as sole Health Officer of his district, it is expedient that a superior Health Officer, debarred from private practice and devoting his whole time to the duties of his office, should be appointed to act over a considerable area, the District Medical Officer standing in the position of deputy Health Officer only.

5. That, pending the introduction of the Dispensary system, which, if generally adopted, would amount to a virtual re-organisation of the service, all additional reports and duties to be required of District Medical Officers should be paid for on a basis to be determined by the Local Government Board.

6. That copies of these resolutions be sent to the Medical press, to members of Parliament, and to the President of the Local Government Board.

UNPRECEDENTED ABSENCE OF VARIOLA IN PARIS.—M. Besnier, in his report on the Medical Constitution of Paris for the months January and February, 1872, in proof of the extraordinary rarity of variola at the present time, states that the whole of the Hospitals of Paris only returned *one death* for the two months united. In order to show how remarkable this exemption is, he furnishes the returns for the same two months during the ten preceding years, 1862-71. These were 50, 23, 36, 44, 64, 10, 51, 46, 159, and 7.—*Union Méd.*, March 28.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, April 2.

PROFESSOR DOLBEAU AND HIS COLLEAGUES—A MEDICO-POLITICAL INQUISITION.

IN continuation of my last on the Dolbeau affair, I have to inform you that, at the request of the Professor himself, an inquiry is being held at the Hôpital Beaujon, presided over by the Count Davilliers, of the Conseil Général de Surveillance des Hôpitaux, and composed of Professors of the Faculty and Medical officers attached to the Hospitals. Another is to be held by the Government; but this, I understand, will not take place before May 1, when the Parliamentary recess will have expired. It is, however, anticipated that, whatever the result of the inquiry, the Medical School will be reopened on Monday next.

Some of Dr. Dolbeau's friends, in their zealous efforts to vindicate his conduct, have very thoughtlessly aspersed the character of some of his colleagues, who they say fled from Paris during the Commune, whereas M. Dolbeau remained at his post. Be this as it may, I think it a pity, even if the above assertion be true, that any allusion should have been made to it, as it cannot in any way serve the cause of M. Dolbeau, and comparisons are always odious. This has excited great indignation among his colleagues and among his Professional brethren in general, and Professor Richet, who was named as one of the runaways, acting as apologist, has sent in a remonstrance to the paper in which the malevolent letter appeared.

AMERICA.

PHILADELPHIA, February 6.

REPRESSION OF QUACKERY AND SALE OF BOGUS DIPLOMAS—THE UNIVERSITY OF PENNSYLVANIA AND THE UNIVERSITY OF PHILADELPHIA TOTALLY DIFFERENT—WHARTON POISONING CASE—SMALL-POX EPIDEMIC—INTERNATIONAL COPYRIGHT—MEDICAL LITERATURE—FILTHY BOOKS—AMERICAN MEDICINE.

SEVERAL additional signs of improvement are visible in the Medical horizon, so far as the repression of quackery is concerned. Of course the Profession is greatly dependent for this desirable consummation on the integrity and energy of its own members, but without the consentaneous action of the law-making powers its good resolutions cannot be enforced among the masses of the population. It can drive from its ranks those tainted with the breath of suspicion, but cannot shield the unsympathising public—who often look upon a disgraced Physician as a victim sacrificed to the mere refinements and niceties of Professional etiquette—from paying the penalty of their misplaced confidence. It sometimes seems, indeed, that the more criminal a man may be in the estimation of those who have hitherto been his Professional associates, and especially if his iniquitousness has given him no claims whatever to Medical fraternity, the more pertinaciously do the wrong-headed and unthinking of the laity support him: It is a good sign when the people themselves begin to inquire who are, and who are not, the good men and true in the ranks of the Profession. Frequent allusion has been made in the Medical journals, both at home and abroad, to the danger to human life inseparably associated with the unauthorised traffic in Medical diplomas, or, as we more familiarly term it, the sale of bogus diplomas. Although other places have also participated in these nefarious transactions, the superior rascality of men with a local habitation in Philadelphia has attracted attention to this city as the centre for the dissemination of false certificates of Medical graduation broadcast through the country and even to distant lands. New York, vociferous as she always is in her claims for superior enterprise and commercial energy, has on this subject yielded the palm to Philadelphia. The time has now come when the sentiment of all honourable men, in and out of the Profession in this city, must be heard in condemnation of this vile traffic, and when the practice must be summarily checked. Cases have been recently accumulating, which, when massed together, cannot fail to produce a decided impression on the public mind.

In the State Senate of Pennsylvania during the past week, a committee was appointed to examine into all facts connected

with the sale and issue of Medical diplomas to persons not qualified by Medical knowledge or education, an Act having been passed by the Legislature last May prohibiting such sale or issue of academic degrees. The institutions particularly referred to in the resolution are "certain Medical Colleges, chartered under the laws of Pennsylvania, and located in Philadelphia, named respectively 'The Philadelphia University of Medicine' and 'The Eclectic Medical College of Pennsylvania.'" The old and honoured University of Pennsylvania, whose reputation is pure, and good name unsullied, has always been naturally sensitive at the existence of a school, pretending to be respectable, but stealing from it almost its very title, merely substituting in its official appellation the name of the City for the State. In other words, speaking of it commercially, it appropriated a respectable trade-mark with which to deceive the unwary, and might have been legally held to strict accountability by its high-toned neighbour had it been deemed expedient to give it the advertised notoriety of a judicial controversy. This confusion of names misled several of your own Medical men, and excited an outburst of feeling from Sir Dominic Corrigan especially, if I remember correctly. The Committee of Senators met in this city last Saturday. It would be well for the Profession in England to be on the alert to detect and punish the corps of quacks set loose among them by the purchase of diplomas here, as it was proved before this Committee that the sale was at least as largely encouraged there as in this country. Letters were read from Dublin, Tyrone, Ireland, London, Yorkshire, and Glasgow, all stating the writers had been approached, both by notes and by word of mouth, and told that if they would pay certain sums they could receive from these agents degrees from any one of the Universities of Philadelphia. They moreover stated that there were in England hundreds of persons claiming to be graduates of the colleges of Philadelphia, and who secured their diplomas by the payment of money. Quite a large number of students come here in the fall, representing that they have purchased in the South and South-West what were called scholarships from \$35 to \$37 each, under the idea that it was to the University of Pennsylvania that they were really paying the money. In the South merchants are in the habit of obtaining these certificates for a consideration so small that when they sell them, as they soon do, they make a considerable profit on them. It was stated that in the sale of these scholarships and diplomas they have been very successful in covering up their tracks, which makes it difficult to accumulate positive evidence on the subject. There is no doubt that the practice will soon be a thing of the past, and that mere "diploma shops" will enjoy but a brief existence.

The "Wharton poisoning case," as it is generally called, which recently, in a sister State, ended in the acquittal of the accused, is interesting to the Profession everywhere, not only as a *cause célèbre* in Medical jurisprudence, but as furnishing another illustration of the much-to-be-regretted fact that Medical testimony is not infallible. The charge against Mrs. Wharton, that she had poisoned with tartar emetic a personal friend to whom she was pecuniarily indebted, was not substantiated, mainly on account of the disagreement among the Medical witnesses as to the character of the symptoms under which the supposed-to-be-poisoned man laboured, and the overwhelming evidence of chemical experts against the accuracy of the modes adopted by the prosecution's witnesses for the detection of the antimonial poisoning. With this discussion was mingled an examination into the properties of hydrate of chloral and yellow jessamine, both of which had been prescribed for him by the attending Physicians during the illness immediately preceding his death; and it was argued that, instead of falling a victim to the malevolence of a "modern Borgia" (as the press sensationally styled the lady in question previous to the trial), he died a natural death from cerebro-spinal meningitis. This difference of sentiment would have been amusing but for the serious aspects of the case. The term "expert" is not properly restricted in its use, for it has come to be applied in this country to such witnesses as are, in the estimation of counsel, fitted by their special knowledge to prove certain vital facts; but the ability of counsel to determine the degree of expertness is sometimes very limited. Although this recent case called forth some of the best forensic Medical talent in the country, it must have been a surprise to the Profession, as it was an injustice to the more learned men on the witness-stand, to associate the term "expert" with all the Medical men examined. A recent writer in one of our Medical journals has justly remarked, in regard to this confiction of testimony, that "the Physician of the present day is in a perpetual state of unpreparedness for the vital questions of the court-

room. The glaring fault to be corrected in this country is the want of a more thorough system of instruction during student-life in the principles of Forensic Medicine." It is certainly the fact that Medical Jurisprudence is usually taught here more as a mere incidental subject, "tacked on here and there to chemistry and Materia Medica in places where it seems to fit, and not as a branch worthy of separate and special study." And yet your own Palmer poisoning case was quite as memorable for diversity of sentiment, although that branch of investigation is doubtless more systematically taught in Great Britain than in this country.

The small-pox epidemic, which has for several months affected the Eastern portion of the United States, is now on the wane, the deaths in New York showing a slight decrease, and those in Philadelphia a falling off of about 25 per cent. Petitions in favour of compulsory vaccination are being circulated, and it is to be hoped that during the present temporary pressure from the prevalence of the disease this measure may be adopted as a relief or protection from future invasions. One would hardly think that politics could become mixed up with such a personal question of human hygiene, and yet it is easy to foresee that even the small-pox might become interesting in that point of view, if the pockets of some of the most corrupt of our legislators could be affected by it. I have previously mentioned that a few unbelievers in vaccination sometimes attempt to unsettle the views of the great majority, but I regret to say that a handful of our own Profession, who should occupy a more advanced position, help to retard any progressive movement in favour of compulsion by their openly expressed doubts of the efficacy not only of revaccination, but even of vaccination. Whatever else their qualifications, they are on this point far behind the spirit of the age.

The oft-recurring agitation on the subject of an "International Copyright Law" is again disturbing the equanimity of Medical book publishers and others throughout the country. So much may be said for and against the passage of such a measure, and indeed has already been said in and out of Congress—in which body the proposition for its enactment has been very recently discussed, or, as we sometimes express it, "ventilated"—that it would hardly be worth our while to enter upon the merits of the case here. In all the arguments of publishers, the sensitive pocket-nerve suffers from a temporary attack of hyperæsthesia, and much allowance should therefore be made for the amount of constitutional irritation developed among this very indispensable class of busy men, when they fear that it may be abruptly punctured. When they hold meetings and pass resolutions indicating that such and such legislation will affect "the interests of the masses," they should add the phrase, "and especially our own," and thus truthfully express the prevailing current of their thoughts. The interests of our own Medical authors are naturally involved in the issue, but these play but a secondary rôle in the estimation of those literary accoucheurs, the publishers. The absence of international restriction enables the latter to keep the market well supplied with foreign Medical literature, but the arrangement is hardly a fair one for the authors of either country. It must be apparent to every reader of advertised lists of books that most of the new Medical works either recently issued or announced in this country are reprints. Finding that they can produce books written abroad for no other expense than the cost of printing, binding, and advertising, publishers pass by our own authors, to whom they would be obliged to pay copy-money—very rarely, by the way, even a fair or proportionate sum—ormerely call their services into requisition as godfathers to such of their literary bantlings as would be pecuniarily benefited by this additional paternity. If the law should ever compel them to compensate the foreign author for his brain-work, many a creditable native production would see the light, and many a native writer be encouraged whose efforts have hitherto been repressed. There is now, indeed, very little outlet of this kind for American Medical literary talent, especially for the younger members of the Profession, as the book-trade will hardly look at any works that are not "practical," as they are usually called, which are generally emanations from older heads on such subjects as will yield a decidedly remunerative sale to the publisher. To a certain extent the latter is right in this view; especially, as one of the most eminent in that business recently remarked to me, as "there seems to be too little interest among the Medical Profession in anything that does not directly put money into their pockets."

As a specimen of the shape which the opposition to the international copyright has assumed, I may quote from the proceedings of a recent meeting representing the most respectable

establishments among the booksellers, binders, and printers of Philadelphia, and following immediately after one held in New York with similar motives. Several Medical booksellers were present; but you will notice that, as a matter of course, the American author is scarcely mentioned. Looking at the matter from their standpoint, however, some of the reasons advanced are certainly forcible, and worthy of consideration. It was said, for instance, that "any legislation recognising the principle of international copyright must necessarily tend, by raising the price of books, to decrease their circulation, thus putting them out of the reach of many people, and greatly thereby injuring the business of all those engaged in the making of books, except the few large capitalists, who will by contracts with the authors have the monopoly of their productions and sale. . . . This was a scheme to centralise, to put into the pockets of a few what should go into the pockets of the many. The British publishers can publish a book upon beautiful paper, and get it up in a beautiful style suitable for a rich man, but the toiling millions were to be deprived of proper intellectual food by reason of being unable to pay the high prices."

The opposition was mainly based upon the following reasons:—"Thought, until expressed or published, is the property of the thinker. When given to the world, like light, it is free to all. As property, it can only demand the protection of the municipal law of the country to which the thinker is subject. The author of any country, by becoming a citizen of this, and assuming the burdens and performing the duties thereof, can have the same protection that an American author has. The trading of privileges to foreign authors for privileges to be granted to American authors is not just, because the interests of others than they are sacrificed thereby. The good of the whole people demands works shall not be made too costly for the multitude by giving the power to foreign authors to fix their prices here as well as abroad. . . . The reprints of really valuable works on science, which are now published at prices so low in this country that the day-labourer can afford to purchase them, would be raised by an international copyright, or any proposed modification thereof, beyond his means, and he would be obliged to confine his purchases mainly to cheap literature, not improving to his mind, frequently immoral in its tendency, and inculcating, not rarely, principles dangerous to the peace of society."

I had not intended entering so fully into this question, but it should be of quite as much interest to the Medical Profession as to any other. It is evident that the whole feeling upon the subject turns upon the effect the proposed law will have upon trade, and has very little to do with the absolute rights of either authors or publishers.

It would occupy too much space to dwell in detail on the numerous contributions to Medical literature from English sources which have just been published or promised by our leading bibliopoles. In the list of announcements for the publishing season of 1871-72, William Wood and Co., of New York, specify American issues of Stricker's "Histology" (New Sydenham Society's edition, I presume), T. Grainger Stewart on "Bright's Disease," J. M. Duncan on "Fecundity, Fertility," etc., Wunderlich on "Thermometry" (New Sydenham Society), Watts's "Supplement to the Dictionary of Chemistry," Sydney Ringer's "Handbook of Therapeutics," W. H. Dickinson on the "Kidneys, Hæmaturia," etc., T. L. Brunton on the "Action of Medicines," and other works of interest. H. C. Lea, of Philadelphia, announces Williams' "Pulmonary Consumption," T. Henry Green on "Pathology and Morbid Anatomy," Robert Barnes on the "Diseases of Women," Thomas Bryant's "Practice of Surgery," and new editions of Roberts on "Renal and Urinary Diseases" and Taylor's "Medical Jurisprudence." Lindsay and Blakiston, of this city, also announce Brunton's work, Harley on the "Urine and its Derangements," Burdon-Sanderson and Michael Foster's "Handbook for the Laboratory," D. Campbell Black on the "Renal, Urinary, and Reproductive Organs," Lionel S. Beale on "Disease Germs" and "Protoplasm," Adams on "Clubfoot" and on "Rheumatic and Strumous Diseases of the Joints," Mackenzie's "Pharmacopœia of Hospital for Diseases of the Throat," Dobell on "Winter Cough," Allingham on "Fistula," etc. These may be taken as specimens of our indebtedness to you, the amount of which would puzzle a Geneva Conference, or mystify the wisdom of the most profound arbitrators. The last-mentioned firm, by the way, among other proposed publications, announce an interesting feature in the shape of a posthumous work of the late Professor Robley Dunglison, whose "Medical Lexicon," "Human Physiology," and other standard works are so familiar to the Profession, and who for nearly half a century

honourably occupied chairs in some of the leading Medical colleges of the country. It is a "History of Medicine," founded on his lectures delivered at the University of Virginia a number of years since, when he simultaneously performed the duties of half a dozen men in teaching anatomy, Surgery, the history of the progress and theories of Medicine, physiology, *Materia Medica*, and pharmacy in that institution.

Several semi-Medical semi-popular works have been put in the market within a few years past, and pushed to immense sales by means of agents and canvassers. Some of these emanate from the pens of men once holding tolerably respectable positions in the Profession; but want of principle, and love of rapidly-gotten, although undeserved, wealth have brought them to this contemptible authorship. They are often men of "battered reputation," as they have been described, who, under the pretended disguise of Medical instruction, are capable of committing any amount of filth to paper. It is our experience in this country that the more objectionable the book—the more profuse it is in elaborate displays of disguised, but transparent quackery that every honourable Medical man would shrink from—so much the more strongly fortified will the author be by an imposing array of the names of clergymen who give the work their recommendation and approval, apparently as cheerfully as if it were a volume of Notes on the Gospel of St. Luke, or a new version of the "Common Prayer-Book." I saw a circular the other day, made up chiefly of a score or two of such endorsements, the writers of which will some day or other be heartily ashamed and confounded, especially if they read the book, which they probably have not yet done; and yet the work was one that they would not dare to show to their wives or daughters, and the name of which they would scarcely whisper to their intimate friends.

Your editorial remarks on "American Medicine" in your issue of January 6 were highly appreciated here as a true recognition of the undoubted advance in Professional culture among the Medical men of this country. We are ourselves conscious of this great improvement, and see almost daily so many evidences of the change to a more refined and more elevated standard from the less cultivated paths in which, in a comparatively new country, the great mass of the Profession at one time laboured, that we naturally feel a certain amount of pride and satisfaction when our onward efforts meet with deserved recognition.

GENERAL CORRESPONDENCE.

POOR-LAW SURGEONS AND MR. STANSFELD'S BILL.

LETTER FROM MR. JAMES MILWARD.

[To the Editor of the Medical Times and Gazette.]

SIR,—Many of the objects for which the Poor-law Medical Officers' Association have so long striven are embodied in Mr. Stansfeld's Public Health Bill, the second reading of which is expected soon after Easter. With much that is good it contains some defects which, if the Bill pass in its present state, will inflict grievous wrong upon the already sufficiently ill-used Medical Service. These defects have been well pointed out by the Medical press, and Union Surgeons throughout the country have been invited to adopt a form of petition to Parliament against the unjust clauses. Hitherto the bulk of us have not taken even this small amount of trouble about our own business—not that we disapprove of the tenor of the petition, for that is impossible, but probably because it is imagined that those gentlemen who have already wrought so hard on our behalf may as well do all our work as nearly all. If any faith be yet left in the members of this down-trodden service, let it be put in the doctrine that "they will be best helped who help themselves," and, without delay, let us put in the hands of Dr. Rogers for Mr. Corrance such a pile of petitions as shall really represent our views on this subject. If it be too much trouble for some of our brethren to transcribe the form for themselves from their Medical journal, they shall have a copy on application to
Cardiff, March 27. Yours, &c., JAMES MILWARD.

THE TREATMENT OF SMALL-POX IN THE WEST INDIES.

LETTER FROM DR. R. H. BAKEWELL.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having seen, in the columns of one of the Medical journals, an article by a Physician of Ireland, recommending

the use of sulphurous acid in small-pox, administered internally in solution, and inhaled in fumigations, I immediately began to try the plan at the Small-pox Hospital in Port of Spain, of which I am the Medical attendant. The results were disappointing. After trying it in about twenty-five cases I gave it up. It appeared to have no effect whatever on the disease, except in one case. The patient was a negro, and had a minute papular eruption, set as closely as possible, on the legs, thighs, face, and upper extremities. It seemed likely to be a very bad case. The eruption, however, proved abortive, and the man recovered without a bad symptom. As, however, he had good vaccine scars, this case proves nothing.

The treatment I pursue at the Hospital is as follows:—A dose of aperient medicine on admission, if the bowels have not acted for twenty-four hours. If the case is a discrete one, which only one-fifth of my Hospital cases are, no other medicine of any kind is given, unless the case is (for a discrete one) unusually severe. Then a bark draught (tinct. cinchonæ co. ʒj., quiniæ sulph. gr. ij., sp. chloroformi acid. hydrochlor. dil. āā m̄x., aquæ ʒjss.) is given two or three times a day. The food at first consists mainly of arrowroot, rice, milk, and invariably beef-tea. When the disease has reached the pustular stage I give stout, finding this to act better than any other stimulant in the majority of cases.

The confluent cases are, during the continuance of the eruptive fever, treated with tincture of aconite and nitrate of potash. The power of tincture of aconite in lowering the force of the pulse and lessening the number of its beats is hardly sufficiently recognised. I have employed it constantly for the last fifteen years, and find that in combination with nitre it forms an admirable febrifuge. During the interval (if there is any) between the eruptive and secondary fever, I give no medicine, except a morphia draught at night if required. When the secondary fever begins I give the bark mixture, with the addition of ten to twenty minims of tincture of opium to each draught. This is given every four hours, except when the patient is asleep. I find this combination soothes the restlessness which is so characteristic of the disease, prevents delirium, and enables the patient to tide over the crisis in a state of drowsiness, which, while it does not prevent him from taking nourishment, seems to husband the vital powers, as only opium can do. It is certainly very gratifying to see some of the cases that pull through. Of course they are well plied with liquid nourishment. Bottled stout *ad libitum*, strong beef-tea, egg flip, arrowroot, etc., are given at frequent short intervals. I have at last succeeded, at the cost of several visits at from 2 to 4 a.m., in convincing the night nurses of the necessity of giving nourishment and stimulants in the night, and particularly in the early morning. The general opinion here is that nobody wants, or ought to want, anything to eat or drink in the night.

The standing orders at the Hospital to the night nurses are to give the morphia composing draught whenever a patient cannot sleep. If this fails they are to call me (I reside at the Hospital). I find the most important indication of all is to procure sleep.

I have had an extremely bad class of cases at the Hospital. No less than 17 per cent. have been petechial and hæmorrhagic. All of these have died or will die. Then there is a class of cases which I call "perconfluent"—where the eruption occupies the whole of the face and extremities in one continuous mass, without any shape or form of pock being visible. All of these die. But we have not lost one discrete case, only one semi-confluent case (a child 9 months old), and only six out of thirty-three confluent cases, excluding petechial, hæmorrhagic, and perconfluent cases. A very large proportion of corymboe cases have come under my notice, and they are very fatal, particularly as they are often combined with the petechial form of disease.

The Hospital consists of an old private house in its own grounds, which is now used only for convalescents. It was at one time much overcrowded, but we had always plenty of ventilation. The outbuildings were also utilised as wards. The new buildings, into which all new cases are put, consist of a series of wooden huts, each thirty feet long, ten and a half feet wide, and ten feet high to the eaves; from these the roof rises about four feet. This seems a small allowance of cubical space; but as the whole of the sides of the building are occupied by windows and doors, the patients are practically living in the open air during the daytime. To provide for ventilation at night, an interval of a foot wide is left between the walls and roof all the way round; and there is a fixed jalousie at the end opposite the door. These huts are placed side by side, and

connected by a covered gallery, in which the patients sit when they begin to get better, and which also form a means of communication for the nurses and attendants. We have nine of these huts, besides the old buildings and a large Hospital marquee bought from the Control Department. Notwithstanding that everything is done to make the patients comfortable, the prejudices of the people are so great that we have a large proportion of empty beds, although people are seen about the streets begging with the small-pox out on them fully! Out of 145 patients admitted, not above a dozen are natives of the colony.

I ought to mention that, after repeated trials of the chloral hydrate, I have given it up as an untrustworthy narcotic in small-pox. I find morphia or "Battley" act better.

Begging you to excuse these few hasty notes,
I am, &c., R. H. BAKEWELL, M.D.
Small-pox Hospital, Port of Spain.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 26.

T. B. CURLING, F.R.S., President, in the Chair.

DR. GRAILY HEWITT read a paper "On the Acquired Deformities of the Uterus; their Importance, Effects, and Results: with a statistical account of observations on the subject at University College Hospital from August, 1865, to December, 1869." The object of the author was to demonstrate by facts and observations the importance of acquired alteration in the form of the uterus as a disease, and to establish for the *acquired deformities* of the uterus a prominent position in uterine pathology. To establish the frequency of acquired deformity of the uterus, the author brought forward statistics of the whole of the practice in the department for diseases of women at University College Hospital during a period of upwards of four years (1865—1869). These statistics, arranged in tabular form, comprised particulars concerning 1205 patients; from which it was shown that, of these 1205 patients, 714 were affected with symptoms referable, in one way or other, to the uterus. Of the 714 patients presenting symptoms referable to the uterus, the diagnosis of the condition present was aided by a physical examination in 624 cases. In 90 other such cases no examination was made. The 624 cases examined and presenting uterine symptoms are arranged in three classes:—First, general, including 65 cases; second, organic etc., including 182 cases; and third, acquired deformities, or change of position of the uterus, 377—making a total of 624. The first class include absence of uterus etc., 6; amenorrhœa and vicarious menstruation, 9; menorrhagia, 7; peri-uterine hæmatocele, 11; leucorrhœa, 12; hypertrophy of cervix uteri, 18; climacteric disorder, 2 cases—total 65 cases. The second class include fibroid tumour or polypi, 96; cancer, 54; pelvic cellulitis, 32 cases—total, 182. The third class: flexions, 296 (retroflexions 112, antelexions 184); prolapsus, 81—total 377. From which it was shown that there were very few of those cases presenting uterine symptoms in which the uterus was not affected with a decided change of shape; this change of shape being, in the author's opinion, the underlying and principal element in the cases in question. In the next place the author submitted particulars of each of the 296 flexion cases in a tabular form, comprising the age, condition, and main facts relating to the 296 cases. These cases were then analysed to show the severity of the symptoms and principal effects. The prevalence of *sterility* and the frequency of *abortion* were especially pointed out, and the following results obtained:—Of married there were 235 cases (100 retroflexion, 135 antelexion). Of the 100 retroflexion cases, 21 were sterile, 12 had had no pregnancy, 9 had abortions but no child; of the 135 antelexion cases, 60 were sterile, 45 had no pregnancy, 15 had abortions but no child. In reference to the frequency of abortion in the 296 acquired deformity cases, the results were as follows:—Of the 100 retroflexion cases (married), 24 had abortions; total number of abortions was 32; greatest number in one case was 3. Of the 135 antelexion cases (married), 27 had abortions; total number of abortions was upwards of 54; and the greatest number in one case was 9. Dysmenorrhœa was almost constantly present

in these 296 cases of acquired deformity. Menorrhagia was very common. Chronic uterine inflammation was also common, but was evidently secondary to the alteration in shape. When miscarriages were observed, and retention of portions of the ovum occurred, such retention was very generally traced to the existence of flexion. The *varieties* of acquired uterine deformity were then described, referable to two principal causes—bending of the uterus forwards or backwards; the importance of the varying conditions of the uterine walls in regard to density, consistence, and thickness was next indicated; the connexion subsisting between these alterations in shape and the occurrence of prolapsus pointed out; the very important effects on the circulation in the uterus and on the nervous relations and susceptibilities of the organ were also indicated. Together with the paper a series of nearly 100 outline drawings, exhibiting pictorially the diagnosis made at the time of the examination, was laid before the meeting.

Dr. ROUTH concurred with Dr. Hewitt's general conclusions, but took exception to some of them—such as that antelexion and retroflexion were the main causes of dysmenorrhœa. In reality there were only a few cases of that kind. Besides, most unmarried women had their uterus more or less anteverted, and in them this condition gave rise necessarily to no discomfort. He did not think the diagnosis of the condition of anteversion difficult. He considered that dysmenorrhœa without flexion was more common than Dr. Hewitt said. The paper did not distinguish between congenital and acquired flexions. He thought the author ignored the former. In these there was often no pain during menstruation, and the same was sometimes true of the acquired condition. It was only when the fundus became inflamed that pain was produced. Some women with flexed uteri were sterile, some not; and the former only because the os was turned in the wrong direction. What was the meaning of "prolapse" as used by Dr. Hewitt? In reality prolapse was rare; the condition commonly mistaken for it—namely, elongation—was not.

Dr. DAY asked what were the miscellaneous cases tabulated. He thought that many diseases of the uterine system and of the chest in young women were united or allied. Amenorrhœa was often only a symptom of the general condition.

Mr. R. J. LEE could understand the origin of a retroflexion following on a parturition when the woman gets up too soon. The uterus would then naturally fall backwards. He thought Dr. G. Hewitt referred to those of mechanical origin only. What was the difference between the congenital and acquired conditions?

Dr. GRAILY HEWITT, in reply, said he was quite aware that slight antelexion existed in the virgin, or, rather, in the child. If badly fed, it might remain after puberty, but it was not natural in a well-developed young woman. With regard to antelexion, he did not say the diagnosis was difficult; he only said it was often not made. In almost all the cases of flexion dysmenorrhœa was a marked feature. His experience as to congenital flexions was quite different from that of Dr. Routh. It was true that the painful symptoms only began when the fundus became inflamed, but that occurred in almost every case, and went away when the position was rectified. His sterile cases did not include those who were sterile after the birth of one child. By prolapse he meant a substantial descent of the uterus, and its appearance externally. He agreed with Dr. Day that a goodly number of cases of amenorrhœa in young women were associated with other bodily states. His cases comprehended unmarried who had no pregnancy as well as married. In the former the change in shape was due to a loss of tonicity, or rigidity in the uterus, which allowed it to be moulded into any shape. After that sedentary occupations might cause it to be antelexed. Flexion was rare without some definite cause.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 22.

Sir WILLIAM GULL, Bart., President, in the Chair.

Dr. SOUTHEY read a paper "On Two Cases of Persistent Omphalomesenteric Duct, leading to Fatal Intestinal Obstruction." In the first case, a lad aged 16, seized with symptoms of intestinal obstruction suddenly in the night, was admitted into St. Bartholomew's Hospital, and died on the ninth day from the commencement of his illness. The post-mortem examination showed a constriction of the bowel at the

point of departure of a diverticulum passing from the intestine shortly above the ileo-cæcal valve, and attached to the abdominal wall two inches below the umbilicus. The part of intestine between the constriction and the valve was gangrenous and empty, and appeared as if it might have been entangled between the diverticulum and the abdominal wall. The second case was that of a tall girl, aged 13½, who was admitted under Dr. Southey's care with symptoms of general peritonitis and collapse, and a history of intestinal obstruction. She died on the sixth day from the commencement of her illness. The necropsy discovered slight general peritonitis, and the cause of obstruction a constriction of the gut, though not to complete occlusion, at the point of departure of a diverticulum five inches in length, which was attached to the umbilicus. The intestine was so much distended above the constriction that its mucous membrane was in many places split. The portion of the gut between the constriction and the ileo-cæcal valve was congenitally narrowed, but was healthy in appearance and contained fecal material. These cases suggested that diverticula were sometimes attended by congenital narrowing of the bowel below them, and that they were perilous to life in two ways: First, by the abruptness of the transition in the calibre of the bowel, leading to hypertrophy and dilatation of the gut above, to enteritis, swelling, and obstruction at the seat of constriction; and, secondly, by offering loops in which knuckles of intestine can be entangled and strangulated. The performance of gastrotomy in intestinal obstruction, without symptoms of intussusception, was the treatment urged by Dr. Southey.

Mr. T. SMITH, having seen Southey's first case, and as having considered an operation unjustifiable, begged leave to say a few words. He considered the symptoms as due, in part at least, to enteritis, and the case when he saw it was almost hopeless. A portion of the gut was found inflamed, but it was not found constricted; it was only supposed to have been so.

The PRESIDENT thought that these cases were perhaps of least interest clinically; because, in point of fact, you cannot make an exact diagnosis. He also suggested that the inflammation of the gut might be connected with the congenital narrowing below the duct.

Dr. POWELL asked if mere twisting ever produced fatal obstruction. He recalled the instance of a child who went to bed in perfect health, but woke up collapsed, and died in a few hours. The lower two-thirds of the small intestine were congested intensely, but the congestion ceased abruptly a little above the valve, where the gut was pale. There was no band or any other obstruction. He thought the obstruction was due to a mere kink.

Mr. C. HEATH thought that the fact of a patient being ill so long without relief should be no reason why a Surgeon should not operate. Matters were much in the same condition now with regard to operating in intestinal obstruction as they used to be in strangulated hernia. Formerly there were all kinds of objections to operate. He could not see why the Surgeon should not open the abdomen, put his hand in, and try what could be done. In ovariectomy they were never perfectly certain of the condition before they made an exploratory incision. That did no harm.

Mr. MAUNDER was exceedingly anxious that Surgery should do something for these conditions; yet Surgeons were not in the same position as in hernia, for they did not know where the obstruction was. He thought opening and handling dangerous. If anything was to be done, he thought that was simple—a small incision should be made in the abdomen, the gut stitched to it and left alone.

Dr. BUZZARD felt strongly that Surgeons might do more good than they did, but he could not agree to Mr. Maunder's proposal. A considerable proportion of individuals do recover, and it would be hard if these had to go about with an artificial anus.

Dr. BRISTOWE concluded that the only cases for operation were those of constriction by a band, and he thought the diagnosis of these fairly possible; yet Dr. Southey's cases were doubtful. There were, however, certain facts to show there was no intussusception. If the condition depended on constriction, then he would operate.

Dr. SOUTHEY, in reply, said the absence of fluid or bloody stools and of flatulent distension made him think there was no intussusception. There were, he thought, about two cases of simple kink a year at St. Bartholomew's. He considered the inflammation of the contracted part of the gut accidental rather than connected with its abnormal condition.

Mr. TEEVAN read a paper on the Treatment of four cases of Impassable Stricture. In each case, frequent attacks of gonorrhœa had been the cause of the stricture; and it was

worthy of note that in no case had an injection ever been used for the cure of the gonorrhœa. The first patient, aged 45, had for many years suffered from severe stricture and frequent attacks of retention. Many Surgeons had in vain tried to pass an instrument. He was ordered to rest in bed for several weeks, during which period Mr. Teevan made many attempts, without success, to get through the stricture. Leeches were then freely applied to the perineum, and afterwards a number quarter silver catheter was successfully passed into the bladder. Gradual dilatation by means of French bougies completely cured this patient. The second man, aged 54, had for ten years passed all his urine through a fistula in the perineum. After a six weeks' confinement to bed, a very small whalebone olivary bougie was passed into the bladder, and the patient was ultimately cured of his fistula and stricture by gradual dilatation. The third sufferer, aged 40, voided all his urine through three fistulous openings in the rectum, perineum, and scrotum. Repeated trials with various kinds of instruments under the very favourable condition of complete and long rest utterly failed; and on January 22 last Mr. Teevan divided the diseased structures in the median line without any guide, and passed a large silver catheter into the bladder. All the urine comes by the penis, and the wound and fistulæ are nearly healed. The fourth case was that of a man, aged 56, who had a similar cutting operation performed on him four years ago for an impassable stricture complicated with fistulæ. The stricture was cured, the fistulæ healed up, and at the present time a large silver catheter can be passed into the bladder with ease.

Mr. McCORMAC asked whether, in cutting from the anus forward, he introduced a sound, or what afterwards was done.

Mr. MAUNDER said success in the first two cases was due to patience and perseverance, qualities which he hoped all Surgeons would use. In the others the stricture was, in all probability, not laid open, and most men would be slow to adopt the procedure. For his own part, he preferred puncturing the bladder per rectum. He had found the plan safe and good; the other not so. Moreover, after the retention was relieved, the induration had time to subside, after which an instrument could be passed.

Mr. HEATH said there were almost as many ways of treating stricture as there were men. He found Mr. Teevan now used a stiffer instrument to pass the stricture. He would recommend a silver one, which a little pressure may get through. As to the cases with fistula, Syme's method, to which he referred last year, would be available. Cutting in the perineum was not very satisfactory.

Mr. BARWELL remarked that both Mr. Solly and Mr. Green used leeches, as did Mr. South, to enable a stricture to be overcome.

Mr. T. SMITH mentioned a plan he had adopted. He made the patient keep his water as long as he could, and then, when the patient was making his water, he attempted to pass a catheter. He had not failed in any case.

Mr. TEEVAN, in reply, said he did not like Syme's plan of lacerating the urethra. He never himself had a death. He generally used filiform bougies, and had tried Smith's plan as well as the rest.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 6.

J. BRAXTON HICKS, M.D. F.R.S., President, in the Chair.

THE following gentlemen were elected Fellows of the Society:—George Bland, L.R.C.P. Lond. (Macclesfield); Alex. Fergusson, F.R.C.S. Ed. (Peebles); Albert Kisch, M.R.C.S.; W. H. Mondelot, M.D.; and Geo. Rigden, M.R.C.S. (Canterbury).

Dr. HEYWOOD SMITH exhibited a preparation consisting of a Fœtus at about the fourth month completely enclosed in a Perfect Sac, through the wall of which, at about an inch and a half from its abdominal attachment, the cord passed to the placenta, which was separate, and had the remains of the membranes as usual at its edge. The specimen was interesting in reference to the subject of "false waters," indicating a separate fluid-containing cavity external to the amnion.

Dr. HEYWOOD SMITH exhibited the Uterus of a patient who had died four days after delivery of a fœtus at about the fifth and a half month, of secondary hæmorrhage, the cervix uteri having been the subject of cancer. A growth

about the size of a small orange was found growing from the anterior lip of the cervix uteri; the posterior lip was small, but not entirely free from induration. The os uteri was slowly dilated under chloroform, one foot brought down, and the child born alive. In the delivery of the head the carcinomatous mass was protruded from the vulva, and, as was thought best, Dr. Heywood Smith removed it with the écraseur. The uterus contracted well, but hæmorrhage occurred on the third day and again on the fourth, and she never rallied after this. The case opened up a point for discussion--Which was the better practice, to induce premature labour, or to allow the pregnancy to advance to the full time, and if the disease precluded delivery *per vias naturales* to perform the Cæsarian section?

Dr. PHILLIPS said that each case must be judged of on its own merits, but upon the whole he thought the former line of practice the better one. He referred to two cases in which, notwithstanding considerable malignant infiltration of the cervix uteri, very slow dilatation by the elastic bags enabled delivery to be accomplished with a successful issue to the mother as far as the labour was concerned.

Dr. HEYWOOD SMITH exhibited a new instrument which he called "Angular Scissors." When they are straight they constitute a pair of scissors similar to those of Sims. They have, however, this advantage: that the small scissors can be bent at any angle with the handles up to nearly a right angle. To accomplish this it has been necessary to make on each leg of the scissors a complicated joint, consisting of three separate movements within the space of an inch and a half. The first of these is the ordinary first joint to connect the scissors with the handles; next comes the hinge-joint by which the scissors are bent at the required angle; then between the pivot-joint and the handles is inserted a rotatory-joint. One of the blades is prolonged into a director point, in front of the other, which has a blunt end. Inasmuch as the scissors may be bent on either side, they will be found useful in dividing the cervix uteri in any position, both on the right and left side.

The PRESIDENT showed a large Fibro-cystic Tumour of the Uterus. (Referred to a committee.)

Dr. A. E. MARTIN, of Berlin, exhibited the Cephalotribe of Professor Martin, and presented it to the Museum of the Society. The pelvic curve is greater than in the English patterns.

Dr. MARTIN then read an interesting account of the collection of distorted pelves at Berlin. The classification is based on the resulting deformity, and not on the cause producing it. A large number of photographs of these pelves were exhibited, and casts of several of them will soon be added to the collection of the Obstetrical Society. Dr. Martin then described pelvimetry as practised at Berlin.

Mr. THOMAS BRYANT read the particulars of a case of Fibro-cystic Disease of the Uterus and of both Ovaries, in which recovery followed the extirpation of the whole. The patient was 26 years of age and unmarried. Menstruation had always been profuse. Fluctuation existed in parts of the tumour. At the operation the broad ligaments were secured separately and the uterus at its neck ligatured in halves. A strong clamp was also put on, and the tumour excised. Recovery was uninterrupted. The clamp sloughed off on the fourteenth day, and in another week all the parts were united. The tumour weighed eight pounds and a half. Portions of the tumour had all the appearances of uterine myo-fibroma, while in other parts there were irregular cystic spaces in the same kind of tissue. The formation of the cysts was well shown to be due to fatty disintegration of the fibrous tissue, with accompanying œdema of certain patches. The ovaries showed the same kind of disease.

The discussion turned chiefly on the diagnosis of uterine from ovarian tumours.

Dr. BANTOCK advocated the use of the sound as a great help in diagnosis, while

The PRESIDENT remarked that the sound was not always to be relied upon. In one case the patient was put under chloroform to explore the uterus. The sound passed the normal length. The tumour, however, proved to be uterine, and it was found that the uterine cavity was greatly lengthened, but that the pressure of part of the tumour had caused adhesion of the uterine walls, above which there was a cavity containing retained menses.

Mr. SPENCER WELLS had also found the uterine cavity of normal length in some cases of large fibroids, and in other cases such distortion that a metal sound could not be passed, although an elastic bougie would sometimes follow a tortuous canal. He had seen the uterine cavity elongated to seven inches by adhesion to an ovarian cyst. In many cases complete diagnosis was impossible without exploratory puncture or

incision. He had only removed the enlarged uterus and both ovaries once, but he had removed very large fibroid outgrowths from the uterus with more or less of the part of the uterus with which they were connected, alone, or with one ovary attached. One case was completely successful. In another case the patient was almost well, when, more than a month after operation, pyæmic pneumonia proved fatal, the cause having been an abscess in the abdominal wall, while the intra-peritoneal conditions were quite satisfactory. He hardly understood why these operations were not as successful as ovariectomy, and hoped that when the details of the different proceedings were better learnt success would increase.

Dr. BANTOCK read a paper "On the Use of the Sponge-tent in the Treatment of certain forms of Uterine Hæmorrhage and Menorrhagia, with special reference to the occurrence of Uterine Hæmorrhage in Women residing in Tropical Climates." After briefly referring to the manufacture of sponge-tents, which, he said, should be made without mucilage and of a certain quality of sponge, the author gave details of three cases in which, after all the usual hæmostatic remedies had been tried in vain, the sponge-tent effected a cure. He then entered at some length into the pathology, combating the accepted view that in our countrywomen residing in tropical climates the menorrhagia is due to inflammatory action. He quoted Dr. Graily Hewitt and Dr. Tilt, who support this view. He pointed out the absence of all the usual signs and symptoms of inflammation, and contrasted these, as described by Hewitt and by Scanzoni, with those characteristic of the cases detailed. He expressed the opinion that the condition was essentially one of relaxation, that the muscular tissue lost its tone and allowed congestions to take place. In the cases which he had seen the uterus wanted that firmness which characterised its healthy state, and the mucous membrane covering the os uteri was often so redundant as to seem as if loosened in its submucous connexion. The action of the sponge-tent was described as being probably mechanical and vital—mechanical by compression of over-distended veins and removal of redundant epithelium, and vital by exciting increased muscular action and restoring tone generally. The author referred to the works of Sir James Simpson and Marion Sims, quoting from them instances in which the sponge-tent had proved its remedial powers, though accidentally. No mention of it as a means of cure was made by Hewitt or Tilt, and one of the principal objects of the paper was to rescue the instrument from its inferior position as an aid to diagnosis, and to raise it to the superior one as a remedial agent. He exhibited a card, prepared for him, according to the directions in the paper, by Krohne and Sesemann, containing several sponge-tents and a corresponding piece of uncompressed sponge to each tent.

Only a few minutes were left for discussion, and Dr. TILT promised to give due attention to the criticisms of the author when he had had a better opportunity of understanding them.

Mr. SCOTT was unwilling that the discussion should pass without a word of warning on the use of sponge-tents. He would not then enter into the question of their utility in the cases under consideration, but the possible occurrence of metro-peritonitis or cellulitis under their use should never be lost sight of.

Dr. AVELING said that hyperæmia of the uterus was an abnormal state well understood and frequently noticed by writers. It had been described by him at some length in a paper "Upon the Value of Arsenic in Menorrhagia and Leucorrhœa," read before the British Medical Association. He had found arsenic of the greatest service in the treatment of this hyperæmic condition of the uterus, and he would recommend its trial before having recourse to tents, the use of which he and others had known to be followed by fatal results.

OBITUARY.

ROBERT HALDANE PATERSON, L.R.C.S. EDIN.,
L.S.A. AND L.M. EDIN., ETC.,

DIED a few days since. He was born and educated in Edinburgh; served articles with the late Mr. S. Watson, Surgeon, Cottingham; and became L.S.A. in 1834. He went to Brigg thirty-eight years ago, and soon established an extensive practice, which he worked until within a few weeks of his death, which took place suddenly at Buxton, where he had gone for the benefit of his health, having for two years suffered from gouty affection of the head. He was eminent as a Surgeon, and acquired a great reputation for his

skill in the diagnosis of disease. He was gentle in manner and prompt in action. In 1868 he received a testimonial of silver from his patients and friends, "in recognition of his valued services in his Profession in the town and neighbourhood of Brigg." Mr. Paterson was universally respected by all who knew him. He has left a widow and seven children, his two sons being in the Medical Profession. He was District Medical Officer to the Glanford Brigg Union, and Public Vaccinator to the Brigg and Broughton District.

WILLIAM PRITCHARD, M.D. GLASG.,

DIED, after a short illness, on the 23rd ult., at Partick, where he had resided for upwards of twenty-five years, and was the leading Medical Practitioner there. "He was," says a local paper, "one whose services were equally at the command of the rich and the poor, and who never allowed anything to interfere with the strict performance of his Professional duties. He was a man of warm feelings, a true friend, and unbounded in his kindness and hospitality."

NEW PREPARATIONS.

BUCKLE'S SYRUP OF SEVILLE ORANGE.

(77, Gray's-inn-road.)

MR. BUCKLE, who represents the culinary or palatable aspect of physic, is always introducing some novel delicacy for use in the sick-room. His latest effort is a syrup of Seville orange-peel and juice, admirably adapted as the vehicle for cod-liver oil, dilute sulphuric acid, or any other tonic and bracing medicine.

NEW BOOKS, WITH SHORT CRITIQUES.

Colburn's United Service Magazine. December, 1871. London: Hurst and Blackett.

* * * This number contains an article on the Army Medical Department, which we ought before this to have brought under the notice of our readers. The author is a well-known Surgeon-Major who has served in all climates, and is as competent to wield the pen as the lancet. He sums up thus: "In fact, let the British reformer, as much as he possibly can, leave the Army Medical Service alone. Let it remain full of inconsistencies, and thoroughly British, with as much individual freedom allowed to every member as is consistent with military discipline. Every military Medical officer has two superiors—first, the combatant officer under whom he serves; and, secondly, the Medical man, whoever he is, who is a better Surgeon than himself. There is no occasion to create a third superior, with perhaps neither of these qualifications, by a unification scheme."

The Leavenworth Medical Herald and Journal of Pharmacy. Edited by J. W. BROCK, M.D., T. SINKS, M.D., and ROBT. J. BROWN. Leavenworth: J. C. Ketcheson. 1872.

* * * The original communications are scanty, but the editors secure a good selection of second-hand intelligence for their readers in the Far West. A case of puerperal convulsions is recorded in a primipara, aged 18, with smoky albuminous urine. The patient was bled to ten ounces; treated largely with bromide of potass, of which she took one ounce, and inhaled four ounces of chloroform during twelve hours. Then, as convulsions continued, and there were no signs of labour, the hand was introduced into the womb, the child extracted, and, spite of an attack of pneumonia, the patient was well in twenty-five days. The attempt to puff cundurango as a cure for cancer is condemned.

LOCAL APPLICATION OF HYDRATE OF CHLORAL.—Dr. Strother states that thus employed it is of excellent service in "neuralgia, pleurodynia, rheumatism, gastralgia, nausea, and vomiting." A saturated aqueous solution is applied over the seat of pain with slight friction, and glycerine, olive oil, or cream is used as a subsequent dressing. There will in most instances be enough of the chloral absorbed to produce a considerable anodyne effect, in addition to its rubefacient action. —*Boston Journal*, Feb. 22.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 2nd inst., and, when eligible, will be admitted to the pass examination:—

- Brayn, Richard, student of King's College.
- Burchell, Edward, of the Leeds School.
- Cobbold, C. S. W., of St. Bartholomew's Hospital.
- Cookson, Hugh A., of Guy's Hospital.
- Davis, Arthur Percy, of St. Bartholomew's Hospital.
- Duran, Carlos, of Guy's Hospital.
- Evans, Henry, of Guy's Hospital.
- Forty, Daniel H., of Guy's Hospital.
- Foster, Reginald H., of Guy's Hospital.
- Frost, William A., of St. George's Hospital.
- Garlick, George, of University College.
- Groves, James H., of St. Bartholomew's Hospital.
- Jones, Cyril L., of Guy's Hospital.
- Lang, William, of the London Hospital.
- Macaulay, Charles T., of St. George's Hospital.
- Mounsten, T. E. W., of University College.
- Murrell, William, of University College.
- Pike, Joseph B., of St. Thomas's Hospital.
- Reid, Matthew, of Guy's Hospital.
- Rendall, John, of Guy's Hospital.
- Richardson, William B., of the Leeds School.
- Sangster, Alfred, of Guy's Hospital.
- Sawtell, Henry T., of St. Bartholomew's Hospital.
- Scott, Edward, of St. Thomas's Hospital.
- Spitta, Edmund J., of St. George's Hospital.
- Taylor, Christopher M., of St. Thomas's Hospital.
- Tomlin, Robert F., of Guy's Hospital.
- Tordoff, Hardy, of the Leeds School.
- Wallace, William, of the Manchester School.
- Weakley, S. J. J., of St. Bartholomew's Hospital.
- Williamson, George E., of the London Hospital.

The following gentlemen passed on the 3rd inst., viz.:—

- Andrew, George, student of St. Bartholomew's Hospital.
- Atkinson, Francis E., of the Leeds School.
- Bingham, Samuel, of Guy's Hospital.
- Bond, George H., of Guy's Hospital.
- Burgess, Edward J., of St. Bartholomew's Hospital.
- Evans, David T., of the Liverpool School.
- Ferrier, John C., of Guy's Hospital.
- Fry, John F., of Guy's Hospital.
- Gray, Alexander, of Guy's Hospital.
- Hartley, John F., of University College.
- Harsant, William H., of Guy's Hospital.
- Kirby, S. J. J., of the Middlesex Hospital.
- Lucas, Henry O., of St. Bartholomew's Hospital.
- McConkey, Thomas C., of St. Thomas's Hospital.
- Mercier, Charles A., of the London Hospital.
- Morley, Thomas S., of Guy's Hospital.
- Paley, William E., of Guy's Hospital.
- Perrin, Alfred C., of St. Thomas's Hospital.
- Pughe, R. N. ap T., of the Liverpool School.
- Reid, Thomas W., of St. Bartholomew's Hospital.
- Roberts, Theophilus L., of the Liverpool School.
- Robson, A. W. M., of the Leeds School.
- Scott, Thomas B., of St. Bartholomew's Hospital.
- Stevens, Alfred F., of St. Bartholomew's Hospital.
- Stewart, David D., of the Liverpool School.
- Talbot, Joseph B., of the Birmingham School.
- Taylor, G. G. S., of the Liverpool School.
- Twort, William H., of St. Bartholomew's Hospital.
- Verco, Joseph C., of St. Bartholomew's Hospital.

The following gentlemen passed on the 4th inst., viz.:—

- Adams, James, student of St. Bartholomew's Hospital.
- Alderton, Thomas G., of St. Bartholomew's Hospital.
- Barnard, Charles E., of Guy's Hospital.
- Boulter, Harold B., of St. Bartholomew's Hospital.
- Bubb, Benjamin, of King's College.
- Churchward, Albert, of Guy's Hospital.
- Clarke, Henry, of Guy's Hospital.
- Couldrey, James, of the Charing-cross Hospital.
- Edwards, Octavius, of Guy's Hospital.
- Hardy, James A., of St. George's Hospital.
- Harrison, Charles E., of St. Bartholomew's Hospital.
- Jones, Arthur H., of Guy's Hospital.
- Lincock, John B., of the London Hospital.
- Macready, Jonathan, of St. Bartholomew's Hospital.
- Medcalf, Ernest S., of Guy's Hospital.
- Mercer, A. R. C., of the Charing-cross Hospital.
- Mills, Joseph, of St. Bartholomew's Hospital.
- Morgan, David C., of Guy's Hospital.
- Morgan, Evan A., of the Liverpool School.
- Sheehy, W. H. P., of St. Bartholomew's Hospital.
- Smith, Roland D., of the London Hospital.
- Sturmer, Arthur J., of St. Bartholomew's Hospital.
- Tomes, Arthur, of the Middlesex Hospital.
- Wharry, Robert, of St. Bartholomew's Hospital.

Out of the 108 candidates examined, twenty-four having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their Anatomical and Physiological studies for three months. Mr. Henry Spencer Smith, F.R.C.S., Surgeon to St. Mary's Hospital, the recently elected member of the Court of Examiners, took his seat on this occasion. It is

stated that another batch of 103 candidates will undergo the written portion of their primary examination this day (Saturday).

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, March 28:—

Bosson, George, Barnstaple, Devon.
 Davies, George Augustus, Newport, Monmouthshire.
 Grogono, Walter Atkins, Stratford, Essex.
 Harvey, William, Gloucester-street, Victoria-park.
 Jones, Thomas, Derlwyn, Carmarthen.
 McDonogh, Augustus William, Clapham.
 Smith, William Robert, Huddersfield.
 Spencer, Edward Richard, Keyston, Hunts.
 Wardale, Joseph Augustus William, Newport, I. W.

As an Assistant in Compounding and Dispensing Medicines—

Blott, Herbert, Alexander-road, Kilburn.

The following gentlemen also on the same day passed their first Professional examination:—

Fenton, George Frederick, King's College.
 Smith, Frank John Shersley, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ARMSTRONG, H. E., M.R.C.S.L., L.S.A.—Lecturer on Botany and Vegetable Physiology at the University of Durham College of Medicine, Newcastle-upon-Tyne.

AYRES, H. M.—Non-Resident Dispenser to the Leamington Provident Dispensary.

CHURCHILL, GEORGE FLEETWOOD, M.B., F.K.Q.C.P.—Assistant-Secretary to the Cow-pock Institution, Dublin.

HILL, J. HIGHAM, L.R.C.P.—Sole Medical Officer to the St. Pancras Workhouse and Infirmary, King's-road, N.W.

LOCK, J. GRIFFITH, M.A. Cantab., L.R.C.P., etc.—Medical Officer of Health for Tenby.

PHILIPSON, G. H., M.A., M.D., M.R.C.P.L.—Lecturer on the Principles and Practice of Medicine at the University of Durham College of Medicine, Newcastle-upon-Tyne, *vice* D. Embleton, M.D., F.R.C.P.L., resigned.

SINCLAIR, E. B., A.M., M.D.—Secretary to the Cow-pock Institution, Dublin.

SMITH, H. L., L.R.C.S.I., L.K.Q.C.P.I.—Medical Officer, etc., for the Keadne Dispensary District, Boyle Union.

SPENCE, ROBERT, M.B. and C.M.—Medical Officer to the Parish of Lochmaber, Dumfriesshire.

STONE, WILLIAM DOMETT, M.D., F.R.C.S. (Exam.)—Surgeon to the St. Marylebone General Dispensary.

NAVAL APPOINTMENTS.

M'SHANE, CHARLES, Staff-Surgeon to the *Minotaur*; Edward T. Mortimer, Surgeon to the *Pallas*; F. W. Laslett, Assistant-Surgeon to the *Pallas*; Dr. Isaac H. Anderson, Assistant-Surgeon to the *Northumberland*.

BIRTHS.

BRICE.—On March 29, at Standley Lodge, Southsea, the wife of Dr. F. A. Brice, R.N., Surgeon of H.M.S. *Pylades*, of a daughter.

COURY.—On March 29, at S. Brent, Devon, the wife of Thomas Coury, Assistant-Surgeon R.N., of a son.

CRONIN.—On March 28, at Old Manor House, Clapham-common, the wife of Dr. Eugene Cronin, of a son.

GAIRDNER.—On March 29, at 225, St. Vincent-street, Glasgow, the wife of Professor Gairdner, M.D. Glasgow University, of a daughter.

HARMAN.—On April 1, at 2, Salisbury-villas, Gresham-road, Brixton, the wife of John Harman, M.R.C.S.E., of a son.

LONGHURST.—On April 1, at The Vicarage, Dunton Bassett, Leicestershire, the wife of Dr. Arthur E. T. Longhurst, 60th Royal Rifles, of a son.

MARRIAGES.

BROWNRIGG—KEY.—On April 2, at Immanuel Church, Streatham-common, John Annesley Brownrigg, M.D., of Streatham, son of the late Robert Brownrigg, Esq., of Norrismount, county Wexford, Ireland, to Louisa Marian, eldest daughter of Sir Kingsmill G. Key, Bart., of Spencer House, Streatham.

LAMB—FORBES.—On April 2, at St. Mark's, Hamilton-terrace, Cecil Stewart, eldest son of the late John Stewart Lamb, M.D., to Mary Maria, eldest daughter of Wm. N. Forbes, of Carlton Lodge, and Dunnotar, N.B.

NUTT—BLOXAM.—On March 30, at the Church of the Holy Trinity, Hertford-heath, Rothery Nutt, of Clifton Villas, Maida-hill, eldest son of the late Wm. Clarke Nutt, F.R.C.S., of Plymstock, Devon, to Kathleen Laura, second daughter of Alfred Bradley Bloxam, of Heathfield House, Herts.

STROVER—FLOWER.—On March 30, at St. Thomas's Church, Camden-town, Frederick Reginald, eldest son of the late Surgeon-Major T. R. Strover, F.R.C.S., Bengal Medical Service, to Caroline Elliott, fourth daughter of the late William Flower, Esq.

DEATHS.

AIR, MARY, the beloved wife of A. Cummings Air, L.R.C.P.L., etc., and youngest daughter of the Rev. W. P. Tiddy, Camberwell, on March 28.

EASTES, FRANK, the dearly-loved elder son of George Eastes, M.B., L.R.C.S., F.R.C.P., of Albion-place, Hyde-park-square, London, at Folkestone, on April 3, aged 2 years and 4 months.

HENDERSON, WILLIAM, M.D., late Professor of General Pathology in the University of Edinburgh, at 19, Ainslie-place, Edinburgh, on April 1, aged 62.

HESS, EDWIN LEOPOLD, youngest son of Augustus Hess, M.D., after a short illness, on April 1, aged 13 years and 4 months.

KING, MARY JOHANNA, widow of the late John King, Surgeon, of St. John's-wood, and daughter of the late Capt. Ashton, of St. Helena, at Ambleside, Westmoreland, on March 29.

KNOTT, W. P., M.R.C.S., L.A.S., of Bugbrooke, Northampton, at Thame, Oxon, from congestion of the lungs, on March 25, aged 30.

MCGRIGOR, MARY, widow of Sir James McGrigor, Bart., K.C.B., late Director-General of the Army Medical Department, at 4, Upper George-street, Bryanstone-square, on April 1.

MANLEY, LILIAN FRANCES GEORGIA, infant daughter of Mr. W. G. N. Manley, Surgeon Royal Artillery, at Woolwich, on March 31.

WEBSTER, GEORGE, F.R.C.S., after a long and distressing illness, at his residence, 73, Upper Gloucester-place, Dorset-square, aged 63.

YOUNG, GRAYDON HARIM, third and last surviving of the four sons of the late Thomas Young, M.D., formerly Surgeon in the Royal Horse Artillery, at Marlowes, Hemel Hempstead, on March 30, aged 45.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BECKETT HOSPITAL AND DISPENSARY, BARNSELY.—House-Surgeon and Secretary. Candidates must be duly qualified. Applications and testimonials, on or before April 8, to Messrs. Newman and Sons, Solicitors, Barnsley.

BETHLEM HOSPITAL.—Two Resident Medical Students, who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the Hospital for a term generally not exceeding six months. Applications and testimonials to be forwarded to Bridevell Hospital, Blackfriars, E.C., addressed to A. M. Jeaffreson, Esq., on or before April 6.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Candidates must be duly qualified. Applications and testimonials to Alexander Bottle, M.D., Secretary, on or before April 17.

CARMARTHEN COUNTY AND BOROUGH INFIRMARY.—House-Surgeon. Must be M.R.C.S. and L.S.A. A knowledge of the Welsh language is necessary. Applications to Mr. H. Howell, King-street, Carmarthen, on or before April 10. Election on the 12th.

CENTRAL LONDON OPHTHALMIC HOSPITAL, GRAY'S-INN-ROAD, W.C.—Assistant-Surgeon. Candidates must be M.R.C.S., and must have attended the practice of some Ophthalmic Institution for at least six months. Testimonials, etc., to be sent to the Secretary, on or before April 6.

DENTAL HOSPITAL OF LONDON, 32, SOHO-SQUARE.—Assistant Dental Surgeon. Candidates must be L.D.S. of the Royal College of Surgeons of England. Applications and testimonials to be sent to Alfred Coleman, Esq., Hon. Sec., on or before April 12.

ECHT, ABERDEENSHIRE.—Medical Officer to the Parish of Echt.

KING'S COLLEGE.—Demonstrator of Practical Physiology.

ROYAL SURREY COUNTY HOSPITAL.—Assistant Honorary Medical Officer. Testimonials to be sent to the Hon. Sec., Rev. C. E. Dallas, Farncombe Rectory, Godalming, on or before April 16.

SALISBURY INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications and testimonials to be sent to the Secretary, on or before April 11.

STAFFORDSHIRE GENERAL INFIRMARY.—House-Surgeon and Secretary. Candidates must be M.R.C.S. of London, Dublin, or Edinburgh, and possess a qualification in Medicine which will entitle to register. Candidates must attend the Infirmary on Monday, April 22, at one o'clock.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Glanford Brigg Union.—The Broughton District is vacant; area 16,906; population 4563; salary £57 per annum.

Malton Union.—Mr. John Coates has resigned the Leavening District; area 18,380; population 2605; salary £40 per annum.

Portsea Island Union.—Dr. Simpson has resigned the Railway District; salary £90 per annum.

APPOINTMENTS.

Beverley Union.—Wm. Wood, M.R.C.S. Eng., L.S.A., to the Fifth District.
 Blything Union.—Edward D. Wallis, M.R.C.S. Eng., L.S.A., to the Fifth District.

Ecclesall Bierlow Union.—John Richd. Taylor, M.R.C.S. Eng., L.S.A., to the Second District.

Elham Union.—Wm. Bishop, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A., to the Elham District and the Workhouse.

Holywell Union.—Jesse C. Davies, M.D., M.R.C.S., L.S.A., to the First Division of the Whitford District.

Macclesfield Union.—Alex. Walker, M.B. & M.C. Univ. Aber., to the Whaley District.

Wakefield Union.—Wm. D. Wood, L.R.C.P. Edin., L.R.C.S. Edin., L.S.A., to the Stanley-cum-Wrenthorpe District.

Walsall and West Bromwich District School.—Alfred P. Evans, M.R.C.S. Eng., L.S.A., to the School.

West Derby Union.—George Andrews, M.R.C.S.E., L.R.C.P. Lond., L.S.A., to the Walton-on-the-Hill District.

DR. ARTHUR STRANGE, son of Dr. Strange, of Worcester, has been appointed Medical Superintendent of the Salop and Montgomery Counties Lunatic Asylum, at Bieton Heath, near Shrewsbury.

RADCLIFFE STUDENTSHIPS have been awarded to Mr. Carey, of Guy's Hospital, and to Mr. Keetley, of St. Bartholomew's.

THE Beaumont Medical Society proposes to give a *soirée* at the Vestry Hall, Baneroff-road, on Wednesday, April 10.

DR. HENDERSON, lately Professor of General Pathology in the University of Edinburgh, died on Monday morning, aged 62.

THE will of Mr. Oswald Copland, of Chelmsford, M.R.C.S. Eng., has been proved under £35,000.

THE Monmouthshire Court of Quarter-Sessions has increased the salary of the Surgeon to the County Gaol from £115 to £150 per annum.

THE Stockton Board of Guardians have increased the salary of Mr. Healey, Medical Officer for the Middlesborough South District, from £60 to £80 per annum.

WE are happy to see not a single application was made for the vacant appointment of Medical Officer for the Lewtrenchard District of the Tavistock Union, £25 per annum; and it is now proposed to amalgamate it with the Lifton District, making together £58 per annum.

A COTTAGE HOSPITAL for four beds was opened at East Rudham, Norfolk, on February 27 last, in commemoration of the recovery of H.R.H. the Prince of Wales.

IT was resolved, at a meeting of manufacturers of Leeds and neighbourhood, on Tuesday, that the provisions of the Public Health Bill seriously endanger the security of the manufactories of the country, and ought not to pass into law, and that a strenuous opposition be made thereto in Parliament, and such measures adopted as will lead to the withdrawal or modification of the objectionable clauses. A committee was appointed to promote the opposition, and a petition against the Bill adopted.

THE *conversazione* at the Medical Club on March 22 was well attended, and the guests had abundance of interesting objects submitted for inspection. Mr. Crosse, of Norwich, contributed the Skull of Sir Thomas Browne, and a Calculus weighing fifteen ounces; Dr. Swetenham, the Skull of Extinct Pigmy Elephant, from Malta; Mr. Frank Buckland and Mr. Critchett, many objects of Natural History; Dr. A. Carpenter, a series of drawings illustrating the Ventilation of Sewers; Dr. Lory Marsh, a collection of Autographs; Dr. Smart, C.B., and Dr. Witt, collections of Works of Art, Virtue, and Ethnological Curiosity.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, on Monday, April 1 (Sir Henry Holland, Bart., M.D., D.C.L., President, in the chair), Louisa Lady Ashburton; Charles Balme, Esq.; Mrs. W. Clement Cazalet; Francis Halhed Ward-Jackson, Esq.; Samuel Morley, Esq., M.P.; S. J. Smith, Esq., F.G.S., F.C.S.; C. Whittingham, Esq., were elected members of the Royal Institution.

THE DENTAL DIPLOMA.—Some important alterations have just been made in the regulations relating to the diploma in Dental Surgery of the Royal College of Surgeons, candidates for which will now have to undergo an examination partly written and partly oral, the former comprising General Anatomy and Physiology, and General Pathology and Surgery, with especial reference to the practice of the dental profession. The oral practical examination comprises the several subjects included in the curriculum of Professional education, and will be conducted by the use of preparations, casts, drawings, etc. A ticket of admission to the museum, to the library, and to the College lectures will be presented to each candidate on his obtaining the diploma; thus giving him nearly the same privileges as those enjoyed by members, the only difference being that the latter can introduce their friends. The next examination will be held the same time in June.

EXAMINATION QUESTIONS.—The following is a copy of the questions on Anatomy and Physiology submitted to the candidates (108 in number) at the primary examination for the diploma of Membership of the Royal College of Surgeons of England, on Saturday last, the 30th ult., viz.:—1. Describe the structure, connexions, and relations of the iris; trace from their origin to their distribution its arteries and nerves. 2. Describe the adult male bladder; its position when contracted and distended, its connexions, and the structure of its muscular and mucous coats. 3. Describe in detail the action of the heart. How do you account for its sounds and impulse?

4. Give the dissection required, and mention in the order in which they appear, the parts that must be removed in order to expose the supinator radii brevis. 5. Describe the pancreas; its situation, shape, and structure, the composition and uses of its secretion. 6. Give the physical characters and chemical composition of urea; state how its presence may be detected in the urine and other fluids.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN MARCH, 1872.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	20·23	0·085	0·127	0·003	14·6	3·8
West Middlesex	20·17	0·055	0·124	0·001	14·9	3·8
Southwark & Vauxhall	20·33	0·079	0·121	0·003	14·8	3·8
Chelsea	20·49	0·079	0·124	0·003	14·8	3·8
Lambeth	20·73	0·081	0·125	0·003	15·0	4·0
<i>Other Companies.</i>						
Kent	26·87	0·018	0·251	0·000	20·2	5·9
New River	19·30	0·030	0·124	0·002	14·8	3·9
East London	22·00	0·066	0·138	0·002	16·0	4·4

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was turbid—namely, in that of the Lambeth, and the Southwark and Vauxhall Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 101,353,285 gallons; and the number of houses supplied was 493,551. This is at the rate of 31·5 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 26·8 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

THE PARIS MORGUE.—The following corpses, or parts of bodies, have been exposed this year at this mortuary, which is situated behind the garden of the Cathedral of Notre Dame:—45 still-born children, 37 live-born children, 15 mutilated fragments of bodies, and 311 corpses of adult persons.

THE NEW FACULTY OF MEDICINE AT NANCY.—In conformity with the recommendations of the Budget Committee of the National Assembly, 162,000 fr. have been voted "to maintain intact and establish at Nancy the Faculty of Medicine and School of Pharmacy of Strasburg." The Assembly has refused the supplementary sum of 91,100 fr., which would have been required had the Strasburg staff of Professors been divided between Nancy and Lyons. This diminution has been made in accordance with the Minister of Public Instruction, who reserves to himself a right to make a proposition for a special law for the foundation of a Faculty at Lyons, which he intends advocating with all his power.—*Gazette Hebdomadaire*, March 29.

PROFESSOR DOLBEAU.—M. Nacquet having put a question in the National Assembly to the Minister of Public Instruction in reference to the closure of the Medical Faculty consequent upon the renewal of the tumult on M. Dolbeau's attempt to lecture, M. Jules Simon stated that, while the Professor properly refused to give to the students the explanations they demanded of him concerning his conduct towards the Communists, he had himself demanded that a committee of inquiry should be instituted under the auspices of the Administration de l'Assistance Publique. In reference to the heroic remedy of closing the schools, which is so often resorted to on the occurrence of any insubordinate conduct on the part of perhaps only a minority of students, Professional opinion has expressed itself very unfavourably, as operating injuriously with respect to the studies of the rest of the classes and the general well-doing of the school. The Assembly has appointed May 1 for the discussion of this subject.

THE MAN WITH THE IRON JAW.—Monsieur d'Atalie, or, as he is commonly called, "The Man with the Iron Jaw," was presented recently at the Surgical Clinic of Prof. Mears in the Pennsylvania College of Dental Surgery, for the examination of his maxillary apparatus. From early life he has been engaged in a gymnasium, and his first effort to raise heavy weights by his teeth was made three years ago, when he attempted to lift a heavy table; the effort was successful, and now he is able to raise 700 lbs. His maxillary apparatus does

not present any extraordinary development, but, on the contrary, its various parts seem not to have undergone any very full development. He holds the heavy weights by placing the part seized between both the anterior and posterior teeth, so as to employ all the elevators of the jaw. His power does not reside alone in the muscles of the jaw, those of the neck and body playing an equally important part in all his feats of strength.—*New York Med. Record*, March 1.

NOTES, QUERIES, AND REPLIES

De that questioneth much shall learn much.—Bacon.

* * * Many communications are in type, and shall be inserted as soon as possible, including papers by Mr. Henry Hancock, Mr. Bryant, Mr. Charles Orton, Mr. Metcalfe Johnson, Mr. F. A. Mahomed, Dr. Robert Liveing, Dr. John W. Ogle, and Mr. J. Beswick-Perrin.

How to Extinguish Child-Murder.—"When the day comes that motherhood is deemed the right of all healthy women, and no disgrace attaches to the manner of it, then child-murder and abortion will cease, and not till then." This gem of purest ray serene is taken from the American "Woman's Rights" organ—*Woodhull and Claflin's Weekly*.

Dr. E. Stöhrer's Induction Apparatus and Constant-current Batteries.—Dr. Stöhrer tells us that, as many spurious and faulty imitations of his induction apparatus and constant-current batteries are now offered for sale in England, he desires it to be known that the only agents in England are Messrs. Krohne and Sesemann, 8, Duke-street, Manchester-square, and 241, Whitechapel-road, London; and Mr. J. F. Pratt, 420, Oxford-street, London, who receive the above direct from his manufactory at Dresden. Every apparatus of his manufacture is stamped with his trade mark.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you oblige me by inserting the following questions propounded at the last pass examination at the College of Surgeons, Edinburgh?

Surgery and Surgical Anatomy.

1. Describe the healing process in wounds of veins. Define diffuse phlebitis; its causes, symptoms, pathology, prognosis, and treatment.
2. What is ranula? Give its treatment.
3. Describe a fracture in the lower third of the femur (supra-condyloid)—first, as to age; second, its symptoms; third, cause of the displacement of the fragments. And how do you treat it?
4. Describe disease in the shoulder-joint, commencing in the hard structures; give its pathology and treatment; and describe the operation for excision of the joint.
5. Describe the anatomical structures concerned in the median operation for lithotomy; give the requisite incisions; and what are the advantages of this operation?

Medicine and Materia Medica.

1. Define acute dysentery. Give its diagnosis, pathology, prognosis, and treatment.
2. Typhoid fever; its synonyms, its diagnosis, pathology, prognosis, and treatment.
3. Softening of the brain. Give its causes, diagnosis, pathology, and treatment.
4. What is an emmenagogue? Enumerate the different drugs having that property, with the difference in action of each, and their doses.
5. What is the therapeutical action of nitrate of silver, externally and internally; in what form is it administered; and what is its dose?
6. Give the botanical name of male fern, with its order; what its officinal preparation, its therapeutical action, and dose; and mention the precautions necessary to exercise in its administration.

Midwifery.

1. Give the relative frequency of twins, and the management of such cases.
2. Describe the process of natural labour from its commencement to its termination, and explain what is expected from the Practitioner in its several stages.
3. What are the causes of post-partum hæmorrhage? What is its treatment?

Medical Jurisprudence.

1. What is the disease which in female children may give rise to charges of rape? How would you distinguish disease existing under such circumstances from the actual crime?
2. What are the symptoms of poisoning by sulphuric acid? What is the character of the stains upon black cloth? Give the different tests for the poison.
3. What are the chemical tests by which you would conclude that a pistol had been recently discharged?

In addition to the above, the candidates had to undergo a clinical examination of thirty minutes at the Royal Infirmary, and a *viduæ vocis* of an hour and a half at the College.

I have trespassed thus upon your valuable space for the information of those gentlemen who labour under the impression that the Edinburgh Surgical diploma is easier to obtain than our own.

London, April 1.

ANGLICUS.

SUPERANNUATION FOR PAROCHIAL MEDICAL OFFICERS IN SCOTLAND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the Bill brought into the House of Commons to amend the Poor Law of Scotland the provisions for the appointment of Medical Officers to all parishes and for fixing their salaries are highly approved of by the Medical Officers, but it makes no provision for their superannuation. This omission is rather surprising, since both the Irish and English Poor-law Medical Officers have had separate Bills discussed in Parliament and

passed into law. The Medical Officers in Scotland should not let this opportunity pass without petitioning Parliament that superannuation be granted to them. The following is a form of petition, which they may copy or alter as may be advisable, and which, after signing, should be sent for presentation to their own Member, or one of the Members for the Universities, or forwarded to Joseph Rogers, M.D., 33, Dean-street, Soho, London, President of the Poor-law Medical Officers' Association, who has kindly undertaken to put into the hands of a friendly Member all petitions which may be sent to him. This should be carried out without delay:—

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The humble petition of the undersigned sheweth—That whereas a Bill, called the Poor-law (Scotland) Amendment Bill, 1872, has been brought before your honourable House which does not provide for the superannuation of Medical Officers who have become incapable of discharging the duties of their office by reason of infirmity or old age, your petitioner prays that the Bill be amended by the insertion of the words "Medical Officer" after the word "inspector" in Clause 37, Superannuations of—Part VII., General Provisions. Your petitioner further prays that no Bill be allowed to become law which does not provide for the superannuation of such infirm or aged Medical Officers.

And your petitioner will ever pray.

This form is for the signature of one Medical Officer only, but by making certain alterations in it, all the Medical Officers of a large town or parish may sign it. This should be done at once and forwarded without delay.

I am, &c.,

2nd April, 1872.

A SCOTCH PAROCHIAL MEDICAL OFFICER.

SWINE NUISANCES, ETC.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I trust that the new Sanitary Bill now before Parliament will enable local authorities to prevent the keeping of swine in towns during the summer months—*i.e.*, from April 1 to October 31—or to abolish the nuisances entirely. It generally happens that animals of this description are kept in the most unhealthy and pent-up places, where they become an intolerable nuisance and a corresponding injury to the health of those residing in such localities. A pig-sty is generally placed at the end of a small garden or court-yard, and the houses in the back street (back to back) frequently receive the greater part of the noxious effluvia. To induce persons to come forward and give evidence of the nuisance is often attended with difficulty, owing to the unpleasantness of one neighbour informing, as it were, against another. The food which is given to swine is generally the refuse of vegetable and animal matter, and unless frequent investigations are made by the Inspectors of Nuisances, the disgusting food is kept in a stinking state. Moreover, the manure of pig-stys is generally carried through the dwelling-house, owing to there being no back outlet; and I need not point out that such a state of things is very detrimental to health.

We know not to what extent these so-called minor nuisances create disease, but I cannot resist stating that those who permit nuisances to accumulate, directly or indirectly, so as to foster disease, are morally responsible for the result. If all the minor nuisances were united together and placed before the eyes of those who are ignorant of their existence, the evidence would be irresistible.

The epidemic of cholera and small-pox has done much to prevent human beings dwelling in pig-stys, privies, etc., but much remains to be done by the Legislature to enable local authorities to deal with all nuisances upon the evidence of Health Officers and Inspectors of Nuisances, without calling witnesses to protest against noxious effluvia which are generating from day to day. The enervation caused by the inhalation of such effluvia tends so much, I fear, to drive many of the working classes to excesses in spirituous liquors, though not conscious as to the cause.

In conclusion, I would mention that the window-tax did much to improve the ventilation of houses and to render them cheerful; but in towns there are many blind streets, courts, and alleys which require opening for the free ventilation of light and air. The exorbitant demand which persons make for their property which occludes streets, etc., requires the attention of the Legislature. All pent-up nuisances are more injurious to health than those exposed to a free current of air; hence it is that an open drain or privy, freely exposed to the air, is generally considered less injurious to health than the escape of gases from a covered drain or closet.

I am, &c.,

Southampton, March 25.

FATAL EFFECTS OF YEW-LEAVES.

On Friday, March 25, 1774, three children of James Buckley, a labouring man at Longsight, near Manchester, were killed by taking a small quantity of the fresh leaves of the yew tree, or *Taxus officinalis* of Caspar Bauhin

(*Taxus bonata*, Linn.). The oldest child was 5, the second 4, and the youngest 3 years of age. They were all supposed to be affected with worms, and this poison was given them, by the recommendation of some ignorant person, as a powerful remedy for that disorder. The dried leaves were first employed, and a spoonful of them, mixed with brown sugar, was divided into three equal doses, which the children took at seven o'clock in the morning. At eight they had each a mess of pottage, prepared of buttermilk, which, having been kept several days, was become very sour. No complaints were made by the children, nor did any bad effects ensue. Two days afterwards the mother collected fresh leaves and administered them in the same dose as before, and at the same hour. At eight o'clock the children breakfasted of nettle pottage—that is, oatmeal gruel with fresh nettles boiled in it, a mess well known in this country. At nine they began to be uneasy; were chilly and listless; yawned much; and frequently stretched out their limbs. The oldest vomited a little, and complained of gripings in his belly, but the others expressed no signs of pain. The second child died at ten o'clock, the youngest about one, and the oldest at three in the afternoon. No agonies accompanied their dissolution; no swelling of their abdomen ensued; and after death they had the appearance of being in a placid sleep. These particulars I learned from the unfortunate parents of the children.—*Percival's Essays*, vol. ii., p. 180, fourth edition.

APPOINTMENTS FOR THE WEEK.

April 6. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

8. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Teevan, "Two Cases of Retention of Urine from Calculus." Dr. Sedgwick, "On the Alkaline Waters of Tarasp."

9. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

ROYAL INSTITUTION, 3 p.m. Dr. Guy, "Statistics and Social Science."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (Ballot, 8 p.m.), 8½ p.m. Dr. Moxon and Mr. Durham, "Case of Abdominal Aneurism cured by Compression of the Aorta." Mr. T. Bryant, "Case of Abdominal Aneurism treated by Distal Pressure."

10. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

EPIDEMIOLOGICAL SOCIETY, 8 p.m. Meeting.

SOCIETY OF ARTS, 8 p.m. Meeting.

11. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. ROYAL INSTITUTION, 3 p.m. Dr. Tyndall, "Heat and Light."

12. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Mr. Gant, "On a Case of Spontaneous Gangrene of both Feet from Disease of the Heart—Amputation, Recovery, etc." Dr. Broadbent, "On a Case of Paralysis due to Tumours in Pons and Medulla Oblongata." Dr. Anstie, "On a Case of Lepa Anaesthetica."

QUEKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Objects only.

ROYAL INSTITUTION, 9 p.m. Mr. John Morley, "Rousseau's Influence on European Thought."

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.31 in. The highest was 29.60 in. at the beginning of the week, and the lowest 29.10 in. on Saturday afternoon.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

HUNGARIAN WINES.

Having for the last ten years devoted all my energies and means to introduce to the favourable notice of the British Public the pure Wines of Hungary—my native country—I gratefully acknowledge that my efforts have been rewarded by a certain amount of present success, with a prospect of its further development under a system of honest and fair dealing—the only legitimate means of upholding and extending the reputation these Wines have hitherto attained.

But I find myself at the same time compelled to warn the Public that certain Firms in London, attracted by my success, do not scruple to imitate my labels, show-cards, price-lists, price-placards, and even the distinctive names of my Wines, and under these disguises to foist upon too credulous consumers an inferior article, consisting partly of wines rejected by me as unfit to be supplied to my customers; one Company, falsely representing itself as Purveyor to the Emperor of Austria, going the length of claiming to have obtained the first prize medal at the International Exhibitions—the last of which was at Paris in 1867, while the existence of the Company itself only dates from January, 1870.

I beg, therefore, hereby respectfully to give notice that my Business has no connexion whatever with any of these Firms or Companies, and that I can only guarantee the pure quality of Hungarian Wines bearing my own label, and having the corks branded with my name in full.

In illustration, I beg to annex copy of a letter officially communicated to me by the Hungarian Government, through the Imperial Royal Consulate-General for Hungary in London, having reference to one of the advertising Firms above alluded to.

I am, respectfully yours,

7, Mincing-lane, London, E.C., December, 1870.

MAX GREGER (from Hungary).

No. 24411-842.—From the ROYAL HUNGARIAN MINISTRY FOR AGRICULTURE, COMMERCE, AND TRADE, to the HONOURABLE MR. SCHAFFER, Aulic Councillor, Imperial Royal Hungarian Consul-General in London.—In reply to your Honour's further inquiry concerning a certain advertising Society in London, I have to observe that no Society of Exporting Wine Growers of such description is known in the country, and that no such Company obtained the First Prize Medal at the International Exhibition, nor are they the direct purveyors to the Emperor of Austria; and that, according to information obtained, the Society signing under such firm in London is formed only of one individual, a former employé of the house of Max Greger, of high repute in the Wine Trade, and likewise honourably known throughout Hungary.—The Minister, SZLAVY, m.p.
Pest, December 10th, 1870.

Natural Mineral Waters of Vals, Vichy, Carlsbad, Seltzer, Kissengen, Homburg, PULLNA, FRIEDRICHSHALL, &c., direct from the Springs; also the Artificial Mineral Waters prepared by Dr. Struve and Co. at the Royal German Spa, Brighton; R. Ellis and Son, Ruthin; and the Natural Bromo-Iodine Water of Woodhall Spa, Lincolnshire.—Agents, W. BEST and SONS, 22, Henrietta-street, Cavendish-square, London, W.

BURN THE "STAR" NIGHT LIGHTS.

PROTECTED BY ROYAL LETTERS PATENT. SPECIALITY FOR THE MEDICAL PROFESSION.

AGNEW'S COD-LIVER OIL JELLY,
Guaranteed to contain not less than 70 per cent. of the finest Newfoundland Oil,
AS SUPPLIED TO HER MAJESTY'S NAVY FOR HOSPITAL SERVICE,
Commands a large sale, and is extensively ordered by the Medical Profession in private practice and in public institutions.
Sold in Half-pints, 2s.; Pints, 3s. 6d.; Quarts, 6s. 6d.

J. AGNEW, INVENTOR AND PATENTEE.
Manufactory and Principal Wholesale Depot, 278, Great Homer-street, Liverpool.

London Agents:—Evans, Leseher, & Evans; Barclay & Sons; Sanger & Sons; Millard & Sons; Edwards; Newbery & Sons; and all Wholesale Houses.

LIEBREICH'S CHLORAL HYDRAT.

To be obtained through all the Wholesale Druggists of the United Kingdom.

Sole Wholesale Agents, A. & M. ZIMMERMANN, 7, Fen-court, Fenchurch-street, E.C.

BOUDAULT'S PEPSINE.

In 1854, after many experiments, PEPSINE was obtained in a pure state by M. BOUDAULT, Chemist, and Dr. L. Corvisart.

Boudault's PEPSINE was honoured with two Reports at the Academy of Medicine, Paris, and with having its formula inserted in the New French Pharmacopœia.

The International Jury of the Universal Exposition, Paris, 1867, awarded to Boudault's PEPSINE the ONLY MEDAL given for PEPSINE and its preparations. (Silver Medal, 1868.)

Boudault's PEPSINE is the only one that has been furnished to the Hospitals in Paris since 1854.

PEPSINE Wine (Sherry), in bottles, 4/ and 8/. Dose—a tablespoonful before each meal.

PEPSINE Lozenges, in bottles, 4/. Dose—3 before each meal. PEPSINE Pills, in bottles, 4/. Dose—3 before each meal.

Boudault's PEPSINE or Poudre Nutrimentive. Dose—15 grains; sold in 1-oz., 4-oz., 8-oz., and 16-oz. bottles.

HOTTOT BOUDAULT, 7, Avenue Victoria, Paris.

London: A. & M. ZIMMERMANN, 7, Fen-court, E.C.

May be obtained through all Chemists.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;
and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

PART VII.

PLEURITIC EFFUSIONS—Continued.

Fatal Cases. Objects and Plan of the Operation of Paracentesis Thoracis—Successful Cases: Bad Cases Recovering without Operation. Utility of Drainage-tubes. Success of Suction Syringe—Cautions—Cases.

On a rough estimate (for I do not always keep notes of slighter cases) I calculate that quite three-fourths of the pleuritic patients treated in private practice recover under medicinal treatment. I have now to notice those in which surgical aid has been required; and they may be appropriately preceded by some fatal cases, from which we may learn where danger lies.

About two years ago I saw a young lady, near Westbourne-terrace, with extensive effusion in the right pleura from sub-acute pleurisy. Cupping, blisters, and diuretics had been used without making any impression on the effusion. The breath was very short and frequent; but as the patient did not complain of it, and there was great dread of an operation, we thought a few days more might be allowed for the action of the remedies. Before those days were elapsed I was summoned in haste, and found her dying; in fact she died half an hour after my arrival, and before we could get a Surgeon to perform the operation. No doubt it was delayed too long. I found on inquiry that the patient had for the two preceding days been much distressed, and her sleep prevented by increased dyspnoea. Under such circumstances there should be no delay.

About five years ago I was called to St. Leonard's to see a gentleman of 60 with pleuritic effusion of several weeks' standing; and from the increasing pallor, weakness, oppression, etc., I had no doubt it was empyema, and that paracentesis ought to be performed. But there was this difficulty: loud bronchophony in the affected side, between the fourth and seventh ribs, showed that the lung was adherent there, and would come in the way where the puncture is most properly and effectively performed. It was done at last, and a quantity of offensive pus was discharged, but the patient sank the next day. In that case some of the bones of the chest had become carious. Such complications are obviously unfavourable. I met with one such in a patient of Dr. Halley, in whom empyema followed a strain of the back, and was complicated by subcutaneous abscess in that region. Free incisions were made, and large quantities of pus were discharged, but the patient died a week or two after; and as I supposed, two of the ribs were found to be carious.

The only other fatal case of pleurisy within the period that I find recorded is one complicated with angina pectoris.

A gentleman, aged 63, after a warm bath went out at night, and next day was attacked with left pleurisy, and—after some temporary improvement under treatment took place—a fortnight after he died suddenly in an attack of angina. Besides the effusion of serum and lymph in the left pleura, the heart-walls were thin and pale—no doubt with fatty degeneration, but there is no note of the microscope having been used—and the coronary arteries ossified.

Before mentioning the cases treated by paracentesis in pleurisy, I must premise that in the year 1834 my attention was forcibly drawn to the subject in consequence of several unsuccessful cases of the operation occurring in the Hospital at which I was attending. After careful investigation of the subject, I came to the conclusion that with proper precautions the danger might be avoided, and the operation might prove the means of saving life and preventing permanent disease in many instances. My views were published in lectures soon after, and reappeared in the third volume of "The Library of Medicine," which is still accessible. My separate works describing them are long out of print. I then pointed out that the object of the operation was not only to remove the fluid compressing the lung, but also to promote the re-expansion of

the lung by natural respiration. The non-admission of air into the pleura thus became an obvious indication, not only on account of the possible injurious effects of the air in irritating the pleura and in promoting the decomposition of the remaining fluid, but chiefly because that air would keep the lung in a collapsed state, and prevent its re-expansion through the natural air-passages. The same consideration pointed out, also, how important it is to perform the operation as early as possible, before the lung becomes bound down by rigid adhesions, and its structure injured by long compression.

The plan which I proposed was to prevent the entry of air into the pleura by compressing the chest until the flow from the canula should no longer run freely; then to close the wound, and not till then to remove the pressure, when the walls expanding would fill the enlarged space by drawing air into the previously compressed lung. This partial relief I expected to be sufficient for the cure in case of serous effusion; and so experience has since proved it to be in many cases. In case of empyema, I recommended the injection of warm water, pure or medicated, to displace the remaining pus by means of a syringe with a double-tubed canula. In this way the place of the pus would be occupied by water, which is more likely to be absorbed; and if more matter continues to form, a weak solution of nitrate of silver or iodine might be injected. "The pleural sac may be treated as an abscess; and if the discharge be unhealthy it is quite proper to correct it, and to promote the healing of the diseased parts by such means as are known to promote granulation and desiccation of suppurating wounds. When the discharge is fetid, it is more decidedly necessary to correct it by injections of chlorinated solutions, mixtures of creosote, or other antiseptic liquids." (a)

Since this period many records of successful operations for pleuritic effusions have been published. One most deserving mention is by Dr. Hamilton Roe, narrating twenty-two cases, seventeen of which recovered. (b)

In July, 1838, the late Dr. Chambers requested me to see a young lady of 14, who had extensive right pleuritic effusion of several weeks' standing, and causing such distortion of the chest that the case had been mistaken for disease of the spine. No improvement followed on the use of ordinary remedies, and Dr. Chambers thought of paracentesis; but that operation had then fallen into disrepute at St. George's Hospital, in consequence of a succession of fatal cases, and, knowing that I had been investigating the subject, he called me into consultation. I had no hesitation in recommending the operation, which was performed under my direction by Mr. George Babington, without the admission of any air, and without any unfavourable symptom following. One pint of serum only was drawn off, but the relief was complete, and improvement steadily proceeded from that time. In two months the remaining effusion was absorbed, leaving some contraction of the side, which also disappeared in the course of the two years following.

In April, 1851, I saw a gentleman, aged 35, with right pleurisy, which had not yielded to blistering and other remedies actively employed for fifteen days. The symptoms were becoming very urgent—the breathing very difficult, disturbing sleep; right side universally dull and enlarged, with intercostals prominent and fluctuating; some œdema of integuments below right mammilla; liver pushed below umbilicus; and heart to left of left mammilla. The chest was tapped, with precautions to prevent the admission of air. Four pints of serum were drawn off; clear, but forming a fibrinous clot on standing. The operation gave immediate relief, with diminution of the distension of the side and displacements. The relief was permanent, and when examined four weeks after the upper parts of the lung were receiving air. The patient was afterwards reported to me as having completely recovered, but I had no opportunity of further examination.

These and similar cases show that, with simple serous effusion causing oppression, the operation may be performed with immediate and permanent relief, although little is drawn off, the remainder being more readily dispersed when the breath and circulation are restored to a more natural state.

In empyema the operation is more indispensable; but the amount of relief may be neither so great nor so permanent, and generally either the puncture must be kept from closing by means of a tent, or the operation will have to be repeated after a time. In chronic cases the freer vent by means of a drainage-tube is the best expedient.

(a) "Library of Medicine," vol. iii., p. 129. Since this was published (1840) this practice has been occasionally adopted, and has proved the facility with which carbolic acid and other agents can be injected with beneficial results.

(b) *Medico-Chirurgical Transactions*, vol. xxvii, 1814.

In the spring of 1852 a groom was sent from the country for my advice in a state of extreme distress from large effusion in the right pleura, with signs of extensive displacements. The profuse sweats, fetid breath, great tenderness of the walls of the chest, and protrusion of the intercostal spaces, together with the tympanitic state of the abdomen, left me little doubt that the effusion was purulent, and I advised tapping without delay. Seven pints of highly offensive matter were drawn off, with wonderful change in the condition of the man. He immediately began to eat and drink heartily, and to sleep soundly; and although it was necessary to repeat the operation in two or three weeks, I heard that he entirely recovered and was well some years after. This was an instance of complete success under very unpromising circumstances.

In May, 1855, Mr. Startin called me to a youth of 15 with extensive effusion in the right pleura, pushing the heart to the left of the left mammilla and causing orthopnoea, which was the more serious as there was some effusion in the left pleura also. There was cough with purulent expectoration. No time was to be lost, and by my advice Mr. Startin punctured the right side above the seventh rib, and let out about twelve ounces of pus with considerable relief. In a week the oppression returned, and the puncture was repeated with a larger discharge, which continued afterwards through the opening. The symptoms all ameliorated from this time under nutritious diet, cod-oil, and tonics; but the greatest improvement took place in July, when the patient was removed to the highlands of Scotland, where the discharge soon ceased, the wound healed, and he recovered strength and activity. He has since been enjoying fair health and employed in a Government office. When I examined him within the last year I found the right lung admitting air pretty freely, but there were still some remains of contraction of the chest on the right side, and also of the left front where the heart was displaced.

Without entering into further details of cases, I would state as the general result of my experience that tapping in empyema is likely to be most successful in young subjects, and also when practised early. I know of several instances in which delay has led to much injury of the walls of the chest from the pus perforating the pleura at several points and forming sinuses under the integuments, so that several openings have been necessary, and the tedious suppuration from this spread of disease has prevented the restoration and adhesion of the collapsed lung. In other cases the lung has been attacked; and although some recover when the matter finds vent through the bronchial tubes, yet others have lapsed into phthisis from the injury thus inflicted on the lung. Whenever, therefore, the diagnosis of empyema is clearly established, and the use of the grooved needle may remove all doubt, the operation should be performed without delay—not merely to relieve present symptoms, but to prevent further injury and destruction of the walls and viscera of the chest.

I have met with several cases in which empyema has made its way through the lung, causing violent cough and discharge of matter through the bronchial tubes—in some instances with a favourable result, chiefly in young and comparatively healthy subjects. The following case of recovery is more rare:—A member of Parliament, aged about 50, in March, 1853, consulted me, complaining of great weakness and breathlessness, with cough of about six weeks' standing. The signs indicated effusion in the left pleura, not very copious, as the heart was not displaced; but the sallow pallidity of his skin gave suspicion of the nature of the effusion. He was put on generous diet, with cod-liver oil and tonics, and nine days after began to cough up large quantities of fetid pus—nearly as much as a pint daily for several days. Under the same treatment, however, the cough and expectoration ceased, and he made a perfect recovery; and he has enjoyed fair health and fulfilled his Parliamentary duties ever since.

In other cases the cough and expectoration continue, sometimes becoming very offensive; and from the entrance of air into the sac of the pleura pneumothorax is added to the purulent effusion. Such a complication is by no means promising, and it is rather surprising that such cases should ever recover, yet they do sometimes, when the subject is young and vigorous. It has always seemed to me that recoveries would be made more frequent by making an opening into the chest sufficiently free to permit the offensive matter to escape, and thus to save the lung from the injury inflicted on it and on the blood by the continual passage of decomposing matter through it, and also to save the patient from the distressing and exhausting fits of coughing necessary to expel this matter. In this case we need entertain no fears about admitting air into the cavity of the pleura. Air has already entered from the lung,

and done its worst in irritating the pleura and promoting the decomposition of its effusion; and to give a freer vent to this pent-up air, and to drain away the offensive exudation, certainly promise a prospect of relief. It is more than twenty years since I recommended this operation, but I have had few opportunities of putting it in practice.

Two or three years ago, in consultation with Dr. Cowan, of Reading, and Mr. Davies, of Yorktown, I saw a gentleman, between 50 and 60 years of age, who had pneumothorax resulting from empyema having made its way through the lung. The patient was worn down by the severe fits of coughing, ending in the discharge of offensive matter and pus; and the occasional escape of sulphuretted hydrogen through the lung was a frequent cause of disgust and distress. At my suggestion, Mr. Davies made a free opening between the ribs, introducing an indiarubber tube. The operation entirely stopped the distressing cough and expectoration of fetid matter, which afterwards passed through the wound, but the patient's strength had been too much exhausted before the operation, and he survived only a few days. Two cases are recorded by Dr. Goodfellow in the *Medical and Chirurgical Transactions* (vol. xlii.) in which an operation was successful. The disease in these instances seems to have been empyema, which had been partially discharging through the lung, but continued to form and wear down the health. An opening was made into the chest, and a bent iron probe being passed in and brought to bear on the lowest intercostal space above the diaphragm, a second opening was made there, and the probe brought out, drawing after it a perforated indiarubber tube, which served as a drainage-pipe, permitting the effusion in the pleura to drain off as soon as it formed. This mode of operation appears to me peculiarly well suited for the cases under consideration (empyema discharging through the lung), as it is more likely to save the lung than simply puncturing the chest.

In all cases of empyema discharging through the walls more or less contraction of the side gradually takes place, and in all but young subjects the contraction is permanent, with more or less bronchophony and diminution of the natural breath-sound and resonance on percussion. I have, however, known several cases in children below puberty in whom time and the progress of growth have removed the contraction and restored the lung to its normal state. Take one instance—A boy of 10 years, first seen in February, 1860, a patient of Mr. Malton's, had extensive effusion in the left pleura, which I was soon convinced was purulent, and I strongly recommended the operation. Owing to the unwise timidity of the parents, this was postponed day after day until the matter made its way through the intercostal spaces at several points, and formed a subcutaneous abscess of some extent, which had to be opened in several places, and took many months to heal. Great contraction of the side followed and seemed likely to cause permanent deformity; yet in two years' time the side had almost recovered its normal dimensions and the lung was pervious throughout. This ultimate success shows the elasticity of the restorative powers during youthful growth; but the process of recovery was tedious and anxious, and it was not achieved without the aiding influence of cod-liver oil, tonics, and sea air.

Note added in 1872.—Several instances of the successful treatment of empyema which have occurred in my practice since these lectures were delivered might be added, but as I wish to notice recent improvements in the operation, I shall only refer to one recorded in our recent work on "Pulmonary Consumption," case 89, p. 240. It was that of a young lady, aged 12, a patient of Dr. Stokes, of Canonbury (first seen November 23, 1865), formidable from the amount and persistence of the purulent formation, and even after the operation becoming offensive and making outlets through the walls of the chest and through the lungs, yet ultimately ending in complete recovery. Except a partial contraction of the left side of the chest, when seen about three months ago, she was a remarkably fine young woman, quite free from cough and other chest symptoms, but considerable inaction of the lower left front remains, and no breath-sound below fifth rib. The heart to left of sternum nearly *in situ*.

It is gratifying to me, as one of the earliest advocates of the operation for pleuritic effusions, to notice how much the practice has been taken up and improved of late years. Nowhere has this occurred so largely or so successfully as among our Transatlantic brethren, since Dr. Bowditch has improved the operation by the adoption of a suction syringe to draw off the liquid. Laennec suggested the principle of suction by cupping-glasses after the operation, to promote the re-expan-

sion of the lungs. This suggestion I commended in 1840 as deserving of trial, with modifications. Dr. H. Roe, in his paper in the twenty-seventh volume of the *Medico-Chirurgical Transactions* (1844), mentions a suction syringe used by Mr. Walsh (now of Worcester) to draw air out of the chest after operation. Dr. Bowditch used a syringe of this kind, adapted to the canula, which is furnished with a tap, all fitting airtight, so that no air can enter, or if by any accident air should get in, it can be pumped out by the syringe. After having performed the operation 250 times, Dr. Bowditch assures us that he never saw any evil or even any very distressing symptom resulting from it, and it proved the means of saving many lives which would not have been preserved without it.

More recently, Dr. Protheroe Smith and M. Dieulafoy have adapted a similar exhausting syringe to a very fine canula, with stilette not larger than an exploring needle, thereby diminishing the pain and the risks of operating. This instrument is called by M. Dieulafoy an "aspirator," and he declares that he is able through the power of the syringe to draw off pus as well as serous effusions; but I should consider a larger canula more sure and less liable to be clogged with the shreds of lymph that are often present in purulent or mixed effusions. An improvement on this instrument by Mr. Weiss, with trocars of different sizes, is now used at the Brompton and other Hospitals, and with satisfactory results.

By proper management with these instruments fluid effusions can be so surely and powerfully sucked out of the chest as to bring a great force into operation to promote the re-expansion of the lung; and it becomes necessary to consider how far to use this force so as not to do violence to any of the delicate structures within the chest. The removal of the pressure of the fluid, if too sudden or carried too far, may cause faintness, or too forcible a rush of air into the collapsed lung, or of blood into the vessels. I remember a case in which severe bronchitis came on after the operation, apparently from this cause, and proved fatal in two days. The coming on of a fit of coughing, or the appearance of blood in the discharging fluid, may be taken as an indication that as much has been withdrawn as is consistent with safety. The operator may also judge by the degree of resistance which he feels to the action of the piston. The strength of the suction power might be still more accurately measured by the mercurial pressure-gauge suggested by Dr. Douglas Powell.

The operation as now performed is so simple and free from risk that it may be recommended generally in those cases of serous effusion which resist Medical treatment beyond the second week in all instances of dangerous oppression; and in all cases of empyema as soon as the more active febrile symptoms have subsided. In chronic or recurring empyema, especially where cough and purulent and fetid expectoration give indication of mischief in the lung, the introduction of the drainage-tube and occasional carbolic acid injections should follow the operation.

On February 28, 1867, I was summoned to a consultation with Dr. Sibson, Mr. Coulson, and Mr. James Lane, in a case of left empyema originating in a pleuritic attack of five weeks' standing. The chest had been punctured in the back a few days before, but only eight ounces of pus were discharged, and the relief was temporary. The oppression was now great, preventing decubitus. Another puncture made in the back the day before had failed to obtain any discharge. I found the left side generally dull, and the heart pushed two inches to right of sternum; but the tympanic sound of the stomach rose as high as the fourth rib at the side. A small flat trocar was passed into the chest above this rib below the axilla, and there flowed out eight ounces of pus. A suction syringe was then applied by Mr. Lane, who drew off twenty ounces more, the last portions of the matter being deeply tinged with blood. The relief to the breathing was complete; the enlargement of the side was visibly diminished; the heart had receded an inch towards the left; and some pulmonary breath- and stroke-sounds became manifest below the clavicle and above the scapulae. I did not see this patient again, but I heard that the wound continued to discharge for a month after. He then went to South Devon, and rapidly improved, the side collapsing considerably for a time; but he soon recovered his usual breath and strength, and I heard of him in 1871 in full exercise of his duties as an officer at Aldershot.

I can do no more than mention another interesting case of extensive and recurring pleuritic effusion in a young patient of Dr. Duffin's, repeatedly operated on by Sir W. Fergusson, who, after being for many months in an apparently hopeless state, ultimately recovered.

In conclusion, I would also refer to a paper by Mr. Berkeley

Hill in vol. iii. of the *Clinical Society's Transactions*, and to a remarkably successful case of operation with carbolic acid injection by Dr. Theodore Williams in the *Lancet* of February 24 of this year.

(To be continued.)

DR. QUAIN'S LUMLEIAN LECTURES, AT THE ROYAL COLLEGE OF PHYSICIANS,

ON THE

DISEASES OF THE MUSCULAR WALLS OF THE HEART.

LECTURE III.

Fatty Degeneration of the Heart.

IN introducing to his hearers the subject of fatty degeneration of the heart, with which his name is so generally associated, Dr. Quain remarked that for the history of the disease up to 1850 he would refer his audience to his original paper which was published that year in the *Transactions of the Medico-Chirurgical Society*. To what had since been determined in respect to the nature of fatty degeneration he would return, after enumerating the leading anatomical appearances of a heart so affected. The pale yellowish-brown or muddy-pink colour and infinitely various shapes of the fatty patches in the heart in the less extensive forms of the disease were then described, as well as the uniform buff-coloured appearance of portions of the heart more extensively affected with the degeneration, and its other and most significant pathological characters—viz., diminution of consistence and increase of friability—specially dwelt upon. It was shown that the extent and degree of the degeneration varied, as a rule, inversely with each other, and were usually dependent the one on a general and the other on a local nutritive defect. And these were the only differences between the so-called "granular" degeneration of the pale, soft, flabby heart and the complete and extreme degeneration of the fatty heart, the two being identical in their real nature. Dr. Quain next described the microscopical appearances of muscular fibre in a state of fatty degeneration, from the stage where a few minute dots are seen, especially around the nuclei, and of a yellowish colour, to the complete occupation of the fibres by oil globules; the gradual transition of these stages into each other, as the focus of degeneration is approached; and the broken, fragmentary character presented by the tissue when a section has been made of it in this friable condition. The disease is most common in the left ventricle.

The nature of fatty degeneration in general, and of that of the heart in particular, was first clearly described and explained by Dr. Quain in 1850, in the paper already referred to. There he expressed his belief that "the molecular fatty matter in the muscular fibre is the product of a chemical or physical change in the composition of the tissue itself, independent of those processes which we call vital." This opinion he supported by three groups of facts, which he was then able to adduce, and to which the advances of the last twenty years have furnished many additions. The first of these groups showed that in dead animal matter removed from the body the place of the nitrogenous elements is found, under certain circumstances, to be occupied after a time with fatty matter, which could not have existed as such during life. Of this the best illustration is the formation of adipocire, in respect of which Dr. Quain has fully shown—first, that in the process as it is seen in nature there is a disappearance of the nitrogenous matters, and an increase of fat; and secondly, that in the process as it may be artificially induced, there is no difficulty in tracing at the same time the physical change of the albuminous tissue experimental on into adipocire, and the microscopical alteration of its elements—*pari passu*—by fatty degeneration, from the first and least to the last and most extreme degree. Analogous to the formation of adipocire from dead animal substances, it is interesting to notice the change of many vegetable matters into oil, and above all the formation of coal from buried plants; so that "it would seem as if England's greatness was founded on the results of a process analogous to fatty degeneration." The second group of facts adduced by the lecturer showed that a similar change into fat occurs in portions of dead animal matter within the living body. The most important illustration in favour of the truth of this statement are the experiments of Wagner and Michalix on the artificial production of fatty degeneration in portions of

healthy tissues introduced into the abdominal cavity of a living animal. These experiments are familiar from their description by Mr. Simon in his article on "Inflammation" in Holmes's "System of Surgery." The same change also occurs in cheesy or "scrofulous" masses. Thirdly, Dr. Quain said albuminous tissues were changed into fatty matter in the processes of nutrition, both physiological and pathological, as is seen in the formation of milk and its homologues, in the development of the compound granular corpuscle, in grey hepatisation of the lung, in fatty Bright's disease, and in the fatty degeneration of physiological involution, as in the uterus, and most probably the heart also, during the puerperal state. It is to the same head of nutritive change—or rather to its arrest—that the remarkable example of fatty degeneration is to be referred which is presented in the tissues of animals dying by phosphorus poisoning. The exact nature of this condition was first clearly recognised by Virchow in 1864; and the immense amount of accurate knowledge which has since been acquired on the subject by the labour of numerous observers, was as recently as last year turned to good account by Bauer and Voit, of Munich, who administered phosphorus experimentally to dogs, and by inducing by this means fatty degeneration of the albuminous tissues, and estimating exactly the ingesta and egesta, were able even to calculate quantitatively the reduction of protoplasm into fat. A full account of these important experiments will be found in the *Medical Times and Gazette* for November 4, 1871.

Having thus discussed the nature of fatty degeneration in general, Dr. Quain turned to the consideration of the circumstances under which the change occurs in the heart. These, he said, while either general or local, are chiefly those of impaired nutrition. The general circumstances are, accordingly, such as slow starvation, phthisis, and hæmorrhages, and, more rapid, diphtheria and fever—as, for example, relapsing fever, in which Dr. Murchison believes that the sudden collapse by which the disease is sometimes fatal is usually traceable to degeneration of the muscular fibres of the heart. Amongst the local causes of fatty degeneration of the heart is the state of the cardiac vessels, whether that of ossification or obstruction, which has been so frequently observed in cases before the Pathological Society, or congestion from dilatation of the right heart. Previous endo- and peri-carditis have also an etiological relation to fatty degeneration of the heart. As regards predisposing causes, the change is two and a half times more frequent in males than in females, is by far more usually met with after the sixtieth year, and, by occurring in half the cases in the lowest classes of society, has an obviously different origin from adipose hypertrophy of the heart, in which the proportions are exactly reversed.

The effects of fatty degeneration of the heart are partly recognisable during life, and so are symptomatic of the disease. They might be shortly stated as impairment of structure and of function. The heart is first structurally changed as regards its size. In more than half the number of cases fatty degeneration of the heart is found associated with increased size of the organ, and of the two changes Dr. Quain believes the enlargement to be usually the primary one, the degeneration supervening from imperfect supply of blood, or from instability of the newly added muscle. In some cases, however, the increase of muscle might be secondary—due to an effort at compensatory hypertrophy. In a small proportion of cases the heart is below the natural size. The cardiac texture also is altered in fatty degeneration, as was already mentioned, and one consequence of this is rupture, which was found in twenty-five out of sixty-eight cases, and which might be either complete or only partial. The functions of the heart suffer in fatty degeneration, and most prominently in the way of loss of power, according to the side of the heart which is chiefly affected. To this must be referred the coma which has been frequently described as occurring in the disease, preceded or not by giddiness. This symptom probably depends upon the right side of the heart being chiefly involved. To the same condition are to be referred such other phenomena of the disease as impairment of memory, and pain and other uncomfortable feelings in the head. To affection of the left ventricle, on the other hand, is due the syncope, which is another usual symptom of fatty degeneration of the heart. In some instances the feeling of syncope amounts only to a sense of faintness, but in a large proportion of cases it proves fatal, and that instantaneously; and this *syncope lethalis*, as Dr. Quain proposed to call it many years ago, is responsible for the death of many distinguished men. At this point Dr. Quain drew the attention of his hearers to the occurrence of sudden death in

females after delivery; in three such cases he found the heart in a state of fatty degeneration. The interest attaching to these observations consists in this, that the degenerative process is perhaps but an extreme degree of a natural fatty change, which had been already referred to as probably present in the puerperal involution of the heart enlarged by pregnancy. The peculiar affection of the respiration present in fatty degeneration of the heart is another manifestation of interference with the cardiac functions; it is partly a form of dyspnoea and partly that peculiar and well-known disturbance of the respiratory rhythm described by Drs. Cheyne and Stokes. Still another symptom is pain—limited, widely distributed, or so complicated with syncope and dyspnoea that the phenomena resemble those constituting angina pectoris.

In regard to the diagnosis of fatty degeneration of the heart, Dr. Quain insisted on the importance of the Physician taking into account not only the mere physical signs, which indicate little more than cardiac weakness, but also the facts referring to the origin and effects of the complaint. Thus, while the characters of the visible impulse and of the sounds might be of some diagnostic value, the symptoms previously enumerated—the predisposing causes, etc., and such obvious signs of bodily decay as ossification of cartilages, and perhaps the arcus senilis; with the characters of the pulse, so often irregular, weak, and peculiarly altered in frequency—will be far more reliable circumstances on which to base a conclusion.

Fatty degeneration of the heart must be treated according to its cause. If the lesion is the result of impaired nutrition during severe illness, the nutrition must be improved; but, above all, the heart must have rest. Even if the cause is local, the Physician should not despair of being able to benefit his patient. He should diminish the amount of cardiac work directly and indirectly, and improve the condition of the still healthy fibres by tonics. These means, combined with careful dietetic and hygienic measures, would certainly help to prolong life, and possibly even effect a cure.

Rupture of the Heart.

Of this comparatively rare disease Dr. Quain had collected 100 cases.

The anatomical characters of the ruptured spot are by no means always the same. The opening might vary in size from a mere point to more than two inches in one direction. The condition of the edges points at one time to a tear, at other times to a perforation or ulceration, as the exact lesion presents. There might be more than one rupture in some cases. A very strongly predisposing cause of rupture of the heart is old age, 63 per cent. of the recorded cases having occurred in persons over 60 years. Rupture is nearly equally frequent in the two sexes. It usually takes place during effort or excitement. The condition of the cardiac tissue is, perhaps, never normal; most commonly the heart is in a state of fatty degeneration. Interstitial hæmorrhage also undoubtedly at times gives rise to rupture. Ulceration frequently leads to perforation; and simple softening, etc., have been also mentioned as causes.

Symptoms previous to those of actual rupture are not recorded as having occurred in the majority of cases; in several it is stated that they were wanting. Often, however, the fatal result was consequent upon symptoms of cardiac disease, such as dyspnoea, palpitation, faintness, and irregularity of pulse, and these either slight or severe. During the occurrence of the rupture the patient suffers from intense distress in the region of the heart, is restless, faint, and pale, and to these symptoms are added dyspnoea, coldness of skin, rapidity and irregularity of pulse, sometimes vomiting, and other nervous symptoms. Death usually follows immediately; yet it is remarkable that one patient lived eight days, one six days, one three days, and five over forty-eight hours from the beginning of the symptoms. This difference in the rapidity of the fatal progress depends much on the seat, size, etc., of the opening. The physical signs of rupture of the heart seem to be increased area of percussion dulness; muffled, distant, and imperfectly developed sounds; and weak, intermittent pulse. According to Dr. Quain's researches, the most common seat of the lesion has been correctly given by most previous observers. Of his cases the left ventricle was ruptured in 76 per cent., and in 45 per cent. on the anterior wall, the right ventricle in 13 per cent., the right auricle in 7 per cent., the left auricle in 2 per cent., and the septum in 4 per cent.

In regard to the condition of the heart on which the rupture immediately depends, it is probably never healthy. As early as 1850 Dr. Quain pointed out the liability of a fattily degenerated heart to rupture; and now he found that in 77 per cent. the organ was in this condition. This result agrees with that of Latham, Böttger, etc., and differs from that of Hope,

Bouillaud, etc., who speak of ulceration as the most common cause.

Rupture of the heart—doubtless always the result of some strain upon the muscular fibres—is of various mechanism. Increased pressure on thin and degenerated walls, or the contraction of healthy fibres around a localised softening, is evidently the immediate cause of the lesion in many cases; in other cases, especially in the left ventricle, it may be that the outer surface of a thick wall tears during strain like the outer circumference of a bent hoop, and the opening extends gradually inwards. In still another group of cases perforation is the cause of the interruption of continuity in the cardiac wall.

Dr. Quain next described the peculiar manner in which the blood poured into the pericardium usually coagulates, and referred to the belief expressed by Dr. Stroud that rupture of the heart was the immediate cause of the death of the Saviour on the cross.

Rupture of the heart might be said to be always fatal; yet wonderful cases are recorded of temporary or permanent recovery from cardiac wounds. Treatment is well-nigh hopeless, and, when there is time to institute it, ought perhaps to be almost negative—the less done the better.

Aneurism of the Heart.

Aneurism of the heart was defined by Dr. Quain as a pouch or sacculus situated in the substance of the muscular walls of the heart, or projecting outwards and constituting a tumour external to the organ, but in every case communicating with one or other of its cavities.

A cardiac aneurism usually presents the appearance of a tumour of various size projecting from the wall of the heart; but at other times there is seen on the endocardial surface a simple depression or an opening into a parietal excavation. There might be more than one sac, and the size varies from that of a small bean to a tumour as large as the chamber from which it grows. The pericardium is sometimes adherent. The mouth and neck of the sac vary in size and shape, as in aortic aneurisms; and the walls in different cases are found more or less thin—partly muscular or not—sometimes cartilaginous or calcified. The lining membrane and contents present the usual aneurismal characters.

Of fifty-one cases of aneurism of the heart, the disease was found by Dr. Quain to be nearly equally distributed in the five decades from 20 to 70 years inclusive. It was found once in a child of 12 years, and once in a patient of 82. Females are about one-third as liable as males to cardiac aneurism.

After reviewing the various opinions expressed by pathologists on the mode of formation of this lesion, the lecturer concluded that cardiac aneurism is almost exclusively the result either of inflammation or of degeneration. Inflammation of the cardiac walls might give rise to aneurism by ulceration of the endocardium (3 out of 32 cases); by simple softening of the myocardium beneath an endocarditic patch; by development and subsequent yielding of a spot of fibroid tissue amongst the muscular fibres (21 out of 32 cases); by the bursting inwards of a cardiac abscess (2 out of 32 cases); and by changes in the so-called fibrinous deposits. As the result of fatty degeneration, aneurism is recorded 6 out of 32 times. In the great majority of cases the lesion occurs in the left ventricle; and of 303 cases where it did so, in 138 it was found at the apex, in 101 at the base, and in 64 in the intermediate part.

It is doubtful, according to Dr. Quain, whether we have at our command the means for determining the existence of cardiac aneurism during life. Symptoms, when present, might be sufficient simply to show that the heart is diseased, and, this being the case, it would be impossible to estimate accurately the duration of the affection. The result, however, is usually a fatal one, either from embarrassment to the heart's action or by rupture. A case recorded by Dr. Wilks proves that a spontaneous cure by solidification and calcification is possible.

PROFESSOR T. LONGMORE, C.B., Army Medical School, Netley, lectures at the Royal United Service Institution, Whitehall, "On the Geneva Convention of 1864, in relation to the aid afforded by Volunteer Societies to Sick and Wounded Soldiers during the late Franco-German War, with a glance at the proper functions of National Aid Societies, particularly the British Aid Society, in the future." Lieutenant-Colonel R. Loyd-Lindsay, V.C., M.P., Chairman of Committee, British National Society for Aid to the Sick and Wounded in War, presides.

LECTURES ON EXCISION OF THE HIP-JOINT.

By HENRY HANCOCK, V.P.R.C.S.E.,
Senior Surgeon to Charing-cross Hospital.

(Continued from page 307.)

GENTLEMEN,—In the year 1857 I wrote a paper for the purpose of combatting those laws by which it was previously insisted that the operation for the removal of the head of the thigh-bone should be governed. These, as you will remember, were—1st, That it should only be performed in the last stage of hip disease; 2nd, that it should only be performed when the head of the bone is dislocated; 3rd, when the cotyloid cavity is free from disease; 4th, when the amount of pelvic disease is but trivial.

In my last lecture we considered the second of the above regulations—"that the operation should only be performed when the head of the bone is dislocated"—and we found, curiously enough, that the very first case of excision of the head of the thigh-bone ever performed, and that successfully, was one in which the contrary obtained; and we also found that of 143 cases, the percentage of recoveries when the head was dislocated was 46, against 23 where the head remained *in situ*.

With regard to the regulation that the operation should only be performed at the last stage of hip-joint disease,—this undoubtedly was enunciated in the early history of the operation, but even then it was difficult to understand what was exactly meant by the term. Was it intended to mean the last stage of the patient's life; the last stage of his powers of endurance; the last extremity of constitutional disturbance, when we are at length convinced that he must sink if that disturbance be allowed to continue?—or was it meant to describe the last stage of the disease in a pathological sense? Year by year experience proves, and that most forcibly, that in deciding upon this operation we should be guided solely by the condition of the patient, and not by any arbitrary rules as to the amount or period of the disease.

The more I have seen and read of this operation, both in my own practice and in that of others, the more frequently have I had to regret the amount of invaluable time which has been lost, and the extent to which disease has been allowed to attain, before the patients have been submitted to our care, so that I have almost felt inclined to echo Hey's axiom with regard to strangulated hernia—"I have often had occasion to regret operating too late; I have never regretted operating too early." The more I see, the more I am convinced that if delayed until the last stage the operation is delayed too long; that the patient, worn out by the terrible and almost insupportable sufferings of the preceding stages, is in an unfavourable condition to bear the shock of the operation, whilst his powers of constitution are rendered too weak to make the efforts necessary to his recovery.

Undoubtedly the assertion that the operation must be delayed until the last stage was the natural consequence upon the law that it must not be performed except in those cases where the head of the bone was dislocated; but we have already seen how many among those who have been operated upon would have died before the proper period could have arrived had this regulation been adhered to.

"The patient was in the last stage of weakness, emaciation, and hectic" is the constant description; and yet, of 123 cases, in 44 the head of the femur remained in its socket. Can any possible benefit accrue to a patient from being for months subjected to the torments of ulceration, the drain of suppuration, the hectic, night-sweats, emaciation, and daily loss of health and strength, and the consequent risk of amyloid degeneration of the liver, consumption, etc.? Surely there are reasons sufficiently grave to render it imperative on the Surgeon to use all his diligence and all his acumen in endeavouring in each case to ascertain the exact period at which Nature abandons her efforts at reparation, unable longer to cope with the ravages of the disease, when the patient's health and strength are giving way; and having assured himself of these facts, to step in without further delay to the rescue of the patient, in whatever stage of hip-joint disease the patient may be.

The third and fourth regulations—"that the cotyloid cavity must be free from disease and the amount of pelvic disease but trivial"—can now, happily, be no longer maintained; experience has shown that they are utterly untenable, since, had they been allowed to prevail, some of the most brilliant

examples of this operation upon record would have been left unperformed. I do not for one moment pretend to deny that, as a general rule, Mr. Syme is right in maintaining that when caries attacks the joint it is not limited to one bone. The majority of cases operated upon prove the correctness of his position. Of the 92 cases, in only 18 is the acetabulum stated to have been healthy; the mortality of these 18 being 6, or 33 per cent.

Disease of the hip-joint, as Mr. Holmes justly observes, rarely commences in the acetabulum. This gentleman mentions a very uncommon preparation in the museum of St. George's Hospital, in which there is no caries, but the only lesion is in the acetabulum. In all the other cases in this collection the femur is affected as well as the acetabulum and in a greater degree. And this quite coincides with the description given of the various cases, for whilst the head of the femur was more or less diseased in 143, in ten it was entirely absorbed. In 119 out of the 143 operations performed the acetabulum afforded more or less evidence of departure from its natural and healthy condition.

In ten cases an opening communicating with the interior of the pelvis was found at the time of operation in the floor of the acetabulum. In four cases there was perforation of the acetabulum and abscess within the pelvis.

In three cases the acetabulum was trephined for the evacuation of pelvic abscess.

In one, Sayre of New York removed the head of the femur, with the cotyloid cavity, with the spine and anterior crest of the ilium. The patient recovered.

In one, Bowman gouged the acetabulum and the horizontal ramus of the pubis. The patient recovered.

In one, Sir William Fergusson removed nearly the whole of the cotyloid cavity.

Of the ten cases in which the acetabulum was found perforated at the time of the operation, six (or 60 per cent.) recovered, two (or 20 per cent.) died. Of the four in which not only was the acetabulum perforated, but there was also abscess within the pelvis, two recovered, two died—50 per cent. either way. Of the three in which the acetabulum was trephined for the purpose of evacuating matter from the pelvis, two (or 66 per cent.) recovered, one (or 33 per cent.) died. So that of the whole twenty cases wherein the operation was performed under the most unpromising circumstances, the mortality was only five, or 25 per cent.

I cannot, therefore, admit that Mr. Syme's observations can be regarded as valid arguments against the operation in the face of these unanswerable facts. The latter must be accepted as conclusive proofs of the fallacy of the doctrines enunciated, and they prove, moreover, this great practical point—that as, in the very large majority of cases, the cotyloid cavity is more or less implicated, the Surgeon should always be prepared, in undertaking the operation, to find the acetabulum involved, and in that case to remove the whole of the disease, which, in the majority of cases, may be done without much difficulty.

After all, who is there amongst us that will undertake to tell beforehand what is the—I will not say exact, but anything approaching to the exact—condition of the acetabulum? And even if we could do so, would any of us, with these facts before us, feel that we were conscientiously performing our duty if we abandoned a patient to his fate and allowed him to die in his agony because we discovered that the acetabulum was diseased? After what we have seen, is not this, so far from being an insuperable objection, a greater reason why the operation should be performed? The greater the amount of disease, the smaller is the chance of recovery by natural means, though, surprising as it may appear, the greater the chance of recovery by artificial assistance; since, of twenty cases in which the gravity of the symptoms was as great as can well be imagined, the mortality was much below the average, being 20 per cent. as against 39 per cent. where the operation was performed under more favourable circumstances. And after all, the value of an operation does not consist in the mere facility of execution, but in the extent of disease it is able to remove, and the urgency of the symptoms and the amount of suffering it is capable of relieving.

Both Mr. Colson and Mr. Henry Smith have laid great stress upon perforation of the acetabulum being an insuperable obstacle to the performance of the operation. I have already given the number of instances in which this complication existed, and shown that so far from being a reason against the operation it infinitely enhances its value, since it affords a prospect of cure, and prolongation of life, in a number of cases and an amount of disease hitherto regarded as beyond the power of amendment. Presuming always that the disease is

confined to this locality, that the viscera and vertebræ are healthy, and the lungs free from tubercles, I do not understand why an abscess within the pelvis, caused and sustained by hip disease or caries and perforation of the cotyloid cavity, should not be cured as well as any other abscess connected with caries elsewhere, provided it can be reduced to the same conditions: Were we called to an abscess within the cranium depending upon caries of the cranial bone, should we hesitate for one moment to remove the carious bone, and to give the patient a chance of life? Why, then, should we hesitate to apply the same rule of practice to the acetabulum? We are told by one of the highest authorities that patients so afflicted *must*—not *may*—recollect—die. Is there anything in the anatomy of the pelvis to prevent our attempting to save the lives of those thus condemned? Mr. Syme himself removed necrosed bone from the tuber ischii, and in another case from the ascending ramus of the ischium and inner margin of the pubic arch.

It is not by any means so difficult to reach the floor of the acetabulum as it is to remove these parts. Mr. Holmes has well observed that, paradoxical as it may appear, the natural position of the joint-surfaces is prejudicial to their recovery, and that spontaneous dislocation is the natural, and in most cases the only natural, cure possible for extensive caries of the articular surfaces. "In excising the hip," he continues, "which I have never done except in cases where no dislocation existed, I have never failed to find that when the incision has been made into the cavity of the joint, a large quantity of pus has escaped, however freely the superficial abscesses may have been opened. Thus it seems to me that the matter is detained in the cavity of the joint while that cavity remains tolerably entire and filled up to a very considerable extent by the remains of the femur." On the other hand, in pelvic abscess depending upon hip disease, the head of the bone, or what remains of it, is often retained in the acetabulum, even after perforation of the latter has obtained. The matter escaping from the joint into the pelvis, the same subsidence of the extreme symptoms takes place as is so commonly observed in spontaneous luxation. Still, such subsidence of symptoms can only be regarded as temporary. The abscess is not cured; the matter is not got rid of, it is only transferred from one situation to another—from the acetabulum to the interior of the pelvis. Such abscesses cannot be cured spontaneously, for the matter, if left to itself, cannot find a depending exit, whilst at the same time the exciting cause or caries still remains. It may be asked why the spontaneous openings of a pelvic abscess cannot effect a cure equally with one made through the acetabulum. The answer is found in the shape of the pelvis. When a patient lies on his side the cotyloid portion is most depending, so that when a free opening is made in that situation, and the patient is turned on the same side, not only does the matter find a free and depending exit, but the contents of the pelvis, gravitating upon the confines of the abscess, tend to consolidate the parts, obliterate the cavity, and assist the cure. And moreover it must be remembered that in removing the head of the bone and the diseased portions of the acetabulum we not only afford a free and depending outlet for the otherwise incarcerated discharge, but by removing the carious bone we at the same time remove the exciting cause of such discharge.

After all, the proceeding is neither difficult nor dangerous; the ilium is separated, for the most part, from the peritoneum and fascia iliaca by the iliacus internus muscle. The ilium, ischium, and pubes opposite and beyond the joint are separated from the abdominal and pelvic cavities and viscera by the pelvic and obturator fasciæ, the obturator internus and levator ani muscles. The matter in these pelvic abscesses lies between the bone and obturator fascia, which in most cases may be found extremely tough and considerably thickened, whilst a considerable interval occurs between the two, so that any part or the whole of the cotyloid portion of the pelvis, and for some distance beyond, may be removed without any risk of injury to the pelvic contents.

But in undertaking these operations it is of the utmost importance that we should thoroughly convince ourselves, by careful examination, of the non-existence of disease elsewhere. We must feel assured that the abscess in the pelvis has been preceded by, and is depending upon, caries of the hip-joint—that it is unconnected with caries of the spine or with psoas or iliac abscess. One point of diagnosis in these cases therefore is the existence of hip disease and the previous history of the case, although unhappily these are not always infallible, since cases have occurred in which caries of the hip-joint has progressed *pari passu* with caries of the spine. Another point of diagnosis is the locality at which the spontaneous openings usually occur. When the matter is poured into the pelvis

through the perforation in the acetabulum, it falls, as we have seen, between the obturator fascia and the bone, and in consequence of the firm attachment of the former to the falciform margin of the great sacro-sciatic ligament the matter cannot reach the skin in that direction, but, gravitating posteriorly by the rectum, it presents by the side of the anus, simulating fistula. It occasionally finds its way into the rectum itself or the vagina, and it has been known by its pressure upon the neck of the bladder to interfere greatly with the process of micturition; but the more frequent position, so far as my experience serves me, is in the outer portion of the groin, near to the anterior inferior spinous process of the ilium, probably induced by the position maintained by the patient at this stage of the disease. This is a point to which I am inclined to attach some importance as affording a means of diagnosis between pelvic and psoas abscess, as the latter usually presents more internally, nearer to the middle of the groin, whilst a probe introduced into the latter passes upwards in the course of the tendon; in the former it passes downwards and backwards into the pelvic fossa. The existence of openings externally in the neighbourhood of the joint will also assist, as pelvic abscess depending upon hip disease very rarely, if ever, takes place without having been preceded by more or less suppuration about the joint itself.

(To be concluded.)

ORIGINAL COMMUNICATIONS.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,

Student of Guy's Hospital.

No. V.

(With Photo-lithographic Plates.)

The Value of the Sphygmograph in Heart Disease—Indicates Hypertrophy, etc.—Various Forms of Pulse consistent with Mitral Regurgitation—The Action of Digitalis in this Disease—The Pulse in Tricuspid Regurgitation.

It appears at first sight but reasonable to suppose that the sphygmograph would be of the greatest value to the Physician in the diagnosis of cardiac valvular lesion, and with this view it is most frequently employed; but no means can be taken to bring greater disgrace upon the instrument or its employers than to use it with these pretensions. A diagnosis in heart disease, made from the inspection of a sphygmographic tracing, must in by far the larger proportion of cases prove a complete failure, and I would most earnestly entreat of all sphygmographers, for the sake of their own reputation and that of the instrument they employ, to refrain from attempting it. The disappointments occurring from this improper use of the instrument have induced many of its supporters to ignore the information it affords, and thus they have lost sight of a great aid to the study of cardiac pathology.

The sphygmograph appears to yield us the following indications in valvular disease:—

1. It often affords reliable grounds on which to form a prognosis.
2. It is a measure of the amount of valvular lesion, and its effect on the circulation generally.
3. It indicates the extent to which the heart has accommodated itself to existing circumstances by compensatory hypertrophy, or whether, unable to perform the increased work thrown upon it, it has become dilated.
4. By its aid the progress of cardiac disease may be estimated.
5. It is a most important guide to treatment, and by it the action of a remedy may be watched in the most perfect manner.
6. It often affords an aid to diagnosis, though for this purpose it should be used with the greatest caution.

It is proposed in the present paper to study the indications afforded by the sphygmograph in insufficiency of the auriculo-ventricular orifices. To this class of cases Plate iii. accompanying this paper is devoted. It should be stated that the tracings which appear as black lines in this plate are due to their having been traced in ink on white paper, instead of on smoked paper in the usual manner.

The effect which disease of the mitral valve produces on the

circulation depends chiefly on the changes which take place in the muscular walls of the heart. By the stethoscope the presence of a bruit may be discovered, and regurgitation through the mitral orifice diagnosed; but whether this regurgitation be much or little, whether the heart be incapacitated or not for its work, the stethoscope cannot tell. The smallest amount of regurgitation will often produce a very loud murmur. Surely every Medical man knows of persons who are going through their daily work with an inefficient mitral valve, and at the apex of whose hearts a systolic murmur is audible; and yet they have none of the usual troubles of heart disease. In these cases there is either a very small amount of regurgitation or else the heart has hypertrophied and accommodated itself to the diseased condition. The sphygmograph distinguishes between these cases and those in which there is free regurgitation and, added to it, a more dangerous condition—namely, dilatation. It then indicates the course of treatment to be adopted, and gauges the amount of repair established—i.e., the amount of hypertrophy produced. The presence of mitral disease cannot, however, be diagnosed by it, except in those cases where the amount of regurgitation is very great, though it may show that the character of the pulse is more compatible with mitral disease than with any other valvular lesion.

The typical form of pulse in mitral regurgitation is that of W. H. (Fig. 9, Pl. iii.), a lad admitted into John ward on January 18, 1871, under the care of Dr. Wilks. On admission he was suffering from well-marked chorea, and the following note was made in the report by the clinical assistant:—"A loud blowing systolic murmur is heard at the apex; it may be heard also at the base less distinctly, and is gradually lost when traced upwards. The bruit is heard very distinctly in the axilla, and also between the scapulæ." During his stay in the Hospital the chorea almost completely disappeared, but the bruit remained unchanged. The characters of his pulse especially to be noted are the following:—Owing to what must have been a large amount of regurgitation, only a small amount of blood enters the arterial system at each ventricular systole; the upstroke is accordingly very short. It has, moreover, another important defect—it is sloping, instead of vertical; this indicates that the percussion element is deficient. The force with which the blood is impelled into the aorta is greatly diminished by the insufficiency of the mitral valve, which now offers no *point d'appui* for the propulsive force applied by the ventricle to the blood-column. One character of this pulse differs from what is usually found in mitral insufficiency—namely, the pressure employed to develop it, in this case six ounces; the pressure usually employed is very slight. In the more advanced stages of mitral insufficiency, when the heart has become dilated and is failing at its work, as seen in those typical cases of heart disease where the constitutional symptoms are well marked, and such as are often met with in the wards of a Hospital, the pulse possesses usually these characters and, added to them, that of extreme irregularity; this constitutes what is known as the "mitral pulse." Unfortunately I have not preserved a single specimen of this form of pulse available for insertion in the plate, nor could I meet with one in the course of some weeks' search in the wards of Guy's, owing to the excellent practice of putting patients in such a condition on the use of digitalis, which very rapidly improves the character of the pulse.

A tracing having similar characters to the preceding is seen in Fig. 10, Pl. iii., obtained from a lad aged 13, when an out-patient under Dr. Moxon with the symptoms of mitral regurgitation, who was soon after admitted into the Hospital under the care of Dr. Habershon. There was a loud systolic murmur heard at the apex, in the axilla, and between the scapulæ; no doubt was entertained of its character. His health afterwards improved, and he left the Hospital. In both these cases there was probably free regurgitation through the mitral orifice, unattended by any compensating hypertrophy. The tracing represented in Fig. 7, Pl. iii., indicates a heart more equal to its work than those that have been noticed previously; it is that of a woman admitted into Guy's, under the care of Dr. Wilks, on October 15, 1871, suffering from subacute rheumatism. The heart's impulse was strong, and there was a loud blowing systolic murmur audible over the greater part of the chest, and masking the first sound completely; the second sound was clear. It may be noticed in the tracing that the upstrokes are sloping, the percussion-wave being lost: the reason for this has been previously stated. The tidal wave also is small, and the diastolic wave very feeble; the arteries being markedly empty during diastole. In this case there was probably free regurgitation, though with some tendency to repair by means of hypertrophy.

In Fig. 4 the arterial expansion is strikingly unstained; the collapse during systole is sudden and almost complete, and the pulse nearly fully dicrotic. The tracing was obtained from a boy aged 15, admitted February 21, 1871, under the care of Dr. Pye-Smith; he suffered from acute rheumatism eighteen months previously. The area of cardiac dulness is much increased, the enlarged heart bulging the ribs of the left side. The apex-beat is well marked but widely diffused, strongest between the seventh and eighth ribs, one inch and a half to the outer side of the left mammary line; also felt as low as the ninth costal cartilage. There is a loud systolic blowing murmur, audible at the apex, in the axilla, and between the scapulæ. The action is rapid; it was tumultuous when first admitted. The constitutional symptoms have been well marked. Here is a heart now doing its work with but a small amount of efficiency, though much more perfectly than on first admission; it had been dilated for some time, and previous to admission reached a climax of inefficiency; it is now probably hypertrophying, owing to the treatment adopted, and increasing in efficiency. A tracing obtained of the apex-beat has some of the characters of hypertrophy, though those of dilatation are most prominent; the contraction is forcible and well sustained (unlike most hearts in which there is mitral regurgitation), but though forcible it is slow, the upstroke somewhat sloping; the summits also are frequently rounded.

Figs. 8 and 3 are both taken from cases in which there was mitral regurgitation, but in which the heart was doing its work with considerable efficiency, especially in the latter instance.

The diagnosis of hypertrophy by physical signs is confessedly most difficult; for notwithstanding the number of indications supposed to be afforded by this condition, and detailed by the text-books, clinically there may be few, if any, present. Dr. Wilks points out as the most constant the alteration in the position of the apex-beat. Unfortunately, this has not been always recorded in the clinical reports to which I am frequently indebted for the notes of these cases. But the indications of hypertrophy afforded by the pulse are themselves almost sufficient for diagnostic purposes; indeed, the sphygmograph is one of the most reliable gauges of hypertrophy we possess. The form of tracing obtained in simple hypertrophy was discussed in the last paper, Bright's disease being the least complicated condition in which it is found. Dilatation may be distinguished from hypertrophy by the short and sloping upstroke, from the diminution of percussion and the slight pressure employed, the systolic expansion being still prolonged.

The tracing reproduced in Fig. 2, Pl. iii., is of peculiar interest. In this case the opportunity was afforded of watching the process of hypertrophy both by the ordinary physical signs and by the sphygmograph.

E. W., aged 15, was admitted into the clinical ward, under Dr. Habershon, November 24, 1871, suffering from subacute rheumatism and heart disease. She had suffered from acute rheumatism eleven months previously; her heart was then affected, and her general health has since been impaired. On admission her pulse was described as small and irregular, its rapidity being 120 per minute. The following note was made by the clinical assistant:—"Loud rasping sound audible over the whole region of the heart, feebly heard over a larger area, synchronous with the cardiac contraction. At the apex, with the first sound, a bruit exists; does not extend upwards; heard over the spine. Apex-beat broad and indistinct; the hand perceives a rough grating movement." On November 29 it is noted—"Rubbing cardiac noise fainter; area of heart's dulness increased; radial pulse scarcely perceptible." On December 5—"Cardiac apex two inches below and a little to the left side of mamma. Pericardial rub almost disappeared." 19th.—No pericardial rub; area of heart's dulness only slightly increased; apex-beat in natural position." About this date I was asked to take a tracing of her pulse, and was able to diagnose mitral regurgitation from the appearance of the tracing alone, it being decidedly characteristic. On January 10 the clinical assistant reports, the mitral bruit is very loud; apex-beat half an inch to the inner side of and one inch and a half below the nipple; dulness extends upwards to the third rib. February 19.—The bruit possessed the same character as before; the apex-beat was forcible and situated between the sixth and seventh ribs, and about half an inch external to the mammary line; the area of dulness was somewhat increased.

Here, then, were the leading physical signs of hypertrophy, developed apparently in the space of two months. The tracing now obtained is especially characteristic of hypertrophy, having a vertical and high up-stroke and a prolonged systolic expansion. Percussion, also, is well marked, and yet probably there was tolerably free regurgitation.

The tracing represented in Fig. 1, Pl. iii., is also interesting, though it possesses none of the attributes of the (so-called) mitral pulse. C. R., aged 12, was admitted to Stephen ward, under the care of Dr. Pye-Smith, February 14, 1872. There is no history of previous rheumatism or dyspnoea; his present illness commenced five weeks ago. When admitted into the Hospital he was suffering from subacute rheumatism and morbus cordis. Heart-sounds clear and loud at the base; at the apex there is a systolic blowing bruit, clearly audible at mid-sternum, faintly in the axilla and between the scapulæ; the heart's impulse is strong, full, somewhat heaving and diffused, strongest between the fifth and sixth ribs, in the mammary line. The bruit remains persistent since his admission. The tracing obtained shows a large, full pulse, with a particularly well-marked percussion-wave, indicating an excited action of the heart; but it also has a large tidal wave, and no apparent deficiency in the amount of blood impelled into the artery at each contraction. The tidal wave, moreover, is somewhat sustained, indicating some degree of hypertrophy. Probably in this case there is a somewhat damaged mitral valve, allowing of a small amount of regurgitation. The heart, feeling its weak point, excites itself with increased vigour to compensate for it. This is gradually producing a condition of hypertrophy, and the powerful systole already simulates it in the pulse.

Fig. 6 illustrates a peculiar form of pulse, not at all like that of mitral regurgitation. There was in this case a mitral murmur and an enlarged heart; the pulse was somewhat irregular. Its most marked characteristics are the large proportion which the percussion-wave bears to the tidal—the latter being hardly discernible—and the fulness of the artery during diastole. The heart appears to be contracting sharply and shortly, impelling only a small amount of blood into the arteries by each systole, owing to the free regurgitation. The diastolic expansion of the artery is well sustained by reason of the venous engorgement.

Fig. 5 is the pulse of a Medical man apparently in good health, suffering no symptoms of cardiac disease, whose pulse I pronounced normal, but at the apex of whose heart a soft systolic bruit is audible. The apex is slightly displaced outwards, there being probably some hypertrophy.

The next four tracings in the plate are intended to illustrate the effect of digitalis on the pulse. This drug is now well known to exercise a specific action over the heart. In no way can this be so well watched as by the sphygmograph. Its action on the heart in the lower animals is well known. It increases the duration and force of the systole, and when administered in doses sufficient to destroy life the heart is found tightly contracted. It appears to be, therefore, a stimulator of the sympathetic nerves. Aconite produces exactly the reverse effect. After death produced by this drug the heart is found to be widely dilated, the same condition being produced by galvanism of the pneumogastric. Digitalis will be found clinically to be of most value in dilatation of the heart. In this condition the pulse becomes very irregular; the heart, on account of its great dilatation, is unable to contract efficiently, and never empties itself completely, merely relieving by each attempted contraction its excessive distension; the pulsations felt at the wrist are small, feeble, and irregular, such as those found in advanced mitral disease. The reason for this may be easily discovered. Place any cavity in the body which is surrounded by organic muscular fibre in a condition of over-distension, and what ensues? Invariably paralysis or loss of power. Take, for example, the inability for powerful contraction of the over-distended uterus, as in hydrops amnii or the over-distended bladder, producing retention of urine; or the intestine distended with flatus, as in flatulent dyspepsia or tympanites. This paralysis may be relieved in two ways: First, by diminishing the distension by forming an outlet for the contents; or, secondly, by stimulating the muscle to contraction by drugs, etc. Either of these ways may be applied to the dilated heart. If the distension be relieved by bleeding, the heart will become more regular for a time, opportunity being given it of completely emptying itself; but this improvement will be only temporary, and purchased at a dear cost. The better and safer plan is to stimulate the heart by digitalis, as one does the uterus by ergot of rye. There is also another condition of the heart in mitral disease in which digitalis is beneficial—namely, where the heart is acting excitedly and the patient is much troubled with palpitations. It is intended to refer to the effect of digitalis on the pulse in each form of heart disease, for under certain conditions it varies considerably in its character. The action of this drug has been investigated very thoroughly, and most interesting conclusions arrived at by Dr. Fothergill in the Hastings Prize Essay for 1870, published in the *British Medical*

Journal of last year. Dr. Fothergill has not, however, used the sphygmograph in obtaining his results, and therefore loses a most perfect mode of illustrating and recording them. He has especially pointed out the possibility of producing hypertrophy of the heart by the continued use of this drug when desirable.

C. L., aged 18, was admitted into Guy's on December 6, 1871, under the care of Dr. Wilks. He has a thoroughly mitral aspect, and suffers much from palpitation, headache, and epistaxis. On examining the heart, a very loud blowing systolic bruit is heard at the apex and all over the front of the chest. It changes in character as you proceed towards mid-sternum, where it is loud, but shorter and harsher (? tricuspid). The bruit is also heard in the axilla and between the scapulae. It often varies in character, and has been musical. I have sometimes thought it presystolic, but the action of the heart has been too rapid to ascertain this certainly. The apex-beat is very forcible and visible, best marked at the lower part of the fifth interspace—about an inch and a half internal to the left mammary line. The area of dulness is increased, especially towards the right; and there is a distinct thrill over the cardiac region. The second sound over the pulmonary valves is peculiarly loud and sharp. The closure of the valves can be distinctly felt on pressing the finger into the second left intercostal space. A tracing of the apex shows a dilated and hypertrophied ventricle, and an hypertrophied auricle. The enlargement is probably chiefly of the right side, as the dulness is increased in that direction. Whether or not there is mitral obstruction, which I believe to be present, there is undoubtedly very free regurgitation. His pulse on admission (Fig. 2, Pl. iii.) was very rapid, splashy, and dicrotic. The systolic collapse in the tracing is sudden, and the diastolic expansion large. Under the use of digitalis this pulse became much slower and firmer (as seen in Fig. 12), the heart acting more quietly and efficiently. The dyspnoea decreased, and his whole condition improved greatly. The amount of dicrotism present in the tracings may be attributed to the venous congestion, which acts mechanically as capillary obstruction.

The next tracings in the plate were obtained from a woman, aged 28, admitted into the clinical ward under Dr. Rees, November 23, 1870. On admission the clinical assistant made the following note:—"The apex beats between the seventh and eighth ribs; lifts the hand. Loud systolic murmur throughout the chest and between the scapulae; second sound obscured. Pulse 72; very feeble and irregular." The constitutional symptoms were well marked. She was put on the use of digitalis, and when the tracing reproduced in Fig. 13 was obtained she had been taking it for three days, and the volume of the pulse had increased, the contractions of the heart being more efficient, though still very irregular. After the use of it for ten days, Fig. 14 was obtained. The pulse was now regular, firm, and of good volume; the general condition was much improved. After discontinuing the digitalis the pulse relapsed into its former bad form, and was again improved by the same means.

Having noticed the leading forms of pulse associated with mitral regurgitation, and finding them almost unlimited in their variability, surprise will not be felt on finding regurgitation through the right auriculo-ventricular orifice (through insufficiency of the tricuspid valve) also produce no diagnostic characters. But it appears that there is one character always associated with this disease, though by no means peculiar to it—namely, variation in the line of arterial tension produced by each movement of respiration; moreover, the percussion-wave is not diminished as in mitral regurgitation.

J. L., aged 56, was admitted into Guy's, under Dr. Wilks, July 6, 1871, with symptoms of morbus cordis and Bright's disease. The following note describes the condition of his heart:—"Area of dulness greatly increased; impulse diffused and fluttering. The first sound is dull, and rather woolly; the second has more the character of the first, more prolonged than usual." Two days afterwards I found a soft systolic murmur at the apex; the second sound was inaudible at the base, well marked but dull at the apex. This bruit was inconstant—lost when the action of the heart was rapid, reappearing as it became slower. The large veins in the neck pulsated. The greatest variety of opinions were expressed as to the nature and origin of the bruit, which was heard by some loudest at mid-sternum.

The tracings obtained (Fig. 15) did not much elucidate matters. It was not the pulse of mitral regurgitation which accompanies a dilated heart. But a tracing of the apex-beat (Fig. 16) was most interesting, on account of the extremely well-marked auricular beat preceding the systole. This is in-

dicated in the tracing by the elevation preceding the main upstroke. By its presence I was able to diagnose an hypertrophied auricle, and therefore expected that the bruit must be presystolic and due to mitral disease. Five days after admission he died very suddenly. At the autopsy, Dr. Moxon remarked, on seeing the external configuration of the organ, "This heart ought to have a contracted mitral;" but, on examination, no valvular disease was discovered. The left ventricle was hypertrophied and somewhat dilated, the left auricle was greatly hypertrophied; the right ventricle was greatly dilated, and the tricuspid orifice much wider than normal. Probably, therefore, the bruit heard during life was produced by regurgitation through the tricuspid valve. Dr. Wilks, however, doubts the possibility of a bruit being produced by regurgitation through this valve when healthy. Still, if there be any truth in the "safely-valve action" of the tricuspid, surely in these cases of greatly dilated right ventricle regurgitation must take place; and, if the bruit was not produced by it, I am at a loss to account for its presence. Moreover, I have more than once heard a bruit at mid-sternum, when the right side was dilated, in chronic bronchitis and emphysema. The characters of this tracing to be noted are the presence of a well-marked percussion-wave, it thus differing from a typical mitral pulse, and the variation in the tension of the blood-column, producing an undulating respiratory line. This I believe to be a constant accompaniment of tricuspid regurgitation. Its mode of production is evident.

The last case in this plate ought, perhaps, to belong to the succeeding one, for both mitral stenosis and tricuspid regurgitation were present.

J. G., aged 17, was admitted several times into Guy's, under the care of Dr. Wilks. On December 20, 1870, when the tracing represented in Fig. 17 was obtained after an examination of the heart, the following note was made:—"There is a bruit which takes place during the end of the diastolic pause and replaces the first sound on the left side at the apex. On the right side of the sternum it has a somewhat different character, and does not appear to commence before the first sound. There is a thrill perceptible on placing the hand over the cardiac region. The veins of the neck pulsate." Dr. Wilks diagnosed mitral contraction and tricuspid compensating regurgitation. The peculiar character of the pulse was the undulation in the respiratory line; this was most marked after exercise. Fig. 18 represents the pulse of the same patient after using digitalis for a fortnight; it is very slow, firm, and of remarkably good tone, and illustrates admirably the effect of this drug on the pulse. Fig. 19 was obtained on December 19, 1871, while he was in Guy's for the last time. His condition was considerably worse than before, and his pulse now presents a bad characteristic; it is slightly hyperdicrotic. It appears, that in heart disease this may be always ascribed to excessive venous congestion, and shows the obstruction to the circulation to be very great. The undulation of the respiratory line is present in a still more marked degree. Gradually becoming worse, he left the Hospital to die at his own home. An examination, which was permitted, fully confirmed the diagnosis. The right auricle was hugely dilated; the right ventricle also greatly dilated, and somewhat hypertrophied; the tricuspid orifice being much enlarged. The left auricle was greatly hypertrophied, the wall being a quarter of an inch in thickness; the mitral valve calcareous, extremely contracted, not admitting the little finger; left ventricle, aortic and pulmonary valves normal. The influence of the tricuspid regurgitation on the characters of the pulse peculiar to mitral stenosis will be referred to in the next paper.

(To be continued.)

HER MAJESTY THE QUEEN has been pleased to grant a donation of £100 to the British Medical Benevolent Fund.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this Society on Friday, April 5 (Mr. J. M. Burton, President, in the chair), Mr. Sydney Jones read a paper "On Some Points in the Treatment of Nævi and other Vascular Aberrations." After briefly reviewing the pathology of the disease, and the different modes of treatment, the author strongly advocated the use of the actual cautery as a means of cure. The paper was illustrated by the reading of several cases, and the exhibition of the galvano-cautery, which was ably superintended by Mr. Ellis, of St. Thomas's Hospital. Drs. Barnes, Carr, Gooding, and Purvis, and Messrs. Burton and Lockhart, took part in the discussion which followed. Dr. Stocker, of Peckham House, was unanimously elected a member of the Society.

SKETCH OF

MAJOR OPERATIONS PERFORMED BY
MR. SPENCE DURING THE SUMMER OF 1871
IN THE
ROYAL INFIRMARY OF EDINBURGH.

By H. AMBROSE LEDIARD, M.B. EDIN., M.R.C.S.,
Late House-Surgeon to the Edinburgh Royal Infirmary.

THE accompanying cases enumerate all the operations performed by Mr. Spence during the summer months which may be dignified by the name of major operations. It will be seen that there were 11 amputations, of which 9 were for disease and 2 primary for accidents, all of which recovered; 4 cases of excisions of large tumours, all of which recovered; 4 cases of excision of joints, 3 for disease, and 1 primary, the only one dying being the primary case.

AMPUTATIONS.

Disease of End of the Bone in an old Stump.—Robert B., aged 35; amputated below the knee on May 12; dismissed, June 28. A not very healthy pauper. The fibula had to be sawn through again during the operation, in order to arrest the hæmorrhage, the vessels having been divided near the bifurcation of the popliteal. Wound healed slowly, and subsequently exhibited some want of action. Result excellent.

Gelatinous Degeneration of Knee going on to Suppuration.—David D., aged 6; amputated at lower third of thigh on May 16; dismissed, August 6. Very strumous subject. Long anterior flap employed; part of the incision involving the wall of an abscess. Wound quite sound in thirty days, when the whole cicatrix ulcerated, and refused to heal for some time. Result very good.

Ununited Fracture of Leg.—William C., aged 11, amputated below the knee on May 23; dismissed, July 20. This was a very interesting case. The fracture occurred in India, and previous to amputation the fracture had been cut down upon, and bones pared by Mr. Spence. The wound healed readily enough, but the bones did not unite, and, as the development of the limb did not keep pace with the other, amputation was adopted by the long posterior and short anterior flaps. This wound united entirely in a week, but a large abscess formed in the calf, which discharged, and closed ultimately in twenty-four days. The boy was a child of a sergeant in the 32nd Regiment, and was kept in for convenience to friends.

Smash of Foot from Machinery (Primary).—James W., aged 10; amputated at ankle-joint (Syme) on June 1; dismissed, July 15. Healthy boy. The line of the incision across the heel lay necessarily through bruised textures. A portion of the heel flap sloughed, which was feared would be the case. With this exception, and the formation of one small abscess in the stump, the wound healed readily enough, leaving an excellent result.

Caries of the Tarsus.—Robert M., aged 31, amputated at ankle-joint (Syme) on June 13; discharged, July 17. Healthy, cheerful man. The case was one of rapid disease of the inner side of the tarsus, with numerous sinuses. There was reactionary hæmorrhage to small amount. Wound healed readily enough, with the formation of one abscess.

Disease of the Tarsus.—Annie S., aged 25; amputated at ankle-joint (Syme) on June 13; dismissed, July 3. Very nervous subject. This case was one in which numerous abscesses formed in the foot, the cartilages of the tarsal bones being intensely ulcerated. Immediate relief followed amputation; but when about to leave the Hospital she took variola, and died July 20, with pleuritic effusion, in the Fever House. The stump continued sound up to the last.

Caries of the Tarsus.—John D., aged 17; amputated at ankle-joint (Syme) on June 20; dismissed, August 8. Healthy subject. This case was one of very chronic affection of the larger tarsal bones. The wound united without a bad symptom, and, if anything, seemed to be accelerated by the formation of an abscess, which formed a drain, and allowed the incision to heal first.

Gelatinous Degeneration of Knee and old Necrosis of Shaft of Femur.—Donald D., aged 42; amputated at upper third of thigh on July 11; dismissed, September 7. Tolerably healthy man; somewhat anæmic. The periosteum of the femur above the knee was much thickened, rendering the case unsuitable for excision. A long anterior flap was adopted. The whole incision united immediately, and a small orifice was kept open from first to last, only to allow of escape of discharge. Cicatrix came well behind.

Chronic Constitutional Ulcer of the Leg.—Allan McK., aged 43; amputated through the knee-joint on July 19; dismissed, September 13. Ulcer was of nine years' standing, and refused every effort to heal. Skin was hard, burrowed under, and much thickened. Man was sallow, and in ill-health. Amputation through the knee was resorted to, removing the patella, and leaving the condyles intact. The flap from the front was of great length, but, together with a posterior flap, just covered the bone thoroughly. An abscess formed in the thigh, of small size. Cicatrix was drawn well behind. Man improved in health.

Railway Accident: Arm entirely Severed below the Deltoid (Primary).—George S., aged 22; amputated at the shoulder-joint on July 30; dismissed, August 31. Healthy and temperate man. The method of amputation adopted was by the lateral deltoid flap recommended by Mr. Spence, and which gives such perfect results. This case, fortunately, was suited for such an amputation. The man was brought six miles in a cab, and had, in addition, two scalp wounds, which, though adding to the interest of the case, did not diminish the danger. The man never had a bad symptom. The brachial artery was torn out to a point the size of ordinary sewing-thread.

Caries of Tarsus.—Henry G., aged 12; amputated at the ankle-joint (Syme) on September 19; previously, partial amputation of the foot on August 16; dismissed, November 30. Delicate boy, of most extraordinarily excitable nervous system. The disease being limited to the outer side of the foot to a very marked degree, and though the operation is not a favourite with Mr. Spence, the chance was given in this case. Intense inflammation set in after the operation; after its subsidence, it was found that the cartilages of the tarsus were in a state of ulceration, abscesses, etc., forming round the ankle. The boy was in a very weak condition, but the second operation was immediate in its beneficial results. A sinus formed, which refused to heal for six weeks. The boy was out of bed at the end of three weeks.

EXCISIONS OF JOINTS.

Gelatinous Degeneration of Elbow-joint, with one Sinus communicating with Diseased Bone.—Elizabeth K., aged 3; operated upon, July 14; dismissed, August 10. Healthy-looking child. Joint was removed by the longitudinal incision. The result was a truly marvellous one; the incision united directly, all except that portion which ran through the old sinus. At the end of ten days all discharge ceased, and the wound was quite sound, and remained so. The child was kept in, so that the movements might be attended to. Two months after she was brought to be seen. The motions of the arm were almost perfect. In this case, simple pads of lint served to keep the joint in the position required.

Gelatinous Degeneration of Elbow-joint: Disease of the Cartilage commencing.—Alexander J., aged 12; operated upon, July 28; dismissed, September 28. Pale, strumous boy. In this case, as in the previous one, the longitudinal incision was employed, and pads of lint only to keep the joint in position. The wound healed slowly, and after all discharge from the interior ceased, superficial obstinate ulcers remained. On dismissal to convalescent-house, these were not entirely healed.

Disease of the Wrist-joint.—Gavin W., aged 21; operated upon, August 3; dismissed, September 28. This was a most unfavourable case for operation; there had been old disease of the metacarpus, leading to shortening of the ring-finger. As many as six sinuses existed on admittance. A single dorsal incision sufficed to expose the joint. With the exception of some sloughing of the extensor common tendons, the wound healed slowly and well. The movement of the fingers was progressing satisfactorily on dismissal.

Compound Fracture into Elbow-joint (Primary).—James N., aged 44; operated upon, August 1; died. A patient of exceedingly intemperate habits. Friends stated that he was rarely sober. There was considerable laceration and bruising of the soft parts; but the violence of the injury had chiefly expended itself upon the olecranon process. The joint was excised upon admission. Delirium tremens came on within twenty-four hours after the operation. He continued to rave for two days, and then died.

EXCISIONS OF TUMOURS.

Small Scirrhus Tumour of Breast, with an Ulcerated Surface: Glands in Axilla affected.—Elizabeth J., aged 45; operated upon, June 27; dismissed, July 31. Healthy-looking woman. No excess of fat; good nervous system. The entire breast was removed, together with the axillary glands. The incisions made to accomplish this joined one another at almost a right angle. The wound healed, partly by primary union, and the

skin being not too excessive, was found to be very advantageous. The axillary part of the wound healed last.

Multilocular Cystic Tumour of Breast.—Mary M., aged 30; operated upon, July 3; dismissed August 12. Very healthy woman. Tumour removed by one incision, the various cysts emptying themselves during the operation. The wound did well enough, uniting secondarily; but the skin being superabundant, turned in upon itself, and delayed the ultimate closure long after all discharge ceased.

Scirrhus Tumour of the Breast: Affection of Axillary Glands.—Ann S., aged 53; operated upon, July 19; dismissed, August 18. This case was treated in the same manner as the one first given. The only point of interest to observe with regard to the dissection of the gland was that the axillary vein was exposed. This wound seemed inclined to unite primarily. For four days there was no discharge, but an abscess formed at the outer end of the line of incision, which continued to discharge for some time, the rest of the incision uniting directly. It may prove interesting to observe that this woman's mother was in the Infirmary at the same time with a large carcinomatous mass in the neck.

Large Scirrhus Tumour of Breast.—Jane C., aged 41; operated upon, September 14; dismissed, November 25. This case was not regarded as a favourable one for operation. The skin over the disease was in a state of acute œdema previous to the operation, which was performed in the usual manner. Twenty-four hours after the operation an erythematous blush appeared over the breast. This spread in all directions, but entirely disappeared at the end of five days under iron treatment and a dressing of tepid lint and Condy. The wound was closing fast, when she took rigors and vomiting, followed by a well-marked eruption, which proved to be small-pox. During her residence in the fever house two large bedsores appeared. At the end of October she was sitting up, bedsores healed, and patient doing well. Wound not quite closed; great want of action.

TREATMENT OF WOUNDS AFTER OPERATION.

It may be observed that carbolised catgut ligatures were used in all cases; as a rule they were not seen again after the closing up of the flaps. To arteries in their continuity Mr. Spence uses silk. Dry cold was applied immediately after operation to all cases unless there was some special reason to the contrary, the method of application being as follows:—The ice is pounded into small pieces, and put into bags made of guttapercha, chloroform sealing up the margin and rendering the bag water-tight. The bags are not to be put over the incision, but on either side. The dry cold was not kept on for more than forty-eight hours; in many cases not so long. The majority of cases were dressed, from first to last, with a piece of oil-silk dipped in dextrine, over the line of incision, and the entire wound covered with guttapercha; the benefit of such treatment being that the discharge is not confined, and it is possible to see what is going on without removing the dressing. After the ice is given up the guttapercha is narrowed to the line of incision, so as not to retain cutaneous transpiration and create moisture, which tends to disorganise the connecting plasma. In all cases stitches were removed as soon as possible, and replaced by ordinary strapping. In three cases of amputation there was reactionary hæmorrhage to small amount, requiring, however, the flaps to be taken down. In the majority of cases small abscesses formed during the healing; these seemed to be of service, allowing the incision to unite, and acting as a drain at a dependant part. The lotions employed were—chlorinated soda, sulphate of zinc, chloride of zinc, carbolic acid, Condy, and in some cases simple water.

CASE OF SKIN-GRAFTING.

This case exemplifies the results to be obtained from skin-grafting upon a callous ulcer of many years' standing, which had originated in a burn of the leg. The surface of the sore was of considerable extent, about five inches in length, and passing almost round the limb. The fascia of the tibialis anticus was softened and disorganised, allowing that muscle to project the surface of the sore beyond the margin of the surrounding skin. She was admitted early in July, and after a few weeks' treatment with lotions of chloride of zinc and chlorinated soda, the ulcer was got into a sufficiently healthy state for grafting, the granulations being florid and bleeding easily, and the discharge not being too excessive. During the first week in August a piece of skin was removed from the inner side of the arm, about the size of a threepenny-piece, cut into small portions the size of a pin's head, and distributed over the surface of a limited portion of the sore. At the end of the first week it was thought that the grafts were all washed away with the discharge from the surface of the sore,

but on the tenth day small points of epithelial growth appeared over the surface of operation, which rapidly spread and joined each other. It is probable that not quite half of the portions of skin employed remained and acted as centres of growth, the rest being either washed away by the discharge, or failing to fall upon congenial soil. This operation was repeated three or four times, until the whole area of the ulcer had been treated as above. From twenty to thirty small bits were used on every occasion, from ten to fifteen of them in every case succeeding. A variation was once had recourse to. The pieces cut from the arm, of a similar size to these first mentioned, were transplanted as they were. These all took root and grew well, but it was observed that the sore was not covered with epithelium half so rapidly from the large grafts as from the small ones, the beneficial results of the latter method depending upon the number of individual centres for epithelial growth afforded. The patient left the Hospital, the leg sound, towards the end of October. The dressing employed consisted of oil-silk coated with dextrine, over which was lint soaked in some lotion which was changed from time to time; over the lint came a piece of guttapercha and a turn of bandage. This dressing may seem somewhat elaborate, but it was found necessary to put some non-irritating body next the sore. The oil-silk dipped in dextrine answered this purpose admirably. The lint soaked in lotion was found necessary to keep the sore in a healthy condition, and the guttapercha, of course, was merely used to prevent the too rapid evaporation of the lotion. After being at the convalescent-house a fortnight, the patient returned with a large portion of the sore reulcerated. It was satisfactory to observe, however, that more than half of the grafted portion remained quite sound. This continued intact through a severe attack of erysipelas which set in, from the toes to the knee, a few days after her return to the Hospital.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

THE LONDON HOSPITAL.

CASES UNDER THE CARE OF MR. HUTCHINSON.

Stab under the Jaw followed by Symptoms of Paralysis of the Lingual Nerve—Probable Division of the Nerve and of the Lingual Artery.

AN Irish woman, aged 35, now (April 1) under care, shows remarkably well the signs of complete paralysis of the right hypoglossal nerve. The symptoms followed a deep punctured wound, which passed from close to the angle of the jaw downwards and rather backwards towards the larynx, and at the bottom of which the greater cornu of the hyoid bone could be felt. Her speech is "thick"; she cannot pronounce all words clearly, because, as she says, "the tongue is too large." She thinks she can articulate more clearly when lying down, because the tongue then falls back somewhat and does not fill the mouth so much. When she puts the tongue out it is pushed over to the right (injured) side very distinctly. The paralysed (right) side is convex, and looks considerably larger than the left side, which (when the organ is protruded) is concave. The paralysed side remains quite flabby and soft when put out, while the sound side becomes firm. When she eats she cannot move the food about in the right side of the mouth, and has sometimes to push it over to the left side with her finger. She lost a very large quantity of blood from the wound, and was, when admitted, blanched, faint, and unable to walk. She said that the blood "poured" from the wound. Before admission a Surgeon had seen her, and applied strapping and a compress. No bleeding was going on when she was brought to the Hospital, nor has any occurred since. The wound was plugged with bits of sponge, two of which were removed on the third day and the remaining one on the fifth.

It seems very probable that the lingual artery was divided as well as the nerve, and that the division was complete. In this way we can account for the rapid loss of a large quantity of blood, while the retraction and contraction of the cut ends would explain the freedom from recurrence of bleeding.

She is going on well, and her difficulty of speech is diminishing, but the paralysis of the tongue is as complete as it was on admission.

Separation of Lower Epiphysis of Humerus, with Partial Dislocation of Radius and Ulna backwards.

A boy, aged 11 years, is now under care for the results of an injury to his right elbow of five months' standing. When admitted the limb was slightly flexed at the elbow, but could neither be straightened nor bent to a right angle. The inner condyle of the humerus is well defined and feels normal, but all the rest of the lower (epiphysal) part of the bone is very much thickened. The olecranon projects backwards, and the distance between it and the inner condyle is increased. Part of the cup of the head of the radius can be felt, but the remainder is still in contact with the humerus; the radius can be rotated freely. At the bend of the elbow the lower end of the humerus forms a considerable projection, which can be readily felt. The external condyle is not distinctly appreciable, being lost in the thickened mass of bone. Mr. Hutchinson thinks it most likely that a dislocation of the ulna and a partial dislocation of the radius backwards took place, together with separation of the greater part of the humeral epiphysis (the inner condyle probably escaping); while the bones of the forearm passed backward, the detached epiphysis came somewhat forwards, and, remaining in its abnormal position, gave rise to the great thickening felt at the bend of the elbow. The boy stated that the injury was caused by a violent blow from a fist dealt on the upper part of the front of the forearm while the latter was bent at a right angle to the arm, the wrist being fixed at the time.

Obscure Case of Abdominal Tumour—(? Abscess in connexion with Pelvic Bone Disease).

The case of Eliza S., aged 47, is of much interest in reference to the diagnosis of abdominal tumours. Her Medical Attendant told her, about six months ago, that she had a tumour, and she began to notice abdominal swelling about the same time herself. During the same period she has had a good deal of twitching and stabbing pain in the left iliac region, and in the lower part of the back, and on standing the pain has often passed down her thighs. Desire to pass water frequently has also come on, and her motions are said to be sometimes very small. The catamenia are normal. She has had several children, the last being about 5 years old. For many years she probably had some displacement of the uterus, for which she wore a pessary, but for the last six months or so she has been obliged entirely to leave off the instrument, as it caused her so much pain. She now has a somewhat unevenly rounded tumour in the lower part of the abdomen, as large as, or larger than, a child's head. It is situated chiefly to the left of the middle line, but passes over towards the right side also; it does not extend up to the umbilicus. Fluctuation is easily felt in it, both on the skin surface and between the skin and the vagina, into which latter the tumour bulges. It is not movable. The uterus is freely movable, and appears healthy. There is no tenderness about the tumour. Although rounded, it does not project far upwards into the abdomen; and this fact, together with its fixity, militates against the diagnosis of ovarian tumour. The mobility of the uterus is against the existence of such a fixed tumour in connexion with it. The unevenness of the surface of the tumour makes the diagnosis of hydatid improbable. It is much too low to have any connexion with the kidney. Mr. Hutchinson thinks that most likely it is a large abscess behind the peritoneum in connexion with diseased bone in the sacrum or ilium. He has come to this opinion from the position, fixity, and fluctuating character of the tumour—features which are better explained by this hypothesis than by any other. The want of inflammatory thickening about it, although to some extent against abscess, does not exclude it.

Probable Hard Chancre on Eyelid.

A married man, aged 27, applied on the 1st inst. to Mr. Hutchinson, at Moorfields, with a round ulcer as large as a fourpenny-piece on the skin of the right upper lid near the outer canthus. The base of the sore was very decidedly indurated, but there was also a great deal of inflammatory swelling of the lids and conjunctiva, so that the precise conditions of the sore and its neighbouring induration were somewhat masked. There were several hard enlarged glands on the same side in front of the ear and behind the ramus of the jaw. There were no secondary symptoms, and no history of contagion could be elicited, so that the diagnosis could not be considered as then quite certain. The duration of the sore was probably about a fortnight, but the man did not give a satisfactory account. He was transferred to the London Hospital, under Mr. Hutchinson's care.

ROYAL PORTSMOUTH, PORTSEA, AND
GOSPORT HOSPITAL.

PENETRATING WOUND OF ABDOMEN, WITH LARGE
VISCERAL PROTRUSION, AND LACERATION OF
OMENTUM—RECOVERY.

(Under the care of Dr. JOHN WARD COUSINS.)

W. T. T., AGED 34, an engineer on board a steam collier, was admitted on October 14, 1871, in a state of collapse, having two hours before fallen eighteen or twenty feet from the side of the vessel into a boat. He was the "worse for liquor" at the time of the accident, and no very definite account of it could be obtained. On examination a lacerated wound of the abdomen was found extending from the cartilages of the seventh and eighth ribs downwards and inwards to the umbilicus. A large portion of the small intestine and part of the transverse colon, together with omentum, were found protruding from the wound, covered with coagula and dirt. The intestines were not injured, but the omentum was much lacerated, and free hæmorrhage was going on from several torn vessels. The wound through the parietes was very irregular. The skin was cut cleanly, but the muscular and fibrous structures were bruised and irregularly torn, as if the injury had been inflicted by some blunt instrument. The sheath of the rectus was lacerated, and the abdominal fasciæ were stripped off the cartilages of the ribs. The head and face were marked with extensive ecchymoses. The patient was confused; extremities cold, and pulse very small and feeble. The protruding viscera were carefully returned without delay, having been previously examined and sponged with warm water to remove all adhering blood and dirt, and the bleeding omental vessels secured with fine silk ligatures, cut off as short as possible. The omentum was replaced last, and the torn portion was left in apposition with the wound, which was then closed with seven interrupted sutures, and covered with carbolic oil dressing. The patient, after the operation, was placed in bed, supported by pillows. Fluid diet and a full dose of opium were ordered, and the House-Surgeon was directed to draw off the urine.

October 15.—Passed a quiet night, and takes nourishment fairly. Abdomen tender, but free from pain; urine scanty, and high-coloured.

17th.—Continues easy. Abdomen tense, and painful around wound; tongue coated.

19th.—Complains of irritability of bladder, and urine contains a great deal of blood.

21st.—Patient more comfortable; urine increased in quantity; edges of tongue cleaning; sleep refreshing.

23rd.—During last twenty-four hours has had several rigors; bowels have acted freely; urine still contains blood; tongue much cleaner. He was ordered to take twenty minims of tincture of perchloride of iron every two hours.

24th.—Much better; urine quite natural; no discharge from wound. Medicine ordered to be taken twice a day, and full diet.

29th.—Stitches removed. Wound completely united in every part.

November 1.—Patient left the Hospital to-day. There was a little fulness at the seat of injury, and he was directed to obtain an elastic abdominal bandage.

The following statement, carefully drawn up by Mr. Edward Madely, the House-Surgeon, represents the range of temperature, etc. :—

	Pulse.	Respiration.	Temperature.
October 15.—Evening . . .	115	—	100·4°
October 16.—Morning . . .	112	—	100
" Evening . . .	115	52	101
October 17.—Morning . . .	110	26	100·4

" Evening . . .	100	30	100·2

cholera has powers of spreading and of proving fatal to healthy adults which are not possessed by its English congener, though identical in symptoms. It seems to become from year to year more intractable and deadly, and it is lucky that its diffusiveness seems limited by laws as yet quite unknown. Human intercourse alone will not explain it, for many ships leave Calcutta with cholera in the crew, and yet how rarely it spreads!

THE MINES REGULATION BILL.

AMONGST the measures of home legislation which the country has been promised during the present session, the Mines Regulation Bill holds a place second only in importance to the Public Health Bill. The Mines Regulation Bill, which has been read a second time in the House of Commons, and comes on for discussion again on Monday next, is in its general character a salutary and creditable measure. Its faults are faults of omission rather than of commission, and might be very easily rectified. But as quite as much evil is wrought through want of thought as through wilful act, so the omissions in this Bill, if allowed to remain, will, we may safely prophecy, reduce it to a very inefficient and unsatisfactory piece of legislation. The attention of the Profession has been recently directed to the defects in the Bill by an able pamphlet issued by the Association of the Factory Medical Officers of Great Britain and Ireland, and we think that this Association, over which Dr. Arlidge, of Newcastle-under-Lyme, presides, is entitled to no little credit for having exercised so opportune a vigilance in reference to a measure which deals with branches of industry lying outside the special sphere of public duty assigned to its members.

The Factory Acts have been an acknowledged success. They prevent the employment of young children in factories, and they withdraw from such employment children unfitted by bodily debility, want of development, deformity, or by disease. In addition, they protect, in a certain measure, the workpeople against injuries from machinery, and against the hygienic evils of want of cleanliness and bad ventilation. They also enforce education for children under 13 years of age. These valuable results are obtained by the agency of an organised staff of Factory Certifying Medical Officers and of inspectors. The admirable results which have attended the working of these Acts in the manufacturing districts justify the assertion made in the Report of the Royal Sanitary Commission of last year—that the Factory Acts “form one of the most important parts of sanitary legislation.” What these Acts have accomplished in the manufacturing districts is exactly what the Mines Regulation Bill might accomplish, and is intended to accomplish, in the mining. But in its present state it must, in a great measure, prove a failure. To quote from the pamphlet of the Factory Medical Officers, the clauses of Part I. of the Bill “regulate the duration of employment, prescribe proper intervals for meals, and arrangements for the education of children under 13 years of age. But they make no provision to guard against the employment of children and young persons who are disqualified by inadequate physical development or deformity, or by the presence of disease; and although they fix certain ages for commencing work, and for the enforcement of education, they lay down no plan whereby such ages are to be ascertained.”

That such safeguards are absolutely necessary may be deduced from the experience of the Factory Certifying Surgeons. It is well known that large numbers of children are rejected in the factory districts, not merely on account of insufficient age, but on account of bodily defect and disease. That at present equally unfit candidates are sent at early ages to work in the mines is tolerably certain, and the early mortality from phthisis amongst some mining populations is thus partially to be accounted for. In addition to an unhealthy

occupation, no attempt is made to shield the originally unsound from its deleterious influences. The ailing, strumous boy has not the slightest chance of resisting the evil effects of a metalliferous mine, any more than he could resist the deteriorating influences of a factory. Then, with regard to age, the Mines Regulation Bill, whilst it fixes certain ages for work and the enforcement of schooling, omits any plan by which the age of the child may be ascertained. The Workshops Act is almost equally defective in this respect. It permits a statement in writing only to be taken as evidence of age; and the result is that boys, rejected by the Certifying Surgeons under the Factory Act as of insufficient age, or on account of bodily infirmity or disease, obtain employment at workshops—that is, factories with less than fifty persons employed in them. But the Mines Act, as we have said, demands no proof of the age of candidates for employment in mines. A certificate of birth registration would be better than nothing; but the registration of births is not universal or compulsory, and there is the danger that younger children may borrow the certificates of older ones—a fraud which is quite within the experience of Factory Inspectors.

The fact is, that if it be the aim of the Legislature to make mining as healthy an occupation as possible, and to raise the moral and physical well-being of the mining population, it cannot do better than introduce the provisions of the Factory Act into the present Bill, at least in the particulars which we have pointed out. The Medical organisation is already in many instances at the very mouth of the mines; for by the Factory Act Extension Act blast-furnaces and forges are placed under the same conditions as other kinds of manufactories, and Medical certificates are required for the children and young persons employed. Even where this is not the case, the members of the Medical Profession who are already acting under the Factories Acts, and others who are practising in mining districts, would be quite ready to undertake the duties of Certifying Surgeons to mines. Without such a provision, the mining populations will remain open to many of the causes of physical degeneration which it is the special aim of this Bill to remove.

FREE LOVE IN AMERICA.

If an American on his arrival in England were to drive down Fleet-street and to buy the *Day's Doings* with its large and licentious woodcuts, which was lately hawked about openly, or if he were to walk up the Haymarket at night, and as the result of his experience were to declare that English literature was filthy and prurient, and that London was composed chiefly of public-houses and tobacco shops, and its inhabitants were thieves, bullies, and flash men about town, he would be just as correct as if the English were to take *Woodhull and Claflin's Weekly*, or Mr. Hepworth Dixon's scandalous “New America,” as fair pictures and samples of American life and manners. To the large and reputable part of the American nation the opinions and practices described are as unknown; or, if known, seem as abominable as they do to ourselves. Alfieri once said of Italy, that “man as a plant grows more robust there than elsewhere, and that the very greatness of the crimes is a proof of it.” So we may say of America, that man grows there with less restraint for good or for evil than here; and that the exuberant and monstrous moral deformities, the fame of which reaches us from across the Atlantic, do but show the growth of ideas, the germs of which are found amongst ourselves, though here they are more under restraint. We may take them, therefore, as specimens of what we may expect when the restraints of our present political and religious system shall be relaxed, and when our lower classes shall have been cursed with an education which shall develop their volubility, their love of high-sounding rhetorical commonplaces, and that ignorant egotism which leads them to believe that the crude theories of “advanced

thinkers" can supersede the morality which has been handed down by our religious ancestors.

Amongst the most "advanced" of American papers is the *Weekly* of Mesdames Woodhull and Claflin, one number of which, with an elaborate oration on "Free Love," has been sent us for special notice; and if we give it that distinction, it is just because the description of a stinking ulcer is in its way as much a part of scientific study as is the contemplation of the most perfect and beautiful organisms; and because, *noscitur ex sociis*, we are able to see from the contents that "Woman's Rights," the proceedings of the "International Association," and the upsetting of all rights of property, of religion, morals, and decency are ardently desired by the patrons of *Woodhull and Claflin*, who report and applaud the proceedings of Citizens Odger, Dilke, and Bradlaugh in this country. The present attack of the American clique is directed against "the family" in all its essentials. That one man shall be knit in bonds of holy matrimony to one woman for life; that a man shall call his wife *his own*, his children *his own*, and that he shall be bound to rear them and take pleasure in the task, are Old World absurdities to be done away with. Men and women are to be free lovers, and the children are to be the property of the State, which is to educate and maintain them.

The oration on "Free Love," printed in conspicuous type, is the work of Mrs. Frances Rose Mackinley, and we may say the only thing in her favour is, that she states somewhat ambiguously that she is not a free lover herself. In a wordy and mystical exordium she intimates that love in man and woman is of the same nature with chemical attraction, and that freedom of love is as essential and inherent a right of theirs as freedom to unite or disunite is of chemical atoms. The matrimonial tie is mere selfishness.

"The freedom I contend for (says the orator) is now habitually assumed in private by all who desire it or find it a necessity of their natures, whatever may be their public and formal pretences.

"Obedience to the conventional restraints of marriage is practically among men such an absurd assumption that, as no one practises it, no one believes it in others.

'That household virtue, most uncommon,
Of constancy,'

as Byron calls it, grows more and more uncommon, as reason takes the place of

'Hoary error, grown holy by traditional dulness.'

"If, with the power of Asmodeus, we could, for one night, unroof the houses of this city, what husband or wife would be secure from some revelation of that undercurrent of life of which its shining outward surface gives no intimation.

"In a perfect condition of society, special loves, which jealously demand the entire consecration of one to the other, will be almost unknown. The fire and enthusiasm and passionate ardour which are now confined to two lovers who feel only for each other, will be shared by all the members of such a community.

"Imagine a society, even as large as the world, where all the inhabitants have the freedom and intelligent recognition of each other's rights which will make them accordant—where all are as developed as it is possible in earth-life, each prompted by a divine humanity, understanding, caring for, and helping the other. Sympathies between them would be continually alive, and their loves as natural and poetical as those of the plants.

"This is what would be called to-day promiscuousness, or anarchy; but in such a consonant state of society it would be as the harmony of the spheres. To the believer in free love, this anarchy, these wild and instinctive vagaries of humanity seeking the true laws of love, are but means to the great end of nature.

'All discord, harmony misunderstood;
All partial evil universal good.'

The world is to be regenerated, and the human race brought to perfection in America:—

"Never before in the history of the race has there been such an awakening of woman to a sense of her rights and duties, and the broadest field opening for their exercise, as now in this country. It would seem like one of those strange histo-

rical analogies, or cyclic recurrence of similar phenomena, which so startle the student of history, as revealing the periodicity of the laws of evolution; as if the free-loving, æsthetic, tasteful, sensuous, and nature-adoring life of ancient Greece of the age of Aspasia were to be renewed in this country with the modification of American civilisation. How free the Greeks were in their love is expressed in their worship. Indeed, all religious worship is love, ultimating in veneration. All antique myths are founded, in all their recitals of the life of the gods and goddesses, upon free love—upon the most thorough abandonment to its two principles, freedom and love. Venus, the goddess of universal love, and the patroness of perfect freedom in the relations of the sexes, was adored, under various names, in all mythologies; and her son Cupid, the inspirer of love, was called 'the god of gods.'

"Free love, as a philosophy, science, art, and rule of life, will be the practice of this perfected race, as it will have been the means of their development.

"Marriage, or matrimony—making one woman the sole mother of one man's children (the meaning of the last term, as its etymology indicates)—is the pettiest of the methods adopted by the artistic energy of nature in the admixture of these types of mankind, now for the first time brought altogether in this cosmopolitan civilisation of America.

"The soldier, sailor, and traveller are as naturally free lovers as they are free thinkers. Prejudices are bred in the bounded horizon of narrow localities, and roughly dissipated by the knowledge and sight of the world."

Of course when no child has any father in particular, it will be vain to expect one to support it:—

"The State now provides for the education of children. The next step must be that it will take upon itself the control and support of them.

"Mothers and fathers must learn to love other people's children as well as they love their own."

The respect paid to marriage is all hypocrisy. Women "who sell the joys of their body for money" are called prostitutes; but it is very unjust to call these public benefactresses by a name of reproach. Is a prostitute who sells the joys of her body worse than a lawyer, doctor, or parson, who sell the use of their tongues or brains? The term "prostitution, as applied to free sexual intercourse, is a prostitution or perversion of its etymological meaning. . . The *social evil* is a social necessity growing out of the imperfection of our social conditions." In few words, would anyone abolish sexual crime, as fornication, adultery, abortion, and child murder,—the thing is easy: abolish all laws and customs which restrict sexual indulgence, and then there can no more be adultery than there can be theft where there is no property.

"A true free lover will bind none, would hold none, except as the other is willing to be held and bound. The most passionate lovers, after the wild enjoyment of fruition has endured for a certain period, cease to physically allure each other. A constant interchange of magnetism exhausts, by a physical law, the conditions of attraction, which are then instinctively sought elsewhere. A true free lover, instead of deploring this physiological fact, submits to and acknowledges the philosophy of circumstances, and seeks to discover the cause of this magnetic repulsion.

"Had Fisk and Mansfield been free lovers, they would have both been spared the tragedy and anguish that have been theirs. The beautiful Josie would have acknowledged the freedom of her lover to devote his attention and passion to another, as she had acknowledged his freedom to devote it to her, or as she claimed and exercised a like freedom for herself."

We have thus developed the hideous ulcer which these American women desire to establish in the body social. The Americans, as a civilised people, despise and abhor them; but it is well to remember that they are but outcrops of the great Red Republican or Socialistic, Democratic, and Secularist conspiracy. The Americans wonder that we in England, who see the serpent fully developed there, are so willing as some of us seem to be to toy with the Woman's Rights people—Republicans, Internationals, and Secularists—who are trying to hatch some of the serpent's eggs here. It is one characteristic of these people, that whilst they have no more faith in Medicine than in Religion, they regard Spiritualism and its kindred quackeries with the most abject devotion.

THE WEEK.

TOPICS OF THE DAY.

Sanitas sanitatum, sanitas omnia, is an admirable cry, but it is neither a Conservative nor a Liberal sentiment, to judge by the cold reception which the Public Health Bill received when it came up for second reading. Dr. Lyon Playfair twitted the Conservative party with their indifference to the adopted watchword of their leader; but in truth, neither side of the House showed much interest in the health of the nation. The Bill was read a second time, but it will have a good deal of criticism in committee. Two deputations have made a visitation on Mr. Stansfeld respecting it—one of the body of philosophers who issue from the Social Science Association, and who dwelt chiefly on the theoretical and administrative features of the Bill. The objection to Dr. Rumsey's schemes is that they are too elaborate, exclusive, expensive, and technical to be accepted by a practical country. As studies of that theoretical perfection which philosophers desire they are perfect; and it is something to have a high standard set up, though it may be unattainable. The other deputation (of Medical Officers of Health) avoided all theoretical questions, and seemed animated with the desire to push through what promises to be a very valuable Bill.

We do not think the statement of Mr. Cardwell with regard to the Militia Medical Officers will be at all satisfactory to those gentlemen. He cuts off the duties which have produced the principal part of their income, and holds out but a very faint hope of granting them any compensation. It is a matter on which the Medical members in the House of Commons should exercise their vigilance.

Lord Abinger's meeting of governors at the Royal Orthopædic Hospital was held on Tuesday, and resulted in a very small majority in favour of the Committee whose report led to the resignation of Messrs. Adams and Tamplin. The Assistant-Surgeon, Mr. B. Brodhurst, who through this resignation has acquired the position of Senior Surgeon to the Hospital, defended himself, whilst—as will be seen from a letter we publish elsewhere—he does not contradict the chief statements made in Lord Abinger's letter. To our limited capacities the share he seems to have taken in the proceedings which have led to these changes in the staff is utterly incomprehensible. We certainly think it a matter which ought not to be left unsifted by the bodies at the head of the Medical Profession.

The trial of William Chester Minor, the American Surgeon who killed George Merritt at Lambeth, has resulted, as was predicted, in a verdict of "Not guilty" on the ground of insanity, and he is ordered to be detained in safe custody during her Majesty's pleasure. The evidence of insanity in this case was very clear. Mr. Minor had been already in a lunatic asylum, and whilst in gaol on the present charge had given ample proof of unsoundness of mind.

PROFESSOR STOKES'S DISCOURSE ON PUBLIC HEALTH.

It is needless to call the attention of our readers to any production of the Dublin Regius Professor of Physic, yet we may give ourselves the pleasure of pointing out how in some controverted matters his opinions are the same as those which our own columns have advocated. We would especially invite our brethren of the Poor-Law Medical Service (or, as we should be glad to call them, the Local Public Physicians and Surgeons) to weigh well what Dr. Stokes says of their employment as Medical Officers of Health. We would also ask our readers to compare his views of the natural history of epidemics with those of Dr. Macpherson, and to note that those distinguished Physicians, whilst not neglecting one item of what is commonly called sanitary work, nor yielding to the inaction of despair, are yet far from countenancing the tone of easy exultation with which some ill-instructed sanitarians speak of stamping

out epidemics. "How many great epidemics," says Dr. Stokes, "have died out, ere sanitary reform was thought of."

THE STUDENTS' ROW IN PARIS.

OUR Paris correspondent says that the Minister of Public Instruction is determined to put an end to the periodical riots which disgrace the Medical School at Paris. For the present, the great iron gates remain grimly closed against the whole body of students, with a written notice affixed, dated April 8, telling MM. les Étudiants that no decision has yet been come to respecting the resumption of the lectures. The tumult began with an accusation against the Surgical Professor Dolbeau, that he had betrayed a Communist patient to the Versailles troops to be shot. This accusation is quoted from the *Révue Scientifique* in another column, but our correspondent assures us that the man is alive and at liberty, and grateful to M. Dolbeau. The official inquiry into this matter was undertaken entirely at the instance of the Professor.

A GOOD EXAMPLE.

THE cry against the penal clause of the Vaccination Act has been raised in many quarters with a vehemence and consistency which may possibly be detrimental to the cause of vaccination. Petitions have been presented to both Houses of Parliament against this clause, and every means have been taken to have it modified or rejected. We are glad to notice, therefore, that the Manchester Board of Guardians last week decided to petition Parliament against the clauses in the new Vaccination Bill to the effect that no parent shall be liable to be convicted for neglecting to have his child vaccinated if he has been previously adjudged to pay the full penalty of 20s., or has been twice previously adjudged to pay any penalty, and in favour of the law being left in its present state.

A MITE FOR NAVAL ASSISTANT-SURGEONS.

THE Admiralty are trying how a little courtesy may affect candidates for the office of Assistant-Surgeon in the Navy. The "boon" is almost too small to acknowledge; but, like a straw, it shows the "way of the wind." It has been decided by the authorities that in future Assistant-Surgeons of the Royal Navy shall not be compelled to pass their qualifying examinations at Somerset House, but shall be examined on the station where they may be serving when they have complied with the regulations.

UNION MEDICAL OFFICERS.

WITH a view of obtaining the "best possible Medical attendance" for the paupers of the Union, the Bromyard Board of Guardians seem desirous of appointing a Medical Officer to that Union who will devote the whole of his time to the fulfilment of the duties of that office. At all events, they have applied to the Poor-law Board for a return showing how many unions in England adopt the system they contemplate adopting. We should anticipate the number of such unions might be almost counted on the fingers.

ACCIDENT TO A SURGEON.

THE *Indian Mail* of this week records a sad accident which occurred on board the flagship of the flying squadron when running from Rio de Janeiro to the Cape of Good Hope. Whilst the *Narcissus* was contending with a heavy gale, Dr. Jack, the Staff Surgeon, was ascending the ladder from the lower deck, and, falling back, fractured his right arm, and was otherwise so much injured that he was compelled to invalid.

TESTIMONIAL TO A SURGEON.

A MOST gratifying ceremonial took place last week at Carnaveron Alford, Aberdeenshire, when Mr. James Walker, Surgeon of that place, was presented by his neighbours and

friends with a massive gold watch and chain, "in appreciation of his sterling worth and integrity as a Medical Practitioner for a period extending over fifty-two years." Mrs. Walker at the same time was presented with an elegant silver tea-service as a "small token of respect and esteem."

SMALL-POX JOTTINGS.

THE favourable reports we have lately given of the small-pox epidemic at Aberdeen continue. Last week there were only eighteen patients in the Hospital, and out of a total of 153 patients received into it, 110 have been discharged cured, and only twenty-five deaths.—During the past week one fresh case of small-pox was reported in Islington, as against two in the week before. There had been two deaths from the disease.—In Poplar during the past fortnight there had been twelve deaths from small-pox registered in the Union, and thirty-nine new cases had been brought under notice. During the same period seventy-seven persons were vaccinated at the public stations. There were twelve small-pox patients under treatment in the North-street Infirmary.—Considerable progress has been made with the subscription for providing a convalescent home for small-pox patients in Dublin, as a necessary means for checking the progress of the disease. At a meeting last week, presided over by the Lord Mayor, £500 was subscribed in the room.—In the Holborn district, in the past three weeks, three deaths occurred from small-pox; and after an interval of a month without there being any case of small-pox, there has been a sudden outbreak of the disease. Seven fresh cases are reported; the sufferers had all been vaccinated, and were all adults in age.—The deaths last week in the metropolis from small-pox, which in the three previous weeks had been 42, 48, and 55, further rose last week to 65, and exceeded the average by 23.—Dr. Aldis, St. George's, Hanover-square, reports in the week ending the 6th instant, four cases of small-pox, three of which were sent to the Hospital.

SMALL-POX IN DUBLIN.—DEPUTATION FROM THE CITIZENS TO THE CORPORATION.

ON Monday last an influential and representative deputation waited upon the Municipal Council of Dublin for the purpose of urging the necessity for the establishment of a Convalescent Hospital for small-pox patients and such other persons as were recovering from acute and contagious diseases. Under the Sanitary Act, the Corporation of Dublin possesses power to levy rates for the maintenance of such a Hospital. Sir Dominic Corrigan, Bart., who was one of the deputation, raised a legal point, believing that, according to the Acts of 1855 and 1866, the Poor-law Guardians were the proper and only authorities who could deal with the matter. The Vice-Chancellor of Ireland and the Right Hon. Abraham Brewster, Ex-Lord Chancellor, took exception to Sir D. Corrigan's view of the case. The Archbishop of Dublin, who headed the deputation, thanked the Lord Mayor for the courteous reception accorded to the members of it, and entrusted the subject to the further consideration of the Corporation.

SMALL-POX.—MEETING AT THE MANSION HOUSE, DUBLIN.

PURSUANT to requisition, a numerous and most influential meeting of the citizens of Dublin was held on Friday week, for the purpose of considering what steps should be taken in the endeavour to stem the progress of the prevailing epidemic of small-pox, and for the relief of those who chiefly suffer from its effects. The first resolution, recommending that a convalescent home should be established without any further delay, was moved by the Archbishop of Dublin and seconded by Sir James Power, Bart. The Rev. Canon Farrell, P.P., proposed that a deputation from the meeting should be permitted to attend the next meeting of the Municipal Council, with the view of urging the necessity of promptly

establishing a Hospital for patients discharged from the ordinary Hospitals, or not perfectly convalescent. Under the Sanitary Act, as remarked by Sir John Gray, M.P., who seconded the motion, the Corporation had the power of constructing such a Hospital and of levying rates for its maintenance. The Vice-Chancellor of Ireland moved—that as the epidemic had been the cause of extraordinary distress and poverty, the formation of a relief fund was an urgent necessity. He was seconded by Mr. James Stirling, an extensive employer of labourers. A committee was then appointed to control the administration of the relief fund, and on it were placed the names of clergymen of various denominations, Medical men, and Poor-Law Medical Officers, with barristers and merchants. The last resolution, which was entrusted to two representatives of the Medical Profession—Drs. Evory Kennedy and William Moore—was to the effect that the establishment of a sanitarium, to which the inhabitants of infected dwellings might be removed for a time, during the process of disinfection, was desirable; and that it was expedient to put in force the provisions of the Diseases Prevention Act, 18 and 19 Vic. A subscription-list was opened, and a sum of over 700*l.* was subscribed before the meeting separated.

VACCINATION IN JERSEY.

JERSEY is still recalcitrant with respect to vaccination, notwithstanding the prevalence of small-pox in various parts of the island. We learn from the Jersey papers that Dr. Low, the indefatigable and able advocate of vaccination, brought his Bill, last week, before the Jersey "States." This Bill seeks to make vaccination compulsory, providing for the vaccination of all children at the age of 6 months, and for their revaccination at the age of 10 years. The measure, as was expected, met with great opposition, and the debate upon it was adjourned. The small-pox, therefore, continues unopposed.

A NEW WAY OF CHOOSING YOUR DOCTOR.

OUR Irish friends are original in many respects—they have a half-humorous, half-savage way of doing some things. To wit: A few days ago a gentleman named Middleton, residing near Mullingar, received a letter, intended, as it appeared, for his son, who is a Medical Practitioner, and threatening his life if he should attend the Milltown Dispensary, because "they"—the persons represented by the writer of the letter—preferred a certain Dr. Hornidge.

FROM ABROAD.—OPERATIONS IN PUERPERAL WOMEN—HYPODERMIC INJECTIONS IN SYPHILIS—INTRAMUSCULAR INJECTIONS IN TETANUS.

THE question of the performance of operations in pregnant and puerperal women has of late been several times before the Paris Société de Chirurgie (*Gazette des Hôpitaux*, Nos. 32, 33, 35, and 36), and the following are the opinions expressed by the various speakers:—

The discussion originated on the presentation by M. Tarnier of a fibro-plastic tumour of the vulva, weighing 470 grammes, which he had removed after delivery as soon as the lochia had disappeared. This tumour had rapidly increased during pregnancy until it attained the size of a foetal head. After delivery (which was easy) it diminished by one-half. M. Tarnier regarded the case as an exemplification of the propriety of the rule of not removing tumours or vegetations of the vulva until after delivery. Such tumours during pregnancy acquire a hypertrophy which will be followed by a degree of atrophy; while in the case of vegetations, there is the danger of causing hæmorrhage or abortion. M. Depaul considered this last caution as somewhat exaggerated, having operated in such cases without inducing abortion. As, however, there may be considerable hæmorrhage, he does not remove all the vegetations at once. He remembered one remarkable case, in which the vegetations, forming a "bouquet" the size of an

adult head, were removed by two operations under chloroform. There was considerable hæmorrhage, which was arrested by chloride of zinc caustic. The woman, who was five months in pregnancy, went her full time without accident. M. Chassaing was of opinion that no absolute rule can be laid down in these cases. He has removed the vegetations in pregnancy by means of the *écraseur*, for they sometimes constitute a serious disease, owing to the excoriations, discharge, and horrible fetor. As a general rule, however, he avoids operations during pregnancy. Abscess of the vulva should be opened by a small aperture (the trocar being the best instrument) on account of hæmorrhage, which, however, is usually easily controlled by hæmostatics. M. Blot also thinks that we cannot absolutely proscribe operations during pregnancy. If vegetations cause great inconvenience, we should try the effects of tannin or other astringents. Where the indication is not pressing they should not be removed for fear of hæmorrhage; and when this is a necessity, *écrasement* is to be preferred. M. Depaul, in accordance with Dubois and other authorities, as a general rule would discountenance operations during pregnancy, but a troublesome tumour may require removal. Vegetations should not usually be removed, for after delivery they may atrophy, while during pregnancy they may be kept under by astringents.

M. Verneuil, in reference to the question of how long a period ought to elapse before operating after delivery, observed that he thought this should be at least two months. The cases in which he has operated after six weeks only have failed; and it is well known that when operations for vesico-vaginal fistula fail, they cannot be repeated under three months. He disapproves of operating during pregnancy in any but urgent cases, and referred to examples in which abortion was the result. M. Trélat remarked that no absolute rule can be laid down as to not operating during pregnancy, and he believes that from three to six months should elapse before undertaking operations after delivery. Some of the instances of abortion produced through operations cited by M. Verneuil might really have arisen from the affections calling for interference. M. Guéniot observed that, while a narrow wound might give rise to abortion, one of larger dimensions would allow pregnancy to go on. As to operations after delivery, the time for these would depend upon the return of the parts concerned to their normal condition and the re-establishment of their functions. M. Desprès stated the results of his experience at the Lourcine. In six women, from 17 to 20 years of age, and from three to seven months advanced in their first pregnancies, he removed enormous masses of vegetations, and in none of them did abortion ensue. Moreover, the speculum is employed in pregnant women, and in them vaginitis is always treated at the Lourcine with alum plugs without abortion being induced. M. Boinet was of opinion that urgent operations should not be too long delayed after delivery. Thus, in rupture of the perineum, he has practised sutures immediately with good results, the sojourn of the lochia in the wound being thus prevented. M. Tarnier had in such a case operated on the forty-fifth day after delivery, thus waiting until the lochia had disappeared. As, according to Wieland, there are still remains of uterine hypertrophy after the first menstruation, it would seem best to delay operations until after the second period. In reference to M. Desprès' statement of the innocuity of the alum plugs at the Lourcine, he observed that these were very different to the plugs employed by the accoucheur for the purpose of producing abortion. M. Blot objects to hasty operations for ruptures of the perineum. These may only involve the skin, or the deeper parts as well. In the former nothing should be done, for they will cicatrise spontaneously; and when the rupture is extensive sutures will not suffice. Three or four menstrual epochs, or even more, should pass before interfering; and by that time the size of the aperture will be found much reduced, and in some cases even to have spontaneously healed or have become capable of treatment by

cauterisation. The operation should be delayed as long as there seems any disposition to contract. M. Demarquay observed that it is not surprising that operations should lead to abortion, for even in non-pregnant women it is common to find them causing the appearance of menstruation before the period. He has frequently removed vegetations, operating at several times, and employing the actual cautery. He has never met with abortion in these cases. Some operations should not be delayed long after delivery. Thus, suture of the perineum should be at once performed, as it is neither difficult nor painful, and may be executed without the patient being aware that anything more than a dressing had been applied. He operates at the end of forty-eight hours, passing only one suture, and is usually successful, there being a great tendency to union at first. If this suture fail, a second may be applied—still without the knowledge of the patient, whom it is desirable not to alarm by the fear of an operation. Notwithstanding the opinions of MM. Desprès and Demarquay, M. Tarnier persists in believing that vegetations should not be removed in pregnant women, and the cauterisation of the wounds they recommend shows that they believe serious accidents have to be guarded against. The vegetations, too, may reappear after operation, and when they occupy the vagina as well as the vulva they cannot all be removed. On the other hand, we can very well assuage the suffering they cause by desiccatives, and so tide on until after delivery. M. Tarnier cannot understand how a suture can be applied to the perineum without the patient being aware of it, for she has to be placed in position for the purpose, while in some cases a long time is required for the procedure. M. Demarquay stated that with Blandin's curved needle the operation can be easily performed while placed at the side of the patient. M. Blot observed that one of the cases adduced by M. Demarquay was not an example of true rupture of the perineum, but of a kind of division made by the forceps during delivery. In such a case sutures might succeed; but in true rupture there are contusion and even partial gangrene, which prevent any immediate union. If success is to follow, the edges of the wound must be vivified. Lacerations occurring after rapid labour are alone capable of uniting. M. Guyon stated that in cases in which the rupture was not very extensive he had successfully employed small *serres-fines*, according to the method of Danyou.

The following is the summary (*Boston Journal*, February 22) of the results of the treatment of syphilis by hypodermic injection of the bichloride of mercury derived from extensive trials made by Dr. R. W. Taylor, of New York:—1. Though a method possessing certain advantages, it is, for various reasons, but of limited application. 2. It is useful in the whole period of secondary syphilis, in roseola, in the various papular syphilides, and in that form of pustular syphilide in which there is only a slight tendency to the formation of pus. 3. It very rapidly cures all syphilitic neuroses, and is very beneficial in the cachexia of syphilis, whether accompanied or not with perceptible lesion. 4. It possesses no advantage over other modes of administering mercury in the treatment of mucous patches and condylomata lata. In the syphilitic lesions of the nervous system and of bone, particularly if late, its use is not to be commended. 5. The very early tertiary syphilitic lesions, provided that they are not of an ulcerative character, may be very much benefited by it; and the simultaneous use of iodide of potassium internally may produce a more rapid cure than when given with mercury internally. 6. The peculiar advantages of the method consist in the smallness of the amount of mercury used, the rapidity of action, and the absence of systemic disturbance. 7. A very minute quantity of mercury, averaging from two to three grains, thus administered may cause the disappearance of very extensive syphilitic lesions and the alleviation of very severe symptoms. 8. In the greater number of cases, an injection every second day of one

eighth of a grain of the bichloride will produce a cure in rather less than two months. In very urgent cases the injections may be pushed to the extent of one or two daily with good effects. 9. Rapidity of cure is the rule rather than the exception, and the time required may be stated as varying between three weeks and two months. 10. When the injections are used only every second day it is very rare to observe any unpleasant systemic effects; and even when they are pushed farther than this their effects are never so severe as when mercury is pushed to a similar extent by the mouth. 11. Relapses are as frequent, as rapid, and as severe as when mercury is given in other ways. 12. There are unpleasant local effects, such as pain of the punctures and over the site of the injection, induration of the connective tissues, and abscesses. In many cases the pain is slight and transitory, but in others it is so severe as to compel a discontinuance of treatment; and in all cases there are some slightly unpleasant local effects. 13. In exceptional cases a low grade of inflammation in the subcutaneous connective tissue produces a decided induration in deep portions of the derma, rendering it advisable to discontinue the injections. In many cases, however, the induration is only of an ephemeral character. 14. If proper care be taken in administering the injections, abscess will rarely, if ever, occur. 15. It is absolutely necessary that the patient should be both intelligent and thoroughly impressed with the gravity of the disease, in order that he may comprehend the advantages to be derived from this method; otherwise he would not subject himself to the inconveniences attendant upon it. 16. While in Dispensary or Hospital practice the injections may be frequently given, the smallness of a patient's means may often be an obstacle in the way of the continuance of the treatment in private practice. 17. While in some cases this method may be useful by means of its rapid action, and in others for the smallness of the dose, the inconveniences which it produces, the objections of patients, and the presence of lesions which contraindicate its use confine its sphere of usefulness to very narrow limits.

We have already made known to our readers (*Medical Times and Gazette*, October 7, p. 499) the results obtained by M. Demarquay from the employment of intra-muscular injections of a solution of morphia in traumatic tetanus, and we now learn from the *Gazette des Hôpitaux* (March 30) that he has made further trials of this means. The constant failure of all medicines administered by the stomach in the very numerous cases that came under his care during the siege led him to adopt the intramuscular method. He had also his attention strongly drawn to the fact that tetanic subjects are very susceptible of cold, so that under the influence of cool air the contractions were often rendered more intense and more painful. These contractions and the trismus, indeed, especially call for attention, by reason that they may give rise to death from painful exhaustion, and that they impede nutrition. As it is not yet known whether traumatic tetanus is dependent upon a lesion of the nervous system, it is incumbent upon the Surgeon to attack the contraction as a symptom. To this end, the patient should be placed in a spacious chamber, which is kept at a temperature of from 64° to 72° F., and an injection of from twenty to twenty-five drops (muriate of morphia 1, water 50 parts) should be thrown into the interior of the masseter muscle, as near as possible to where the nerve which supplies it emerges. Some minutes after the pain and contraction cease, and the patient is enabled to swallow broths or to assuage his distressing thirst. To the two cases of traumatic tetanus which M. Demarquay has already reported as cured by this means he now adds one of chronic tetanus:—

This patient, from the country, aged 35, was admitted into the Maison de Santé on February 21. On January 13 he had fallen from a vehicle, and had received some slight wounds of the leg. Soon after taking cold on the 21st, he exhibited tetanic symptoms, so that, according to his own account, he had not been able to separate his teeth for a fortnight, and suffered

severe tetanic pains in the limbs and base of the chest, these being accompanied by utter sleeplessness. On his admission he was found suffering from cramp in the limbs, the recti muscles were rigid and projecting, and the jaws could only be separated by 1½ centimetre. He was at once placed in the warm chamber, and an injection was made into each masseter, warm drinks being also ordered. On the following days injections were made into the recti muscles, the limbs, back, and in fact wherever the painful contractions manifested themselves. In from two to five minutes afterwards, first the pain and then the contractions ceased—the group of muscles to which the injected one belonged remaining from half an hour to five or six hours without a re-appearance of contraction. They produced an abundant sudation and stimulation of the skin. The patient's sleep and power of digestion also were restored. From eight to ten injections of 1½ centigramme of the mixture were made in the twenty-four hours, and no suppuration was produced in the substance of the injected muscles. On March 1 the patient was able to be up, and continued to do well, with the exception of some slight relapses, always brought on by chills. He left the Maison on the 17th.

It may be objected that cases of chronic tetanus are usually cured; but however this may be, these three cases prove that intramuscular injections have the power of subduing not only the pain, but the contractions, and that by relieving the trismus they allow of the patient being supported. It is evident also that it is of great importance to have at our disposition a means which even temporarily relieves contraction of the masticatory and respiratory muscles. The maintenance of a constant elevation of temperature and injection of morphia subdue the two elements, cold and pain, which bring into play the excito-motric action of the spinal cord, upon which the tetanus depends.

PARLIAMENTARY.—MILITIA SURGEONS—THE PUBLIC HEALTH BILL—
THE CONTAGIOUS DISEASES ACT.

In the House of Commons, on Friday, April 5,

Sir E. Lacon asked the Secretary of State for War as under the new regulations Militia Surgeons were not allowed to examine recruits, give Medical attendance to the permanent staff, or to attend preliminary drill of the recruits, from which sources the principal part of their pay had hitherto been derived, and as many had partially or wholly abandoned private practice to enable them to perform their Militia duties, in what way he proposed to remunerate them.

Mr. Cardwell: It is, I hope, to be expected that a considerable saving will be expected in this respect, as in some cases at least the expenditure has been larger than can be justified. I am not prepared at present to give any undertaking with respect to compensation, beyond saying that if any claims be put forward they will be properly considered.

On the second reading of the Public Health Bill being moved, Mr. J. Fielden, who had given notice of his intention to move its rejection, intimated that he should reserve his opposition for committee. At the same time he criticised various portions of it, objecting to its tendency to over-centralisation, and to the clauses relating to the pollution of rivers and the disposal of sewage, which, he believed, it would be impossible to carry out.

Dr. Playfair gave a warm support to the general principles of the Bill, and offered some suggestions for the improvement of its details, especially insisting on the expediency of enlarging the areas, and raising the qualifications for the Health Officers as high as possible. Ventilation and cleanliness were the two chief objects, and if these were secured the Act would not have been passed in vain.

Sir H. Selwyn-Ibbetson, while generally supporting, demurred to the local authorities proposed for the rural districts, thinking that the boards of guardians were already overworked.

The discussion was continued for some time in the same vein of desultory criticism of the clauses by Mr. Whitwell, who deprecated striving after too high a standard in regard to the pollution of rivers, and by Mr. Dimsdale, who canvassed the measure under three heads—the improvement of labourers' cottages, the pollution of rivers, and the rural boards. Mr. Muntz, Dr. Lush, and Mr. Corrance urged almost identical objections to selecting boards of guardians; and

Sir C. B. Adderley replied to these objections, pointing out that to create new bodies would have taken time, while the subject would not wait; and that by taking advantage of these bodies and their staffs there would be a considerable saving. Sir Charles, while repeating his regret that consolidation had been postponed, eulogised the Bill, which would complete and give vitality to our present system, and asserted that it would not cost the ratepayers a shilling which would not be remunerative.

Sir T. Acland also approved the selection of the boards of guardians, but at the same time urged the importance of improving the local boards.

Mr. Hardy, though conscious of the defects of the boards of guardians, did not object, under the circumstances, to make them the local authorities, but insisted on an independent inspecting authority. Moreover, as the present authorities failed in their duty chiefly through ignorance of their powers, he suggested that a digest of the present law should be drawn up and circulated among them.

Mr. W. H. Smith complained that some of the most important clauses did not apply to the metropolis.

Mr. Stansfeld, in replying, explained at length his motives for choosing the union as an area and the guardians as the local authority, and defended the clauses relating to the pollution of rivers. With regard to the Medical Officers, Mr. Stansfeld said it was his intention that the Act should be started with a competent staff, and he meant to propose a vote to Parliament for the purpose. As to Mr. Hardy's suggestion for a digest of sanitary law, he stated that he had one already in hand.

The Bill was then read a second time, as also was Sir C. Adderley's Public Health and Local Government Bill.

On Monday, in answer to Sir J. Trelawny, who indulged in some severe reflections on the Government for abdicating its responsibility in the matter, Mr. Bruce promised that ample notice should be given of the second reading of the Bill repealing the Contagious Diseases Act, in order that Sir J. Trelawny might have ample opportunity of moving his contemplated "call of the House."

ON STATE MEDICINE.

A DISCOURSE DELIVERED BEFORE THE UNIVERSITY OF DUBLIN,
ON SATURDAY, APRIL 6, 1872,

By WILLIAM STOKES, M.D., F.R.S.,
Regius Professor, etc.

AFTER an eloquent exordium, in which the nature, importance, and branches of State Medicine are described, and a sketch given of the Report of the Royal Sanitary Commissioners, of whom Dr. Stokes was one, and of recent efforts at legislation down to Mr. Stansfeld's Bill at present before Parliament, the distinguished Professor continues:—

The proposal to employ the Poor-law Medical Officers as Officers of Health has been objected to by some able writers on two grounds principally—one, that the education of these gentlemen has not been sufficient to enable them to deal with questions of State Medicine; and the other, that from their too often dependent position in relation to members of local boards, they will be crippled as to their action for the public good. This last objection would, I believe, apply far less to Ireland than to England.

But granting that they have some foundation, what is the proper way of meeting them?

It may be admitted that in many rural districts the education of the Dispensary Medical Officer, sufficient to qualify him for being placed on the Register, is often so completely technical that he cannot do more than deal with curative Medicine as he best may. Should such a man be called to report on questions of State Medicine, he will probably be found, at first at least, defective. But necessity is a great instructor, and it is in the nature of things that he will every year improve. Self-education can do wonders. He will be assisted by skilled inspectors, and his good sense, probity, and honourable ambition will do the rest.

With respect to the second objection, if it be true, so much the worse for all parties. But there are better times coming. The Dispensary Surgeon will be placed in a higher and more secure position, from having to perform duties which are related, not to his district solely, but to the public weal. He will be in communication with the Minister, as it

were *inter instrumenta regni*—not like the Roman prisoner of old, for purposes of evil, but for those of good—and cannot be displaced without his sanction. Therefore he will in time be treated with greater consideration, and the country will come to perceive that professional honour implies public safety.

It is clear that similar Commissions with a view to sanitary legislation should be issued for Ireland and Scotland; for if ever there was a case demanding similar legislation for the three countries it is that of public health. The machinery of the law may require to be varied in the three kingdoms as regards local authorities and areas of taxation, but sanitary science is the same for all men. In this respect England is far in advance of us, both as to the knowledge and as to the practical application of the laws of public health. In Ireland, the habits of the poor as to uncleanness and overcrowding call for great reform, especially in our towns, where poverty, neglect, and overcrowding so often make them foci of epidemical disease. The condition of our country towns and villages is simply deplorable, disgraceful to the local authorities, and, in too many instances, to the proprietary, frequently heedless as to the social and physical condition of those who live under them. Even the state of the metropolis, possessing a Public Health Committee, is shocking, as has been ably shown by Dr. Grimshaw in a recent communication. Let me read some extracts of a letter from a gentleman of great ability and truthfulness, who holds an important public appointment in the South of Ireland. He had been requested by the Town Commissioners of a certain place in that part of the country to inspect the state of the town, and report on the works necessary for sewage improvement.

It was about the year 1865, when there was some apprehension of an epidemic of cholera:—

"I went," says this gentleman, "through every lane and street, and examined all the tenements of every class in the latter end of January or beginning of February. There were no main sewers in any but the principal streets, and none of these had them for their whole length. The lanes and alleys leading off from these streets were mostly very narrow, and had no outfalls for sewerage discharge except surface channels, and very few of the houses had any back entrance; a good many had neither yards nor back entrances. But all had dung-pits. If not behind, they were contrived in the widest parts of the lanes by being sunk and enclosed with walls, so as to hold from eight to twelve cubic yards of manure each. Where the tenement had not the 'easement' of a dung-pit or yard, or right to part of the common way, the manure was stored in the dwelling-house. Most of the houses were thatched cabins, but several rows of two-storied houses were built, and a good many one-storied slated houses of small size were to be found containing four apartments. I discovered in one of these rows, which had very small back yards (not half the size of the house in any case), that the whole of the ground-floor and part of the house, except the staircase and passage leading to it, were filled with manure (the scrapings of the roads and streets) tightly packed to the height of eight feet; and in the rooms above there were two families living—one in each room. The manure had of course heated, and was steaming up through the chinks of a badly laid floor, the under side of which was dripping wet from the fermentation below. In several of the rows having back yards the surface water was allowed to run through the whole length of the lane from yard to yard, and the occupier of the lowest tenement was looked upon as having the most valuable holding of the whole lot, and something like the Chinese care of liquid manure was shown by extra mould or refuse being provided to absorb or soak it up. The parts of the town to which this description may apply covered about twenty-five acres, and almost every part of that surface was teeming with effluvia from such decayed substances of every sort as are admitted to be of the most noxious kind, without any provision whatever for carrying off the putrid water which is always to be seen in so wet a climate as this. The population is about 6000, of which two-thirds live in cabins furnished with the inevitable dung-pit. These cabins contain 700 families at the least. The dung-pit averages ten cubic yards in capacity; so that on twenty-five acres we have at least 7000 cubic yards of fetid matter, with 4000 people breathing the exhalation of such an accumulation as could not, I think, be found elsewhere even in Ireland. But nevertheless the town of Killarney has always been a remarkably healthy place. There is a Fever Hospital which has not been full since the famine dysentery in 1847-48, and which is very frequently empty. There is no dislike on the part of the poor to go into this Hospital, because it is not the workhouse, so that the few fever cases that do occur are quickly removed out of the crowded houses

It was asked—“How can such a state of things be? or, how can it be accounted for that such good public health can exist amidst all this rottenness giving rise to the miasmata so well-known as certain producers of fever and cholera?” I suggested that there were two great advantages in favour of health—namely, an ample supply of the very best water, and smoky houses. The subsoil of the town is gravel and sand to a great depth, and in this there are many strong springs, the purest water being met with at six or eight feet under the surface. The fuel used is all turf, and the blackened walls of the inside of the houses showed that the inhabitants lived in an atmosphere of peat smoke. I cannot help thinking that such smoke, possessing as we know preserving or antiseptic properties, must act as a deodoriser and preventive against infection or malaria. I asked one of the occupiers who lived over his dung-heap in an upper floor how he could expect to escape death by fever or cholera to himself or some of his family (a wife and five children), and his reply was, ‘Sure we might as well be dead as never to have a bit of dung for the garden.’ Some legislator has said that ‘Ireland is an anomaly’; maybe the sanitary statistics of this town are another proof of this.”

The inhabitants of this place escaped the epidemic so common in other towns of the South of Ireland, perhaps because, in addition to the pure water and turf smoke, an intimacy with malaria for many generations had at last made them insusceptible to it.

The influences of impure air and water, imperfect drainage, and overcrowding have been held by sanitarians to account for the origination of epidemical or endemical disease. The subsidence of any such disease after the adoption of sanitary reform is appealed to in evidence that it sprung from preventable causes. But the argument is defective. It is like that of the therapist as regards essential diseases, which run their appointed course, and then subside independently of any specific treatment. Like isolated cases of fever, epidemics have their period of invasion, maturity, and decadence; and the conclusion is obvious how many great epidemics over the world have died out before sanitary reform was ever thought of.

There is in many minds a tendency to attribute great phenomena to too limited a source.

“The supposition of a single cause,” says a learned writer, “is quite unsupported by nature. Every animal, every plant, every rock requires for its production the co-operation of many causes, and probably of many that we have not yet discovered. All nature depends ultimately on a single cause, but it has pleased that Almighty Cause that the effects which concern us immediately should arise from the co-operation of several of His creatures.”

But the question before us is—Are such influences as I have mentioned the sole or the chief causes of fever in this country? It is difficult to believe that they are, because in Ireland, not only in the isolated dwellings of the poor, which are scattered over the face of the country, but in the towns also, all those causes which result from the imperfect drainage of dwellings, from the accumulation of decomposing organic matters in their vicinity, and from imperfect ventilation, are, I regret to say, but too constant and too general; and yet the production of fever, whether sporadically or epidemically, is inconstant and irregular in the highest degree. Why should these causes produce fever at one time and not at another? Why should districts remain for years free, or comparatively free from fever, while the supposed exciting causes continue in full force? Or, again, why, if the cause be constant, should the epidemic character of the fever vary? We may say, excluding the consideration of isolated cases, that each epidemic has a special or predominant character.

In the present state of our knowledge, are we to hold that preventable influences are the originators of disease? No doubt civilisation demands that all things injurious to health, or noxious to the senses, should not be permitted to exist. But the question remains whether, leaving the origin of disease undetermined, sanitary reform does not act as much by the improvement of the health of the population as by the lessening or extinction of the exciting causes of zymotic affections. The community being better prepared to resist the advent of disease, its spreading will be influenced and its severity lessened when it does come.

This, I apprehend, is the safe and practical way of looking at sanitary reform. It is fortunate that theoretical questions in no way touch the working out of such reform. Questions as to whether the spread of cholera is influenced by the dryness or the moisture of the air; as to the spontaneous generation of germs; or as to whether, when the sewerage of a town is spread out upon the fields, there may be a struggle for exist-

ence among various organisms, so that the cholera molecules die out—such questions only divert the attention from more important matters. The sanitary reformer is not to wait for the advent of epidemical disease. It is rather when a country is free from such that he can best work in removing or mitigating all those causes which experience shows to act against the health of man.

No one, who has not had a lifelong experience of epidemics, can estimate the difficulties which exist as to their origin, as to the absence of essential fever in places where, theoretically, it ought to prevail. The appearance of epidemics at irregular periods, while their supposed exciting causes remain constant; their disappearance, though the causes continue in full operation; their outbreaks in all latitudes, climates, and seasons; their different modes of spreading; the want of constancy in their symptoms and history (for every great epidemic has its own character); their varieties as to the extent, nature, and effect of the secondary affections which arise in their course; the varieties in their mode of subsidence and behaviour under treatment; their degree of mortality and contagiousness—all these things constitute the difficulties which surround us in our investigations as to zymotic disease. They bear on the supposed specific or constant origin of disease, on the error of drawing hard-and-fast lines between essential affections, and are with difficulty reconcilable with the germ theory.

But still, though differing in history, symptoms, nature, and mortality, these essential affections have their resemblances. They are all under the influence of the law of periodicity. We do not know of any treatment by which they can be cured. No man ever *cured* a fever, be it the yellow fever, plague, cholera, small-pox, or scarlatina. In these diseases it is simply a question of time, and if life can be prolonged by proper support, and by meeting the secondary accidents of the disease, the patient will recover spontaneously—as it were on the striking of a clock.

Again, these diseases are all, to a greater or less extent, contagious—a characteristic of which the best evidence is found by the application of the “doctrine of chances.” In the progress of an epidemic in Ireland (and doubtless, also, in other countries), in a family of twelve persons, the disease has been known to attack eleven out of the twelve. In some cases the passing of the fever through so large a proportion as eleven individuals out of twelve has taken a very considerable period of time, as you may readily understand. It has taken about three months to go through them all. Now, my father proposed these two problems to the then Bishop of Cloyne (Dr. Brinkley) for solution:—

1st. “An epidemic prevails so severely that one person out of seven sickens. A family of twelve is selected in a particular district, before the epidemic has visited it. What is the chance that eleven out of that family shall take the disease, supposing the sickness of one of the family does not promote the sickening of another—that is, supposing the disease not to be contagious, and supposing the family to be not unusually liable to the disease?”

The answer furnished by Dr. Brinkley is, that the probability against such an event is 189,600,000 to 1. This is a very singular and extraordinary result.

2nd. “The same general conditions being assumed, and also that the number of inhabitants of a district is 7000, what is the chance that, in a family of twelve within the district eleven will sicken?”

Answer: “The chance then is 300,000 to 1 that no family of twelve persons, in a population of 7000, will have eleven persons sick.”

These numbers furnish proofs so convincing of the truth of the doctrine of contagion, that it is hardly necessary to go further. The facts on which they were based are ascertained facts; they have been common facts in epidemic fever; but, recollecting that they were common facts, the chances against their happening, if the disease were not contagious, would be 189,600,000 to 1 in the one case, and 300,000 to 1 in the other.

But we know also that any depraved state of the public health in a community renders it more liable to outbreaks of some of these forms of disease; destroys the power of resistance possessed by the human body, which in the depressed state induced through preventable causes falls a ready prey to the pestilence.

The great end of sanitary science is to preserve intact the health of the body. In dealing with large masses of men—most of them ignorant, many of them powerless—it will not be sufficient, as Miss Nightingale well insists on, to trust to legislative enactments to do the whole work. Education must lend its aid; and until this has acted not only on the ignorant masses

of men in this country, but on the millions of India, the work of sanitary reform will be imperfectly done, though enforced by an enlightened despotism. Her remarks were made as regards India. But education is required at home, not only among the artisan and peasant class, but in those who constitute boards of guardians and other local authorities, to say nothing of the landed proprietors themselves.

It has redounded much to the credit of this University, so long remarkable for its faculty of reading the signs of the times, and so forward in all measures of educational improvement, that a qualification in State Medicine in connexion with Trinity College has been instituted. To obtain it the candidate must be a Doctor of Medicine, and pass a comprehensive examination. Though possessing a great Medical school, Trinity College has recognised the distinction between Preventive and Curative Medicine. Upon the Court of Examiners for that qualification are the Professors of Law, Chemistry, Engineering, Natural Philosophy, Hygiene, and Medical Jurisprudence, and the "Testamur" has been already obtained by four gentlemen, whose University career has shown that those most distinguished in Medicine have been also eminent in their course of Arts. Oxford in the person of its Regius Professor of Medicine is identified with the cause of State Medicine, and the Medical Syndicate of Cambridge have already agreed upon the subject.

It is plain that the old teaching Universities are in the best position for instruction in State Medicine, and in this place the existence of a School of Engineering, many of the pupils of which occupy important positions in various parts of the world, gives it a peculiar advantage.

It may be asked what is meant by "Sanitary Engineering." Dr. Rumsey, in a letter with which he has favoured me, observes that the real effects of structural works on health have not been fairly ascertained. "Civil engineers," he remarks, "have only lately begun to study the relations of the various matters of their profession to human life. The influence of different modes of construction of dwellings, roofs, drains; the size of rooms and public buildings; the effect of local drainage; the study of river and air currents, and their effect on the health of the people, are not mere problems of statics and dynamics, nor are they simply questions of elegance of design, convenience of use, or durability of structure."

Let me illustrate the matter by examples. The sanitary engineer will not sink a well in places where the water may be polluted, or so construct it that it may be fouled by surface water, or by decomposition of matters thrown into it. In the year 1868 the drownings in the Bombay Presidency numbered 1608. Of these, whether from accident or from suicide, 1101 were in wells. He will have to deal with water-supply as to its source, constancy, purity, fall, and the nature of the soil through which it runs. The whole subject of drainage and of sewerage must be familiar to him—the disposal of sewage, and its application towards fertilising the soil, to say nothing as to the proper construction, with reference to ventilation and warmth, of Hospitals, gaols, barracks, passenger ships, and schools.

The remainder of Professor Stokes's discourse consists chiefly of an eloquent appeal for India, claiming for the millions of inhabitants a full participation in the benefits of physical and moral science.

PUBLIC HEALTH BILL.—DEPUTATIONS TO MR. STANSFELD.

ON Monday a deputation from the Social Science, British Medical, and Poor-law Medical Officers' Associations visited Mr. Stansfeld at Gwydyr House, to suggest various amendments in the Public Health Bill. The chief speaker was Dr. A. P. Stewart, who presented a memorial complaining of the injurious restriction of the scope of the Royal Sanitary Commission, and urging several amendments in the Public Health Bill, especially that there shall be a high-class sanitary authority in each district, subject to the central authority; that there shall be one or more Chief Officers of Health for each district, giving their whole time to their duties, and that Medical Officers appointed by the local authorities shall be the deputies to the Chief Officers, and be responsible directly to them; that the sickness returns be passed through the hands of the Chief

Medical Officer; and that a moiety of the expense of Medical and scientific officers under this Bill be borne by the national exchequer.

Dr. Rumsey said that the fundamental defect was the absence of a national council of public health, composed, as in some Continental States, of specially qualified persons. Then it was held that the local machinery proposed by the Bill was complex and inadequate, and he urged there was a want of an extensive unit of area to secure good government and to prevent a duplication of authority.

Mr. Stansfeld said there was more in the Bill than appeared on the face of it, for he had taken powers that districts should be united, and he was not in favour of multiplying petty authorities, as the deputation seemed to think. He differed from the deputation with regard to there being a central authority in each district, for he thought that by an intervening power such as this there would be entailed much cost. He allowed that he did not look to make the law perfect by this Bill, and he thought that much which the deputation sought would be covered by the powers which the central authority would gain by the passing of this measure, for by means of those powers measures which had not been enforced could be pressed, by judicious inspectors of the central authority, to a satisfactory conclusion.

On Thursday, the 11th, Mr. Stansfeld received a deputation of the Association of Medical Officers of Health, including Dr. Druitt (late Medical Officer of Health to St. George's, Hanover-square), Drs. Letheby, Stevenson, Vinen, Lord, Aldis, Tripe, and Woodforde. Mr. Stansfeld entered with these gentlemen into a long, minute, and laborious analysis of the working clauses of his Public Health Bill which relate to the definition and suppression of nuisances injurious to public health. This part of the subject was well elucidated by Dr. Letheby. It would be tedious to report the discussion on dust, disinfection, removal of the sick, closing houses unfit for habitation, and the like; but Dr. Letheby strongly urged that all laws relating to adulteration shall include not only food, or "food and drink," but tea, coffee, cocoa, sweetmeats, confections, and condiments; so that poisonous tea or sugar-plums, salt adulterated with plaster of Paris, and the like, might be prohibited, whereas at present magistrates seem unable to decide that these substances are articles of food or drink. A better definition of adulteration was suggested, and a division into two kinds—one consisting in the admixture of mineral and noxious substances, the other consisting in fraudulent additions for the purpose of increasing bulk. Power was also claimed for sanitary authorities to close unwholesome wells and pumps, public or private, and it was the opinion of the gentlemen present that all or most of these clauses might beneficially be applied to the metropolis. Dr. Stevenson dwelt on the precaution to be used in the appointment of analysts, and the expediency of giving a full share of work to chemists in the large towns. Dr. Tripe mentioned the necessity of disinfecting corpses before they are taken into churches or chapels, and mentioned a case where small-pox was caught by the mourners at the funeral of a person who died of that disease. Mr. Stansfeld expressed his thanks to the deputation, and said that, with regard to applying the clauses of his Bill to the metropolis, he thought it the best policy to let the metropolitan members consider the Bill, and then accept it if they thought it likely to be serviceable to their constituents; and this Mr. W. H. Smith and others seemed inclined to do. The same with regard to the sanitary authority for the Port of London; he wished to hear the sentiments of the various bodies who were competent and prepared to undertake that office. The members of the deputation were much impressed with the thoroughness and grasp of Mr. Stansfeld's knowledge of the above somewhat intricate details.

EXTRAORDINARY LONGEVITY.—The obituary of the *Times* of Wednesday, the 3rd instant, contained some remarkable illustrations of prolonged existence in eleven persons—viz., nine gentlemen and two ladies—whose united ages amounted to 946 years, giving an average of exactly 86 years to each. The oldest lady was 93, the other 82. Of the opposite sex, the oldest had reached the great age of 95; the youngest was 80 years of age.

THE dengue fever has broken out at Poona and Sholapore. It is supposed that both of those places have been infected by the troops which arrived by H.M.'s troopship *Crocodile*.

REVIEWS.

Dr. Pereira's Elements of Materia Medica and Therapeutics. Abridged and adapted for the use of Medical and Pharmaceutical Practitioners and Students. Edited by ROBERT BENTLEY, M.R.C.S., Professor of Materia Medica and Botany to the Pharmaceutical Society of Great Britain, etc.; and THEOPHILUS REDWOOD, Ph.D., etc., Professor of Chemistry and Pharmacy to the Pharmaceutical Society of Great Britain. London: Longmans. Pp. 1093.

THIS book is a mistake—nay, more, it is an injustice. Whilst fully admitting the necessity for such a work, or one founded on the same principle as the old dispensatories, we may well demand—by what right is the name of Dr. Pereira coupled with it? Is the work in any way such a volume as he, had he been now alive and in full possession of his faculties, would have written? To anyone familiar with the writings of Pereira there can be but one answer.

There is beyond doubt a want for a book which should embody the main facts of pharmaco-dynamics with a *Materia Medica*. Such a work must be wanted by pharmaceutical students; and now that all pharmaceutical chemists have to pass an examination before the examiners appointed by the Society, they might well expect that somebody would take the trouble to provide a book suited to their wants. Now, there can be no men better fitted for this duty than Professor Bentley and Dr. Redwood, and their part of the work is thoroughly well done; but that said, all is said. In their preface these gentlemen say—"The work now submitted to the Profession is based upon that of which Dr. Farre was the principal editor." Deeply do we regret, for the sake of Professor Bentley and Dr. Redwood, that it should be so, for a more unsatisfactory book was never published. On the other hand, the old edition of Pereira, completed by Rees and Taylor, remains to this day a wonderful source of information.

Now, we admit that all this seems very hard on Professor Bentley and Dr. Redwood—and it would be impossible to have a higher esteem for these two gentlemen than we have. Professor Bentley is a first-rate botanist, as well as the most genial man you can meet with—a man of whom willingly no one would say an evil word; moreover, his part of the work is thoroughly well done. We have just by chance hit upon an article which thoroughly well illustrates this. Ergot of rye is described and figured better than in any book we have seen dealing with *Materia Medica*; but we turn to the portion of the work relating to its physiological and therapeutical effects, and then—we cannot say we are grievously disappointed, for we expected nothing beyond—not a word of anything, save what refers to the uterus—not a word as to the effects of ergot on unstriped muscle elsewhere—not even a reference to its effects in causing gangrene when bad rye is used for bread.

We turn again to the Cinchonaceæ, the portion which last received the finishing touch from the pen of the lamented author whose name is inscribed on the work. There, too, Professor Bentley's work is well done; the later researches, especially those embodied in Howard's splendid work, are duly utilised and embodied. But we look to Ipecacuan, and we find two lines or so devoted to the use of this remedy in dysentery, and not a word as to the dose to be given in it. So, too, some of the most important properties of quinine are overlooked.

We turn to Digitalis, an article which seems better brought down than many others: the same defects prevail. Professor Bentley's remarks as to the gathering of the plant and its botanical characters are good; but, as a model of wrong-headedness, we can cite the following:—"In simple hypertrophy or hypertrophy with dilatation (of the heart) we have to reduce the preternatural thickness of the heart's parietes, and this we do by removing, when it can be done, any obstruction to the circulation, by using low diet, by repeated blood-letting, and by the employment of digitalis." We had thought of giving other instances to justify the very harsh expressions we have used with regard to this book, but it would be impossible to surpass such a sentence, which we allow to stand in its naked deformity.

A word with regard to Dr. Redwood's share in the book. No better or fitter man could be found to comment on the pharmacy of the Pharmacopœia, for it is well known to many that he was the principal author of the pharmaceutical portion of its last edition. In every way he is well qualified for his task, and to his work we can find no objection worth mentioning here; but here, too, good work is damned by being bound up

with bad, and we can only commiserate with both editors on having been so ill-advised as to accept the edition of Pereira which they took as their basis. For these two gentlemen we are sincerely sorry, and to them we can only say, by way of compensation—let them bring out a work on their own account, without any foreign basis, and it will surely meet with a very different reception from that accorded to what, speaking as Physicians and Surgeons, we can only call a degenerate edition of a great work.

NEW BOOKS, WITH SHORT CRITIQUES.

Zymotic Diseases, their Correlation and Causation. By A. WOLFF, F.R.C.S. London: J. and A. Churchill. Pp. 177.

* * * The author dissents from the notions generally entertained, that each zymotic disease has a special poison of its own distinct from all others. He seeks to establish that the various forms of zymotic disease are strictly correlated; that they are essentially processes of textural inflammation tending to textural disintegration; that they vary in their phenomena in accordance with the special texture primarily affected; that in their causation correlation is as evident as in their symptoms; that their cause is invariably the presence of decaying organic matter, and that the mode in which this decaying matter acts is by overcoming the resistance of the natural actions of repair and growth, and inducing in their stead a process of inflammatory disintegration. The volume is highly suggestive.

On Mental Capacity in relation to Insanity, Crime, and Modern Society. By CHRISTOPHER SMITH, M.D., late of Paris. London: Baillière, Tindal, and Cox. Pp. 71.

* * * We candidly confess that we do not quite understand this book. Nevertheless, confiding in its wisdom, we can admire the style in which it is composed. It is dedicated to Dr. Forbes Winslow, and we cite the introductory lines of the dedication. They are very fine:—"Prithee, do not bestow one mental vibration of your powerful sensorium that would imply censure on me for not soliciting your indulgence in submitting to your dedication remarks upon a subject which you have displayed such transcendent talent and consummate skill in elucidating. Your well-merited reputation as an alienist and prince of psychological science must pay the penalty and bear the burden of world-wide fame which you have long since acquired, and consequently be the involuntary objective in matters immediately connected with insanity in its various forms." Such writing, and the invention of a psychometer which the author describes, are sure to make the reputation of the book.

The London Medical Guide: containing a Complete Directory of the Names, Addresses, Qualifications, Appointments, and Published Works of all Qualified Medical Practitioners residing in London and the Suburbs in 1872. London: Kelly and Co. Pp. 203.

* * * This is a very handy and convenient book for those who desire to limit their world to London, and to whom London is the world, but we doubt if it can attain, even among these, to the popularity of the old "Medical Directory." The amalgamation of the directories of the three kingdoms was deliberately adopted, and we can hardly look upon a separation of the London Directory from the others as an improvement. There is, however, one feature in which the present little volume excels the other: it includes not only all London Practitioners, but also all the suburban ones, who indeed may still be looked on as metropolitan. It has always been a bore to turn to the Provincial Directory for a name which should have been included in the Metropolitan one, and we would strongly urge the editor of the old "Medical Directory" to include within his metropolitan area all gentlemen practising within the twelve-mile radius. This is a new venture on the part of Messrs. Kelly, and their workmen seem to be badly acquainted with Medical terms, etc., for there are a good many misprints in the volume.

Observations on the Climate of Uckfield. By C. LEESON PRINCE, M.R.C.S.E., etc. London: J. and A. Churchill. Pp. 239.

* * * Mr. Prince really deserves much greater credit than we fear will be bestowed upon him. His work has lasted for many years—from 1843 to 1870. His observation has been keen, and his notes careful. Mr. Prince has, in point of fact, followed in the steps of White of Selborne, looking out year by year for the arrival or appearance of various animals and plants. We fancy there could be few pleasanter recreations on a fine spring afternoon than to take a drive with Mr. Prince on his round of visits.

The Englishwoman's Review of Social and Industrial Questions.
London: Trübner.

. In the current number of this review is one of those twaddly articles one is constantly encountering on the subject of "Medicine as a Profession for Women," having the signature "A. B. Le Geyt" appended. It goes maundering over the same subjects which have so often been discussed, and again we are told that there is no argument against women-Doctors which will hold water. It will on the whole be admitted, we think, by reasonable beings that it is not advisable for women to act as Medical attendants on males—male modesty forbids, if female does not. No one objects to the education of women for the purpose of attending on their own sex and on infants under a certain age. Such an education need not be a mixed education. We do not want mental and moral hermaphroditism, although the personages who now represent the female Medical movement seem to be content with nothing less. This, again, male modesty forbids. But if women will have a place of their own, and an education of their own, by all means let them have it.

On the Cause of Death in Fever. By R. T. HUNT, M.R.C.S.E., Consulting Surgeon to the Royal Eye Hospital, etc., Manchester. (Pamphlet.) Manchester: Cornish.

. The substance of this pamphlet was read as a paper before the Manchester Medical Society in 1842. The additional experience of twenty-nine years, says the author, only confirms his opinions. The fevers he refers to are those which leave behind them no trace of lesion. He holds that the torpid state of the bowels in fever is frequently beneficial to the patient, and ought on no account to be disturbed by aperient medicines, otherwise dangerous consequences may follow. No doubt, sound in many instances, especially true of typhoid fever, but little is said of the cause of death—the pamphlet deals rather with treatment.

FOREIGN AND COLONIAL CORRESPONDENCE.

WEST INDIES.

PORT OF SPAIN, TRINIDAD, March 10.

THE SMALL-POX EPIDEMIC.

THERE has been a marked decrease in the epidemic in Port of Spain since I last wrote. The close, muggy, hot, rainy weather lasted until far into January. The air was almost perfectly calm, and the usual brisk and refreshing breezes of the dry season were entirely absent. As long as this was the case, the severity of the epidemic was unabated. None of the sanitary measures (such as they were) which were tried had the slightest effect in mitigating the plague. But when the dry weather came, and with it the steady trade winds, an immediate change took place, not only as to the number of cases, but as to the character of the disease. The petechial and hæmorrhagic cases diminished, and even some of those which commenced as petechial did not become progressively worse, as had previously always been the case, but improved and ultimately recovered. The following shows the number of cases and deaths reported at the Health-office from the beginning of January:—

	Cases.	Deaths.
In the month of January ..	1742	416
February 1 to March 3 ..	113	41
Week ending February 10 ..	240	74
" " 17 ..	155	55
" " 24 ..	97	46
" March 2 ..	86	26
" " 9 ..	42	8
Totals ..	2475	666

The worst week of the epidemic was that ending February 3, in which there were between 400 and 500 new cases reported. The cases reported are admitted at the Health-office to fall far short of the actual number, as the most strenuous efforts were made to conceal cases.

The worst is over now in Port of Spain, but the epidemic is spreading all over the country districts. In the only other town in the island, San Fernando, there has been a large number of cases. In one short street, at one time, there were said to be sixty cases. But the disease is nowhere so severe as in Port of Spain, although hæmorrhagic cases have occurred everywhere.

A very useful measure has been adopted by the Board of

Health, at the suggestion of Dr. Crane, the Medical Officer of Health, and that is to order that all vessels arriving in the harbour from any foreign port shall be visited by the Health Officer of Shipping, and neither passengers nor crew shall be allowed to land until certified by him to have had small-pox or to have been vaccinated. This measure has been violently attacked by the organs of the mercantile classes, who, with their usual shortsightedness and greed for immediate gain, cannot be made to see that the epidemic will never come to an end as long as hundreds of people are allowed to land unprotected by vaccination or small-pox. The slight delay and obstruction outweigh, in the minds of the trading community, every consideration about the public health.

GENERAL CORRESPONDENCE.

THE ROYAL ORTHOPÆDIC HOSPITAL..

LETTER FROM MR. B. E. BRODHURST.

[To the Editor of the Medical Times and Gazette.]

SIR,—It is well known to all who have watched the history of the Royal Orthopædic Hospital that for many years there has been going on a struggle between the general body of the Committee and the two Surgeons, who have been supported by Lord Abinger and a small minority of the Committee.

Prior to most of the annual and special courts an active canvass for governors has taken place—a practice which it is well known prevails in almost every institution in which there are pending existing questions.

At the special court in March last some of my friends determined to propose that there should be created an office of third Surgeon, with the view that I should hold the appointment. For this proposition (which would not in any way affect the positions of the two Senior Surgeons) they sought the support among their friends of additional as well as of old subscribers. Not unnaturally they sent the names so obtained to me, with a request that I would see them properly placed on the register. This I did, and it is all that I did. And that I acted in good faith is sufficiently proved by the fact that I made no concealment about it, but gave to the Secretary, together with the names, my own cheque for the amount due from the subscribers—some of whom sent me the money previously, and others subsequently, to my paying it.

This is, I believe, all I need say in vindication of my conduct as a member of the Profession. I cannot ask you to judge between Lord Abinger and myself. He has on more than one occasion openly expressed the ill-will he has long borne towards me; nor is it necessary for me to enter into the question between the Committee and the two Surgeons. That question has now been twice decided against the Surgeons; and on this last occasion in spite of the most strenuous efforts of Lord Abinger and his friends.

It is to be hoped that the charity may now at length be permitted to continue to perform its beneficial functions undisturbed by further Professional quarrels and personal disputes.

I am, &c., B. E. BRODHURST.

20, Grosvenor-street, April 9.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 2.

Mr. HILTON, F.R.C.S., President, in the Chair.

MR. ARNOTT read for himself and Dr. Duffin a report on Dr. Dowse's specimen of Mollities Ossium. All the cancellous tissue was gone, and in its place was a soft gelatinous tissue, consisting of small spherical and oval cells like granulation tissue. This contained a little oil, but very little. No opinion was expressed as to the nature of the growth.

Mr. T. SMITH exhibited a specimen of Triple Aneurism of the Aorta in the sinuses of Valsalva, from a patient whose case has already been reported. One of these was three-quarters of an inch in depth. The aortic orifice was not interfered with, so there was no sign of regurgitation during life. The clubbed fingers were rendered natural partly by rest, but entirely after the operation on the subclavian, showing that they were probably connected with pressure by the aneurism on the vein. In other cases clubbed fingers seemed to be due to other

causes, as obstruction to the blood-stream through the lung. Thus they are common in empyema and chronic phthisis. They may club in pneumonia, and get well as the patient gets well; yet they do not occur in emphysema, chronic bronchitis, etc. General exhaustion had nothing to do with their appearance; he had never seen them in spinal abscess and the like.

Mr. SQUIRE said they did sometimes occur with emphysema. He had a case of this disease now, of some standing, where the fingers were beginning to club.

Dr. CRISP asked if there was any atheroma of the vessel.

Dr. MOXON said the origin of clubbing of the fingers was obscure. He thought it might be allied to that condition of the nails mentioned by Dr. Wilks as brought about by illness, and afterwards gradually passing off. The condition did occur in emphysema, but if so, then the emphysema was founded on old phthisis.

The PRESIDENT asked what was the condition in the fingers themselves.

Dr. MOXON replied that he had never made sections. After death the fingers did not seem to be clubbed, only the nail altered, as the points of the fingers shrink.

Dr. PYE-SMITH suggested that this showed the condition was mainly one of œdema. Two things were confounded, clubbing and incurvature of the nails. He had examined the toes as well as the fingers, and had found both clubbed.

Dr. POWELL said people complained of pain in such fingers. He had seen the condition come on acutely in patients the subjects of chronic phthisis. He found it in the toes also.

Mr. HAWARD said the nose might be clubbed too.

Dr. CRISP suggested that in all cases it was associated with slow circulation in the parts.

Mr. T. SMITH, in reply, said the aorta was enlarged and atheromatous. He considered the clubbing as due to no single cause. It was common in congenital heart disease, very rare in the acquired form.

Dr. KING exhibited a Malformed Heart from a boy aged 4. He was not cyanotic. Two years ago he began to complain of pain in the head, and a discharge came from his ear. This continued for a while, but afterwards ceased. Next he became paralysed on one side, the limbs on that side trembling much. Fits came on, and he died. There was a large abscess in the cerebrum, apparently of long standing, and the lateral ventricles contained pus. This was on the right side. The mastoid bone was necrosed at one point. The lungs were small and healthy. In the heart the interventricular septum was deficient. The aorta was small and atheromatous, the pulmonary orifice exceedingly narrow, and the artery dilated. There was no ductus arteriosus.

The PRESIDENT referred to the heart of a soldier he had seen. The man had been quite equal to any exertion, yet he had a large orifice in the ventricular septum. He had no cyanosis. He thought the muscular fibres of the ventricle determined the direction of the blood-stream.

Mr. SYDNEY JONES exhibited a very large Tumour removed from the Parotid Region of a lady aged 58. Mr. Travers had removed such an one from her many years ago. Some months after that she received an injury in the parotid region; the present tumour began to form, and it gradually increased for twenty-three years. Fourteen months ago the skin over it ulcerated, and some hæmorrhage occurred from time to time. The tumour was pedunculated and easily removed. He clamped the peduncle, so no blood was lost. In texture it seemed cartilaginous in one part, in others cystic.

The SECRETARY suggested that in the drawing the structure seemed like that of epithelioma.

Dr. CRISP exhibited a specimen of Abscess of the Wall of the Heart occurring in a child aged 4. She had first an ulcer in her heel, apparently caused by a boot; then there was pain in the middle of the thigh, redness, etc. The child died, and abscesses were found in various parts of the body, especially in the joints. There were three in the heart containing thick creamy pus. The thigh was not examined.

Mr. T. SMITH said it was only too common to have such symptoms from disease of the thigh-bone, though rare from such an injury to the heel.

Dr. MOXON said without doubt there had been acute suppurative periostitis of the thigh-bone. Such, he thought, had always a tendency to form abscesses in the heart and kidney.

Dr. PAYNE had recently seen three cases of pyæmia without external wound, but with periostitis and necrosis. There was no heart affection in them.

Dr. CRISP narrated a case of Intestinal Obstruction in a man aged 62. He exhibited pain, tympanitis, constipation, etc.

He had long been subject to colic with flatus, which was best relieved by elevating his legs. He died in forty-eight hours. The sigmoid flexure of the colon was twisted, and contained dark grumous fluid. He suggested that puncture might have been of some service.

Dr. CHOLMELEY said puncture had not only been suggested, but had often been had recourse to in such a condition—frequently, too, with good results.

Mr. SQUIRE remembered a similar case in the female. The sigmoid flexure had adhered to the uterus; and about the age of 46, when the uterus began to contract, it drew down the gut, and obstruction followed.

Mr. CROFT exhibited two Colloid Tumours of the Breast. One had been observed for three years; latterly blood began to ooze from the nipple. He removed the mass. The tumour was variously constituted—part being colloidal, part containing blood; part was mere hyperplasia of gland tissue, part resembled carcinoma. The other was of two years' growth, and was the size of an orange. Here, too, blood oozed from the nipple. There was no enlargement of the axillary gland. It was removed, and found partly colloidal, partly scirrhus. Both were probably degenerations of scirrhus. There were two varieties of colloid growth—one original and one a degenerated tissue. He did not say what was the origin of the colloid matter.

Dr. MOXON showed a specimen of Syphiloma of the Liver. There was a prominence on the surface of the liver, which fluctuated during life, and was supposed to be an abscess. Really, however, it turned out, after death, to be a syphilitic growth of large size, softened and broken down like an abscess.

Mr. SQUIRE exhibited a specimen of Cancer returning after removal by caustic. (Referred to the Morbid Growth Committee.)

The Society then adjourned.

OBITUARY.

THOMAS BARNES, M.D. EDIN., M.R.C.S., F.R.S.E., ETC.,
DIED on Sunday, the 31st ultimo, at Bunker's-hill, Carlisle, in the 79th year of his age. Having chosen Medicine as his Profession, he became an apprentice of the late Dr. Joshua Rigg, of Wigton, at that time the only Medical Practitioner in the district. There were then neither druggists, veterinary Surgeon, nor dentist in Wigton, and the Doctor's apprentice was expected to take the place of all three. After his apprenticeship he went to Edinburgh in 1811, and entered as a student of Medicine at the University, where his zeal and diligence soon attracted the notice of the Professors. He passed two winter sessions there and one session in London, having entered at the London Hospital. In 1815 he became a Member of the Royal College of Surgeons of London, and then studied for some months on the Continent, visiting the chief Hospitals both in France and Germany, and attending several classes of the Paris Faculty of Medicine. It may here be mentioned that he was present at the battle of Waterloo, and he used to relate many curious incidents in his adventures of that period. On returning to this country he proceeded to Edinburgh, and took the degree of Doctor of Medicine at the University in August, 1817. He was anxious at first to settle in London or some other large town, but whilst looking about him a vacancy for a Physician occurred in Carlisle; he was at once appointed Physician to the Dispensary. He was very active and diligent in the acquisition of Professional knowledge, accurate in diagnosis, and a thorough advocate of the old school of treatment. As a Consulting Physician, twenty-five years ago he had few rivals in the northern counties. Ever anxious for the advancement of Medical science, he was not backward in giving the results of his own observations, and contributed many valuable articles to the Medical and scientific journals. Of these a catalogue will be found below:—"Observations on Fever and Vaccination at Carlisle" (*Edin. Med. and Surg. Journal*, vol. xv., 1819); "Two Successful Operations for Strangulated Hernia performed on the sixth day" (*Edin. Med. and Surg. Journal*, vol. xv.); "Cases of Five Individuals in one family having Small-pox twice" (*Edin. Med. and Surg. Journal*, vol. xix., 1823); "Sketch of an Epidemic Varicella which prevailed at Carlisle in the Summer and Autumn of 1826, preceded by Observations on the relative state of Small-pox and Vaccination during the seven years previous" (*Edinburgh Med. and Surg. Journal*, No. 90); "Account of William Dempster, who swallowed a table-knife."

nine inches long, with a notice of a similar case in a Prussian Knife-eater" (*London Med. and Phys. Journal*, vol. lii., 1824); "History of an Uncommon Case of Laborious Parturition" (*Edin. New Med. Journal*, vol. iii., 1827); "A Table of Diseases treated at the Carlisle Dispensary from February, 1826, to February, 1827" (*Edin. New Med. Journal*, vol. iii., 1827); "Case of Vicarious Menstruation with Singular Discharge from the Ear, with Remarks" (*Edin. New Med. Journal*, vol. ii., 1826); "Account of Mr. Robert Bowman, of Irthington, in Cumberland, who has completed his 115th year" (*Edin. Phil. Journal*, vol. iv.); "Biographical Notice of Mary Noble, of Penrith, Cumberland, who is (1823) in the 107th year of her age, with some Remarks on Longevity" (*Edin. Phil. Journal*, vol. x.); "Remarks Explanatory and Tabular Results of a Meteorological Journal kept at Carlisle for Twenty-four Years" (*Transactions of the Royal Society of Edinburgh*, vol. xi.); "On Abscess of the Lungs" (*Eighth Report of the British Association for the Advancement of Science*, vol. vii.); "Biographical Sketch of the late Dr. Robert Jackson, Inspector of Military Hospitals" (*Transactions of the Provincial Medical and Surgical Associations*, vol. iii.); "Observations on the Expediency of Establishing a General Infirmary at Carlisle," 1828 (second edition, 1831), "Lecture on the Structure and Physiology of Man and of the Lower Animals," "Topography of Cumberland," and "Topography of Dumfriesshire" (*Penny Cyclopædia*); "Reports of the Carlisle Dispensary," "Reports of the Carlisle Fever Hospital," "On the Average Amount of Rain in Carlisle and Neighbourhood" (*Transactions of the Royal Society of Edinburgh*, vol. xxvi.). His paper "On the Meteorology of Carlisle for Twenty-four Years" was read before the Royal Society of Edinburgh in 1827, and procured for him the title of F.R.S.E. He was elected in the same year as the late Professor Syme, and at the time of his death was one of the oldest Fellows. He was a member of the Royal Medical and Chirurgical and Wernerian Societies of London. He was one of the earliest members of the British Medical Association and of the British Association for the Advancement of Science, and was elected a life member of the latter body in 1864. On the formation of the Cumberland and Westmoreland Medical Association in 1868, he was elected unanimously as its first President, and in his inaugural address he gave "a forcible exposition of the waves of Medical thought and practice which had passed within the scope of his recollection." It has already been stated that he was appointed Physician to the Dispensary on his settling in Carlisle, and he continued Physician-in-Ordinary to that institution until 1838, when he was made Physician-Extraordinary to fill the vacancy caused by the death of Dr. Heysham, and after fifty years' tenure of office in his Professional capacity, he was in 1866 appointed a Vice-President. He was the founder of the Carlisle Fever Hospital, and had been its Senior Physician since its opening in 1820. For a period of thirty-four years he was its sole Physician. He took an active part in establishing the Cumberland Infirmary, was the first Physician appointed to it, and may be regarded as one of its chief founders. He was the founder and secretary of the Carlisle Humane Society. He was a warm friend to the Carlisle Mechanics' Institute, and delivered the first lecture in that institution. In 1849 he ceased to reside in Carlisle, gave up active Professional work, and retired to Bunker's Hill. Shortly before that he had been appointed a county magistrate, and he acted for many years, taking a prominent part in county business. His failing strength and advancing years at length compelled him to relinquish these duties, and for some time past he had not been able to undertake any public work. His last illness was only of a fortnight's duration. His end was peaceful, and he may be truly said to have died "full of years, full of honours."

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 9th inst., and, when eligible, will be admitted to the pass examination:—

Baly, William, student of St. Bartholomew's Hospital.
Barlow, John, of Glasgow.
Benton, Samuel, of St. Bartholomew's Hospital.
Bott, Henry, of St. Bartholomew's Hospital.
Brown, George, of the Charing-cross Hospital.
Comins, Denis W. D., of St. Bartholomew's Hospital.
Crocker, Henry R., of University College.
Davies, Lewis, of Guy's Hospital.
Davies, John W., of Guy's Hospital.

Day, Edmund O., of Guy's Hospital.
Dhanjisha Navroji Parakh, of University College.
Eales, Henry, of University College.
Friend, Frederick W., of St. George's Hospital.
Griffiths, John, of Guy's Hospital.
Harper, Gerald S., of St. George's Hospital.
Helby, Alfred J. H., of St. Bartholomew's Hospital.
Henwood, John D., of the Charing-cross Hospital.
Hooper, Alfred, of Guy's Hospital.
Leeds, Henry, of the Charing-cross Hospital.
Manning, Charles J., of University College.
Mason, John W., of Guy's Hospital.
Morton, Andrew S., of University College.
Rossiter, George F., of St. Thomas's Hospital.
Roth, Bernard M. S., of University College.
Rudd, Leonard, of Guy's Hospital.
Swift, W. J. C., of University College.
Willans, William B., of King's College.

The following gentlemen passed on the 10th inst., viz.:—

Allden, John H., student of the London Hospital.
Bickford, William, of St. Thomas's Hospital.
Boase, William F. F., of the London Hospital.
Briggs, George J., of the Hull School.
Cree, William E., of the Middlesex Hospital.
Crowther, Arthur B., of Guy's Hospital.
Denby, Timothy C., of the Leeds School.
Gonsalves, Manoel Martinho, of St. Mary's Hospital.
Hart, Philip N., of St. Bartholomew's Hospital.
Hopkins, John, of University College.
Jackson, William, of the Leeds School.
Jelley, Richard, of University College.
Maclea, Thomas E., of University College.
Newham, Lewis J., of the Charing-cross Hospital.
Reynolds, Edward O., of Guy's Hospital.
Sellon, John W. G., of University College.
Smith, Winckworth T., of University College.
Squire, William, of St. Bartholomew's Hospital.
Tyrrell, Frederick, of St. Mary's Hospital.
Verdon, Henry W., of St. Thomas's Hospital.
Vines, Edward P., of King's College.
Wilding, Leonard J., of Guy's Hospital.
Woodforde, Alfred P., of St. Bartholomew's Hospital.

The following gentlemen passed on the 11th inst., viz.:—

Butler, George B., student of St. Bartholomew's Hospital.
Ellerton, John F. H., of the Leeds School.
Fowler, James, of King's College.
Hales, Robert T., of St. Bartholomew's Hospital.
Hobson, John M., of Guy's Hospital.
Hood, Frank E. C., of Guy's Hospital.
Johnston, Wingate K., of Guy's Hospital.
Leghtoller, H. Martin, of the Manchester School.
Lindsay, William V., of St. Mary's Hospital.
Lumby, John R. H., of the Birmingham School.
Miller, Robert B., of King's College.
Morris, Price, of the Glasgow School.
Newman, Charles, of the Bristol School.
Newsham, Francis, of the Manchester School.
Parkinson, John R., of the Manchester School.
Potts, Edward, of the Birmingham School.
Pring, Peter B., of the Glasgow School.
Quinton, Richard F., of King's College.
Roberts, Humphrey, of the Glasgow School.
Sandes, W. H. Fitton, of St. George's Hospital.
Scatliff, Arthur W., of St. George's Hospital.
Scatliff, J. M. Elborough, of St. George's Hospital.
Thomas, Robert T., of St. Bartholomew's Hospital.
Walker, Hyde E., of the London Hospital.
Williamson, Francis, of St. Thomas's Hospital.
Wood, John E., of St. Thomas's Hospital.

Thirty-one candidates out of the 107 examined having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for the usual period of three months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, April 4:—

Brumwell, James Parker, Kendal, Westmorland.
Donaldson, Henry, Cambridge-road, Hammersmith.
Evans, Thomas, Trinity-square, Borough.
Pitts, Robert Laccheus, Hingham, Norfolk.
Scott, John Walter, Torpoint, Cornwall.
Wright, Francis James, Preston, Lancashire.
Wright, John Frederick, Seymour-street, W.

The following gentleman also on the same day passed his primary Professional examination:—

Jennings, William Oscar, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BORHAM, W. T., L.R.C.P., M.R.C.S., L.S.A.—Medical Officer to the Abbotsbury District of the Weymouth Union, and to the Long Bredy District of the Dorchester Union, *vice* T. Parker, M.D., resigned.

BREWER, Professor, M.R.C.V.S., of the Veterinary Department of the Privy Council Office, and late Professor of Veterinary Surgery at the Agricultural College, Cirencester—Chair of Physiology, Therapeutics, and Pharmacy, Royal Veterinary College.
 BUNTINE, ROBERT, L.F.P.S. Glasgow.—Medical Officer for the Brough District of the East Ward Union, Westmoreland.
 CUNNINGHAM, WM. L., L.R.C.S.E.—House-Surgeon to the Paisley Infirmary, *vice* Wm. Lewis, M.B., C.M., L.R.C.S.E., etc.
 GRAY, ALEXANDER COTHILL, M.D.—Medical Officer to the Selby District, Yorkshire.
 STRANGE, WM., M.D.—Honorary Physician to the County Prison, Worcester, *vice* Dr. Williams, deceased.
 LEWIS, THOMAS HOPKIN.—Dispenser to the Stepney Union.
 VORES, WM. MALLAM, B.A. Cantab., L.S.A.—Junior Resident Medical Officer to the Royal Free Hospital, Gray's-inn-road, W.C.

NAVAL AND MILITARY APPOINTMENTS.

MEDICAL.—John Lyon, Assistant-Surgeon to the *Swallow*; W. C. Sandys, Assistant-Surgeon to the *Royal Adelaide*.
 BORHAM, W. T., L.R.C.P., M.R.C.S., L.S.A.—Admiralty Surgeon to the Coastguard Stations of Laughton, Herring, and Abbotsbury.
 CHRISTISON, ALEXANDER, M.D., Surgeon, to be Surgeon-Major in the Bengal Army.

BIRTHS.

BARCLAY.—On April 9, at 30, Stafford-street, Edinburgh, the wife of Alexander Barclay, M.D., Deputy Inspector-General of Hospitals, of a son.
 CHARLTON.—On April 5, at Southborough, Tunbridge Wells, the wife of Alfred Charlton, M.R.C.S.E., of a son.
 COOPER.—On March 30, at Prospect-place, Southampton, the wife of Robert T. Cooper, M.D.T.C.D., of a son.
 DANSON.—On April 4, at Roseville, Dartmouth, the wife of F. Adams Danson, M.D., of a son.
 DICKSON.—On April 9, at 36, Albany-street, Edinburgh, the wife of Dr. Frank K. Dickson, of Wyc House, Buxton, of a daughter.
 INNES.—On April 8, at Netley, the wife of Dr. W. F. Innes, C.B., Inspector-General of Hospitals, of a son.
 KERR.—On April 3, at Markyate-street, Bedfordshire, the wife of Norman S. Kerr, M.D., of a son.
 LAKE.—On April 7, at 13, East-park-terrace, Southampton, the wife of Dr. G. A. K. Lake, of a son.
 LEADAM.—On April 8, at 26, Gloucester-terrace, Hyde-park-gardens, the wife of W. Ward Leadam, M.D., of a daughter.
 LIVING.—On April 1, at 9, Manchester-square, the wife of Robert Living, M.D., of a son.
 NUGENT.—On April 4, at 151, Ledbury-road, Bayswater, the wife of H. Nugent, M.D., of a son.
 RICKARDS.—On April 3, at 8, Cavendish-place, Cavendish-square, the wife of Walter Rickards, M.D., of a son.
 SMITH.—On April 2, at Islip, Oxon, the wife of Walter Wyke Smith, L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

ABRAHAM—BURNETT.—On April 3, at the parish church, Alton, Hants, Philip Boyle Abraham, barrister-at-law, only son of Augustus B. Abraham, of the Middle Temple, to Mary, third daughter of the late Charles Mountford Burnett, M.D., Westbrooke House, Alton.
 DAVIES—STEPHENS.—On April 9, at St. Clement Danes, Arthur Capel, only son of David Davies, M.D., late of Belgrave-street, to Jane Helen Mary, only daughter of Edward Bowring Stephens, Esq., A.R.A., of Buckingham-palace-road.
 FEGGE—BRISCOE.—On April 4, at West Hackney Church, Charles Hilton Fegge, M.D., F.R.C.P., of St. Thomas's-street, Southwark, to Emily Mary Christiana, elder daughter of the late John Briscoe, Esq., of Upper Sydenham.
 HILLIARD—JEWELL.—On April 9, at St. Gabriel's, Warwick-square, Herbert Brewitt Hilliard, fourth son of G. R. Hilliard, M.D., of Cowper Lodge, Deal, to Rebecca, youngest daughter of the late R. J. Jewell, Esq., formerly of Newport, Isle of Wight.
 LANCHESTER—PAGE.—On April 4, at St. Peter-at-Arches, Lincoln, Henry Thomas Lanchester, M.D., of Croydon, to Catherine, only daughter of W. T. Page, Esq., of Greetwell-road, Lincoln.
 PLASKITT—WEBB.—On April 4, at the church of St. Matthias, West Brompton, Joshua Plaskitt, F.R.C.S., of Chapel-street, Belgrave-square, to Lydia Frances, second daughter of the late C. T. Webb, Esq., of the Island of Mauritius, and of Petersham, Surrey.
 LE SUEUR—DANIELL.—On February 6, at St. Mary's Church, Port Elizabeth, Cape of Good Hope, by the Rev. E. Pickering, M.A., assisted by the Rev. W. Greenstock, R. T. Le Sueur, M.D., District Surgeon, Port Elizabeth, to Florence, daughter of the late Captain Daniell, R.N., and niece to George Dunsterville, F.R.C.S. Eng., etc.
 SALZMANN—SINNOCK.—On April 4, at the parish church, Hailsham, Sussex, Frederick William Salzmänn, M.R.C.S. Eng., of Brighton, to Clara Selina, youngest daughter of H. C. Sinnock, of Hailsham, solicitor.
 SANDFORD—WALMSLEY.—On April 4, at St. Barnabas, Kensington, Edward Sandford, M.D., of Baschurch, Shropshire, to Mary Ann, youngest daughter of the late Robert Walmsley, Esq., of Newton-on-the-Hill, Shropshire.
 SHEPPARD—NISBET.—On April 9, at Trinity Church, Paddington, Major T. W. Sheppard, late H.M. 87th (R.I.F.), to Margaret Agnes, daughter of the late M. Nisbet, M.D., Bengal Medical Service.
 SHORTT—WOODS.—On April 4, at Birr Church, Parsonstown, James Fitzmaurice Shortt, Esq., Knockacollar, Queen's County, eldest son of the late William Shortt, M.D., to Lizzie Kate, eldest daughter of William Woods, Esq., Parsonstown.
 SPENCER—HARVEY.—On March 12, at Agra, Lionel Dixon Spencer, M.D., Bengal Medical Staff, youngest son of the late William Spencer, of New-

castle-on-Tyne, to Elizabeth Gordon Lamond, eldest daughter of Alexander Harvey, M.D., Professor of Materia Medica in the University of Aberdeen.
 WEBSTER—PEARCE.—On March 27, at Vaynor Church, Brecknockshire, Thomas J. Webster, M.R.C.S. Eng., L.S.A., to Fanny Elizabeth, daughter of Thomas J. Pearce, Esq., Pen Bryn, Cefn, Merthyr Tydvil.
 WILLIAMS—HUGHES.—On April 3, at Libanus Chapel, Morrision, John Williams, M.D., of Swansea, to Mary Elizabeth Ann, only daughter of Richard Hughes, Esq., of Yuistawe, and of the Landore Tin-plate Works.

DEATHS.

ANGUS, GEORGE, late of the Bengal Medical Service, at 13, Golden-square, Aberdeen, on April 7, in the 78th year of his age.
 BARNES, THOMAS, M.D., F.R.S.E., and J.P. for Cumberland, at Bunker's-hill, near Carlisle, on March 31, in his 79th year.
 DIVER, FLORENCE HELENA, the daughter of Ebenezer Diver, M.D., at Caterham, on April 2, aged 2 years and 6 months.
 DWELLY, FANNY, the beloved wife of Dr. H. J. Dwelly, at Rye-lane, Peckham, on April 8.
 HUGHES, CAROLINE MADELINA COKE, the wife of J. Vaughan Hughes, M.D., L.R.C.P., M.R.C.S., L.S.A., accidentally burnt by her dress-catching fire, and lockjaw supervening on the eighth day, at George-street, Hanover-square, on March 30.
 MALDEN, FRANCES, relict of the late Jonas Malden, M.D., of Worcester, at her residence, 11, Royal-crescent, Cheltenham, on April 1.
 WAUGH, MARGARET EDITH, youngest child of Dr. John Neill Waugh, at Brisbane, Queensland, early in February, aged 1 year and 5 months.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
 BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Candidates must be duly qualified. Applications and testimonials to Alexander Bottle, M.D., Secretary, on or before April 17.
 DUNDEE ROYAL INFIRMARY.—A qualified Medical man, to act as Joint House-Surgeon. Further particulars may be learned from the Secretary, D. Gordon Stewart, Esq., solicitor, 13, Meadow-side, Dundee, to whom applications, with testimonials, must be sent on or before May 1.
 ECHT, ABERDEENSHIRE.—Medical Officer to the Parish of Echt.
 GOVAN.—Medical Officer for the Patrick District. Applications and testimonials to be sent to Mr. Mackenzie, Sub-Inspector of Poor, Govan Parish, on or before April 16, marked "Medical Officer."
 INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.
 KING'S COLLEGE.—Demonstrator of Practical Physiology.
 MIDDLESEX COUNTY LUNATIC ASYLUM, HANWELL.—Medical Superintendent of the Male Department. Candidates must be Fellows, Members, or Licentiates of one of the Royal Colleges of England, Scotland, or Ireland, and duly registered in Medicine and Surgery. Copies (only) of testimonials, accompanied by a form (which will be forwarded on application), must be sent to Richard William Partridge, Clerk to the Visitors, on or before Saturday, May 4.
 PARISH OF KENSINGTON.—Medical Officer for the Workhouse and New Infirmary; also a Dispenser. Forms of application may be obtained from the Clerk to the Guardians, 1, Devonshire-terrace, Wright's-lane, Kensington, W., and must be sent in by April 15.
 ROYAL ALBERT HOSPITAL, DEVONPORT.—Resident Medical Officer. Candidates must be unmarried, and duly registered Medical Practitioners. Applications and testimonials to be sent to the Honorary Secretary, Alfred Norman, Esq., endorsed "Application for appointment," on or before Saturday, April 20. Canvassing is strictly prohibited.
 ROYAL SURREY COUNTY HOSPITAL.—Assistant Honorary Medical Officer. Testimonials to be sent to the Hon. Sec., Rev. C. R. Dallas, Farncombe Rectory, Godalming, on or before April 16.
 STAFFORDSHIRE GENERAL INFIRMARY.—House-Surgeon and Secretary. Candidates must be M.R.C.S. of London, Dublin, or Edinburgh, and possess a qualification in Medicine which will entitle to register. Candidates must attend the Infirmary on Monday, April 22, at one o'clock.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Skirlough Union.—Mr. J. H. Clark has resigned the Aldborough District; area 9590; population 1734; salary £32 per annum.

APPOINTMENTS.

Burton-on-Trent Union.—Spencer Edmonds, M.R.C.S., L.S.A., to the Lullington District.
 East S onehouse Parish.—Thomas Leah, M.R.C.S. Eng., L.S.A., to the Workhouse and Parish.
 St. Thomas Union.—John Rayner, L.R.C.P. Edin., M.R.C.S. Edin., L.S.A. Lond., to the Woodbury District.
 Uxbridge Union.—Wm. Rayner, M.R.C.S. Eng., L.S.A., to the Workhouse.

THE EARL OF DERBY formally opened the new Hospital in the Derby-road, Bootle, on Wednesday.

DR. WOODWARD, whose energy in carrying out the provisions of the Compulsory Vaccination Act in Worcester is well known, has received the Government award for meritorious vaccination.

A NEW HOSPITAL is to be built at Peterhead.

THE School of Medicine in Paris, it is stated, will reopen this week.

At their meeting last week the St. Pancras Board of Guardians carried, by 4 to 1, a vote of thanks to Drs. Bridges, Claremont, and Dowse, for their fidelity and despatch in regard to the affairs of the Workhouse Infirmary.

THE Islington Board of Guardians have increased the salary of Mr. Broome, the Vaccination Inspector, from £100 to £120 per annum.

At Zurich, during the last session, 1871-72, there were 145 male Medical students and 24 female.

ACCORDING to the *Kentish Express*, the Committee of the Dover Hospital have appointed a Dispenser at a salary of 5s. per week! We pity the patients.

THE Halifax Sanitary Committee have awarded Mr. Hodgson Wright £52 10s. for services as Medical Officer during the small-pox epidemic. They have also resolved to appoint an Officer of Health for the borough.

THE *Times of India* says that the Agricultural Department is about to commence a crusade against the drug gunga. Mr. Hume adduces statistics showing that of all causes of insanity in India gunga is the most prolific.

MEMOIR OF SIR JAMES Y. SIMPSON, BART.—We understand that, at the request of the executors of the late baronet, his friend, Professor Duns, D.D., F.R.S.E., has undertaken to write his biography.

SUDDEN DEATH OF A PHYSICIAN.—Dr. Masfen, of Stafford, was, we regret to say, found dead in his room on Monday evening, between nine and ten o'clock. One of the servants went into the room and left him writing, or about to write, a letter. On his return he lay upon the floor, and it was then found that he was quite dead. The deceased was 41 years of age.

UNIVERSITY OF DUBLIN.—SCHOOL OF PHYSIC.—The opening address of the summer session was delivered in the Examination Hall, Trinity College, on the afternoon of Saturday the 6th instant, by Dr. Stokes, Regius Professor of Physic. The subject of the discourse was "State Medicine." A large and distinguished assemblage was present, including the Presidents of the Colleges of Physicians and Surgeons, the Governor of the Apothecaries' Hall, the Provost and Vice-Provost of Trinity College, Mr. Justice Lawson, Sir John Gray, M.P., and many others.

PROFESSOR DOLBEAU.—The following is the occurrence as stated by M. Alglave in the *Révue Scientifique*, which has brought such odium upon Professor Dolbeau, and which excited so tumultuous a demand for an explanation by the students of the Faculty:—M. Dolbeau, during the war of the Commune, received into the Beaujon one of the federalists who had been wounded in the foot. The wound being very slight, M. Dolbeau was about to send the man away, when he supplicated him to be allowed to remain, declaring that he did not wish to fight any more for the Commune, but that if he returned home he would be compelled to do so in spite of himself. M. Dolbeau allowed him to stop. About a fortnight afterwards, the Versailles army having gained possession of the *quartier*, M. Dolbeau spontaneously indicated to an officer of the army, who could not conceal his surprise, this federalist who had been under his care. The soldiers seized him and were about to shoot him, when a general passing by commanded them to desist. It is quite certain that two of M. Dolbeau's *internes*, one of whom had received the gold medal, instantly quitted his *service*, and a month elapsed before their posts could be filled up.

DR. ROBERT FOWLER, who for sixteen years was a District Medical Officer of the late East London Union, was this Easter nominated one of the Guardians of the Parish of St. Botolph, Bishopsgate. It was the first vacancy that had occurred since Dr. Robert Fowler, although the Senior Medical Officer of the three City Unions, failed at Midsummer, 1870, in being appointed one of the District Medical Officers of the Amalgamated City of London Union. The clerk of the Union has, however, struck out Dr. Fowler's name as being disqualified. The Local Government Board has yet to decide judicially whether the fact of Dr. Robert Fowler being an annuitant under the Poor-law Amendment Act, 1867, section 20, and being paid his annuity out of the Metropolitan Common Poor Fund, as enacted by the Metropolitan Poor Amendment Act, 1869, is thereby amenable to the proviso of 5th and 6th Vic., c. 57, sec. 14—viz., "That no person receiving any fixed salary or emolument from the poor-rates in any parish or union shall be capable of serving as a guardian in such parish or union." Dr. Robert Fowler has also been

solicited to stand for the present vacancy in the number of Common Councilmen for the Ward of Bishopsgate.

THE FRENCH PROVINCIAL MEDICAL FACULTIES.—Great local exertions are being made on every side for the promotion of these. The Government has, as we have already noticed, determined upon the establishment of that of Nancy, in lieu of the Strasburg Faculty; but to this end great local resources will be contributed. A deputation from Bordeaux has been most favourably received by the Government, and has received a promise of legislative sanction for the efforts about to be made by the municipality, which has agreed to provide all necessary buildings, and to contribute a large annual sum towards the expenses of the new Faculty. The municipal authorities at Toulouse are also on the point of sending a deputation to the Government, hoping, they say, to obtain that recognition from a Republic of their claims to the establishment—or rather to the re-establishment—of a Medical Faculty which the Imperial Government repeatedly refused. The Lyons municipality, finding that the Government, for financial reasons, cannot just yet raise the Medical School of that city into a Faculty, has determined, in most courteous and gratifying terms, to provisionally increase the very moderate payments of the Professors of the School, and has promised large assistance in the event of the Faculty being established.

NOTES, QUERIES, AND REPLIES

He that questioneth much shall learn much.—Bacon.

C. O., Oundle.—You shall hear next week.

41, Davies-street.—We fear that we cannot furnish Miss Witton with any further information.

Health of Scarborough.—The Scarborough authorities have published a report on the condition of their town, in which they say that they have spent £50,000 in street improvements and drainage; that they have twenty-one miles of streets and roads, of which four miles and a half remain to be built on; that they have twenty-two miles and a half of sewers; and that no part of the inhabited area of the borough is without drainage. The estimated population on April 2 was 24,259, but in the season it is nearer 50,000. The rate of mortality (duly corrected for this increase of population) is not above 19 per 1000; nevertheless, they have taken the opinion of Mr. Bazalgette with regard to the extension and ventilation of sewers and the removal of refuse.

THE BAKER BROWN FUND.

This fund is being raised on behalf of Mr. Isaac Baker Brown, who is paralysed, and in great pecuniary distress.

ADMINISTRATION OF ALCOHOL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Would you grant me a small space in your valuable journal to express my thorough concordance with the valuable paper of Dr. Lionel S. Beale in your impression of last week on "The Propriety of Prescribing Alcohol for the Sick," and on the "Medical Declaration respecting Alcohol."

It is a sad and most lamentable state of things to think that 250 of our metropolitan Professional brethren out of some hundreds (as well as thousands of provincial Medical men) should take upon themselves to censure the rest of the Profession with performing and being the means in their malpractice of causing such an awful and heartrending condition of the country as the "National Temperance League" have the audacity to express is the case in their pamphlet.

The accusation is made, I think, against provincial men more than metropolitan, because the Declaration excludes the names of the former.

It is also giving the National Temperance League, as well as other teetotal societies, the advantage of making great capital out of it, and also depreciating the influence of the Profession generally, except those who have, I think, unjustly signed the Declaration.

If a typhus or typhoid fever patient on recovery should still have the weak resolution to continue taking stimulants to excess, simply because it was found necessary in treatment, and the only means to keep the flickering spark of life from disappearing, why should the Medical attendant be

libelled with the cause of his or her intemperance, when no doubt if he saw it was necessary he would use all moral persuasion to the contrary, as well as diminishing the quantity of alcohol gradually as life was approaching a state of convalescence, in a similar manner that the influence of opium is got rid of? Apologising for trespassing upon your valuable space,
I am, &c., MEDICUS.

VACCINATION ETIQUETTE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
SIR,—When a district vaccinator, from error in judgment, vaccinates persons in the district of another vaccinator, and being afterwards convinced of his error, still applies for payment and receives it from the Government, owing to the latter not wishing to be too particular in their payment of accounts at a time of emergency, ought he to retain the whole sum or hand over a portion of it to the district vaccinator in whose district he had performed the service by mistake?
I am, &c., V. V.

[He ought to hand over half the fees to the vaccinator whose district he invaded.—Ed.]

PILES AFTER LABOUR.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
SIR,—Any of your readers engaged in the practice of midwifery will confer a great obligation by informing me any means their experience has taught them of averting hæmorrhoids after labour, either by prophylactic or direct treatment. A patient of mine suffers severely from them after each labour, and so severe and continuous is the anguish for four or five days and sleepless nights, that she anticipates the pains of labour as nothing in comparison.
I am, &c., R. E. P.

APPOINTMENTS FOR THE WEEK.

April 13. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Mr. R. A. Proctor, "The Star Depths."

15. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. Thorowgood will exhibit some new French Pharmaceutical Preparations. Dr. Leared, "A Remarkable Recovery after a Pistol-shot Wound through the Thorax." Mr. Royes Bell, "On Enchondroma of the Thumb." Dr. Edwards-Crisp will read an abstract of the Fothergillian prize essay for the year 1872 "On Croup."

16. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Dr. Thorowgood, "Stricture of the Oesophagus." Dr. Langdon Down, "Abscess of the Liver, with Ulceration of the Colon." Dr. Bristowe, "Effusion of Blood into the Corpus Striatum, and Gangrene of the Lower Extremities owing to Obstruction of the Aorta by a Clot;" "Carcinoma of the Descending Colon, causing Fatal Obstruction." Dr. Payne, "Intra-cardiac Tumours." Dr. Moxon, "Lymphoid Cancer of the Small Intestine." Dr. Kelly, "Heart with Vegetations on the Valves from a Case of Acute Chorea associated with Embolism." Mr. Durham, "Intussusception of the Rectum." Mr. Croft, "Osteo-sarcoma of the Lower End of the Femur."

ROYAL INSTITUTION, 3 p.m. Dr. Guy, "On Statistics, Social Science, and Political Economy."

17. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

SOETY OF ARTS, 8 p.m. Meeting.

18. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Dr. J. F. Payne, "On a Case of Injury to the Cervical Sympathetic."

ROYAL INSTITUTION, 3 p.m. Dr. Tyndall, "On Heat and Light."

19. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 9 p.m. Mr. A. Vernon Harcourt, "On the Sulphurous Impurity in Coal Gas and the means of removing it."

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 6, 1872.

BIRTHS.

Births of Boys, 1193; Girls, 1166; Total, 2250.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.67 in. The highest was 30.31 in. on Saturday, and the lowest 29.16 in. on Sunday, the 31st ult.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

ROYAL MEDICAL BENEVOLENT COLLEGE.

BIENNIAL FESTIVAL.

The Council have the pleasure to announce that the Right Hon. the Viscount MIDLETON has kindly consented to take the Chair at the BIENNIAL FESTIVAL of the College, which will be held at WILLIS'S ROOMS, King-street, St. James's, on FRIDAY, the 10th of MAY next. Dinner at Half-past Six o'clock. The following Gentlemen have undertaken to act as Stewards on the occasion, when it is hoped that there will be a large gathering of the friends of the Institution:—

Adams, William, Esq., F.R.C.S., Henrietta-street.	Graham, G. Y., Esq., M.R.C.S., Stockport.	Monckton, D. Henry, Esq., M.D., F.R.C.S., Rugeley.
Alexander, William, Esq., M.D., F.R.C.P., Halifax	Hall, John Charles, Esq., M.D., F.R.C.P., Sheffield.	Newman, William, Esq., M.D., F.R.C.S., Stamford.
Baggallay, Sir Richard, M.P., Q.C., Queen's-gate.	Hall, John R., Esq., J.P., The Grange, Sutton.	Nicholson, John F., F.R.C.S., Stratford-green.
Bateman, John F., Esq., F.R.S., D.L., Moor-park, Farnham.	Hamilton, John James, Esq., St. Helen's-place.	Oldham, Riton, Esq., F.R.C.S., West Hartlepool.
Blackburn, Joshua, Esq., J.P., Brockwell Hall, Dulwich.	Hammond, Joseph H., Esq., M.D., M.R.C.P., Preston.	Owen, Harvey K., Esq., M.D., F.R.C.S., Clap- ham-road.
Bleek, Charles, Esq., F.R.C.S., Warminster.	Hancock, Henry, Esq., F.R.C.S., Harley-street.	Peek, Henry W., Esq., M.P., Wimbledon House.
Britton, W. S., Esq., M.R.C.S., Acacia-road.	Hancock, H. J. Burford, Esq., Garden-ct., Temple.	Penrhyn, E. H. Leicester, Esq., J.P., East Sheen.
Burrow, John S., Esq., Great Malvern.	Hardman, William, Esq., J.P., Norbiton Hall, Kingston.	Philson, William, Esq., M.D., L.R.C.S. Ed., Cheltenham.

Dickson, Walter, Esq., M.D., R.N., Trinity-square.	Kerswill, Robert, Esq., M.R.C.S., St. German's.	Taylor, Charles, Esq., M.D., M.R.C.S., Camber- well-green.
Drage, Charles, Esq., M.D., M.R.C.S., Hatfield.	Kingsford, Edward, Esq., F.R.C.S., Sunbury-on- Thames.	Taylor, Thomas, Esq., M.R.C.S., Bocking.
Dunn, Robert, Esq., F.R.C.S., Norfolk-street.	Kingsley, Henry, Esq., M.D., M.R.C.P., Stratford- on-Avon.	Thompson, C. R., Esq., M.R.C.S., Westerham.
Easty, J. M., Esq., J.P., D.L., Wellesley House, Croydon.	Leslie, Louis, Esq., M.D., M.R.C.S., Alton.	Thomson, J. Roberts, Esq., M.D., M.R.C.P., Bournemouth.
Elliot, Robert, Esq., M.D., M.R.C.P., Carlisle.	Locock, Sir Charles, Bart., M.D., F.R.S., Hert- ford-street.	Turner, Roger, Esq., M.D., L.R.C.P.E., Petworth.
Fergusson, Sir Wm., Bart., F.R.S., F.R.C.S., George-street.	Lomax, Henry T., Esq., M.R.C.S., Stafford.	Walker, Joseph, Esq., M.R.C.S., Burslem.
Garraway, Edward, Esq., M.R.C.S., Faversham.	Manby, Frederic, Esq., M.R.C.S., East Rudham.	Watney, James, jun., Esq., M.P., Hyde-park-gate.
Goodwin, Robert D., Esq., F.R.C.S., Ashbourne.	May, George P., Esq., M.D., L.R.C.S. Edin., Maldon.	Webb, Francis, Esq., Southampton-buildings.
Griffin, R. W. W., Esq., M.D., M.R.C.S., South- ampton.	Mews, John, Esq., J.P., Westbourne-terrace.	Wildash, Henry C., Esq., M.D., M.R.C.S., Hythe.
Gurney, Samuel, Esq., J.P., F.R.G.S., Hanover- terrace.		Wilson, Erasmus, Esq., F.R.S., F.R.C.S., Hen- rietta-street.

Dinner Tickets, price One Guinea, may be obtained from the Treasurer, Henry Sterry, Esq., F.R.C.S., or from the Secretary, at the Office of the College, 37, Soho-square, where Donations and Subscriptions will be thankfully received. By order of the Council,
ROBERT FREEMAN, Secretary.

PEPSINA PORCI.

Messrs. BULLOCK & REYNOLDS

Beg to direct the attention of the Profession to the experiments upon Medicinal Pepsin by Professor Tuson, recorded in the "Lancet," Aug. 13th, 1870, which incontestably prove the very great superiority of their preparation in point of digestive power over every other Pepsin, British or Foreign. Dose—Two to four grains.

Messrs. BULLOCK and REYNOLDS will be happy to forward a Reprint of Professor Tuson's Paper on application.

3, HANOVER-STREET, HANOVER-SQUARE, W.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;
and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

NEPENTHE.

PREPARED EXCLUSIVELY FROM OPIUM. (Dose the same as Tinctura Opii.) Price 8s. per lb.

From the "Lancet," Dec. 18, 1869.

NEPENTHE, OR ANODYNE TINCTURE (PREPARED BY MESSRS. FERRIS AND CO., BRISTOL).

This preparation really consists, as stated, solely of opium, resembling somewhat the liquid extract of the British Pharmacopoeia. It is claimed for it that it does not produce headache, stupor, giddiness, depression of spirits, diminution of nervous energy, prostration of strength, nor constipation; it is doubtless less stimulating than those preparations of opium made with the solid and crude drug; and a further commendation of Nepenthe is its uniformity of strength. The Nepenthe intended for subcutaneous injection is of double the ordinary strength; and that it is really so we have verified by analysis.

May be procured direct from the Sole Manufacturers,

FERRIS, BOORNE, TOWNSEND, and BOUCHER,
Wholesale Druggists, Bristol,

And through all leading Wholesale and Retail Chemists in Great Britain and the Colonies.

NOTICE.—Notwithstanding the enormous and increasing advance in Opium, the price of Nepenthe remains the same, and it is now the cheapest as well as the best preparation of this important drug.

N.B. Two Pounds NEPENTHE, or One Pound NEPENTHE and Three Pounds Ferris and Co.'s SYRUP of CHLORAL, will be sent, Carriage Paid to any Railway-station on receipt of P.O.O. for 16s.

ORIGINAL LECTURES.

LECTURES ON THE
COMPARATIVE ANATOMY OF THE ORGANS
OF DIGESTION OF THE MAMMALIA.DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE IV.

THE second family of Apes, the *Cercopithecida* or *Cynomorpha* of Huxley, contains all the rest of the Old World species. It is divided into two groups or sub-families, chiefly distinguished by the structure of their digestive organs.

The one which is usually placed first consists of monkeys generally of slender form, with elongated limbs, very small anterior thumbs, and a long pendent tail. Of these, some are Asiatic, and constitute the genus *Semnopithecus*, the common hunooman or entellus monkey of India being the best known species; others are African, and being distinguished externally from the last by a still more rudimentary condition, or even absence, of thumb, have been generically separated under the name of *Colobus*. Among the Asiatic forms one of the largest species is remarkable among all monkeys for the extraordinary development of the external nose, which is far more prominent even than in man, whence by many naturalists it is made into a distinct genus under the name of *Nasalis*, though in all other respects its structure has not been shown to deviate from the other *Semnopithecii*.

None of the animals of this group appear to have been dissected by Hunter, and, with the exception of certain parts of the organisation of one or two of the commonest forms, their anatomy has never been properly described. With the exception of the hunooman the habits of the whole group in a state of nature are very little known, but it is probable that they are more exclusively vegetable feeders than the ordinary monkeys; young leaves and fruits are said to constitute the chief sources of their food.

Of the digestive organs of the entellus monkey the Museum contains several preparations. The tongue is rather thick and fleshy, with nearly parallel sides and a truncated tip. The circumvallate papillæ are three in number, of which the posterior or median papilla is smaller and less prominent than the other two. The fungiform papillæ are scattered pretty evenly over the surface, except upon the middle of the dorsum. The filiform papillæ have a thick, hardened epithelial covering, and are rather short, pointed, and mostly directed backwards. The lateral groups of vertical follicles in front of the attachment of the palato-glossal folds are strongly marked. As in the gibbons, there is a lamelliform triangular sublingual papilla ending anteriorly in a pair of long, narrow, pointed processes. The uvula is long and pointed. As far as is known, none of the *Semnopithecii* have cheek-pouches. Statements to the contrary met with in some works have never been substantiated by actual observation.

The remarkable condition of the stomach of these monkeys—briefly noticed by Wumb(a) in the proboscis monkey, described by Otto(b) in *Semnopithecus leucopymnus*, and more fully by Owen(c) in *Semnopithecus entellus* and *fascicularis*, and subsequently by the same anatomist in *Semnopithecus maurus*, by Martin in *S. nasalis*,(d) and now known, in short, to be characteristic of the whole group—may be described as follows:—An ordinary stomach must be supposed to be immensely elongated, and gradually tapering from the cardiac end to a very prolonged, narrow, intestiniform pyloric extremity. Then two longitudinal muscular bands, corresponding in situation to the greater and lesser curvatures of an ordinary stomach—the former commencing just below the fundus, and the latter at the cardiac orifice, and both proceeding towards the pylorus(e)—are developed, so as to pucker up the cavity into a number of pouches, exactly on the same principle as the human colon is puckered up by its three longitudinal bands. These pouches are largest and

most strongly marked at the œsophageal end, and, becoming less and less distinct, quite cease several inches before the pylorus is reached, the last part of the organ being a simple smooth-walled tube. The fundus, or cardiac end of the stomach, is formed by a single large sac, slightly constricted on its under surface by the prolongation of the inferior longitudinal band, or that corresponding to the great curvature. The œsophagus enters into the upper part of the left or pyloric end of this sac, or rather at the point of junction between it and the second (also a very large) sacculus. Furthermore, the whole of this elongated sacculated organ is, by the brevity, as it were, of the lesser curvature, coiled upon itself in an irregularly spiral manner, so that when *in situ* the pylorus comes to be placed very near the œsophageal entrance.

There is little ground for describing the stomach as composed of three divisions; in fact, the anatomist whose description is generally followed in this respect, expressly guarding himself against being “understood to suppose these as being equally distinct with the different cavities of a ruminant or cetaceous stomach,” says—“they are not characterised by any essential difference of structure, for none of them possess a cuticular lining.” The only internal difference observed was “greater vascularity and more abundant distribution of nerves”(f) in the pyloric portion, as, in fact, is the case with most other stomachs. I am not aware of any observations having been made upon the distribution of the glandular structures in the walls of this curiously constructed organ.

It is in the sacculated stomach of monkeys of this genus that one of the most highly-prized varieties of oriental bezoars is found.(g)

With regard to the alimentary canal, Professor Owen gives the length of the small intestine of *Semnopithecus entellus* as thirteen feet six inches, or as 8 to 1 in proportion to the length of the body, being relatively longer than in either *Cercopithecus* or *Macacus*, in which he found the ratios to be respectively $6\frac{1}{2}$ to 1 and 4 to 1. The large intestine was two feet ten inches long; the cæcum four inches, simple and conical, without any contraction dividing off a “vermiform appendage”; the biliary and pancreatic ducts entered the duodenum together about three inches from the pylorus.

I will return to the form of the liver in this genus after speaking of its structure in the next, in which I have had an opportunity of examining it more satisfactorily.

In an adult specimen of colobus (*Colobus vellerosus*), received from West Africa in spirit, there are no traces of cheek-pouches.(h) The tongue is long and narrow, with three large circumvallate papillæ, forming the corners of a triangle, with the apex directed backwards; close behind each of the large anterior ones is a smaller one of the same form. At the lower part of the frænum is a short and thick fleshy salivary papilla, constricted at the base, then dilating, and pointed and bifid at the extremity. The uvula is only represented by a muscular thickening in the middle line of the soft palate, producing no prominence on the edge, which is evenly arched. All the salivary glands are greatly developed, but more especially the submaxillaries, which are oval, compressed, two inches long, and one inch and a quarter in greatest width, and half an inch in greatest thickness, and in the usual situation, being concealed beneath the greatly expanded angular region of the jaw-bone. The masseter muscle is immensely powerful.

Unfortunately, the abdominal viscera of this animal had been removed before it came under my examination, but the Museum contains several preparations from a young example of the same species, which died in the Zoological Society's Gardens in 1864, which furnish some interesting information.

The stomach shows almost exactly the same form as that of *Semnopithecus*, a fact previously observed by Owen in the allied species *C. polycomus* (*C. ursinus*, Ogilby),(i) and by Dr. Murie in the East African species *C. guereza*.(k) The colon is very little sacculated, and the cæcum is extremely short and simple, in form a blunt cone three-quarters of an inch in length, and relatively shorter than in any other monkey which I have examined.

The liver is very remarkable, being very small and pushed up by the immense stomach quite into the left hypochondrium, no part of it passing the middle line. On the other hand, it is

(f) Owen, *Transactions of the Zoological Society*, vol. i., p. 67.

(g) An excellent account of the physical and chemical characters of these concretions is given by Mr. Taylor in the Catalogue of the Calculi and other Animal Concretions contained in the College Museum (Part ii., 1845).

(c) *Transactions of the Zoological Society*, vol. i., p. 65, Pl. 8 and 9. 1833.(d) *Proceedings of the Zoological Society*, 1837, p. 70.(e) Martin mentions three muscular bands in *S. nasalis*, but this does not correspond with other observations.

considerably extended from above downwards, in consequence of its very oblique position. What are the usually more or less horizontal anterior and posterior borders are nearly vertical.

noy's brief description of the livers of the entellus and the doue (*S. nemæus*), (1) I have little doubt but they are also similarly constructed. It is a form that does not bear out the idea of the author just quoted that it is intermediate between that of the anthropoid and the lower apes; but it rather appears to have been constructed on the type of the latter, and modified by, or accommodated to (as it were), the extraordinary development of the stomach with which it is found associated.

We now pass to a group of monkeys comprehending all the remainder of the Old World species, and which, though extremely different in outward form and habits—as may be seen by comparing the gentle and sprightly little round-faced, long-tailed *Cercopithecæ* with the heavy, ferocious, dog-faced, quadrupedal, stump-tailed baboons and mandrills—yet are wonderfully alike in essential anatomical characters, and include so many intermediate or connecting forms between the extremes just mentioned that it is extremely difficult to divide them into well-marked sub-groups or genera. They are, however, usually arranged in the following genera, each of which has a tolerably restricted geographical distribution:—(1) *Cercopithecus*

The umbilical fissure is well marked, extending nearly half-way across the liver. The right segment is divided by a very deep cleft (right lateral fissure) into two lobes, of which the central (Fig. 13), *rc*, is the larger. The fissure extends quite to the posterior or attached border, and is so deep that the right lateral lobe, *rl*, is only connected with the central by a thin layer of hepatic substance in the bottom of the middle part of the fissure. The left segment consists of a large lobe, *lc*, with a rounded external margin, and with its upper part curiously flattened, as if by the pressure of the great stomach. A small quadrangular flattened lobule, *ll*, attached to the upper part of this, to the left side of the fissure of the ductus venosus, appears to be a rudimentary and caudate lobes (Fig. 14), developed and elongated downwards, joining each other at an acute angle above; the former has a narrow neck and an expanded lobed termination. The vena cava, *vc*, runs quite superficially in its normal situation. The gall-bladder, *g*, is attached near the left side of the right central lobe, not reaching to its free border; and what appears to correspond with the cystic notch in livers of more normal form is a branch from near the middle of the umbilical fissure, running into the right central lobe opposite the fundus of the gall-bladder.

In two specimens of *S. nasalis* which I have examined the liver (one of which is mounted in the Museum) is formed on exactly the same general principle, and from Duvernoy's brief description of the livers of the entellus and the doue (*S. nemæus*), (1) I have little doubt but they are also similarly constructed.

and (2) *Cercocobus*, both African, rather small, slender monkeys, with long tails. The common green monkeys and vervets belong to the first; the mangabey to the second. (3) *Macacus*, almost entirely Asiatic, with one exception, which extends along North Africa to Barbary, and even the rock of Gibraltar. The rhesus and pig-tailed monkeys are examples of this genus. (4) *Cynocephalus*, including all the monkeys commonly called baboons, distinguished by the elongated muzzle and terminal position of the nostrils, all inhabitants of the African region, including part of Arabia.

As far as is known, all of these monkeys are characterised, as relates to their alimentary organs, by the possession of cheek-pouches, or special dilatations of the buccal mucous membrane, in which they can stow away a considerable portion of food until a quiet opportunity occurs of masticating and swallowing it. They have also all a simple stomach and a rather short conical cæcum.

As an example of this group, I may describe the digestive organs of a well-known species of baboon (*Cynocephalus anubis*), preparations of which are now before you. The animal was a nearly full-grown male, which died in the Zoological Society's Gardens on December 29, 1871.

One of the most characteristic features of the genus to which this creature belongs is the great elongation of the jaws, both upper and lower, the mouth projecting forwards in front of the nostrils and eyes, thus giving a far less human expression than in the comparatively round-faced monkeys constituting several of the allied genera. The baboons, in fact, present the extreme of prognathism met with in the whole order. The lips are thin and flaccid; none of the mucous surface appears externally when the mouth is shut. They are connected to the gums by a well-marked median frænum above and below. Their mucous lining and that of the cheeks is soft, smooth, and without papillæ, but thrown into folds near the angle of the mouth. The cheek-pouches are not greatly developed; each forms, when distended, a hemispherical cavity about two inches or rather less in diameter, placed far back on the side of the lower jaw, at the junction of its horizontal and ascending ramus, not shut off by a very distinct constriction from the general cheek-cavity, but only by projecting folds of mucous membrane, the anterior of which is about an inch within the angle of the mouth, and opposite the first lower molar. The integument and other tissues covering these pouches are thinner and more translucent than in the other parts of the cheek.

The duct of the parotid gland opens on a papilla in the upper part of the cheek-wall, close to its union with the gum, and opposite the interstice between the second and third molar teeth. It is altogether above the boundary of the cheek-pouch. The palate is long and narrow, its lateral boundaries, formed by the upper molar teeth, being nearly parallel. It is arched from side to side, more so posteriorly than in front. The mucous membrane is raised into a double series of crescentic ridges, one on each side of the middle line, harder and of a whiter colour than the spaces between them, extending from the front of the palate as far back as the last molar tooth, ten on each side, not symmetrically disposed, and smaller and more irregular at the two ends of the series. Each ridge has two unequal faces meeting at an angle on the summit, one, which is larger and more sloping, being turned forwards, the shortest and steepest face being directed backwards, so that their mechanical tendency would be to cause substances rubbed in contact with them to pass backwards rather than forwards. Behind the molar teeth the palate is redder, softer, and glandular.

The isthmus of the fauces is very small, and when the tongue is depressed is almost a square with the corners rounded off, the anterior pillars or palato-glossal folds being very strongly marked. The space between them is one inch in width, and they are situated five inches behind the incisor teeth. The soft palate terminates in the middle line by a uvula, rather shorter and more pointed than in man. The tonsils form well-marked elevations, the surface of which is covered with the openings of large follicles, as in man.

The tongue is 4.6 inches long, very narrow behind (not more than 1 inch), but broader (1.9 inch), almost spoon-shaped in front, with a very obtuse apex. Near the posterior part of the dorsum, a little way in front of the attachment of the palato-glossal fold, are a pair of very large circumvallate papillæ, with smooth, tumid, elevated outer walls, seven-tenths of an inch apart. In the middle line posterior to these (so that the three form the corners of an equilateral triangle) is another, much smaller and less conspicuous. Near this are several irregularly placed and still smaller papillæ that may be grouped

(1) Cuvier's "Anatomie Comparée," 2de edit., tome iv., 2de partie, p. 437. 1835.

in the same class, though they pass insensibly into the next. The fungiform papillæ are numerous and large, scattered pretty regularly all over the surface, but more numerous near the sides and apex, and most scarce in the middle part of the dorsum. They are circular in outline, and vary considerably in size. The conical or filiform papillæ are abundant, long, and almost hair-like over the greater part of the dorsum, where they are mostly directed backwards; shorter and more simple at the apex and sides.

At each side of the hinder part of the tongue, extending forwards for the distance of an inch from the point of attachment of the palato-glossal fold, just below the line of junction of the papillated with the smooth mucous membrane, is a row of slit-like orifices, about ten in number, placed obliquely, their upper ends slanting forwards, doubtless the openings of secreting follicles. A similar structure, though in a less developed condition, was observed in man and the other forms of apes which have been treated of.

The free folds of mucous membrane, diverging backwards from the apex, previously noticed on the under surface of the anterior part of the tongue in man and the chimpanzee, do not exist.

The tongue is attached in the middle line below by a large lax frænum, commencing an inch and a quarter behind the tip. Rather below the middle of its anterior edge is a soft, fleshy, flattened body two-tenths of an inch in length, terminating anteriorly in a pair of conical-pointed papillæ, and with notched lateral margins.

The submaxillary gland is of a flattened and broad oval form, an inch and a quarter in greatest diameter. Its duct (Wharton's) leaves its anterior edge (where are three or four loosely connected accessory lobules), runs straight forwards between the sublingual gland and the genio-hyo-glossus muscle, and terminates by a minute orifice on the upper or lingual surface of the sublingual papilla of the corresponding side, nearly two-tenths of an inch from the apex and very near the middle line. The duct is four inches in length.

The sublingual gland consists of an elongated mass in the usual situation between the mucous membrane of the mouth and the genio-hyo-glossus muscle, two and a half inches in length and three-quarters of an inch in greatest breadth. Its ducts (about a dozen in number) open by minute orifices along the side of the frænum linguæ, the first one being on the under surface of the sublingual papilla, others as far as two inches behind. In the anterior part of this region the openings are situated on the lower surfaces of a row of flattened papillæ continued backwards from the lateral margins of the large anterior sublingual papilla.

Abdominal Viscera.—The great omentum hangs down from the lower border of the stomach, and completely covers the intestines, passing down in front of them into the pelvis. It adheres to the large intestine only at the right extremity of the transverse colon, and sometimes to part of the ascending colon, the remainder of this intestine being quite free (as noticed by Hunter in his dissections of monkeys), and simply overlaid by, and not enclosed within, the omentum. It is formed, as usual, by a double layer of peritoneum descending from the stomach and returning behind that organ, enclosing a cavity which passes behind the stomach and communicates with the general peritoneal cavity by the foramen of Winslow. (m) The colon is larger and more convoluted than in man, especially on the left side. The three longitudinal bands are very strongly marked, and it is much sacculated as far as the commencement of the rectum, which is the narrowest part of the whole intestinal canal.

When the stomach is inflated *in situ*, with all its natural connexions, its pyloric end turns forwards against the anterior abdominal wall. Its shape scarcely differs from that of the human stomach; but the pyloric portion is rather more elongated, tubular, and bent upon the small curvature. It is not so distinctly constricted from the main cavity as in some of the *Simiide*.

The small intestine is 110 inches long, or rather more than four times the length of the animal. Its mucous lining shows no trace of valvulæ conniventes. The villi are numerous, but soft and small. Peyer's glands are large, about twenty in number altogether; most abundant in the lower half of the

intestine, where they are mostly one inch and a half to two inches long, and half an inch broad. The bile-duct enters the duodenum not quite two inches from the pylorus.

The large intestine is altogether fifty inches in length; therefore much longer in proportion to the small intestine than in man. Throughout its mucous surface are scattered dark-coloured follicles, of the size of pins' points, either solitary or aggregated in groups of from two to six or eight in number, arranged in an oval form, the long diameter of which is transverse to that of the intestine.

The cæcum is three inches long, obtusely conical; the true apex (as indicated by the disposition of muscular bands which centre in it) is terminal, but it is not constricted or lengthened out into an appendix vermiformis. (n)

The pancreas is very like that of man in form and connexion, the right end adhering very closely to the duodenum. It is five inches in length.

The liver appeared large for the size of the animal. When laid out flat on its under surface its outline is rather square, but longer transversely than from before backwards, being seven inches and a half across, and six in greatest depth. The notch for the umbilical vein, one inch and a half in depth, is situated an inch to the left of the middle of the organ. The united central lobes are nearly square in shape. The great lateral fissures are very deep, especially that on the left side, which almost entirely cuts off the left lateral lobe from the rest of the liver. The lateral lobes are about equal in size, but of different shape, the left being subtriangular with a rounded outer margin and a pointed anterior extremity, the right being four-sided.

On the under surface (Fig. 15) the umbilical fissure, *u*, is

FIG. 15.

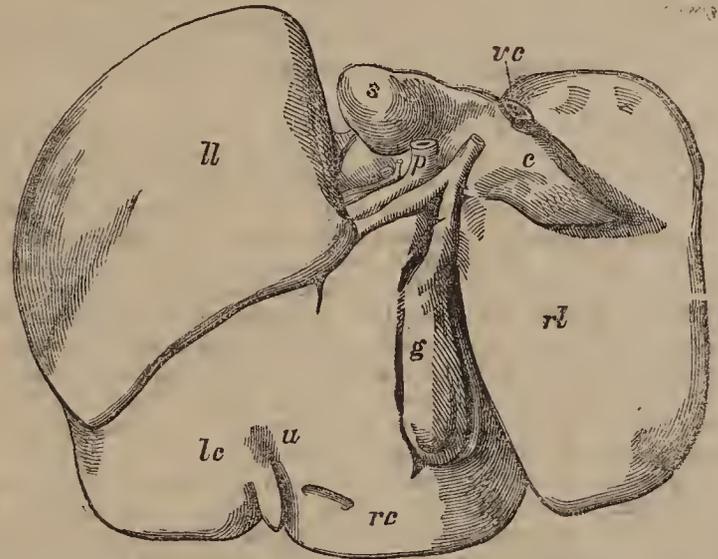

FIG. 15.—Under surface of liver of Anubis Baboon (*Cynocephalus anubis*): ll left lateral lobe, lc left central lobe, vc right central lobe, rl right lateral lobe, s Spigelian lobe, c caudate lobe, u umbilical fissure, ve vena cava, p vena portæ, g gall-bladder.

bridged over for the middle two-fourths of its extent, but the fissure of the ductus venosus is deep and distinct. The transverse fissure is an inch and a half in extent. The fossa of the vena cava is not bridged over, the vein being quite superficial. The Spigelian lobe, *s*, is rather small, forming a simple, sub-compressed, nipple-like prominence, directed to the left. The caudate lobe, *c*, is distinct, trihedral, sharp-pointed, free from the right lateral lobe in the greater part of its extent, two inches long, connected with the Spigelian lobe by a broad base, and with its apex not reaching the edge of the right lateral lobe by nearly an inch. The gall-bladder is rather small and narrow, deeply embedded in a fossa near the right border of the right lateral lobe, the free anterior edge of which its apex does not reach by a distance of an inch.

A similar form of liver characterises all the other members of this family; in the deeply cleft lateral fissures it differs from that of the *Simiide*, and in the comparatively small pointed caudate lobe from that of the families next to be spoken of.

(To be continued.)

(m) I have found this arrangement of the great omentum in all the members of this group which I have dissected, though M. Broca, who has recently written on this subject, says:—"Chez la guenon mono (*Cercopithecus mona*) et chez le papion (*Cynocephalus sphynx*), le grand épiploon ne se compose que de deux feuillets . . . il ne renferme aucune cavité." ("L'Ordre des Primates Parallèle Anatomique de l'Homme et des Singes." Paris, 1870, p. 119).—See Lecture ii., p. 291.

(n) In a specimen of *Macacus silenus*, Hunter noticed "an appendix cæci of about half an inch long, and of a pyramidal figure." ("Essays and Observations," vol. ii., p. 13). I have seen, in a young *Cynocephalus hamadryas*, the terminal portion of the cæcum suddenly constricted and forming a kind of appendix; but these are cases of individual variation, approaching the condition characteristic of the higher family of *Simiide*.

CLINICAL LECTURES ON INTESTINAL OBSTRUCTION.

By THOMAS BRYANT, F.R.C.S.,
Surgeon to Guy's Hospital.

LECTURE III.

GENTLEMEN,—In the two preceding lectures we have considered in its Surgical aspect the subject of intestinal obstruction, and we have traced this out to causes either inside or outside the intestine; to simple atony of the bowel, to tumours either within or external to and pressing on the gut, to bands, or to intussusception, and we lastly came to consider the subject of hernia, but only in its displaced form. I purposely avoided the ordinary palpable form of hernia that comes before us so very generally, for I have been willing to assume that, as regards the diagnosis and treatment of such cases, there is nothing but what you are already quite familiar with and fully understand. I propose to-day to follow up that subject, and more particularly with regard to the question of exploration in hernia. I have told you in a previous lecture that in all cases where you feel called upon to explore, and a hernia exists, you should begin your abdominal examination at that part. I illustrated that last time by those cases of hernia known as inter- and intra-parietal hernia. I showed you how in one case, the congenital form, the tumour had simply been caused by the pushing up into the abdominal cavity of the vaginal process of peritoneum that forms the covering to the cord in such cases. In the second case, I told you that rupture had taken place at the neck of the sac, and the intestine had been pushed through the opening; and in the third that a new sac had been formed by the dilatation of one side of the neck of the original sac.

I explained to you how reduction *en masse* could occur, and illustrated it by two cases—one my own, and one kindly lent by my friend Mr. Morris. What, therefore, I should like you to bear in mind as a clinical rule in practice is this—In all cases of hernia, always (if there are symptoms of intestinal obstruction) explore it; but I would even go further than this, and say—In all cases of intestinal obstruction, not only when a hernia exists, but whenever there is a history of old hernia, or whenever you have a tittle of evidence that a hernia may exist, it is your duty to explore it, and, as I have before said, to begin your exploration at that spot. Failing to find there any local cause for the symptoms, you may then have to enlarge your opening into the abdominal cavity itself.

I propose now to draw your attention to cases, not of hernia, but of tumours simulating hernia, in which the symptoms of hernia exist, and which may give rise to this fallacy. One of the most striking of such cases I will now read to you from my notes taken at the time:—

Case simulating Strangulated Hernia—Suppuration of the Tunica Vaginalis of an Undescended Testicle.

On August 16, 1871, I was called by Mr. Baxter Forman, of Stoke Newington, to visit a young gentleman, aged 14, who had symptoms of strangulated intestine. He showed no signs of puberty, and his left testicle had not descended below the inguinal canal. Three days before my visit, without any assignable cause, he was seized with abdominal pain and vomiting, constipation existing. A swelling in the left groin also appeared. Mr. Forman saw him on the second day, and thinking it probable that some hernia had descended into the open vaginal process of the peritoneum, applied the taxis, but with no good result. He had, however, some slight relief from the bowels. When I saw him on the third day he was in great pain, vomiting whatever he took; the abdomen was tender. In the left groin a swelling the size of an egg existed, in which was the testicle. This swelling fluctuated, and was elastic. The pulse was 120; tongue furred. I felt nothing was open to us but to explore the tumour, and this I did.

I laid open the canal, and then the vaginal process of the peritoneum which included the testicle, and in doing this a quantity of pus at once escaped. The peritoneal process was much thickened, and its cavity was lined with lymph. The testicle was small and apparently uninvolved. There was no hernia nor any communication with the abdominal cavity.

After the operation all symptoms disappeared, and a good recovery ensued. It was clear that all the symptoms were due to an acute inflammation of the tunica vaginalis; they had nothing to do with the bowel.

This boy's case was a very striking one; from a clinical

point of view it is full of interest. There were all the symptoms of strangulated bowel, accompanied by a local tumour in the groin, just in the position in which a hernia would be naturally found, and the Surgeon unquestionably had not the shadow of a doubt as to its being a hernia. Holding that opinion, he applied, and rightly applied, the taxis. He told me at the time it was not very forcible, and I had no reason to think from the appearance of the tumour that it was; there was no ecchymosis or other such external marks as one generally expects to find as the result of rough usage. What, then, was to be done? Acting on the rules I have given you, it was clearly my duty to explore it, and then I discovered it was nothing more than acute suppuration of the tunica vaginalis—acute hydrocele, I might call it—involving that particular part of the cord. After the operation, recovery ensued. What I would wish you to bear in mind however, is this—that we may get suppuration in the tunica vaginalis in the groin, simulating hernia and associated with all the symptoms of strangulation; but it does not make the treatment differ in the least from that which I have laid down. In the case before us there was suppuration, and, had we not opened it externally, it would have been more likely to have travelled up into the abdominal cavity rather than to have discharged itself externally. Allow me now to quote another case of great interest, in which some difficulty in diagnosis existed; it occurred in the practice of the Messrs. Toulmin, of Upper Clapton. The case is as follows:—

Mark C., aged 4, was suddenly seized, on January 27, 1872, with a painful swelling occupying the left scrotum and groin, the neck of the swelling passing well up to, if not through, the internal ring, from which it could not be separated. The swelling was painful, and was associated with constipation. Mr. Toulmin was sent for, and, regarding it as a case of hernia, he applied the taxis. No success following its application, he sent for me. When I saw the boy, twelve hours after the first appearance of the tumour, I found the left groin filled with a tense swelling, having a longer transverse axis than vertical, and the scrotum distended with a translucent swelling. The two swellings were apparently continuous, if not the same. The scrotal could not be separated from the inguinal, nor the inguinal from the abdomen. The parts were very tender, and could only be examined when the child had been anæstheticised. There was no vomiting; but local pain, abdominal pain, and constipation existed. I accordingly tapped the transparent scrotal swelling, and drew off some blood-stained fluid that coagulated into a solid mass on boiling. The inguinal swelling, however, remained unaffected. Pressure upon this made no impression upon it. Thinking it possible, therefore, that the inguinal tumour might be a hydrocele of the cord, as the scrotal was evidently a hydrocele of the testicle, no further proceedings were undertaken; for with the chance of its being a hernia the operation of tapping was discarded, and with the chance of its being a hydrocele any exploratory cutting operation was postponed till some evidence of strangulation appeared—for it must be remembered that no vomiting had taken place.

Under these circumstances it was agreed to leave things alone, and wait. Twelve hours after chloroform had been given, he vomited once, and then remained quiet for twenty-four hours, when he vomited again, but so slightly that it was thought it might have been due to food which he had taken, as the child was hungry. When it reappeared, after the lapse of another day, I was again summoned.

I then found the tumour had altered in shape, and clearly presented the long pyriform appearance of a recent congenital form of hernia. It was then agreed upon to explore it.

With this view chloroform was again given, and the taxis applied, the tumour suddenly disappearing—that is to say, its inguinal portion passed upwards into the abdomen with the sudden rush of a hernia, and the scrotal portion was left. The hernia was reduced, and the hydrocele remained. A good recovery ensued.

How it was that the taxis had failed when originally applied it is difficult to decide; but it was clear that Mr. Toulmin's original opinion as to its nature was the correct one, and that the presence of the hydrocele when I saw it made me doubt the fact.

Here we had clearly a compound case—acute hydrocele with hernia. Of course some might say, Would not the hydrocele be due to the taxis that had been applied? Well, that is a fair possibility; it might have been produced by the mechanical irritation set up. But, however, waiving that point, let us return to the case. Recognising the fact of the lower part of the swelling being due to hydrocele, I was somewhat disposed

to think the upper part might be owing to the same cause. But I am bound to state that the Medical man attending the case still adhered to his first opinion, and believed it to be a hernia. The true nature of the case, however, being manifest, it was easy to see how the symptoms were caused. The hernia could not descend into the tunica vaginalis through the external ring on account of the presence of this watery bag below, and thus we see that the tumour had its longest diameter transversely between the internal and external rings, simply because it was mechanically prevented from coming down by the hydrocele. Here are two cases, then, the clinical value of which I do not think can be well equalled.

So much, then, gentlemen, for the subject of hernia as a cause of intestinal obstruction; we will now pass back again for a few moments to discuss a point connected with the treatment of intestinal strangulation. I told you that in cases of acute intestinal strangulation of bowel I did not think the Surgeon should any more hesitate in performing an abdominal section than he would hesitate in opening a hernia when symptoms of strangulation existed. I cannot help speaking strongly on this point. I do think the two cases are precisely similar. We all know that in a case of strangulated hernia, if relief is not given, and given speedily, death is the inevitable result; and we as well know that in cases of acute intestinal obstruction, if relief is not afforded, death must as inevitably occur. Why, then, should we resort to a remedy that proves so successful in the one set of cases, and hesitate to apply it in the other? The only thing that has hindered the Surgeon is a general horror of the operation, and the greater magnitude of it. When you get it associated with the presence of a hernia, we have already seen your course is clear before you. You are bound to explore that; and, finding nothing there, are bound to go up further. But I am talking now of cases where you find nothing of the kind—such cases, I mean, as bands or twists; cases of internal strangulation. Let us consider what means the Surgeon has at his disposal for their treatment. If you just ask yourselves what a strangulated bowel really means, you will easily see that other means than those which we have already discussed might be thought of, by which relief could possibly be produced. I will lay before you the line of thought in the way in which it presented itself to me. Here is a piece of intestine passing through a tight ring. We will assume for the moment that the ring is a solid ring—one that does not stretch or expand. The intestine beyond the ring becomes distended and enlarged from flatus or fæces. The bowel becomes strangulated in its unnatural position by a want of fair relationship between the intestine and the ring. It may be an effusion of serum takes place on account of pressure on the vessels preventing the return of blood; the bowel becomes irreducible and inflamed—in fact, strangulated—and if left alone would subsequently slough, just as my finger would slough if I tied a piece of string tightly round it. The bowel becomes strangulated by causes acting within the ring in the bowel itself. Now, I think it is not difficult to understand that if we could empty that intestine of its contents the arrest of the flow of blood out of the intestine would cease, the circulation would go on, the strangulation would cease. Now, you see what I am aiming at as regards the possibility of taking away the cause of strangulation. We cannot take away the constriction of the ring, of the neck of the sac without division; but cannot we give relief through the intestine itself? Let us consider this point.

You know the question of the desirability of puncturing the intestine when distended with flatus has been well ventilated of late. Many cases have been recorded in which the operation has been performed with more or less success. I honestly say that my prejudices have been much against it, although there is every reason why it should have been otherwise, because at this institution it has been tried more than at any other. Mr. Stocker, who has more clinical experience than almost any man in London, has always been in favour of it. He always used to say, when a man was suffering from wind in this way, "Tap him; the cow-keeper taps his cows and they recover, and why should we hesitate to tap in similar cases?" I have done it myself on two occasions in cases of ileus, and with immense relief. Of course the great argument against it is this: you tap an intestine that is full of flatus, fluid, or fæces, and in putting your needle in there is the danger that some would escape into the abdominal cavity and set up peritonitis. It is solely that fear that has prevented my doing it except in extreme cases. But I think I can give you a case which will help you to form some idea as to the correctness of these conclusions. It is as follows:—

Strangulated Scrotal Hernia (Cæcal)—Herniotomy—Puncture of Intestine—Recovery.

On August 18, 1871, my friend Mr. Kelson Wright, of Kennington, asked me to see with him a case of strangulated hernia in an old, half-childish man, aged 71. He had been the subject of a right scrotal hernia for thirty years, and had worn a truss. He had had occasional difficulty in its reduction after its descent; but Mr. Wright had always succeeded in reducing it. On the present occasion the same effort had failed, and when I saw him vomiting had existed for two days, and a large hernia existed in the right side of the scrotum; one portion of it felt tenser than the other. Chloroform was given, and the taxis employed, but without success; consequently herniotomy was performed, it being necessary to expose the bowel. When this was done the cæcum escaped, dragging down with it some three inches of small intestine covered with peritoneum—the external ring pressing firmly upon it. With some difficulty the bowel was returned, the wound brought together, and the whole carefully bound together by means of a pad and spica bandage of strapping. A morphia suppository was given.

During the night, however, this old man would get out of bed, and in the attempt he tore off all the dressings. As a consequence, the bowel came down again; vomiting returned, with abdominal pain. Mr. Wright was sent for, but all his efforts to return the intestine were fruitless. I was consequently sent for. I found the old man lower than when I saw him before. The hernia was down larger than ever. I gave him chloroform, and attempted reduction, but failed. I then increased the opening at the internal ring; but on doing this more large intestine came down, and no effort of mine could reduce it. I consequently punctured the intestine in four or five places with a grooved needle, and let off the wind; this measure enabling me to do what, under other circumstances, I could not do—reduce the hernia. The wound was then re-adjusted, and a good pad firmly secured on with strapping, opium being given; and, I am pleased to add, no one bad symptom followed these rough measures, and a good recovery ensued.

Mr. Wright tells me the wound united without a drop of pus appearing, the whole uniting by primary union.

It was interesting to note that when the bowel was punctured nothing but wind escaped, except in one spot, where the smallest drop of blood oozed out, evidently from the congested intestinal walls. None of the contents of the intestines escaped even after the rough manipulation to which they were subjected.
