ORIGINAL LECTURES.

SKETCHES OF
SUCCESS AND FAILURE IN MEDICINE.

BEING THE SUBSTANCE OF THE
LUMLEIAN LECTURES AT THE LONDON ROYAL COLLEGE OF PHYSICIANS
IN 1862.

By CHARLES J. B. WILLIAMS, M.D., F.R.S.(a)

To one long engaged in the practice of Medicine, there are few conclusions more striking than the general one of the uncertainty of the art. His whole career seems to be made up of a series of failures and successes. He may deem himself fortunate if the successes preponderate over the failures, or, at least, by their magnitude and prominence they throw these latter into the shade. Of course, much may be said of the imperfections and shortcomings of the art; and more still may be urged on the intractability of disease, and the inevitability of death. It is not to be supposed that we are to make our patients immortal. But it is not unreasonable on the part of the public to expect us to say what we can cure, and what we cannot cure, and to look for results more or less in accordance with our predictions; and it is equally reasonable on our part to point out that although in many instances we can fulfil these expectations, yet in others the powers of health and disease, of life and death, may be so nicely balanced that it is impossible to predict the result with any certainty. And this candid avowal of failure in our prognostic powers is more safe and more honest than bold guesses at the result, which may be denounced as sheer gambling with the chances of life and death.

In truth, the fair appreciation of success and failure in Medicine will depend much on the intelligence of the community. No doubt, of late years, the public mind has become more enlightened, and can distinguish between organic and functional disease, and will not expect great achievements in the former, where structure and mechanism are extensively injured. But neither the public nor the Professional mind is always alive to the equal impotence of Medicine in those terrible disorders in which a noxious ferment, brewing in the living blood, converts its life-giving stream into a channel of deadly poison, which arrests and perverts the functions, and reduces the whole body to a mass of corruption.

Observe a bad case of malignant scarlatina, from the first proclaiming the overwhelming virulence of its poison. Note the preceding languor, headache, and loss of appetite, then the rigor, followed by unequal reaction and abnormal heat, with extreme prostration of body and mind, the pulse, first fluttering and unequal, then frequent, liquid, or thready; the stupor, or muttering delirium, dim eye, dusky rash, dark, congested, and swollen throat, secretions (if any) murky and offensive in the extreme. What is such a case but one of inevitable death? A person plunged into boiling water, or poisoned with a large dose of prussic acid, is not more hopelessly beyond the reach of art. All Medicine there is powerless—all failure! And it may be well if two, three, or more of the family are not swept off by the irresistible pestilence.

Look, again, at an instance of unmodified petechial or purpuric small-pox, with its livid congestions and blood-oozing tissues, showing the poisoned state of the blood; the eruption copious, but flat-spreading, with no protective margins of fibrin, so that the whole body becomes speedily imbued with the fatal poison, with no power to resist it. Medicine here is all failure! The full-blown plague comes like the blast of death itself!

So, too, of cholera and other diseases in their most malignant forms, the destroying force is so strong that the powers of life, and the agents by which we support them, offer little or no resistance. In all such cases Medicine proves a failure.

Sometimes, likewise, we find other kinds of disease baffle us by their intensity, their extent, the vitality of the organ attacked, or the destructiveness or malignancy of the morbid process. Thus, severe inflammation attacking vital organs, especially when rapidly proceeding to alteration of structure;

organic disease, mechanically or otherwise injuring important functions; and even functional disorders, when intensely affecting a vital organ—as the heart or the medulla—may overmatch our remedial powers, and make Medicine a failure.

CAUSES OF FAILURE IN MEDICINE.

- I. Overpowering nature of disease—
- Structural, from { Extent } of part involved.
 - { Vitality }
 - { Malignancy. }
 - { Destructiveness. }
 - Functional, from { Intensity. }
 - { Duration. }
 - { Vitality of organ { e.g., syncope, shock, tetanus, etc. }
 - Blood-poisoning . . { Strength of poison. }
 - { Defective power of resistance and elimination. }
- II. Error in { Diagnosis. }
- { Prognosis. }
 - { Therapeutics { Drugs. }
 - { Diet. }
 - { Regimen. }

This table brings before us a classification of the chief causes of failure in Medicine. The first class includes those already noticed, in which the amount or the intensity of the disease exceeds the powers of nature and art to overcome it; and the consideration of this limit to our art may well keep us humble. But, that we may be heedful as well as humble, the table warns us that failure may arise also from errors on our own part in diagnosis, prognosis, and in treatment. Such errors, although more or less the common lot of humanity, are to be held up as avoidable; and it is our obvious duty to watch and guard against them with all possible vigilance and energy.

Now, in order to avoid as much as possible these causes of failure, and to aim at achieving the greatest attainable amount of success, it may be profitable to go back to principles, and survey in the abstract the chief objects of Medicine. In the fulfilment of these are comprehended the elements of success; and we may hopefully and profitably comment on this side of the picture for our encouragement.

OBJECTS OF MEDICINE.

- Preliminary { Diagnosis { Detection } of disease
- { and distinction }
- { Prognosis { Valuation } of powers of { Health
- { and calculation } of disease. }
- { and disease. }
- Final { Cure. } Success A.
- { Prevention. }
- { Mitigation and retardation of disease. }
- { Prolongation and utilisation of life. }
- { Alleviation of suffering. } Success B.

The preliminary objects of Medicine—the distinction and appreciation of the true nature of disease, and of its relation to the health-force of the body—are of the highest importance to the scientific Physician, inasmuch as they are generally fundamental to his success in the final object, the treatment of disease. Diagnosis is not the mere detection of disease as a name, or a distinct entity; it is such a knowledge as enables one to discern disease in all its characters and bearings, in relation to other diseases, and in relation to the powers of health remaining in the body. Such a knowledge, combined with that supplied from past experience of similar cases, will furnish us with the surest means of prognosticating the result; and further, conjoined with a due acquaintance with the powers of remedial agents, will prove the grand final object, the cure of disease.

So, too, prognosis does not consist in a mere empirical observation of good and bad signs, such as any experienced nurse or shrewd attendant, however ignorant, might exercise with some rude semblance of success. Scientific prognosis is to be founded on a careful valuation and calculation of the relative powers of disease and of health in the system, and, by the light of past experience, estimating and striking the balance between them. It is by such a rational and circumspect procedure that we may hope to escape those errors in prognosis and diagnosis which we have classed among the causes of failure in Medicine.

Proceeding next to the final objects of Medicine, obviously the greatest are the complete cure and entire prevention of disease, the substitution of life and health for disease and death. To accomplish these is to achieve the grandest success of our art. To restore a person from an extreme of suffering

(a) Various circumstances have delayed the appearance of these Lectures, of which no authentic report has yet been published. Their delivery was undertaken at the urgent and repeated request of the late Dr. Mayo, then President of the College. He went out of office in the following year, and the usual custom of appointing the same Lumleian Lecturer for two successive years was discontinued; therefore, the latter parts of these papers, although prepared for the lectures, were not delivered.

and weakness, from frightful disorders of body and mind, from a dangerous struggle with death itself, to a state of ease, health, and strength, is indeed the best work of the Physician. But he must expect often to divide the credit with nature or the sound constitution of the patient; and it surely is not less creditable to his sagacity and prudence, if his interference consists mainly in watching for and promoting the health-restoring processes of nature, rather than in a random exhibition of empirical remedies. These great successes may be looked for in cases of acute disease, fevers, inflammations, and in a large proportion of functional disorders; and they are the more signal, the more intense and aggravated the disease has been.

Such cases are, however, more commonly within the scope of the ordinary family Practitioner than of London Physicians. These, especially the consulting class, have hardly a fair share of curable cases. They are rarely called in till danger is imminent, too often not till hope is past, and disease triumphant; and if they now and then do get the credit of rescuing a case from impending death, more frequently they have the melancholy office of endorsing a death-warrant, sometimes reserving in their own breasts the secret regret that they had been called in too late. But there is also a secret success that will now and then gladden the heart of the consulting Physician, and give him the inward satisfaction of doing good, although he would fain conceal it from public notice. It is where Medicine has hitherto failed through error in diagnosis or treatment (see table of failures), and it is not too late to retrieve the error. The Physician confidentially instructs the previous attendant, alters the treatment, and thereby transfers the case from the list of failures to that of successes.

It cannot be questioned that the prevention of disease deserves to take rank among the noblest aims of Medicine, and we may well award the highest grade of success to the signal manner in which the mortality, in certain localities and in certain classes of persons, has been reduced by proper attention to the dictates of sanitary science. The lives thus to be saved may be counted by hundreds and by thousands. Yet how little of individual gratitude does the sanitarian reap from all his beneficent labours! If he who showed how to draw lightning from the clouds and send it harmless to the earth was hailed as a public benefactor, not less should those who point out how to stop the risings of the noisome pestilence, whether in the air we breathe, in the water we drink, or in the ground we tread, or to render it comparatively harmless by processes of cleanliness, ventilation, or purification. I lately had occasion to advert to malignant small-pox as one of the terrible forms in which a death-plague defies the power of art. Honour, then, to the man who found the way to stay that plague; who discovered that the seeds of this very malady, by being transplanted to another soil, might be so mitigated, without destroying their identity, as to produce a trivial and harmless degree of the same disease, which should yet prove a protection against the invasion of the malignant forms! This *preventive success* is, indeed, a triumph of our art—perhaps the greatest that it has ever achieved.

Does not, then, the discoverer of vaccination well merit a foremost place of honour? And if we raise in our public forum to the gaze of the admiring multitude statues of the heroes of a hundred battles, whose good deeds and glories, great as they undoubtedly are, have been achieved through the horrible scenes of the battle-field, amid bloodshed and death, suffering and slaughter, lamentation and woe, shall we banish into obscurity the image of our immortal Jenner,^(b) whose priceless discovery, whose bloodless victory over disease, has been the means of saving more lives than all that were sacrificed, and of preventing more misery than all that was perpetrated, in the battles of Napoleon, Nelson, and Wellington? To displace the statue of such a benefactor of mankind is an outrage on humanity and a disgrace to an enlightened age; but, alack! it is too much in keeping with the ignorant and senseless caprices of many of a so-called upper class, who pretend to set up the monstrous absurdities of homœopathy and mesmerism, in opposition to the facts and reasonings of science.

(To be continued.)

ACCORDING to the *Buenos Ayres Standard*, the health of the city was never better. Immigration was again active, there having been 1500 arrivals from the Mediterranean during the previous fortnight.

(b) Allusion is here made to the statue of Dr. Jenner, which had just been erected in Trafalgar-square, close to the College of Physicians, but was afterwards removed to an obscure site in Kensington-gardens.

CLINICAL REMARKS

ON

TUMOURS OF THE EXTERNAL EAR.

By THOMAS BRYANT, F.R.C.S.,

Surgeon to Guy's Hospital.

TUMOURS situated upon or involving the external ear are not of very common occurrence; when they do occur they are the source of considerable annoyance, both on account of their position as well as from the disfigurement they produce.

Amongst the tumours which appear peculiar to the ear must be mentioned that singular form described as hæmatoma; it seems, in some way or other, to be associated with mental disease, for it has not been described except as in connexion with insanity. It is foreign to my purpose to enter into this subject.

Another special form of tumour of the ear, however, has to be described, which comes frequently under the observation of the general Surgeon, and is the result, apparently, of the operation of puncturing the ears for the purpose of carrings. It is of the fibroplastic nature, and grows from the point at which the puncture has been performed. Such a tumour may grow to a tolerably large size, and I purpose to record an example which was about the size of a walnut. I shall quote other cases of sebaceous tumours, whole and fungating; of fibrous tumours, as well as of epithelial and cancerous—such growths appearing on the ear as well as on other parts of the body.

Case 1.—Sebaceous Tumour, situated on the upper part of the Pinna of the Left Ear.—William W., 12 years of age, came under my care at Guy's Hospital, on March 18, 1867, for some tumour of the left ear. It had been growing for three years, was quite painless, and caused annoyance only from its size. It was as large as a walnut. The skin over the tumour was quite free and uninvolved. The growth, apparently, could be moved upon the ear. I excised the growth, and it turned out to be purely sebaceous. A good recovery followed. The mass readily turned out of its bed on dividing the integument. No direct connexion with the skin could be made out in this case.

Case 2.—Fungating Sebaceous Tumour of the Ear, simulating Cancer, in an Old Man.—Edward R., aged 74, came under my care at Guy's Hospital on January 13, 1864, for a tumour situated in the concha of the right ear. It had existed for eight years, and had grown gradually; but for some months it had been discharging, and had increased in size somewhat rapidly. When coming under observation, an irregular fungating growth was seen, the size of a large nut, projecting from a capsule of skin—to the margins of which it was not connected—situated at the lower part of the concha of the ear. It was discharging a sero-purulent fluid. The growth put on much the appearance of an epithelial cancer, but the history of the case, and the fact that the skin itself was sound, pointed to its being one of the fungating sebaceous tumours. The contents of the cyst were readily turned out with the thumb-nail, and nitrate of silver was applied to the cyst-wall. A good recovery followed. On examining the growth none of the elements of epithelial cancer were to be discovered.

Case 3.—Fibrous Tumour the size of a large walnut growing from the posterior part of the Pinna of the Ear.—Robert B., aged 53, came under my care at Guy's Hospital on April 23, 1866, for a tumour situated on the back of his right ear. It had existed for eighteen years, and had grown very slowly. It was firm to the feel, and the skin over it was quite sound. Excision was advised and performed. A good recovery followed. The tumour turned out to be fibrous, and grew from the cartilage.

Case 4.—Fibroplastic Tumours of both Ears following the operation of Puncture.—Esther L., 34 years of age, came under my care on April 16, 1866, at Guy's Hospital, for two tumours situated in the lobules of either ear. They had been growing for two years, and had appeared six months after the ears had been punctured for earrings. Both tumours were about the size of nuts. They were excised by means of a V incision, and the edges of the wounds were carefully adjusted. A good recovery ensued.

Case 5.—Fibroplastic Tumours of the Lobules of the Ears, the result of Puncture.—Eliza A., 24 years of age, came under my care at Guy's Hospital on December 4, 1865, for tumours situated in the lobules of the ears. They had existed for four years, and had clearly originated directly after the parts had

been punctured for carrings. The tumour on the right side was globular, and nearly one inch in diameter; that on the left was about two-thirds the size. They were both very hard, and appeared to be made up of fibrous tissue. They were both removed with a V incision, and the edges of the wounds carefully adjusted. A good recovery followed, the ear being in no way disfigured by the operation. The tumours were made up of fibroplastic elements.

Case 6.—Pedunculated Cancerous Growth on lower part of the Pinna.—James H., aged 50, a healthy man, came under my care at Guy's Hospital on August 11, 1862, for a growth upon his left ear. It had existed for seven months. It appeared as a kind of wart, and had rapidly increased. When I saw him, it was as large as a walnut, and pedunculated. Its surface was ulcerated, and was discharging. It had all the clinical features of the epithelial cancer. There was no enlargement of any of the absorbent glands. A ligature was placed upon its peduncle, and the growth at once fell off; a healthy cicatrix subsequently appeared.

Case 7.—Cancerous Tumour growing from the upper part of the Pinna of the Left Ear.—John H., 70 years of age, came under my care at Guy's Hospital on May 6, 1867, for a tumour, the size of a filbert, situated on the pinna of the left ear. It had been growing for a year and a half, and ulcerated for three months. By a little pressure the contents of the cyst were readily turned out, and proved to be cancerous. A return of the disease took place within a month, when he was admitted into the Hospital, where the growth was excised. A good convalescence followed.

Case 8.—Epithelial Cancer involving nearly the whole of the Pinna of the Left Ear.—Commander R., aged 74, came under my care on June 6, 1864, for an extensive cancerous affection of the left ear. The disease had existed for eight years, and had gradually increased till it had involved all the pinna of the ear with the exception of the lobulus. Nothing except excision of the part could be entertained. The operation was performed on June 15, and a good recovery followed. The lobulus was left with the tragus. The disease was a very good example of epithelial cancer. Some years subsequently (October, 1868) he was quite well, no signs of any cancerous disease existing. He could hear as well with the left ear as with the right.

Case 9.—Congenital Outgrowth from the Anterior Surface of the Tragus.—James J., 9 weeks old, was brought to me at Guy's Hospital on December 11, 1862, for a congenital outgrowth, the size of a haricot bean, growing from the anterior surface of the tragus of the left ear. It was apparently only made up of skin and cellular tissue; it was very firm. I excised the growth, and the wound healed favourably.

Case 10.—Laceration of the Lobulus of the Ear—Plastic Operation and Recovery.—Lucy S., 19 years of age, came under my care at Guy's Hospital on February 27, 1868, for a deformity of the lobule of the left ear. It had existed for many months, and was the result of the complete laceration of the lower part of the lobule, from the forcible tearing out of an earring. A plastic operation was performed, similar to that of harelip, fine sutures being alone used. A good recovery followed, the line of union being scarcely visible.

ORIGINAL COMMUNICATIONS.

CASES OF INTESTINAL OBSTRUCTION.

By C. HANDFIELD JONES, M.B., F.R.S.

Case 1.—T. W., aged 55, admitted May 4, 1858 (1862). He was taken ill May 2, after dinner, having eaten cauliflower; he had pain all over abdomen and vomiting, took medicine, but nothing passed through him. His bowels had been purged for a week before he was attacked, but he had not been laid up. Pulse thready and very weak; skin cold, clammy; tongue moist, coated. Retches up a bilious yellow fluid. A flexible tube was passed up the rectum for about two feet; some mucous fluid and specks of blood came away, but nothing else except flatus. He got shortly after out of bed to go to the close stool, but lapsed into syncope and died in a few minutes, in spite of some brandy that was poured down just before he died. I felt the pulse as distinct almost as it was

before his faint, and he resisted me strongly with his arms, which I was keeping still while the brandy was being given.

Post-mortem.—On opening the abdomen, peritonitis was found to have occurred, but not very considerable. The cæcum was so distended as to occupy the greater part of the abdomen; it was also turned over, so that the lowest part was highest in the abdomen, and the posterior surface was anterior. It was of a bluish colour. The mucous membrane of the cæcum was normal, except some traces of inflammation; its cavity contained a very large amount of flatus and fæces. When the cæcum was restored to its proper situation, its contents flowed immediately into the transverse colon, which previously was empty and shrunken. The rest of the intestines were natural. In the thorax there was nothing remarkable, except that the heart was rather enlarged and flabby; its fibres were not at all fattily degenerated when examined under microscope. Lungs to some extent emphysematous. Arcus senilis marked.

The previous diarrhœa in this case acted as a predisposing cause to more serious derangement of the bowels. The neuromuscular functions becoming enfeebled generally, local paralysis seems to have ensued in the part whose muscular coats are thinnest, and which is therefore most liable to distension. The descending cæcum and ascending colon gradually turned upwards and became sharply flexed at their junction with the transverse colon, so as to form an actual occlusion of the canal by the approximation of its opposite sides. In instances of this kind it is well seen how increased distension of the upper portion of bowel augments the sharpness of the bend, and consequent obliteration of the passage at the seat of the flexure. There can be no doubt, I think, of the correctness of Abercrombie's opinion, that in cases such as these the paralytic dilatation is the primary and essential mischief, and that spasmodic contraction of the bowel beyond has nothing to do with its production.

The heart's action was speedily paralysed by the morbid impressions conveyed by the abdominal nerves, and death ensued at a much earlier period than might have been expected, or than would have passed had the sufferer's system been better organised. As there was no fatty degeneration of the heart, its paralysis must be referred to a peculiarly impressible state of the nervous centres, to some infirm or vulnerable condition of the ganglion-cells, which made them less resistant to perturbing influences. That such states exist is a well-known fact. An attack of gastralgia in some persons will reduce the pulse to a mere flutter. Had opium been freely given at the outset to this patient, with diffusible stimulants, the result might have been different. It might have rendered the heart less sensitive to the morbid impressions, and restored tone and vigour to the intestinal nerves.

Case 2.—Miss J., aged 10, a very healthy girl, was quite well on February 19, when she was suddenly seized with severe pain in abdomen, with call to stool, and vomiting took place. The bowels did not act, although castor oil was given; and before twenty-four hours had passed she was in a state of such extreme collapse that, when Dr. Frampton saw her, she was pulseless and appeared dead. Brandy, however, freely administered, revived her. He gave calomel and a strong aperient once, and large warm water enemata, but nothing has come away up to the present date (February 24). The abdomen is somewhat distended, dull on the right side at its lower two-thirds, resonant in middle, and rather dull in left flank. It is tender generally, but most over the right lower part; it is not tense. No tumour can be felt, not even in the region of the cæcum. Pulse 115, weak; tongue red and coated. Much stercoaceous vomiting. Opii gr. $\frac{1}{3}$, 4tis horis.

March 20.—On the 9th day after I saw her (March 5) the bowels acted for the first time; a little was passed in the warm bath, and a good deal more after. Since then the bowels have been confined for two or three days, and then have acted again. Two stools were shown me to-day; they were pretty copious, semi-solid (or rather more), and very pale—partly, I suppose, from the amount of milk taken. She has eaten some meat occasionally; did so yesterday and to-day. She is sadly emaciated, and evidently suffers much, especially when "the eggs come in her belly," as she says. By the eggs she means portions of distended bowel, which rise and become prominent on the surface, leaving between them transverse furrows. During my visit these became very apparent—one ran across the upper abdomen, and another about the middle; they were resonant. Before these prominences appeared the abdomen was smooth and moderately full, but not tense; dull in all the left half, especially at the lower part. Pulse very small and weak,

over 120; temperature, 36·8 (98·2). She derives great relief from the hot baths, and asks and waits anxiously to have them repeated.

27th.—Died yesterday, having suffered extremely with pain in abdomen for about twenty-four hours before death.

Autopsy.—Abdomen greatly distended by coils of small intestine prodigiously swollen; the lower and most distended of these were of a deep blackish-red from congestion; their tissue was much softened at one spot, which had given way, and allowed fecal matter to escape. These especially diseased coils belonged to the ileum; the upper part of the alimentary canal, and the large intestine, and the termination of the ileum were normal. The obstruction seemed to have been caused by the twisting of the mesentery upon itself; there was no intussusception, nor any constricting band or internal stricture. In one coil, however, or loop of the congested intestine, the two sides adjacent to each other were closely adherent in a way which must have interfered with the normal peristaltic movement. There was no fluid in the peritoneal cavity.

The existence of intussusception was considered probable in this instance, though the absence of tumour and of bloody dejecta constituted an objection to this view. The sudden way in which the symptoms set in, and the rapidity with which prostration came on, pointed decidedly to the small intestine as the seat of mischief. The warm bath and opium gave very much relief, and in all probability prolonged life considerably. The cessation of the obstruction and restoration of a tolerably free passage of the intestinal contents was a remarkable change, such as one would expect to be followed by complete recovery. Abercrombie, however, warns us that we must not hastily pronounce on a favourable issue because feculent evacuations have occurred; for, in spite of these, the disease may be going on to a fatal termination. The softened and weakened state of the intestinal parietes seems to have been produced by long-continued passive hyperæmia and distension.

Case 3.—J. P., aged 20, shop porter, admitted July 19, 1867. The first ailment he had was pain in left flank, or hypochondrium, which came on six weeks ago. It lasted four weeks, then ceased for seven days, then returned all over the abdomen, and has now existed five days. His bowels have not acted during this time, and only scantily just before; usually they are regular. Since the bowels were confined he has had pain, and there is now notable distension. He thinks he strained himself while working at a sausage-machine, turning a wheel, five months ago. No sleep at night, or very little. His mother states that he has vomited some fecal matter to-day, before he was admitted. There is marked tenderness in both flanks, especially the right, including the iliac fossa; this flank is very dull. Liver-dulness of normal extent. No abdominal movement in respiration; the upper ribs play very evidently. Pulse 125, of good force and volume; respiration 26 in minute. Can lie with legs extended. No hernia; tongue red and coated; feels sick now and then; has vomited some pills he has taken, but not beef-tea. Face rather flushed; feels very hot; temperature 99·5°. Urine appeared natural yesterday; before that it was thick; quantity small. Tinct. opii mxl . + aq. $\text{f}\text{i}\text{s}\text{s}$. stat. opii gr. j., 2dis horis.

July 20.—Pulse 100; tongue coated, rough. Has vomited some acid green matter, but not the food which has been given to him—viz., beef-tea Oj., and some bread. Urine in fair quantity, and of a very deep red; pupils not contracted.

21st.—Has had a good free evacuation from the bowels; very offensive and dark. Feels much better; urine dark-red, contains some bile. Abdomen full; resonant except at right flank, but even there the dulness is less extensive; tenderness less. Pulse 88; temperature 98°; no vomiting; appetite returning; pupils natural. Pt. c. pil.

24th.—Doing quite well. No pain or tenderness in abdomen; it is rather full, but the dulness in right flank is much less. Appetite improving. Bowels open once or twice every day; stools light yellow. Omit pills; fish, pudding. Is up and about.

31st.—Gone out.

In this case the symptoms never attained a great severity, though the occurrence of fecal vomiting shows that the situation was serious enough. The cause of the obstruction was not ascertained, but, from the gradual way in which the symptoms came on, the occurrence of pain in the left hypochondrium as the first and nearly persistent symptom, and the marked dulness in the situation of the ascending colon, it seems probable that the descending colon was the seat of mischief. There may have been some narrowing of the gut at this part, and hardened feces may have collected above it. Possibly without aid recovery might have occurred, but I can scarcely doubt that the opium contributed materially to the favourable

result. In fact, it was given so freely, that had it not acted for good it must certainly have proved injurious. Ten or twelve grains of opium per diem are no placebo.

(To be continued.)

ON PARTIAL CONVULSIVE SEIZURES, WITH PLUGGING OF CEREBRAL VEINS.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P.,

Physician to the London Hospital, and to the Hospital for the Epileptic and Paralytic.

EPILEPTIC or epileptiform seizures not very rarely occur with disease of the ear—that is, with disease of the apparatus of hearing. It is impossible, without post-mortem examinations, to know that there is a relation of cause and effect; but in cases of epilepsy or epileptiform seizures we cannot afford to overlook any realistic condition. Disease of the ear leads to cerebral abscess through the veins—there is a local pyæmia; and my speculation as to the connexion between ear disease and epileptiform seizures is, that by blocking of veins, also, there results a minor pathological change: one permitting instability of grey matter—a condition allowing occasional excessive discharge on muscles (convulsion).

The following case illustrates this supposed connexion. There was no disease of the ear, but there was an equivalent state of things: there was purulent matter in the right lateral sinus, and a vein was traced from this sinus to the part of the hemisphere most diseased. The changes, however, as will be seen, were far too extreme and too widespread to enable us to give the case as more than a hint towards settling the question as to the connexion of ear disease with epileptiform seizures. Moreover, the course was acute. The case is of further interest as showing a sequence of spasm in one variety or degree of convulsion.

Phosphorus-Necrosis of the Bones of the Face and Skull— Pyæmia of Brain and Lungs.

December 7, 5.30 p.m.—I saw a patient, 41 years of age, who had been admitted under the care of Mr. Hutchinson for phosphorus-necrosis of the left upper jaw, and who had very frequent attacks of spasm, affecting chiefly the left side of the face. I saw six attacks in about half an hour. The description of what was observed in the third (apparently the severest) is as follows:—There was drawing of the mouth to the left almost horizontally; the spasm gradually spread over the left side of the face, and even to both sides of the forehead. After the face was well in action, both eyes turned far to the left, and the head turned a little, but very decidedly, to the same side. Later still both eyelids blinked (shutting and opening), but the left much the more—i.e., they closed more completely, but whether more frequently was not noted. The mouth was closed throughout the attack, and respiratory efforts—for a time, at least—were suspended. At one time, early in the fit, a slight snapping sound was heard, believed to indicate occasional action of the masseter and temporal muscles. When towards the end of the fit, the arm was felt (by taking gentle hold of the upper arm and forearm), there was the very faintest movement of the limb—apparently of the limb as a whole.

After this and after subsequent attacks there was no affection of speech proper—i.e., of speech in the sense of “propositioning”—nor was there any considerable defect of speech in the sense of talking; there was only the slightest muffling of articulation. This muffling no doubt depended on paralysis of the face, for the face was paralysed on the left in the intervals of the fits. It was much drawn to the right, and when he spoke the cheek bagged on the left. He could not close the left eye nearly so firmly as the right, and when the lids of the right eye were separated, in order to use the ophthalmoscope, there was very great resistance, but none, or scarcely any, on the left side. In the attacks the patient did not speak, for his mouth was closed, and he was no doubt unconscious, although we fancied that in one attack he nodded to his wife, who called him by name.

The above does not pretend to be a full account of what took place in the seizure. The observation was begun after the very beginning of the attack. It is impossible to observe all the details of the very complex march of a fit affecting even so small a part as one side of the face. In another attack, whilst I observed the left arm (which in this attack did not suffer at all) and the face, Mr. Haydon kept one of his hands on the chest and the other on the abdomen. He reported that at first there was action of the abdomen (diaphragm)

at shorter intervals; the chest stopped moving two inspirations before the abdomen. This—the stoppage of both—we may suppose was the climax; then (to continue Mr. Haydon's observations) there were little jerks, a sigh, and lastly deep inspirations, in which both chest and abdomen shared.

In this attack I observed, further, that the two eyes were well turned to the left before the eyelids were closed—the eyelids were indeed at that time very widely open—and that later the eyelids rapidly opened and closed, the left eye closing very much, the right eye not closing completely or strongly, at all events. It was not noted whether the left eye closed oftener than the right.

In still another attack the fit was noticed from the very beginning. It was then seen that there was, at the *very* first, confused movement (so to speak) of the mouth, as if the orbicularis oris *all round* was in action—not the left half of this muscle only. There were slight, perhaps doubtful, movements of the lower jaw up and down. Distinctly after the "mouthing," the horizontal drawing of the face to the left began, and the face part of the fit occurred as before.

In one attack the left arm was raised from the body—rather, it was observed raised—and there was seen the very slightest movements of the fingers *backwards*.

The spasm was clonic. It cannot be affirmed that there was no transient tonic spasm before the clonic spasm began; probably there was. The movements were supposed to be at more rapid intervals the later the fit, so far as the horizontal drawing was concerned. There is, however, very great difficulty in observing this point; the wider the movement the more obvious it is.

9.30. p.m.—I saw him again with the House-Surgeon, Mr. R. W. Parker. I saw one fit, and in it the fingers of the left hand were slightly moved; the hand itself was thrown back in slight jerks. The face as before. He had, it was said, not had one fit since I left him, but little had been seen of him. Faradisation was tried, but it could not be tried fairly, as he cried out, and there was no justification for disturbing him. The left side did act, at least equally, if not slightly more than the right. The cheek near the angle of the mouth was galvanised. He had one very trifling fit; there was only a little "mouthing," preceded by a deliberate up-and-down movement of the lower jaw. He died on the 9th.

Autopsy.—On cutting the dura mater on the left side there was a spurt of dirty thin pus, and when this membrane was cut round in the usual way so much of the right hemisphere as was then exposed was seen to be covered with pus, which lay above the arachnoid. On gently raising the brain a vein was seen passing from the right lateral sinus to a patch to be presently spoken of over the lower wall of the Sylvian fissure. The vein was like a white, tough cord. When cut into it exuded, not blood, but a thin, creamy fluid.

The pia mater and arachnoid were thickened and infiltrated with lymph for about two square inches (but the limits were very ill-defined) over the upper and outer parts of the parietal and anterior lobes. On removing the brain no abnormality was seen on the under surface of the posterior lobes, and none on the part of the brain which lay over the lateral sinus. There was a little pus over the optic nerves, also under the right anterior lobe and over the fissure betwixt it and the left lobe; but the membranes were not thickened. The pus lay above the arachnoid. The chief disease of the brain-substance itself was at the patch above spoken of. Here the membranes were thickened and adherent to the convolutions; not firmly adherent, but the convolutions were so soft that they tore when the membranes were removed. It was supposed at first that the large quantity of pus was the result of rupture of a cerebral abscess; but, although the convolutions of the lower wall of the Sylvian fissure (about opposite the lower end of the fissure of Rolando)—that is, the convolutions subjacent to the patch—were softened into a dirty mixture of brain and pus, no abscess was discovered—that is, no walled abscess—rupture of which could have caused a large "effusion of pus." At this point the overlying veins were turned into thick, dark cords—cylinders of coagulated blood—and one vein, with thin, creamy contents, passed, as aforesaid, to the right lateral sinus. The extreme damage was very limited. There was purulent softening of about a cubic inch of the lower boundary of the Sylvian fissure, and very little extension deeply in the fissure. In the convolutions near to the part most affected were, however, many red specks (red softening). The hinder part of the island of Reil was affected; it was affected as the convolution under the patch, for about the size of two peas, but doubtfully by direct continuity. The convolutions of the anterior, posterior, and temporal lobes all

round the principal lesion were slightly softened, and of a slightly greenish hue, such as is seen in decomposing brain. The corpus striatum and the optic thalamus, crura cerebri, pons, and cerebellum were normal.

The convolutions of the left—the comparatively sound hemisphere—were flattened and pressed together. The arachnoid surface was greasy-looking, and through it was seen a little—but very little—dirty serous fluid in the angles of the convolutions. The substance of this hemisphere was normal.

The superior longitudinal sinus contained pus mixed with blood, and a soft yellowish-looking clot. In the right lateral sinus were chiefly flakes of purulent matter, and a soft yellowish clot. The right cavernous sinus seemed to contain nothing but pus. The left cavernous sinus was normal. Mr. Parker removed the left (*sic*) superior maxillary bone, and saw that the bone was extensively necrosed. The disease had extended to the body of the sphenoid. The dura mater over it was raised, and on removing it the bone was seen to be dark and slightly rough. All the organs in the chest and belly were normal, except the lungs and spleen. The lungs contained numerous infarctions. They were nearly all in the "apoplectic" stage, and one or two were (on section) large, raised, and quite like those more commonly seen in cases of heart disease. In the centre of two or three of the smaller ones only was there any purulent matter, and this was but slight in amount. The spleen was large and soft.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

GUY'S HOSPITAL.

LARGE PLEURITIC EFFUSION TREATED WITH THIRST.

(Under the care of Dr. MOXON.)

[Reported by Mr. EWART.]

M. W., AGED 24, was admitted into Guy's Hospital on June 19. She is a domestic servant, and has always had good health. About three years ago she had some fever; does not know what. Four months ago faucied she caught cold; had cough, etc., but was not ill enough to lay up. For last three months has had more or less pain in chest, with some difficulty of breathing. About a fortnight ago she felt so weak, and her difficulty in breathing had so much increased, that she could not do her work, and sent for Medical advice. Latterly had been spitting up a good deal of phlegm, and has been getting thin; also sweats at night. Family history good.

On admission: The patient is a dark, delicate-looking girl, fairly nourished. Has some cough, not very troublesome, and raises a moderate quantity of phlegm, no blood. Has pain at lower part of sternum when she breathes, and also has a "difficulty" in breathing. The right side is quite dull up to the neck about the clavicle, where there is a hollow, remote resonance. The dullness passes some distance to the left of the median line. Apex of heart beats half an inch outside left nipple. Right hypochondrium looks full. No feverishness. On auscultation of right side no breathing-sound is heard except at apex and interscapular region, and there it sounds distant and hollow; the voice-sound is raised in pitch and lessened in force. Breathing on left side loud, supplementary.

The patient was directed to limit the quantity of her drink in the twenty-four hours to ten ounces, and a mixture containing pot. iod. gr. v., amm. chlorid. gr. v., was given thrice daily, and elcet. potass. bitart. in the morning. She adhered very firmly to the abstinence from fluid, and on the 28th the report says—"There can be no doubt that the dullness has decreased, there being now resonance down to the second rib, and vesicular murmur in breathing can be heard as low down as this. July 4: Resonance is good down to third intercostal space; she feels quite comfortable, with the exception of being very thirsty. After this the decrease of the fluid was even more rapid, so that, by the middle of the third week of treatment, the signs of the presence of fluid were gone so far that only slight and doubtful difference in the percussion-note posteriorly at the base remained. No change occurred in this during the remainder of her stay; she left the Hospital feeling well and active, and having regained her flesh and strength, and wishing to return to her

work. During the treatment the quantity of urine was less than normal; its quality was natural.

The rapidity with which this case recovered from so large an effusion drew the attention of all who witnessed it. We occasionally see large effusions of liquid in the peritoneal cavity disappear very rapidly when small doses of mercury and digitalis are given, but then the flow of urine always becomes very free. In this case the urine was scanty throughout, and we must look to some other cause for its disappearance, although diuretics were given; for the diuretics did not act. Though not certain, yet, as a probability, the thirstiness maintained in the vessels may be regarded as the cause of cure. It commends itself easily to one's mind that empty vessels should absorb better than full ones; and experiments show that fluids are absorbed from the stomach more quickly during a fast. Some of the experiments of Kussmaul and Tenner collaterally bear on this question. These experimenters found that they could not carry out their wishes on the medulla oblongata of dogs, because the poor animals bled to death before the cutting operations were complete. In this dilemma they hit on the plan of keeping the miserable things without water for several days before vivisection. By this method they found that the blood grew thick and tarry enough to prevent its escaping from the divided vessels until physiology had exacted her demands in full. Thirst empties the bloodvessels and diminishes the blood-pressure within them, so favouring the entry of fluid from without.

If the case had been treated by tapping there is little doubt it would have been cured in time, but Dr. Moxon thought the effort to absorb the fluid should first be made, having a belief that the thrusting of weapons into the principal cavities of the body is not to be regarded as a safe common rule of practice in cases where diet and medicine suffice to cure. Simple pleuritic effusion, practically, always gets well.

ST. THOMAS'S HOSPITAL.

POLYPUS UTERI REMOVED BY ÉCRASEUR.

(Under the care of Dr. BARNES.)

In further illustration of the series of uterine polypi which we are now publishing in our Hospital Reports, Mr. Churchill has forwarded to us the notes of a case recently under his care, operated on by Dr. Barnes at St. Thomas's Hospital.

R. E., aged 50, a widow, was suffering from palpitation of the heart and extreme spanæmia, dependent upon uterine hæmorrhage, more or less constant during the past two years. As local applications and constitutional treatment failed to arrest the hæmorrhage, Mr. Churchill recommended her to apply for admission to St. Thomas's Hospital, under the care of Dr. Barnes. The polypus was attached to the cervix uteri, and it projected into the vagina through the os.

The catamenial periods were regular up to two years ago; since that time she has had almost constant metrorrhagia with intermissions of a few days only. She has passed large clots of blood, and a thin watery discharge, which was not offensive. During the past six months she has suffered considerably from pains in the back, giddiness, and anorexia. She is of a stout habit of body, but the soft parts are lax, flabby, and very bloodless-looking. She has had some general œdema. There is a faint systolic murmur at the base of the heart, probably anæmic in character.

Dr. Barnes removed the polypus, passing the noose of a wire écraseur around the neck of the tumour. The surface of the tumour was smooth; it was about the size of a small orange, with a distinct but thick pedicle. The structure of the growth was made up of interlacing fibres, and of very firm consistence.

There was no recurrence of the metrorrhagia. She was dismissed cured in five weeks, having regained her strength, and the cardiac symptoms having almost completely subsided. We are indebted to Mr. Pike, the Clinical Clerk, for the notes of this case, who informs us that the above is one of several polypus cases operated upon by Dr. Barnes recently.

BIRMINGHAM GENERAL HOSPITAL.

ANEURISM AT THE ROOT OF THE AORTA LYING IN THE SEPTUM VENTRICULORUM, WITH RUPTURE OF ONE OF THE AORTIC VALVES.

(Under the care of Dr. RUSSELL.)

The special interest of the following case lies in the conjunction of an aneurismal pouch behind the valves of the aorta with

laceration of one of the aortic valves, and in the influence which the presence of the aneurism appears to have exerted in producing the laceration of the valve, and also in modifying very remarkably the symptoms to which the laceration gave rise.

The aneurism itself presented one among the many varieties belonging to that disease when it affects the heart. There are three cases of cardiac aneurism recorded in the *Pathological Transactions*, which present considerable resemblance to the present one, in respect of the seat of the aneurismal pouch. In the volume for 1851-52 is a case by Dr. Peacock, in which a small aneurism, associated with malformation (probably congenital) of the aortic valves, was referred to an endocarditis fourteen weeks before death; one by Dr. Lichtenberg (vol. xvi.); one by Dr. Moxon (vol. xvii.) In each of these cases, owing to a difference of relation, the aneurism made a prominence into the tricuspid orifice in the first two; into the left auricle in the last. In my case no prominence into any of the cavities was visible after death. In vol. xvii. of the same *Transactions* is a case by Dr. Weber of an aneurismal dilatation of all the sinuses of Valsalva, to which was added a perforation of one cusp of the aortic valves by atheromatous ulceration; but the nature and history of the case were quite different from those of my own.

Cases of rupture of the valves of the heart (generally of the aortics) whilst in a state of health, through external violence, are known in all pathological records. In the *Transactions* from which I have already quoted there are many interesting illustrations of this accident, and they all tend to confirm the remark that fixation of the chest, in the course of a violent bodily effort, is the most important element in the mechanism through which the injury is inflicted. A man-cook stretching over some high coppers, and, whilst doing so, making an extraordinary effort to seize a particular vessel (Dr. B. W. Foster); lifting a heavy load of bricks (Dr. Dickenson); pulling at a sugar hogshhead, the hand slipping, and striking his side (Dr. Peacock); working a sledge-hammer; trying in a passion to open a door; running with a horse (Dr. Quain); and again, in this journal, pulling at a capstan bar (Dr. Allbutt)—all operated as causes of a rupture of a valve, and, in all the cases but one, of an aortic valve. Occasionally the ascending aorta has yielded; but in such instances superficial violence, acting indirectly, seems to have been a more general cause than simple effort. Such cases, observes Dr. Wilks, illustrate "a point of interest, in the fact of deep-seated parts being often the subject of injury when the body has been submitted to superficial violence. The explanation is to be found often in simple mechanical causes, whereby the most fixed parts become separated from the most movable, and thus the weakest structure soonest suffers." When, however, the aorta is in a diseased condition, cases of rupture, even without any obvious violence, are more common; and it is needless to add that, under such circumstances, aneurisms may be formed.

In the following case the violence in which the disease originated was conformed to the usual type, but the order of symptoms and the mode of production were different from those usually observed in cases of valvular rupture. The case did not commence with the sudden and severe symptoms of cardiac distress which are well known to attend the class of accidents to which I am now alluding; but, on the contrary, though the symptoms soon became sufficiently severe, a marked gradation was observable in their increase—a gradation which was distinctly retained in the patient's memory. There can, indeed, be no doubt that a leakage was established through the aortic valves, prior to the occurrence of the rupture, in consequence of the formation of the aneurism and of traction exerted upon two of the segments through their attachment to its wall. In this particular the case resembles those which are described by Dr. Allbutt in a paper on "Overstrain of the Heart" (*Medical Times and Gazette*, May 20, 1871), in which "the excessive effort does not seem actually to drive a valve before it, but so strains it that some leakage occurs, and this leakage slowly enlarges the chink until serious regurgitation becomes possible." The mechanism, however, was different. From the relation which the ruptured segment bore to the sac of the aneurism, it is most probable that the rupture of that segment was a consequence of the formation of the aneurism, resulting directly from the dragging applied to it at each dilatation of the sac. It is remarkable that though inquiries were made from the patient, with special reference to a suspected rupture of an aortic valve, the symptoms produced by the rupture had not assumed prominence in the memory of the patient over those which preceded its occurrence, though they were observed and subsequently described by the sister.

Case.—Post-mortem Examination.—The heart weighed 22 oz.; the ventricles were proportionately hypertrophied and dilated; the tissue was firm. A pouch capable of containing a fair-sized walnut sprang from the left side of the aorta just at its origin, and, pointing downwards between that vessel and the pulmonary artery, buried itself in the septum of the ventricles. It was lined with an irregular, half-formed membrane, which left spaces of cardiac tissue uncovered. The orifice of the pouch was of considerable width, and opened into the aorta just behind the sigmoid valves, involving the right and left coronary segments in a somewhat singular manner. The left coronary segment was carried entirely into the pouch, but the right coronary segment (the opposite extremity of which was on the outside of the pouch) was completely torn down, the rent extending even into the cardiac tissue. About half the curtain hung loose; the remaining portion seemed to have turned upon itself and become adherent, forming a "hem." The torn segment was not at all thickened, nor was the inter-coronary segment; the left segment, however, was rather more rigid than usual. The inner coat of the aorta was opaque above the valves. There was a white opaque patch below the opening of the innominate, and some spots of atheroma at the lowest part of the thoracic and in the abdominal aorta. The mouths of the coronary arteries were free. The right lung was completely compressed by fluid effusion, and its surface was covered with recent lymph. A small mass of rather old pulmonary apoplexy existed in the base of the right lung, and another small mass, of recent date, at the base of the left. A considerable branch of the pulmonary artery, with its subdivisions leading to the latter, were occluded by fibrin, but only a fine twig lying in the heart of the former. With this exception the pulmonary arteries were free throughout their course. The lung tissue was healthy, and free from œdema; the compressed lung could be inflated. The tubes contained some mucus. The kidneys were healthy.

The man's age was 34. He had been a soldier, and a heavy drinker, but had left the army for two years, and had been employed as an engine-fitter. His work was very laborious, often involving the raising of great weights. Both himself and his mother, independently of each other, agreed in referring the beginning of his complaints to a period nine or ten weeks before his admission into the Hospital. He himself explained his illness by his having "caught a cold and cough" through working in steam; but it appeared that he had been employed in unusually hard work—in lifting a large fly-wheel by means of levers and pulleys. It was, however, not until a week afterwards that he began to have "a tearing cough," of so much violence as nearly to throw him down; with it he expectorated blood "in flakes," unmixed with phlegm, "and coarsely bubbled"; he continued to have hæmoptysis for a month. A fortnight afterwards his breath became short, but he did not leave work; indeed, he went to another similar job next week, though having often to stop in his work through shortness of breath. He was not aware of the occurrence of any sudden change in his condition; but, after his death, his sister told our Pathologist (Mr. Rickards) that one day, about three weeks before he came into the Hospital, he was attacked with pain in his chest, difficulty of breathing, faintness, and sickness. He was obliged to leave work and go home, promising to return next morning, but was unable to fulfil his promise.

I had only the opportunity of making a rather hasty physical examination of his chest at his admission, before the fatal attack. I can therefore only state that the ordinary signs of aortic regurgitation were present in their most characteristic form. On the evening of the following day he was seized with a prolonged attack of extreme dyspnoea of a very threatening character, accompanied by blueness of the face. Next morning the dyspnoea had subsided, but effusion was discovered in the right chest. The chest symptoms increased in severity; he expectorated large quantities of semi-transparent mucus, copiously mixed with blood, floating in a dirty blood-coloured fluid, on one day to the amount of two pints in twenty-four hours, and he sank in flesh rapidly. His urine was deficient in chlorides, but free from albumen. The temperature continued normal for the first two days, then steadily rose, and in four days registered in the evening 103.4°; thence it fell to an evening temperature of 100° for two days, after which it continued normal till death on the tenth day. Expectoration ceased suddenly and entirely two days before death, with increase of effusion.

It is proposed to build a new Infirmary at Bridgwater, at a cost of £5000.

Medical Times and Gazette.

SATURDAY, JANUARY 6, 1872.

1872.

AMID the congratulations which usher in the New Year, perhaps none are more sincere than those which are exchanged by persons who are mutually of use to each other, and whose connexion of reciprocal obligation waxes stronger as time rolls on. We are under the pleasing belief that a connexion of this kind exists between the readers of, and occasional contributors to, the *Medical Times and Gazette* and its editorial staff. We, on our side, gladly acknowledge our great obligations to the Profession of Medicine at large, without whose support our journal could not have been now entering the forty-second year of its existence, and especially to those members of it who, amid the hurry and excitement of their daily Professional work, have snatched valuable hours to record in our pages the results—often of priceless worth—of their thought and observation. On the other hand, we hope that our readers derive some benefit from the weekly fare we provide for them; and we know from ample experience that in not a few quarters our labours are rewarded by generous appreciation and acknowledgment. Thus mutually obliged, we venture to offer both readers and contributors our congratulations on the commencement of another year, and to assure them that no effort shall be wanting on our part to make the *Medical Times and Gazette* of 1872 the worthy representative of its long line of predecessors. That we have taken the means to secure to them a constant succession of Medical literature from the pens of the most active and accomplished cultivators of the art and science of Medicine in the metropolis and the provinces, our published list of promised contributors for 1872 will prove. That list contains the names, not only of the young and aspiring workers of the Profession, but those of many of the men who have made British Medicine what it is, and who now, in the zenith of Professional success, are garnering the fruits of vast experience. For ourselves, we can only say that it is our fixed determination to pursue that path of independence, fairness, and loyalty to the interests of the Profession, both scientific and social, which has never hitherto been deviated from by the management of the *Medical Times and Gazette*. It is our boast that we are the automaton of no Association—the echo of no coterie. It is our wish to recognise merit wherever it exists, to open our pages to all qualified Medical Practitioners who have anything to say worth the hearing, and to exclude from them everything instigated by personal or private bias.

Steering by this chart, we confidently launch our bark for another trip, relying upon the breeze of Professional favour and the full tide of Professional support.

FAMILY SECRETS.

SOME young Practitioners are apt to flatter themselves that they are become pretty firmly established in the confidence of their patients, and that they have secured the substratum of a good and firm connexion, because their patients do not scruple to consult them about the most delicate family secrets. As is but too well known to anyone who has some slight experience of society, there is a eupboard in every house which is kept from the eyes of the world as scrupulously as the famous closet of Bluebeard. Female frailty, drink and idleness, pecuniary embarrassment, and speculation or bill transactions, are the hidden diseases of society, and it is not because a man may be a peer, a prelate, or a judge that he may not have some scapegraces amongst his nearest relatives, whose misconduct may drain his pocket in the effort to keep things quiet, or, maybe, put him perpetually in fear of some damaging disclosures. So the young Practitioner who gets on tolerably well will some day find himself closeted with some personage amongst his patients, revealing to him some hidden ulcer of misfortune or depravity, and seeking his counsel, or— even more probably—demanding his co-operation, in order to buy off a troublesome hanger-on, to send some scapegrace to America, to be the channel of anonymous benefactions to some discarded grisette, or of the weekly pension of a nurse-child. Our inexperienced friend is flattered by these confidences, which are sure to be buttered with the most adroit compliments on his good sense and kindness and discretion, and with the remark that there are very few people to whom such terrible secrets, involving the honour and happiness of so many and high families, could be confided. As to his Professional skill, that, he is told, is of the highest order, and our friend is bid rely on the support and confidence of an influential family circle, who will soon push his name and fame into deserved prominence.

Now, it may be strange, but our young Practitioner will find it to be true, that when the occasion is over—when the secret mystery is somehow hushed up and put out of sight—he may find himself suddenly *cut* by the very people who had laid such stress beforehand on his judgment, his humanity, his discretion, and his skill.

We could give a dozen histories to the point. One young Practitioner had received the greatest civilities during his studentship from an old solicitor, a friend of his father's, who became one of his first and most liberal patients. Everything went on smoothly, till one day the solicitor, who had been for some time dyspeptic and ailing, sent for the young Surgeon, took him into his inmost *sanctum*, and then, bursting into an agony of grief, told him how that he was a ruined and disgraced man; how his wife stood on the brink of the workhouse, and himself of the Old Bailey; how he had squandered his own resources, and meddled with the money of his clients; and what a thin partition lay between his former self—rich, honoured, and trusted—and his future self—beggared, disgraced, and shunned. Our young friend was quite equal to the occasion; he knew that the solicitor had been out of health and spirits, and saw in this confession but the first outburst of melancholy madness. So he exerted himself prodigiously to induce the solicitor's wife to take him away into the country, to a place where he would be under good Medical advice, good diet, air, and exercise, and in the course of some weeks the patient recovered his health and spirits. We say the Surgeon was obliged to exert himself prodigiously, because he had the ordinary battle to fight which every Practitioner must fight, who desires to pound into the heads of a mad patient's friends that low spirits, delusions, and self-accusations are not things to be argued or preached away, but that they come from bodily illness, and must be dealt with as if they were stomach-ache instead of mind-ache. The reward he got was a rather grudging mode of paying his very moderate account, and the fact that he never was invited to dinner, nor employed Pro-

fessionally afterwards. In fact, he was *cut*, and never saw the solicitor till, some years afterwards, he was called in by some of the friends to assist at the post-mortem examination; for the patient died suddenly, in the night, of angina pectoris. In this case, the patient shrunk from meeting the man to whom he had revealed his secret mental weakness.

The same train of events is sure to follow when a Practitioner finds out that the highly religious wife of one of his most substantial patients has no small devotion to the brandy-bottle; or when a teacher of religion and morality is scorched by the intensity of one of the passions which he is paid to keep in subjection in other people. The young Practitioner is apt to find such treatment discouraging; he finds out that people are more selfish and ungrateful than he thought, and discovers that the zeal of a friend, added to the skill of the Medical adviser, do not always enable him to keep his ground. However, he need not despair; let him go on and do his duty, and accept the consequences cheerfully—time will bring some compensation.

But there is another kind of family secret, of which the inexperienced Practitioner should take heed in time. In the cases we have already cited, he is only asked to do ordinary Professional work, and such services as one confidential friend may render to another, without any loss of self-respect or Professional dignity. But unluckily there are many cases in which the Practitioner, if young and inexperienced, may be cajoled—or, if poor and mercenary, may be bribed—into doing things which involve the loss of both. There is no Practitioner who is not at times asked, begged, nay, implored to save the honour of a family—by procuring abortion in a single woman. It is becoming, unhappily, frequent now for married women to ask some means of limiting their families. In cases of doubtful sanity, the Practitioner may be asked to witness a signature to a will, or to yield to a friendly bias in giving evidence in favour of the mental soundness and testamentary capacity of a dying man. When a respectable person commits a crime, of course the Medical Practitioner is asked for evidence of the “mania” which shall be a ground of irresponsibility—no matter whether it be klepto-, or pyro-, or dipso-, or phoneuo-, or mœchæo-, or pseudomartyrio-, or epithumeo-mania—for we suppose that each of the ten commandments has a special mania to match, which causes it to be broken without responsibility. Now, in any one of these cases, it may add force to the natural repugnance with which every honourable man would receive such propositions, to know that none of these things *pay*. No connexion worth having was ever based upon deeds which make a man despised by the very people who use him as their tool; and we may add that many a time, where a man has been beguiled into doing work that smacks of the dirty and unprofessional, his employers snap their fingers at him when he asks for payment. They know that he dares not sue them in public. Let us assure the young Practitioner that the more strictly he keeps to the duty of healing the sick, and the less he knows of “family secrets,” the better it will be for him.

NATURE-WORSHIP.

It is a singular and lamentable fact, that we find from time to time in the writings of scientific men, deservedly eminent in their respective circles, instances of the most dismal want of appreciation of the true scope of the Medical art and science. We have a remarkable instance before us, in an article lately published in the periodical called *Nature*, which is evidently conducted by men of the highest scientific standing, and is the favourite method of intercommunication between such men as Tyndall, Huxley, Carpenter, and others whose names might be supposed to give some sort of sanction to the notions of which we complain.

It is an old sarcasm against certain Physicians of the

"expectant" school, that their practice is merely to look on at their patient struggling with his malady, and cautiously to abstain from giving him any assistance. Such men, instead of practising the healing art, were said (we think by Borden) simply to indulge in a "*meditation sur la mort.*" It is said, too, of some few amongst ourselves, that their desire to study the natural history of disease is so strong that they are loth to do anything that shall interfere with the chance of making a post-mortem examination. But we certainly never thought we should have met with the semblance of approbation of such a system in a modern scientific journal. But in the pages of *Nature*(a) we meet with the following passage, which we shall be glad to learn that we have misunderstood. In an article on the "Brown Institution" (the new Pathological Hospital and Museum for animals, placed under the care of Dr. Burdon-Sanderson) we read as follows:—

"The pathologist at the bedside is not in the position of an experimenter, but only in that of a student, who stands by at a greater or less distance, while another, over whom he has no control, performs experiments in his presence, without deigning to explain to him their nature or purpose. The true Physician fears to meddle with the processes of which he is the attentive and anxious spectator. Although the more ignorant members of the Medical craft—the so-called 'practical' men—may sometimes, with the best intentions, experiment on their patients with harmful drugs, such experimentation is repudiated by the man of science."

Well, extremes meet, anyhow. For here, in a paper devoted to the newest results of science, we find the superstitions and false philosophy of two thousand years back unconsciously reproduced! There is not a line in it which does not betray some fallacy in argument or mistake in matter of fact. Let us see.

We are told emphatically that the Physician must be a looker-on, while "another, over whom he has no control," performs experiments in his presence. Does this mean that the "Nature Worshipper" is still in the "theosophical" stage of philosophy, and sees, in disease, as the untutored savage does, an evidence of the *ira deorum*, with which he dares not meddle? If so, we respect his piety, but, on his own ground, would remind him that the same Being that sent disease gave also the Physician, and the drugs, and that ineradicable desire to obtain relief which constitutes a primary instinct in the human being.

But peradventure the writer may say, "I don't mean God, but I mean 'Nature.'" Then we ask, "Do you believe there is such a force as 'Nature' elsewhere than in your own conceptions? Are you still in the 'metaphysical stage' in which half-tutored man believes in the real existence of abstractions?"

Two thousand five hundred years ago the Medical world revered the operations of "Nature" in disease. A man was exposed to marsh miasm, and imbibed the morbid influence. "Nature" took the alarm; she testified her concern by shivering, followed by chills and burning fever. This process was repeated daily, or on alternate days; and to the sweats there was added a copious red sediment in the urine, and perhaps a diarrhoea. "See the efforts of Nature," said the philosophers of the day; "how, by a succession of febrile paroxysms, she produces 'coction' of the *materies morbi*, which she then expels by critical evacuations. The true Physician will fear to meddle with these processes, of which he is the attentive and anxious spectator." If an ignorant—so-called *practical*—man were to interfere with the divinely directed "efforts of Nature," we should have the *materies morbi* thrown inwards on the vital parts, and a swelled liver and dropsy would soon finish the scene.

But, lo! "an experiment" was made in the seventeenth century—not by the "true Physician," so far as he might be represented by the leaders and teachers of the Profession, but by the wild, untutored Indian, then by the fathers of the Jesuit community, and then by the irregular Practitioners of Europe.

A bark was discovered, which made the true Physician aghast at the temerity of those who used it. The advocates of this audacious experiment derided the efforts of Nature; refused to wait for coction, or critical times, or critical evacuations, but simply cut short the disease by a powder that acted in a way that science could not explain, and never has explained to this day. So much for the true Physician as a spectator of a process he is not to meddle with! We wonder much what either of the eminent contributors to *Nature* would say if their Physician desired to be a spectator of an ague, or malarious neuralgia, or influenza, and refused to cut it short with quinine.

The man of sense treats "Nature" simply as a phrase for "what is," and deals with it according to his judgment and experience. If a disease is best let alone, or treated by rest and diet, he does so; but if it be the result of experience that he can shorten its duration and abridge its sufferings by a purge, or a dose of opium, or chloral, bromide, or any other drug, he remembers that drugs are part of "Nature," and that it is in accord with civilized man's nature to use them. As for the *practical* men whom our philosophers sneer at, we may say that to practise Medicine successfully—to satisfy the mind, gain the confidence, and assuage the sufferings, real and imaginary, of the sick—requires as much minute observation, shrewdness, practical tact, inventiveness, patience, and good temper as would qualify the possessor for eminence in any scientific pursuit whatever.

AMERICAN MEDICINE.

WE this week publish the first of a regular series of letters relating to the affairs and position of our Profession in America, which we trust will alike prove useful to our subscribers here and gratifying to our American brethren. It has ever been our desire to foster progress in Medicine; and as there is no means more useful towards that end, or more honourable in every way, than giving credit to whom credit is due, we have deemed it advisable to secure the services of one of the most eminent men in the United States and in our Australian colonies respectively to keep our readers *au courant* with what is doing in their several localities. The *Medical Times and Gazette* is essentially a *Medical journal* rather than a newspaper with a Medical whitewash. Gossip, even though London gossip, is neither generally cared for nor even understood; and it is accordingly our endeavour to supply the wants of the hard-working Practitioner, with but little time at his disposal, not with the *on dits* of the Medical societies, but rather with that which may enable him to put an honest guinea in his pocket—some practical hint or some scientific fact which gives him a deeper insight into his Profession.

But it is not so much with regard to these things we now desire to speak; rather we take the opportunity of saying something on a subject which has long engaged our attention, and which recently has been rapidly assuming a greater and greater importance. It is at once our duty and our pleasure to watch the changes of Medical doctrine and the improvements in practice, as they are gradually evolved at home and abroad, and nothing has struck us so much of late as the marvellous strides American Medicine has made within a few short years. This was most forcibly brought home to us a little while ago, when we were asked to recommend a book as the best on each of a certain number of subjects. The list was not a long one, and yet about one-half of those we had it on our conscience to recommend were American. Now, if this is not saying much for ourselves, it is saying much for our American brethren. There has always been a number of Physicians and Surgeons in America quite on a par with the best in this country, but that number used to be very limited. Furthermore, the American school was marked by certain characters of its own—the curriculum was exceedingly short, only the merest smatterings of Medicine and Surgery could be picked up in

the period; and, with the exception of those educated in the older schools and abroad, few of its representatives could boast of great scientific attainments. Nevertheless, the men so educated, had to encounter the exigencies of Professional life as best they might; and here the vigour of the national character came prominently into play—so that, though rough, the Medicine and Surgery of the States had an exceedingly practical character. We have used the past tense here; for all this, although within the memory of most men now in the Profession, is already a matter of history. American Medicine has fairly passed into the scientific stage of development. It is well for us to look this matter fairly in the face, and to ask how it has been that, in America, Medicine has made such mighty strides in such a short space of time. As to the reality of the advance there can, we think, be no question; it is evidenced in many ways, but in none more powerfully than in the modern Medical literature, periodical and permanent, of the United States. With the abandonment of their dirty calf-binding and bad paper, the Americans seem to have made other changes important in every respect; and though we have not yet done them the compliment of pirating, as it is called, their works on this side the Atlantic, it is not because they are not used, for they are daily to be seen in the hands of students and Practitioners alike.

We have heard it said that most of the American literature, as it comes to us, is not new—only reproduced—and undoubtedly the criticism is in some sense true; but the existence of such a literature implies a demand for something more than the scanty facts of pocket text-books, and is itself an evidence of the advance of which we speak.

But this eager desire for the higher kinds of knowledge is made still more clear, to those of us connected with certain London institutions, by the crowds of men from America who flock there and elsewhere, seeking to prepare themselves to take a position in their own country. We are constantly meeting Americans—young and old—who have left America for one or two years, which they are spending in travelling from school to school, here and on the Continent, picking up everything that is to be learnt, and storing it up for future use. Go to Vienna, and the great majority of the English speakers there to be encountered are Americans; so, too, though in a less degree, in Berlin; and so, too, it used to be in Paris. These men have left their homes in search of knowledge, and we may be sure that, having acquired it, they will reproduce it with interest when the proper time arrives. These are the signs of American advance, and true indications of future American greatness.

We ourselves here in London would do well to ponder these things, for there is, unhappily, a tendency among us, more especially manifested in certain schools, to a display of self-satisfaction fatal to progress. Unfortunately, our system of Hospital education leads to foster this; it is diligently instilled into the minds of our students that to learn their Profession aright it is unnecessary to stir beyond the walls of their own Hospital. When ideas are bred in-and-in too long, the result is as disastrous as it is in animal life: a puerile conceit is apt to take the place of a masculine breadth of thought, and to beget its like in the minds of others. But our English students neither pass from Hospital to Hospital enough, nor do they go abroad. Of all the means available for expanding the mind, none are equal to travel; nor for producing catholicity in Medicine is there anything like foreign study. In this we fear even now the Americans are beating us. In the future we shall have to look to our laurels.

PRIVATE WARDS AT THE LONDON FEVER HOSPITAL.

THE Committee of Management of the London Fever Hospital deserves every praise the Profession and the public can bestow

upon it, for being able to say that “for many years not a single case of contagious fever has been refused admission to the institution and sent back to act as a new focus of disease.” To appreciate the amount of good which the Fever Hospital has thus rendered the metropolis, we must bear in mind that until the opening of the new pauper fever asylums it has been the only institution of the kind in London. Its doors were open (as they were intended to be at its establishment) to all and to every class of fever-stricken patients, from the rich to the poor; and not only these, but paupers were received as well—half unwillingly, indeed, but still unavoidably, if one of the chief objects of the institution was to be fulfilled: the prevention of the spread of contagious fevers.

The opening of the new pauper fever asylums has, however, now relieved the Hospital of the objectionable portion of its applicants for admission, leaving to it such fever patients only as are independent of parochial relief, whether rich or poor. To accommodate these in a better way, the Committee of Management has availed itself of the space thus thrown into its hands, and it has taken the opportunity, at the same time, of setting aside part of this for the reception of cases of fever occurring in families in good circumstances, or in schools, hotels, among the *employés* of large commercial houses, etc.

As yet the arrangements can be considered as little more than provisional—we might almost say, experimental; but experience and encouragement will, we trust, gradually give them a more perfect development. At present they are these:—“Patients will be admitted into the general wards on the recommendation of a governor or annual subscriber of one guinea, or, as heretofore, on payment of two guineas on admission or of one guinea weekly. For such patients as require isolation and better accommodation than that offered by the general wards, eight large rooms have been prepared and furnished with every requisite for comfort, in which a single patient, or two children of the same family or from the same school, can be received. The payment for one of these rooms, with the attendance of an experienced nurse and the care of the resident Medical Officer and Physicians, and including food and medicines, has been fixed at three guineas per week.”

We have been afforded an opportunity of examining the wards and rooms referred to above, and we are much pleased with the manner in which the Committee has carried out its undertaking.

Of the general wards we need say nothing; they must be familiar to every member of the Profession in the metropolis who feels especial interest in contagious fevers.

The new rooms we inspected with interest. They are eight in number—four on either side of the house; and of these, two are on the ground floor, and two on the one above. While they are all as similar in appearance as possible, they differ in this respect, that four are of one size, and four of another, the larger ones being intended to hold two beds, should these be required, as has been said, in the case of a couple of patients happening to belong to one family or school.

Each room has abundant cubic space; they are lofty and well lighted, and we need not add that the provisions for ventilation have been made as perfect as possible. The walls are painted of a pleasant light colour. There is a large and cheerful fire, and above this a handsome gas-bracket. The floor is of wood, uncovered, except with a couple of short strips of carpeting by the bedside for the sake of personal comfort; the bare floor being preferred in a room devoted to the reception of fever patients, for reasons easily comprehended. The absence of every kind of fabric that might be supposed to retain contagious matter is indeed striking; the blinds are made of wood, and the chairs are cane-bottomed. The other furniture comprehends every necessary to be found in sick-rooms of the better class, while whatever is useless, and so objectionable, is dispensed with;

for the use of the convalescent patient there is a special folding-chair, which will be found very serviceable.

In these days of typhoid fever and sanitary inspections, we inquired, with considerable interest, about the provisions adopted in the way of commodes and water-closets; but we were disappointed to find that they are not yet definitely made. Fixed water-closets there indeed are beside the rooms, but movable stools are as yet unsupplied. We were told that the Committee had entertained the idea of adopting the dry-earth system, but that they hesitate to do so from having received an unfavourable report upon it. A large movable bath will be in use in the rooms when required; in the upper floor there is also a special room set apart for this purpose.

It will be seen that we have here a most happy combination of the necessarily rigid construction of the ward with the arrangements of the bedroom—a combination, however, which retains only the advantages, and dispenses with the disadvantages, of each. So that while the former element provides the patient with all the benefits which experience and science can devise in the way of making his bodily condition as favourable as possible, the latter cannot fail to affect his mind in the most salutary manner; for he will find himself isolated, yet in a room where he is filled with a sense of homely comfort and contentment.

We need hardly add, that in addition to these advantages the patient here enjoys others even greater—the advantages of the best nursing and the best Medical treatment to be had in London. Altogether, the arrangement of the Committee of Management recommends itself to us, as it must to all who have had practical experience of what is meant by treating cases of typhus and typhoid fever in private houses. It is to be hoped that a hearty response will be made to the earnest appeal of the Committee to all directly or indirectly interested in the public health—to publish, as generally as possible, the knowledge of the existence of such philanthropic arrangements.

HEALTH OF THE NAVY.

THE recently published Statistical Report on the Health of the Navy for the year 1869 contains ample evidence that, with the exception of some of the vessels employed on the North America and West Indies station, and on the south-east coast of America, the health of the total force afloat during that year maintained the progressive improvement which has of late years been observed with so much gratification by the country, and credit to the Medical Officers of the Navy. The total number of cases of disease and injury entered on the sick-list was in the ratio of 1221.9 per 1000 of the strength, being a decrease compared with the preceding year of 30.5 per 1000. The average number of sick daily was 46.2 per 1000, being a reduction compared with the preceding year of 2 per 1000. The number invalided was equivalent to 32 per 1000—less by two than the preceding year; and the mortality was in the ratio of 9.9 per 1000, being an increase of 1 as compared with the preceding year. This increase in the mortality was entirely attributable to the destructive influence of yellow fever in the West Indies. From disease alone the death-rate was 7.3 per 1000. Had it not been for the fatal exposure of certain vessels to the yellow-fever poison it would have been only 6.2, which would have been below the ratio of mortality of 1868 to the extent of .3 per 1000. The death-rate on the North America and West Indies station from disease was 19.7, and from violence 3.7 per 1000, being a total of 23.4, and showing an increase of 14.2 per 1000, the largest which occurred during the year. On the south-east coast of America (which was also subjected to the yellow fever) the mortality from disease was 19.3, and from violence 2.1, or a total of 21.4 per 1000. The lowest death-rate from disease was on the Mediterranean station, and was only 4.2 per 1000, while the deaths from violence were at the rate of 3.7 per 1000.

On the home station the deaths from disease were at the rate of 5.1, and from violence 1.8 per 1000. Compared with the preceding year there was a reduction in the death-rate on the home station of .6 per 1000; on the Mediterranean of .7; West Coast of Africa and Cape of Good Hope of 2.8; and on the Australian station of .4. It is observed that on the West Coast of Africa and Cape of Good Hope station the benefits derived from removing the vessels of the squadron to other stations after a limited period of service continue to be experienced. The total death-rate on that station for the year was 10.4 per 1000, being the lowest on record; and there was a reduction in the rate of admissions of 248.1, on invaliding of 19.5, and in mortality of 2.8. The two stations of West Coast of Africa and Cape of Good Hope were amalgamated during the year. It would be premature to attribute the favourable results to this cause, although it probably exercised a considerable influence.

The history of the many and serious outbreaks of yellow fever among the crews of vessels on the North America and West Indies station is given at considerable length, and fully confirms the generally received opinions as to the communicability of the disease, its limitation to certain well-defined localities, and the immediate benefit to be derived by removing infected vessels to Northern latitudes. In some instances there appears to have existed an unhappy necessity for keeping fever-stricken ships in localities where a high temperature prevailed. And on this point it is very justly observed that it cannot be too often repeated, nor too strongly stated, that the only chance for a ship's company, amongst whom yellow fever has made its appearance, is to have them conveyed with the utmost speed to a cold latitude. Nothing but the most urgent necessity should justify any temporising or procrastination in respect to this measure. There is reason to fear, however, that in some instances senior and commanding officers have not appeared alive to the instant necessity of adopting it, and thus valuable lives have been sacrificed, which a clear appreciation of the position, and promptitude of action, might have saved.

One hundred cases of yellow fever on the above-named station were entered on the sick-list, and of these forty-eight proved fatal. This is more than double the average mortality of the disease, and is accounted for by the fact that many cases returned as simple continued fever were doubtless instances of the more fatal type. Surgeon R. C. P. Lawrenson gives a minute, yet concise and admirable, report of the outbreak of yellow fever in the *Barracouta*. He complains of having been left in ignorance of the unhealthy condition of Havana on the arrival of the vessel at that station. The authorities on the island must have been aware of the state of the public health, but it was during a visit to the military Hospital that Mr. Lawrenson first became aware of the extent to which the "*vomito prieto*" was prevailing. He immediately took all necessary steps to prevent the communication of the disease to his ship. His efforts were much aided by the prevalence of northerly winds, blowing from seawards, and the vessel enjoyed an immunity from yellow fever while at Havana. Having left that port on July 1, the *Barracouta* arrived at Port Royal, Jamaica, on the 6th, between which dates three cases of simple fever were under treatment, and became convalescent at the latter port. No additional cases were entered till the 11th, when two of the crew presented the primary symptoms of yellow fever. On the 13th and 16th respectively there was a fresh case; and on the 25th, while the vessel was undergoing a twenty-one days' quarantine at Bermuda—where she was unavoidably detained, being specially employed in assisting to take the floating-dock into the harbour—another, and the last, case having occurred, the vessel was ordered to Halifax.

Mr. Lawrenson was at first inclined to connect the origin of the disease with the epidemic at Havana, but he was afterwards

more disposed to credit Jamaica, if not with the whole responsibility, most certainly with a share. The place was beginning to be very unhealthy, and, as there was a great influx of visitors to the ship, although no leave was given to the ship's company, the disease could easily have been imported. One of the patients, also, whose case terminated fatally on the 20th, had been every night on shore, between the 6th and the 10th, so that his illness may, most probably, be traced to that place. It is nevertheless true, as observed with reference to Mr. Lawrenson's complaint of his not having been informed of the existence of yellow fever at Havana, that the concealment of the prevalence of epidemic diseases in foreign ports by the local officials is culpable, and "that the only safeguard against it would be vigilance and prompt action on the part of our consular establishments when any of our men-of-war are signalled as approaching the harbour. This, however, unhappily does not appear to constitute any part of the consular duties, and our vessels, for the most part, are first made acquainted with the existence and prevalence of infectious diseases by their sudden appearance amongst the ship's company."

The outbreak of yellow fever on the *Eclipse*, as reported by Surgeon R. F. B. Head, was attributable to exposure at Havana. A young officer who had been a good deal on shore at Havana was the first to suffer; he was attacked on arrival at Nassau, having been unwell during the passage. Two other officers, a carpenter, the paymaster, the boatswain, the chief-engineer, and the captain were subsequently attacked. The captain died; but the ship, after consultation with the principal military and Medical officer, having started with all dispatch for Halifax, there was an immediate arrest of the disease, with an improved condition of those suffering from it, as the temperature became reduced. The fatal results of delay at an infected station were exemplified in the cases of the French men-of-war *Curieux* and *D'Estrees* at Port-au-Prince. The former vessel lost her commander, Surgeon, several subordinate officers, and, eventually, almost the whole of her original crew. Our own ship *Philomel*, after the occurrence of seven cases at Port Royal, was ordered to Halifax, touching at Havana, where, on the recommendation of the Medical officer, she was detained, to be disinfected and fumigated, eleven cases in all having occurred—three of which, including that of the commanding officer, having been fatal. With reference to this case, it is observed that, "happily, the disease did not spread further; but nothing could justify the adoption of a step so flagrantly in opposition to all experience as to detain a yellow-fever-stricken ship in the harbour of Havana, for the purpose of having her disinfected and fumigated. It was most unfortunate that, at a time when every hour was of such momentous importance to those on board, the exigencies of the public service should have necessitated the *Philomel* being ordered to the Havana, instead of making a direct course, and with as much speed as possible, to Halifax."

During this epidemic Assistant-Surgeon T. B. Thomas, M.D., on the second day of the voyage from Bermuda to Halifax, in the gunboat *Albacore*, with marines and sailors suffering from yellow fever, was attacked by the disease. His conduct, under such trying circumstances, his desire (to prevent alarm) that the nature of his illness should be concealed from the others, are described as having been marked with the most self-denying thoughtfulness for those under his Medical charge. He succumbed on the evening of the fifth day, "the service being thus deprived of a young officer of rare promise, and of the highest Professional attainments."

The Deputy Inspector-General in charge of the Royal Naval Hospital at Port Royal contributes a very valuable series of observations on yellow fever, in continuation of those which have already appeared in the Statistical Report of the Navy for 1867.

Surgeon D. O'Connor, M.D., of the *Dryad*, gives a most

interesting and valuable report of the epidemic of cholera at Zanzibar and along the east coast of Africa. He states that Dr. Kirk, the well-known African traveller and political agent at Zanzibar, has no doubt that the epidemic reached the coast from the Masai country, in the interior of Africa; but how it got there is much more difficult to make out. There are objections to every supposed mode of importation. Its advent from the Gambia overland, across all the natural obstacles of the whole African continent, from north-west to south-east, is against all probability; its passage by the Cape is not more probable, and is opposed to the fact of the disease having been prevalent in the interior before appearing on the east coast; its introduction from India direct is rendered unlikely by the fact of its having prevailed at Masai as early as September, 1869, at a season when the south-west monsoon puts a stop to all intercourse between Kurrachee and the African ports on the east; besides, it was not till the end of 1869 that the disease had extended down the Indus to Kurrachee. The difficulty, also, of explaining the immunity of the coast through which it must have passed still remains. The objection to its having been imported by Arabs and Eastern merchants trading with Abyssinia by the Red Sea is that there is no evidence of the disease having existed in any of the Abyssinian ports in 1868, nor was Dr. O'Connor aware of its having been there in 1869, although, having spent some months of that year at Bombay, he had some opportunities of hearing if such had been the case. The only question, therefore, is as to its origin *de novo* in the interior of Africa, Dr. O'Connor's own ideas being in favour of this presumption. He admits that there are many good reasons for the generally received doctrine of the present day, that every outbreak of cholera, in whatever portion of the globe it may appear, can be traced, link by link, with some outbreak in its "endemic home" in India. He does not, however, consider it to be yet established with certainty, and thinks that, so long as any doubt remains, "the probability of its origin *de novo* cannot oppose any principle of nosology nor involve any Medical heresy. Very little is really known of the physical features of the interior of the vast continent of Africa, still less of its geological or meteorological condition, and absolutely nothing of the history of its nosology. These are factors that all must admit play an important part in the outbreak and spread of cholera, and these are points that must not be forgotten in the question of regarding Bengal as the only source and home of cholera."

The question raised by Dr. O'Connor is certainly of considerable importance, and can hardly be lost sight of in the consideration of epidemics of cholera in the African continent. It will be long, however, before our knowledge of that country on the various points mentioned by Dr. O'Connor will enable Medical science to give a definite reply, either affirmative or negative, to the suggestion of the possibility of cholera having another endemic area besides that so long recognised in Bengal.

THE WEEK.

TOPICS OF THE DAY.

WE are heartily glad to chronicle the progressive improvement of the Prince of Wales. His convalescence has been no doubt delayed by the local affection in the neighbourhood of the left hip, which has been mentioned so frequently in the bulletins. This affection has been the result of the protracted *decubitus* and of the long stages of exhaustion and debility through which His Royal Highness has passed. Medically, the occurrence of sore from pressure in such a case is a fact of interest for it proves that the most anxious care and highest skill will not suffice to ward off a sequela of long-continued fever, which is not seldom regarded by non-Professional persons as the consequence of inattention on the part of those who minister to the sick. Often have charges of neglect been brought

against the Medical attendants of the poor, based on the occurrence of the same local malady from which the best Medical and Surgical skill and the most accomplished and careful nursing have not been able to defend the Prince. This is a lesson which we think should not be lost. We are happy, however, to be able to announce, in the words of Thursday's bulletin, that "the local affection is subsiding," and that the Prince is surely and steadily gaining strength.

The scheme for a partial Conjoint Examining Board, formed by the Committees of the Royal Colleges of Physicians and Surgeons, and agreed to by the Universities, is, we learn, beginning to take a tangible form. The opinion of counsel has been obtained as to the legality of the proposed scheme, and has been given in its favour. A meeting of the Committees of the two Colleges took place at the Royal College of Physicians on Wednesday last, and we are informed that the favourable opinion given by the lawyers was read. There only now remains the discussion of details, which, we presume, will be settled before the scheme is submitted to the General Medical Council. Of course the great objection to the scheme is its imperfect character, and the exclusion of the general Practitioner of Medicine and Surgery from all participation in the examination of his own class in the Profession. Such exclusion, we believe, may work injuriously for the best interests of the rank and file of the Profession, and we therefore hope that the General Medical Council will not give their sanction to any plan which will throw the examination of the general Practitioner into the hands of pure Physicians and Surgeons only, or which will introduce a new class of registered Medical men with one diploma only—the licence of the Apothecaries' Society.

The Report of the Local Government Board "On the Result of their Inquiry into the Management of the Hampstead Small-pox Hospital," may be summarised in one word—"whitewash!" Of the seven charges which gave rise to the investigation—the first and second, that delirious patients were tied down in bed, and that strait-waistcoats were employed, are defended as having the highest Medical sanction; and on this point, at least, there is no difference of opinion as to the occasional necessity for such means of restraint. The third charge, of an inadequate supply of milk and beef-tea, is explained away by supposing that the patients who proved it did not draw any distinction between food and drink; that milk and beef-tea were in truth food, and therefore the patients ought not to have drunk them up so fast, but ought to have quenched their thirst with some less nutritive fluid. There is nothing, however, said as to whether any less nutritive fluid was supplied. Of the complaints of bad food, only that of the bad quality of meat is allowed to have any foundation. It is allowed that three children died in their beds without any person being aware of the fact; but the Local Government Board find it to be a matter of *satisfaction* that death in these cases was not unexpected, and that the nurses' ignorance of death having taken place did not imply that anything could have been done to prolong the children's lives! Lastly, it is quite true that a stinking dead body remained in the bath-room of a ward for many hours, but the circumstance led to no prejudicial results, and the only person to be blamed is the Assistant Medical Officer who gave orders to the nurse to have it removed. The Local Government Board, however, allow that patients were admitted into the Hospital without proper Medical examination; that the linen and clothing were insufficient; that fresh linen was supplied damp and imperfectly washed; that new patients were put into beds without any change of sheets; but all these shortcomings are condoned on the ground that the Managers were suddenly called upon to perform an arduous and previously unprecedented duty. On a previous occasion we have shown in a leading article on the subject that this was no excuse. As our views on the results of the Hampstead Inquiry have now been adopted by many other organs of public opinion, we forbear to enlarge upon this one-

sided and unsatisfactory Report. The Report itself, we may remark, is the report of the Office, and is signed by Mr. Fleming; it is not the report of Mr. Henley and Dr. George Buchanan, which is a secret document, and has never yet been made public. We cannot refrain, however, from quoting the remarks of the *Times* of Wednesday on the whole bearing of the case—remarks which echo the opinions we advanced at its conclusion:—

"But this conclusion is not without qualifications, which throw a burden of blame upon the Local Government Board itself. The faults discovered are held to be venial, on the ground of the previous want of preparation, and of the absence of the necessary machinery, in skeleton, for meeting an epidemic. But Mr. Hardy's Act threw upon the Poor-law Department in 1867 the business of providing for such contingencies, and it was the evident duty of the Poor-law Board to have made such provision. The moment at which epidemics may occur is not to be accurately foretold, but in the present sanitary condition of great cities their occurrence is so frequent that it is an almost criminal negligence not to be duly prepared to meet them. Of the epidemic of small-pox there had been ample warning during the whole of the summer. It came not suddenly, but gradually, and after long threatening, and the Poor-law Board were in possession of official figures, showing the insufficiency of vaccination in the population of the metropolis, and the unprotected condition of masses of the people. They were equally aware of the stringent rules which close ordinary Hospitals against small-pox patients. Had they taken earlier and more efficient measures for enforcing on the guardians the duty of appointing vaccination officers and superintending the fulfilment of the functions of those officers, the epidemic could not have attained the huge proportions to which it finally developed. Had they considered in time the proper means for the due performance of the responsibilities which they assumed before Parliament, they would not now be called upon to excuse the admitted shortcomings of their agents, by alleging that they were suddenly called upon, without adequate preparation, to cope with an epidemic which, if the Board had done their duty, they would have been fully prepared to meet.

"Nor did the Poor-law Board show a much greater anxiety to test the efficiency of this huge and rapidly fitted Hospital than they had done to anticipate the necessities which called it into existence. It was a notable fact, elicited in evidence, that the Metropolitan Medical Inspector had visited the Hospital only six times from December to August, that the night nursing had not been tested at all, and that the information of the Board as to the character of the dietaries, the changes made in them, and the general administration of the Hospital was very imperfect. The character of the Poor-law Board was almost as much at stake in the course of this inquiry as that of the Managers; but this issue the inspectors, who were themselves officers of the Board, were not competent to try. It may be remembered that when the Bill which created these asylums and constituted their Boards of Management was passing through the House of Commons, the President of the Poor-law Board was pressed to undertake that there should be the same safeguards for efficient Hospital management by visiting Physicians as are provided at the great voluntary Hospitals. That pledge was officially given, but it has not been redeemed. The Local Government Board are now of opinion that the shortcomings of the Hampstead Hospital are largely due to the imposition of too many duties upon the Medical Superintendent, upon whom were piled the duties of House-Governor and Superintendent, as well as those of Visiting Physician. This in its turn led 'almost necessarily' to a neglect of duty by the Resident Medical Assistants, who, being called upon to resign, subsequently appeared as complainants. The status of a resident Medical officer at a small salary is, in fact, not always sufficient to impose respect upon his assistants (who are but little his juniors), or to afford adequate guarantees to the public for the efficient Medical treatment of this great mass of actually sick persons. From all these defects it is the sick who suffer. The Local Government Board has not yet raised the organisation of its Hospitals to the standard of that of the great voluntary Hospitals with which it must expect that they will be compared, and with which they ought to compare favourably. It has, at least in one essential respect, fallen short of its own promises. Had it fulfilled that pledge much of this scandal could never have occurred. The Medical Superintendent would have been less overworked, and could have attended to his duties

more thoroughly; the Assistant Medical students would have yielded a ready obedience to a visiting officer of obviously senior standing, and the representations of such an officer would have sufficed to obtain immediate remedy of temporary deficiencies such as are proved to have existed, and which no Hospital Physician would have tolerated. It is easily within the means of the Local Government Board to learn by experience and to strengthen the organisation of their staff against future emergencies. In acquitting the managers, the Board have themselves assumed the blame; it behoves them to see that they do not again incur a like reproach."

The friends of decency in the Infirmary and University of Edinburgh have met with two temporary defeats. The subscribers to the Royal Infirmary have, by a narrow majority, returned new Managers who are known to be favourable to the admission of women-students to the wards; and the Edinburgh University Court has declined to give effect to the resolution of the Senatus, which represented to the University Court the propriety of rescinding its resolution and regulations in reference to the admission of women to Medical education in the University. We have already remarked on the insane policy which the authorities of the University seem bent on pursuing—a policy which is certain, if persisted in, to ruin Edinburgh as a Medical School. *Quos Deus vult perdere prius dementat.*

Mr. Quain, the new judge of the Court of Queen's Bench, is a brother of the distinguished Surgeon-Extraordinary to the Queen, and a cousin of Dr. Richard Quain, F.R.S., one of the representatives of the Crown in the General Medical Council.

We hear that Dr. Guy has resigned the chair of Medical Jurisprudence at King's College, but that institution will still retain his valuable services as Professor of Hygiene.

THE PATHOLOGICAL SOCIETY.

THE annual meeting of this flourishing Society was held on Tuesday, the 2nd inst. Perhaps from its following so close on the Christmas holidays, the number of members present was somewhat less than is usual on such occasions. The President and principal officers were this year re-elected with one exception, which we cannot pass over without remark. The labours of the Secretaries to this Society are unusually onerous, and press very heavily on those who undertake the duties of the post. Dr. Dickinson has for some time been Medical Secretary, and has fulfilled his arduous duties in such a fashion as to give satisfaction to everyone who had dealings with him. He has now resigned this post, and carries with him, we are sure, the best wishes of all connected with the Society. Dr. Cayley, of Middlesex Hospital, is his worthy successor. The Council and Treasurer had a satisfactory report to make: the finances of the Society are flourishing, and the transactions of the Society keep up their high character. Fewer specimens have been exhibited during the past year than usual; but this is a subject to which we may again revert.

LONDON POOR-LAW MEDICAL DISTRICTS.

IN regard to the area and population of Medical relief districts, an order has been issued by the Local Government Board, removing the present restrictions, on the ground that the circumstances of the metropolis are so exceptional that the limit prescribed by the Regulations of the Board is not required. The order will have the effect of legalising several recent appointments, in which the Medical officers had a larger area and more numerous population than were prescribed by the Poor-law Regulations.

CHARING-CROSS HOSPITAL.

A MOVEMENT is now on foot for laying down asphalt in the streets which surround this Hospital. Situated as it is, in the immediate vicinity of one of the noisiest thoroughfares in London, such a change is much to be desired on behalf of Physicians, Surgeons, nurses, and patients. In the meantime

the Hospital is surrounded on every side by streets paved with the usual blocks of granite; close to it are the great theatres, so that at the very time the poor patients should be hushed in sleep they are kept awake by the noise of cabs and carriages. Those who know how insufferable that din is to sick ears will also best know the great advantage such a change as that proposed in the streets would be to the Hospital patients. We can, at all events, promise the movement our cordial sympathy and support.

DISEASE FROM HOUSES WITHOUT DRAINS.

WHAT ingenious contrivance may next be resorted to to save expense at the risk of the health of the population it would be vain to speculate on. Just at this time, when the question of imperfect drainage is occupying the attention of most persons, and means are being taken to remedy defects, what do we find? That in the parish of Lambeth it has been discovered that some of the houses newly built are positively without any drainage whatever. They have, to all appearance, the appliances for drainage, but no connexion has yet been made with the main sewer. Here is a field for the new Medical Officer of Health to explore! No wonder that typhoid is so frequently found in the parish, and fever so often fastens upon the poor. It is really shocking to think of families occupying houses standing, as it were, in cesspools which are gaining a poisonous power every day. Are these houses the only ones having sham drains? We trust that the matter will be thoroughly investigated, and the builder be adequately punished. A heavy responsibility rests upon those who let tenements with a knowledge of this state of things, and it behoves all persons taking newly built houses to look to their drains.

AMERICAN MEDICAL MILITARY AFFAIRS.

THE following extract is from the report of the Surgeon-General, Brigadier-General of America. He (J. K. Barnes) says:—

"The current expenses of the Medical department in the year are \$267,477. The number of military posts requiring Medical attendance on July 1, 1871, was 206, at many of which the number of troops was so large, or the nature of the duties so onerous, as to require the constant services of the Medical officers. The Surgeon-General therefore recommends that the restrictions as to promotions and appointments in the Medical corps be removed, as it would, in any event, require several years, under the prescribed modes of annual examination, to restore it to the standard number allowed by existing laws. He thinks the stoppage of promotions and appointments has proved to be prejudicial to the interests of the service, both in a sanitary and economical view. The number of persons who have availed themselves of the provision of Congress under the Acts of June 17 and 30, 1870, to receive artificial limbs in kind, or a stated commutation in money, up to June 30, 1871, was 8918. These received 1117 legs in kind, and 3114 commutation; 104 arms in kind, and 4087 commutation; the rest received apparatus for resection. The number of persons furnished with limbs under Acts previous to June 17, 1870, was 7887. The health of the army has not been equal to that of the previous year. The total number of deaths reported was 519, or 17 per 1000 of mean strength. The mortality-rate is thus greater than that for the previous year, the chief increase occurring in the proportion of deaths from disease. The proportion of deaths from all causes to cases treated was one death to 122 cases. One thousand and ninety-one white soldiers are reported discharged on Surgeon's certificate of disability, being at the rate of 37 per 1000 of mean strength. The number of coloured soldiers discharged on Surgeon's certificate of disability was 71, or at the rate of 27 per 1000 of mean strength. There are now recorded in the division of Surgical records a total of 235,398 cases, of which 5210 were recorded during the past year. Part first of the 'Medical and Surgical History of the War' is near completion, and will be laid before Congress during its coming session. The Surgeon-General urges an appropriation by Congress to complete the remaining parts."

SMALL-POX JOTTINGS.

FORTY-FOUR small-pox patients—being the highest yet experienced—were admitted into the North Dublin Union during the past week. There were 180 cases under treatment in the Union, and seven died during the week.—Five new cases of small-pox are reported in the Medical relief district in Islington during the past week, against two in the previous week; there had been no death from the disease in the same period.—Small-pox was fatal in four cases in St. Peter's district, Newington.—Small-pox is still increasing in Wolverhampton. At the meeting of the Town Council last week, Mr. Collins, a Surgeon, charged the Corporation with indifference to vigorous measures if they involved outlay. They would not erect an auxiliary small-pox Hospital outside the town. The Officer of Health cannot prevail upon the Sanitary Committee to purchase a disinfecting machine.—One fresh case of small-pox and four deaths last week, against two fresh cases and no deaths in the preceding week, have occurred in Kensington.—In the Homerton Hospital four deaths are recorded from small-pox during the past week, and one from fever; there had been eleven new cases of vaccination, and eight successfully terminated.—In consequence of the prevalence of small-pox in Edinburgh the Public Health Committee intend to erect a temporary wooden building to accommodate thirty patients, for the use of the convalescent, who will be removed to it from the Hospital; and an extra inspector has been appointed to enforce the necessary sanitary measures.—At Wakefield, twenty-four fresh cases of small-pox during the past fortnight have been reported.—At Shrewsbury the disease is on the increase; it prevails chiefly amongst the Irish residents.—Small-pox has broken out at Whitby; several fatal cases have already occurred.—In Poplar Union four deaths from small-pox occurred last week, and eleven new cases are reported. In the same period eighteen persons had been vaccinated at the public stations. There were at that time fourteen small-pox patients under treatment in the North-street Infirmity.—The disease is spreading at Halifax; twenty-seven persons are in the workhouse afflicted with it, and there are nine cases of enteric fever.—After landing two cases of small-pox at Lisbon, the Medical officers were enabled to vouch for a clean bill of health on board the ships composing Rear-Admiral Beauchamp Seymour's flying squadron.—An increased number of small-pox cases of a virulent type is reported in the village of Hanwell. The Lambeth police-magistrate last week fined a resident at Peckham £5 for having removed his son (who was suffering from small-pox) in a cab without proper precaution.—The Ellesmere Board of Guardians have agreed to pay their officers by certificate of successful vaccination, 1s. for each certificate.—Five fresh cases of small-pox were admitted last week into the Darlington Union; nine still remained—five convalescent and four under treatment.—Ninety-seven persons died from small-pox in London last week.—Two cases of small-pox are reported by Dr. Aldis, of St. George's, Hanover-square—one in the in-wards, removed to the Hospital; the other in the out-wards.

AMERICAN LAW ON THE CIVIL LIABILITY OF MEDICAL MEN FOR CARELESSNESS.

"THE apothecary sold to a person for tincture of rhubarb two ounces of laudanum, which were administered to a sick man, from the effects of which he died some hours after. The Supreme Court of Massachusetts decided that the cause of action survived to the administrator, without regard to the question of privity of contract between the apothecary and the sick man, the ground of action being the injury caused to the body of the intestate by the apothecary's act."—*American Law Register*.

Divested of all technical phraseology, this decision simply means that a Medical man who, through gross ignorance or carelessness, kills a patient, is not only amenable to the

criminal law, but is liable in damages to the representatives of the deceased. The conclusion at which the American Court has thus arrived by a process of induction, was long ignored by the expounders of the law of England, until, by an Act of Parliament, 9 and 10 Vict., c. 93, known as Lord Campbell's Act, it was enacted that, "whenever the death of a person is caused by some wrongful act, neglect, or default which would (if death had not ensued) have entitled the injured party to an action, then the person who would have been liable if death had not ensued shall be liable for damages, though the death was caused by an act amounting to felony; and the action shall be for the benefit of the wife, husband, child, etc., of the deceased, and in the name of the executor or administrator," etc. It redounds much to the credit of the Medical Profession that no such action has yet been brought against a member of the Profession; but this piece of legislation has anticipated the construction put upon the common law by the Court of Massachusetts—statute law being, after all, but a declaration of what the common law is and always has been, although the ancient law may have fallen into disuse or have become disputable. The maxim that there is "no wrong without a remedy," is the principle of the common law, although the nature of the remedy may, for avoiding all doubts and difficulties, require a remedial statute to declare it. The present statute is, however, not the less forcible because it has not yet been appealed to.—(See "Weightman's Medical Practitioner's Legal Guide," p. 38.)

MR. HOLMES COOTE.

THE friends of Mr. Holmes Coote, Senior Surgeon to St. Bartholomew's Hospital, will be glad to learn that his health is so far improved as to enable him to resume the practice of his Profession.

FROM ABROAD.—M. RABUTEAU ON THE PROPERTIES OF THE CHLORIDES—M. DECAISNE ON SUICIDES IN FRANCE—M. BEAUNIS ON THE AMBULANCE AT JURANVILLE.

AT the meeting of the Académie des Sciences on December 26, M. Rabuteau presented a communication on the "Physiological Properties of the Chlorides." The following is the abstract of its contents furnished by the *Union Médicale*:—

"The chlorides of sodium, potassium, and magnesium render nutrition more active. Experiments prolonged over several days have shown that they increase in a notable degree the elimination of urea, and that they raise the animal temperature. Under a slightly saline regimen, followed by a strongly saline one (to the extent of ten grammes of chloride of sodium a day), the variation of the quantity of urea eliminated in the twenty-four hours has nearly reached 20 per cent. The chlorides of ammonium and potassium, taken to the extent of five grammes, have given rise to nearly the same variation in the quantity. But, while the chlorides of sodium and ammonium render the circulation more rapid, that of potassium renders it more slow; this last, therefore, exerting a double action—as a chloride increasing nutrition, and as a salt of potassium rendering the pulse slower. The action on nutrition is explained by the increase in the quantity and acidity of the gastric juice, caused by the chlorides of sodium, as also (as shown by MM. Plouviez and Poggiale) by an increase of the number of the red globules of the blood by its use. In this way are explained the physiological and therapeutical effects of this salt. They show us why animals subjected to a saline regimen are in better health, in consequence of their nutrition being rendered more active, and why, although they have more appetite, they yet do not increase in weight (as shown by the experiments of MM. Boussaingault and Dally), since their deassimilation is increased.

"The perchloride of iron, when introduced into the economy, is reduced on coming into contact with albuminoid matters and various organic substances. It does not coagulate the albumen, and is very easily absorbed by the stomach. M. Rabuteau, having proved that reduced iron and the oxides and carbonate of iron are transformed into protochloride by contact with the hydrochloric acid of the gastric juice, proposes the

substitution of this salt for Medical uses, in place of the other preparations.

"The chlorides of gold and palladium administered to rats underwent reduction, and, when their use was prolonged, gave rise to an albuminuria connected with lesions of the kidney. M. Liouville has described an argentine albuminuria, and M. Ollivier a saturnine. M. Rabuteau in the present experiments also found albumen passing into the urine after the administration of the acetates of cadmium, uranium, etc. These forms of albuminuria might be designated by the general term, *metallic albuminuria*."

At a recent meeting of the same Academy, M. Decaisne read a note on "Three of the Modern Causes of Suicide in France."

He observes that Paris is the city of the world in which the largest proportion of suicides is met with, having now reached the fearful number of one in seventy-two deaths; and, moreover, while the number of voluntary deaths is decreasing in London and New York, it is continually on the increase in Paris. The three causes which M. Decaisne terms "modern" are—(1) The influence of political passions, and the new democratic spirit; (2) the weakening of religious ideas; and (3) the increasing progress of alcoholism. With respect to the first of these—the modern *morbus democraticus* of the Germans—he quotes the opinions of MM. Brierre and Legoyt in proof of its reality. On the other hand, M. Vacher, in his excellent account of the comparative mortality of Paris, London, Vienna, and New York, denies the influence of the democratic spirit in the production of suicides, pointing out that the United States, under the most democratic of *régimes*, produces very few suicides. Moreover, he does not believe that suicide is on the rapid increase in France supposed by some. M. Le Roy also shows that at troubled political crises—such as 1830 and 1848, for example—there are really fewer suicides than in calmer times. But M. Decaisne maintains with Esquirol that political influences act as exciting causes, which bring into play this or that passion, and impress this or that character on insanity. It is to be borne in mind that, if these influences do not immediately betray themselves by an increase in the number of suicides, they generally, in subsequent years, give rise to a recrudescence of cases of insanity, among which many voluntary deaths take place. As to the second cause, M. Decaisne has nothing beyond a general *à priori* statement to advance. In alcoholism he believes that he sees something more definite—as well he may, if the statement be authentic that the suicides from drunkenness have risen from 142 in 1848, to 471 in 1866. It is said that one female death takes place from this cause to seven male deaths.

As an appendix to his interesting narrative of the campaign on the Loire, publishing in the *Gazette Médicale*, M. Beaunis furnishes some account of the ambulance which he established at Juranville. Here he had to treat 236 wounds, under most difficult circumstances and great privations. They were for the most part very severe, some of the men having two or even three of these. The patients altogether amounted to about 300; of these a few were Prussians, and of them M. Beaunis observes that he considers their vital power is greater than in the French, for they bore better the immediate consequences of the wounds—the nervous irritation, agitation, shock, and traumatic fever being less considerable and slower in appearing than in the French. This was no effect of courage or stoicism, for they cried out under the pain of operation just as loudly as the French did. "It is rather a consequence of a less delicate and more blunted physical sensibility." Most of the French were young men accustomed to labour in the fields, but not yet habituated to the hardships of a campaign. Their constitution was more robust in appearance than in reality, for although their limbs were large, bone and cellular tissue prevailed over muscle and nerve. Of a lymphatic or lymphatico-sanguine temperament, they were devoid of energy and elasti-

city, dejection and discouragement rapidly replacing the factitious excitement of the fight. As to the medium in which they were treated—216 wounded were distributed among sixteen houses of the village, comprising in all forty-three rooms, each containing a mean of five patients. Of the forty-three rooms only seven or eight were suitable, while twelve were only cattle-sheds or stables. As this wide dispersion of the wounded over a large space involved much labour in attending to them, it was proposed to transport as many as possible into the church; but to this M. Beaunis positively refused to consent, for however useful churches may be as temporary receptacles for the wounded crowding in just after a battle, as permanent ambulances they are to be proscribed—a rule the utility of which has been shown in many instances during this campaign. At all events, the wounded were disseminated, which is always an important point when they exist in large numbers; and, in fact, in spite of the severity of the wounds, their course was very favourable, and the mortality was very slight.

As in most other ambulances, sword and bayonet wounds (*armes blanches*) were completely wanting. This may arise to some extent from the fact of the wounds caused by them being slight, and allowing of the soldiers following the army; but it is far more due to the long range of the arms now in use and the rarity of bayonet charges. Another fact observed was, that the wounds from balls were incomparably more frequent than those from fragments of shells, the proportion being, in fact, 220 to 16. Cold water was the principal means employed in treating these wounds, adding phenic acid during the suppurative stages. Opium was the only internal medicine at command, not even purgatives being attainable. The patients complained much of the prolonged constipation, which there was no means of relieving; but this spontaneously yielded after some days, and did not seem to exert any injurious effect upon the progress of the cases. The cases of injury of the head were few in number, which is explained by the rapid death of many of such patients, a large proportion of those dying soon after the battle having had this lesion. Penetrating wounds of the chest were numerous, amounting to seventeen cases, in two of which there was hernia of the lung. In six cases there were penetrating wounds of the abdomen. The great majority of the cases were wounds of the limbs, forty-four fractures being produced, fifteen of which were fractures of the thigh. The treatment of these cases, in the utter absence of all apparatus, was a matter of great difficulty. It was observed that the *immediate* effects of fracture of the leg were more serious than those of the thigh. In the former, erysipelas, inflammatory œdema, and gangrene were met with, while fractures of the thigh in general pursued a tolerably favourable course. Wounds of the knee (although these were generally accompanied by fracture of the bones or lesion of the synovial membrane), did not give rise to such disorders as to call for immediate amputation; usually they pursued a simple course, no accident of importance arising during the first twelve days. But the prognosis in such cases should be none the less guarded, for it is just in wounds of the knee that lesions in appearance of the most simple character pursue an insidious course, presenting, when recovery would seem assured, the most dangerous complications. No case of really serious hæmorrhage presented itself during the treatment of the 236 wounds in question. Although an advocate of immediate amputation—*i.e.*, before traumatic fever has appeared—in severe injuries, the circumstances in which these patients were placed precluded the author resorting to it in more than five instances. During the twelve days which he remained with the ambulance only twelve of the patients died, and he attributes this favourable result solely to the dissemination which the necessities of their position compelled. He found most deaths occurring on the third, fourth, and fifth days, and then on the ninth day.

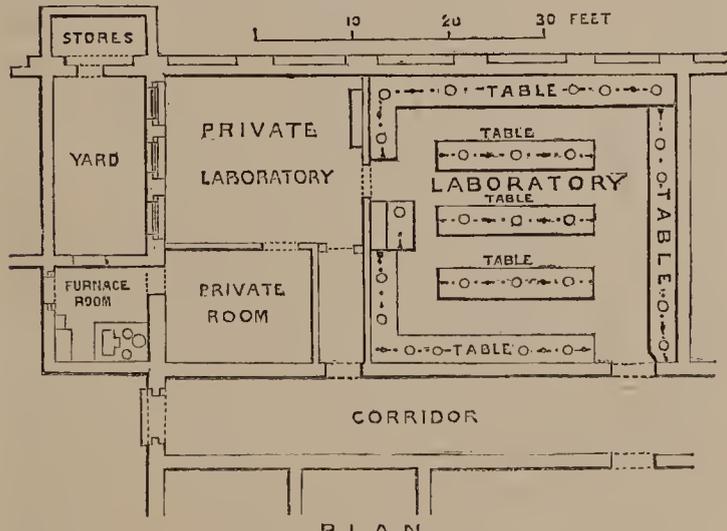

OPENING OF THE PHYSIOLOGICAL LABORATORY AT ST. THOMAS'S HOSPITAL.

DECEMBER, 19, 1871.

ADDRESS BY DR. JOHN HARLEY.

GENTLEMEN,—The arrangements for the study of Practical Physiology in this School are now completed, and Dr. Ord and I have called you together this afternoon to introduce you to the laboratory, and to give you, in brief outline, a notion of the kind of work which we propose to do in it. And I must say that it is with feelings of deep satisfaction and delight that I witness the inauguration at St. Thomas's of what has been to me for many years a pleasant and hopeful thing to dream of, but without any prospect of this speedy accomplishment—I mean the practical study of Physiology in our schools. To-day, however, this is amply provided for, and my utmost wishes are fulfilled. Similar feelings of pleasure and satisfaction will, I trust, animate each one of you as you realise the conveniences devised for you, and by means of which you will be enabled yourselves to demonstrate the facts which have been brought before you in the systematic course.

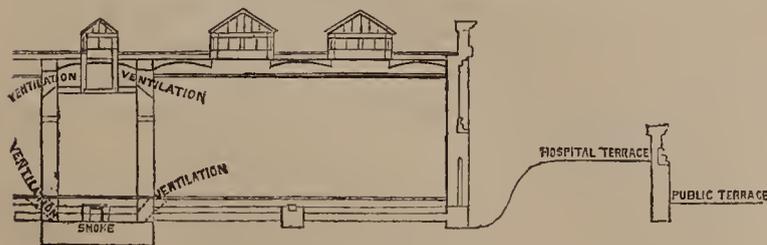

In this crowded island and murky atmosphere, we are most fortunate in possessing those two first essentials of a work-room, ample space and abundant light; and besides these, we have good ventilation and an uninterrupted supply of hot and cold water. The department of Practical Physiology enjoys the use of this spacious room in which we are assembled, and which contains sixty-four work-tables, at which the same number of students may work simultaneously; of a large inner laboratory; of a private room; of a furnace-room for combustion, evaporation, drying, etc., supplied with steam and every convenience for analytical research; of an enclosed yard in which we can keep animals required for our experiments; and of a store-room—the whole occupying an area of nearly 2000 square feet, the rooms *en suite*, and the whole separate from every other department.

PLAN

FIG. 1.—Ground-plan.

For the completeness of this arrangement, and for the means of making these bare walls and floors what you now see them, we are mainly indebted to the foresight of our thoughtful Treasurer, and to the keen interest which he has taken in this as in every other department. Our architect, Mr. Currey, too, deserves our thanks for giving us those essentials to our health and comfort to which I have already alluded, and which, as we are well aware, are not always attained, even under the most favourable circumstances. The two long skylights of clouded glass, which traverse the whole length of the roof,

SECTION.

FIG. 2.—Section across Physiological Laboratory and Corridor.

give a most perfect light for microscopical work, and so abundant is it that I have been able to continue my investigations as late as four o'clock in the afternoon of these shortest days of our year, without once thinking of artificial light.

But, to come to details, and, first, the means of work. We have accommodation here in this room, as I have said, for sixty-four students, and elbow-room enough for all. The tables are so arranged that each student has the command of a low Argand gas-lamp for the microscope, of a Bunsen's burner for heating, and of a tap of water, placed over the centre of a fair-sized basin, furnished with overflow- and waste-pipes. The water-pipe is so arranged as to serve the purpose of a retort-stand on either side, and is fitted with running clamps to take various forms of supports. Each table is further supplied with a removable iron rod and supports for the more complicated apparatus required in volumetrical analysis, and with a rack for holding test-solutions, tubes, etc. Carrying now the eye a little below the surface, you will see first a large drawer, and beneath this a smaller drawer and closet on one side, and a knee-hole on the other. The larger drawer is for the storage of apparatus only occasionally required during the course. The smaller drawer and the closet are fitted with the same key, and this will be given in charge to the student to whom the particular table is allotted. In order to give you individual security, each set of drawers and closet is furnished with a different lock and key. The smaller drawer is fitted with a rack holding the necessary colouring and preservative solutions for the tissues, and cement for microscopical cells; there are also compartments for knives, needles, glass slips, etc. The rest of the furniture consists of a soft cloth, of a piece of cork upon which you can make your sections, and of a preparation-box (shown in the figure).

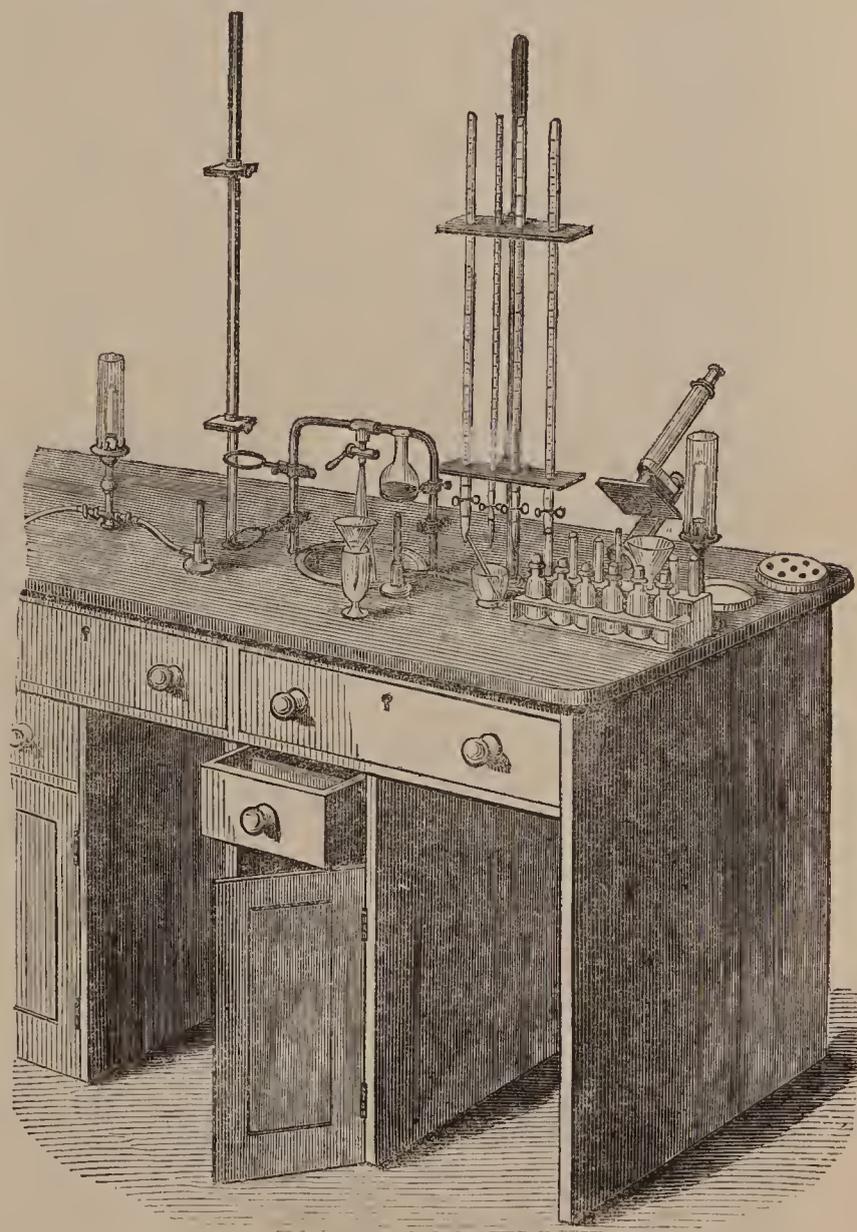

FIG. 3.—One of the work-tables

This latter will be a very useful addition to the table. It is a sort of round palate or compound gallipot, furnished with a cover, and contains seven small but rather deep circular

depressions, in which the animal tissues may be soaked in their appropriate solutions before they are mounted. The cells are numbered, so you may note in your book "No. 1, kidney," "No. 7, muscle," and so on. Messrs. Copeland, of New Bond-street, have made me this little article, and they will soon be ready to supply you with an additional one, should you want it for home use. These boxes will be equally useful in some of our chemical investigations. If you wish to be extravagantly neat, you may get a writing-diamond to use in lieu of labels, a turntable to finish off your cells, and any other accessory apparatus you please, and you will find plenty of room for them in your drawers. The closet, I need not say, is for the reception of your microscope and cabinet of specimens. The tables around the walls have a slightly different arrangement, and they have the additional convenience of shelves. Those of you who do not already possess a microscope will be able to obtain one sufficient for our work for the sum of £5. Two good makers (Messrs. Baker, of Holborn, and Pillischer, of New Bond-street) have both courteously accepted our suggestions, and have produced, in your behalf, instruments which we can confidently recommend to you. The stands are steady, and furnished with coarse and fine adjustments, and simple roomy stages. Each possesses a good quarter-inch object-glass and a single eye-piece. Mr. Pillischer has expended all the labour on these, and charges the instrument to you at £5. Mr. Baker gives a black box in addition, and supplies the whole for £4 15s. But I cannot mention a box without objecting to it. I think there is no greater hindrance to microscope work. The microscope is so perfectly fitted to, and packed in, its box, that you naturally feel a repugnance to disturb them; and then the time one wastes in packing and unpacking! Pray do not hamper yourself and your neighbours here with a box, but deposit your microscope in its brazen nudity in your closet; and then, I am sure, you will use it on the slightest occasion. But you "will want to take it to the seaside," you say; well, you can roll it up in your dressing-gown, and put it in your portmanteau, or borrow a soap-box from the kitchen. To put the case in another way—£5 expended on a microscope alone should produce better optical results than £5 expended on a microscope *plus* a case. It is quite another matter if you are expending a sum of £20 or £30 on an instrument. But to return to these particular microscopes—they are such as will, I am sure, satisfy your Medical wants, not only in this laboratory, but at home, and when you have become the busy Practitioner; and I hope that when we meet after the Christmas recess you will each be provided with one.

So much for the means of work. Now as to the work itself. I am afraid that very erroneous impressions have been made respecting the nature and scope of Practical Physiology, and that those who are watching its development in England with an intelligent eye, have just cause for regarding it, so far as the student of Medicine is concerned, as *impractical* physiology. But very little truth can be elicited, I think, by the rack; and that mind must be exquisitely, not to say cruelly experienced, and gifted with uncommon penetration, which is able to find the truth, to eliminate it, and to calculate its amount when the functions of the body are so unnaturally interfered with, and the whole system is affected with the tremor of fright or exhaustion. How, for example, is it possible to estimate the natural force of the heart, or the amount of arterial pressure, in a mutilated animal upon the rack? Why, the very emotions cause fluttering of the heart and dilatation of the bloodvessels; and if you do but speak to a dozing dog, his pulse and breathing will be doubled in a few seconds! No, we must get at the truth some other way than this. I do not say that we shall not divide this or that nerve to illustrate its function. What I mean is this: that vivisection will form no part of our practical course, and that we shall take every opportunity of making Nature interpret herself by taking Pathology for our constant guide. Nature has prepared for us every conceivable experiment, and daily exhibits them in man himself, in our wards and our prescribing-rooms. The last time I examined my Hospital patients, we saw the effects of prolonged ligature of the common bile-duct; of atrophy, in one case of the lower, and in another of the upper part of the spinal cord; of the effect of pressure on the hypoglossal nerve; and of disease of one portion of the nervous system causing complete atrophy of the whole of the muscles of one limb. It is at the bedside, in the out-patient rooms, and in the pathological theatre that you must study experimental physiology. By exercising your best powers of observation in these places, and bringing your facts to bear upon the work of this laboratory, I promise you we shall be able to discover many of Nature's subtlest workings.

Our work will be divisible generally into two great branches

—microscopy, and physiological chemistry. The former will embrace the examination of every tissue and product of the body, normal and morbid. The latter will include an examination of the physical forces as they are manifested in the body, and will be applied to the examination of its fluids and excretions, and the variations of these under different conditions; and to the mode of elimination of medicines. And thus, by the aid of all these three means of study—direct observation of the experiments prepared by Nature or resulting from accident, the use of the microscope, and the application of the balance and test-tube—we shall be able to learn the structure and development of the divinely-fashioned machine, and much, if not all, of the modes of its wondrous working. We shall leave "vital force," with the philosopher's stone, behind us—fit companions of our early days of ignorance—and, thus untrammelled, penetrate into those marvellously directed and controlled reactions and interchanges of matter which unfold to our view the power and goodness of the Creator, with a clearness and certainty compared to which the empty-returning fancies of hereditary superstition are doubt and darkness. To such a task—the widest, deepest, and most interesting that can engage the intellect—we must bring humility, earnestness, and painstaking care. We must wrestle well and patiently for the truth, and strain every nerve to get it, for we know that it is this alone can make us free.

REVIEWS.

Lectures on the Principles and Practice of Physic. By Sir THOMAS WATSON, Bart., M.D., F.R.S., etc. etc. Fifth edition. Two vols. London: Longmans, Green, and Co.

[FIRST NOTICE.]

As a general rule, when any work proves so acceptable that repeated editions of it are called for, no review of any but the first issue seems necessary or desirable, nor any notice beyond the simple announcement of each edition as it appears. But it is impossible so to deal with this edition of Sir Thomas Watson's famous work; for not only are very special and hearty thanks due to him for having undertaken the great labour of giving us another edition, but the work has been revised throughout, and has been largely added to, so that though diseases of the eye (with the exception of inflammation of the iris) have been omitted, the work consists of a considerable number of pages more than it did in the fourth edition. On the first appearance of the book, in 1843, it at once became first favourite among Medical works, and, ever since, each succeeding edition has been eagerly and anxiously looked for. Who does not cherish a grateful recollection of the surprise and delight with which he first read "Watson's Lectures"? We have all been charmed with the ease and lucidity of the style, the vigorous and graphic descriptions of disease, the felicity of expression and happiness of illustration, the fulness of knowledge and experience, the utter absence of anything like pretentiousness or display; we have felt throughout the presence of wisdom as well as knowledge in the teacher, and have been impressed by the high tone of thought and feeling, and the unaffected reverence for exactness and honesty of scientific observation and record. Indeed, the very beauty and charm of the writing might almost be charged as faults in a book for students; all seems so clear and simple, that there is perhaps some danger that one may be led to read on and on without really giving to the subject-matter the attention and thought necessary to make the knowledge one's own, and which might be forced from us by less happiness of expression and a less flowing and limpid style. But no one can be so captious and ungrateful as to advance such an objection as this seriously, and we confess to envying the Medical youngsters who have yet to read these lectures for the first time. At the same time, we will dare to confess that we think the first edition of "The Principles and Practice of Physic" was, and is, *the edition par excellence*. All who have not, and cannot have that, must, most rightly, be deeply grateful to Sir Thomas Watson for the labour bestowed by him in giving them the succeeding editions; but the work as it first appeared was a book by itself in character and kind, and each attempt to keep it up to the Medical science and art of the day, as the successive editions appeared, has, in our eyes, somewhat detracted from its peculiar beauties and excellencies. It may be said that this is only a way of saying that we are growing old, and still best love the loves of our more youthful days; but we think these lectures do belong to that kind of work which does not well bear retouching.

In taking up this new and thoroughly revised edition, one—naturally, perhaps—looks first to see what Sir Thomas Watson says on bloodletting. There is, we think, a growing and widening conviction that that powerful means of remedying or lessening some diseases has been vastly too much decried and neglected, and that the almost absolute disuse of it in these days is as great an abuse as the over-use of former days was. So we turn to see what the wisdom and ripe experience of Sir Thomas Watson have taught him on the subject. We find it most clearly and ably treated of in Lecture xiii. Having pointed out the difference between *general* bleeding (or bloodletting) and *local* or *topical* bleeding as remedies, he observes: "The failure to perceive this paramount distinction—first noticed in print, so far as I know, by Dr. Markham—has been the main cause of the strange and wide fluctuations of opinion respecting the true value of bloodletting that deform the annals of practical Medicine. In times past, no doubt, bleeding as a remedy was apt to be employed inopportunistically, to be misdirected, or to be pushed beyond its proper and safe limits; but of late, practical Medicine has rushed to the very opposite extreme. Which of the two mistakes is calculated to be most injurious to the human family it would not be easy to estimate. I remember the time when a Surgeon who found a man lying in the street in a fit, was blamed and abused by the bystanders if he did not at once open a vein in his arm. To do this nowadays would be to incur the charge of murdering the man. One melancholy consequence of blind submission to authority, or of the senseless influence of what is called fashion, is the almost total want of experience about bloodletting among the current generation of Medical men. I have heard of a London Physician who, being desirous of having one of his Hospital patients bled, could find no one among the House-Surgeons, or advanced pupils, who had ever seen the small operation of venesection done, or knew how to do it." This we can easily believe. A few months ago we wished one of our Hospital patients—a man suffering from intense pulmonary congestion—to be bled from the arm, and our House-Physician, a pupil of one of the largest Medical schools in London, had had no practical experience whatever of the "small operation." Sir Thomas goes on to remark that "the trade in leeches has dwindled to a miserable fraction of its former magnitude; and the art of cupping, and the once thriving and useful race of cuppers, are extinct. It is argued by those who denounce bloodletting absolutely and altogether—and to whom some of our American brethren have applied the coarse but expressive nickname of *blood-funkers*—(in which, by-the-by, they unconsciously follow Galen, one of whose patients called him *ἀμαφοβος*, because he would not bleed)—"that every deviation from sound health implies a loss or lowering of vitality," and that the taking away of blood, being itself depressing, must increase rather than redress a morbid condition. "Now," he says, "there is abundant evidence that this great dread of abstracting blood is a mere bugbear." Sir Thomas then discusses the subject of local bleeding, and, having given several very telling and happy illustrations, he says, "I hold it, then, to be certain, that in many cases of inflammation *local bleeding* is a powerful, a safe, and, therefore, a proper and eligible remedy, and that its beneficial operation consists in diminishing, by direct withdrawal, or by diversion, the quantity of blood distributed to the part or organ inflamed. But what of *general bleeding*? what of venesection in particular, as a remedy for inflammation? It is in this matter, I am bound to admit, that great mistakes have formerly been made, that a potent agency has been misdirected." And after a full and most instructive discussion, he arrives at the conclusion—"I hold it, then, to be certain, that for some special morbid conditions, which inflammation may or may not accompany, general bloodletting, and especially venesection, is a potent and life-preserving remedy; that there are many exigencies for which it is not only safe to employ, but safe and unpardonable to withhold it. I shall have to return to this subject hereafter, but I may repeat now, in brief terms, that the condition which cries out for and obtains relief so signal and immediate from phlebotomy, may be described as that of great, and often sudden, engorgement of the vessels that (I use Dr. Johnson's phrase) carry black blood—of the systemic veins, of the pulmonary artery, and especially of the right chambers of the heart. In this embarrassed condition of the circulation, with so unequal a distribution of blood in the two different systems of vessels, it is the veins that require emptying, not the arteries. As the tension of the stretched and almost paralysed right ventricle is lessened, the hollow muscle again becomes capable of contracting upon and propelling its contents, the clogged

lung is set free, the functions of the oppressed brain are eased and retrieved, and the balanced play of the heart and lungs is restored. This, as it seems to me, is the true philosophy of bloodletting in disease, approved by reason and justified by experience. The credit of having been among the first to rectify the vague notions that formerly prevailed on the subject is fairly due to Dr. Markham."

And then we are given some further directions to guide us in the use of bloodletting, as to time and opportunity, age, sex, general temperament and condition of the patient, and so on.

We believe that no standard work on Medicine is so much read by non-Medical men of education and mark as "Watson's Lectures," so we may hope that Sir Thomas's opinions of the value of bloodletting may influence the outside world in favour of that remedy, as well as incite and encourage Medical men again to call in its aid more frequently in the treatment of disease.

Two additions have been made to the specially admirable and well-known lecture on the "Different Modes of Dying." Observing that, after death from mechanical closing of the larynx, "the lungs are always found empty of blood, while there is vast engorgement of the right heart, of the great veins, and of the pulmonary artery up to its minutest ramifications," this condition is thus explained:—These facts "show that some opposing power must have been called into play, more than equal to the propelling power of the right ventricle of the heart. Now, such a power—and it is the only conceivable one—actually exists at the very place where the venous current meets with its curb, and it consists in the firm contraction of those muscular fibres of the minute arteries, the function of which it is to regulate the blood-supply in accordance with the varying requirements of the part. This function again is determined by those unsleeping sentinels, the (vaso-motor) nerves. Were it allowable, for the sake of illustration, to impersonate the vital forces concerned in this marvellous adaptation, we might liken the process to the intelligent stopping of the traffic on an obstructed line of railway by a backward telegram. Or take another illustration. The blood passes into the pulmonary capillaries in order that it may be aerated. Whenever this process of aëration is suspended, a nervous signal is sent from the capillaries to the minute pulmonary arteries, enjoins their contraction, and then stops the bloodstream. The purpose of the arterial spasm is to prevent the flow of blood into the pulmonary capillaries upon the cessation of the function of respiration. If the stopcock of a gas-burner could be made self-acting, so as to maintain at all times a constant and exact relation between the supply of fuel and the rate of combustion, and so as, further, to turn off the gas and prevent its escape when, by any accident, the flame is extinguished, that would represent with sufficient accuracy the working of the living arterial stopcocks in the lungs." The other addition is an account of the phenomena which follow plugging of the pulmonary artery by embolism, or thrombosis. "It is remarkable," Sir Thomas observes, "that an impediment to the supply of blood to the lungs through the pulmonary artery causes dyspnoea as urgent as an impediment to the supply of air to the lungs through the air-passages. Physiologically, this is explicable by the want, common to both cases, of aerated blood by the system; expressing itself in the chemical cry from the famishing tissues for the indispensable oxygen. What is peculiar to this mode of dying is that the circulation is stopped, yet not by asthenia; and the function of respiration is suspended, yet not by apnoea. Death does really, in this case, begin in the lungs, and the mode of dying may, with literal accuracy, be called death by *pulmonary asphyxia*, or pulselessness in the pulmonary artery."

In the next lecture, on the "Causes of Death," Professor Huxley's physiological explanation of the immunity from harm to those who are subject to or court excessively high temperatures is given; and, in connexion with the effects of cold on the human body, mention is made of the results (observed by Dr. Richardson) of diminishing, in birds, the temperature of the brain by means of ether spray. And in discussing hereditary tendency to disease, an illustration is drawn from Dr. Arthur Mitchell, Deputy Commissioner in Lunacy for Scotland, and notice is taken of Mr. Darwin's views on transmission of acquired peculiarities. This must suffice to show how much care and labour have been bestowed on this edition of the work. We cannot, of course, pretend to go all through the lectures in this way, but must content ourselves with noticing a few more instances of careful addition and revision, and some of what we will venture to call the weak points.

(To be continued.)

FOREIGN CORRESPONDENCE.

AMERICA.

PHILADELPHIA, December 6.

THE Medical world on this side of the Atlantic is not at the present moment seriously agitated upon any question of general or vital importance. The Profession is liable to periodical exacerbations once a year, when representatives of various Medical societies and institutions throughout the country assemble together in a national convention; but there is really but little material to awaken a common interest even on such occasions. Sometimes with excessive ardour, and a good deal of unnecessary fermentation, a few zealous partisans of special measures and riders of favourite hobbies endeavour there to arouse a general enthusiasm in favour of their pet projects for reform in Medical instruction, for the recognition of woman's right to wield the scalpel, etc.; but the temporary excitement soon subsides, and when the delegates return to their homes, which may be a thousand or two of miles away, they carry back with them many agreeable social reminiscences, but very few permanently fixed and practical additions to their general store of Medical knowledge. Though some of the rust and roughness may be worn away by this opportunity of unwonted contact with the outer world, yet when they resume at home their Professional avocations—many of them in out-of-the-way country places, where, with excessive labour by day and night, they toil away their lives in drudgery—they have but little time or disposition to concern themselves with topics extraneous to their immediate routine duties. If they practise these with fidelity to principle, and to the requirements of the Professional code of ethics, they are content; but it must be a mighty cause that simultaneously affects the whole fabric of Medical science in this widespread country. The woman question is one of the latest and best illustrations of this fact. Although periodically revived in several State societies, and agitated in the National Association, there are hundreds—perhaps thousands—of Physicians in the United States, scattered through villages and small towns, who never go to conventions, but depend for novelties in information on the columns of the single Medical journal to which they subscribe, who have not been in the slightest degree affected by all the discussion of the few years past upon the admission of women to the rights and privileges of Practitioners. Although old women abound in every village here—as they do in every village all over the world—whose self-estimated knowledge and experience are greater than are possessed by the best-informed in the Profession (and doubtless there are many men in the latter everywhere who are, in mental calibre, but little in advance of these meddling beldames), still the modern woman-Doctor—made such by education and practical information—has hardly yet come in direct competition or collision in the smaller towns with other Practitioners of Medicine. There is not, therefore, among the latter the same tenacity of opposition—for it is not at once brought home to them as a disturbing element; and hence we find in all State Medical conventions the country delegates much less sensitive than those from the cities to the adoption of measures which vitally affect the interests of the latter especially.

A notable feature in the American character is the rapidity and facility with which, after violent agitation, a perfect calm is restored in the public mind. This applies to questions pertinent to the Medical Profession, as well as to those affecting the moral, political, and physical health of the community. There is always danger, after such a lull, that the immediate cause of perturbation may soon be forgotten, and remain uncorrected until the recurrence of similar wrongs again excites the popular sympathy or indignation. Not long since, a prominent abortionist of New York, who, after all, is only a typical specimen of the irregularity and criminality secretly practised by scores of others in our larger cities, was punished for the murder of a young girl on whom he had produced, by instrumental interference, metro-peritonitis. The crime was first detected, you may remember, by his failure to get rid of the remains at the railroad-station in the shape of a trunkful of luggage. Had his punishment been death, instead of imprisonment for a term of years, the moral effect upon the rest of his vile class would have been potent for good, and fatal to their terrible practice. But the trial once over, and the public attention diverted to other channels of guilt, or to other sensations of the hour, no thought of the possible horrors daily perpetrated now disturbs the calm current of business or pleasure;

police vigilance sleeps, and the publishers of the objectionable invitations to deceived and unfortunate victims, which formerly occupied conspicuous positions in papers of large circulation and influence, are once more relieved from the immediate fear of condemnation and punishment. We may therefore expect, at no very distant day, to have the thin verbal disguise which now vainly conceals the wickedness beneath to be wholly removed, and the old familiar advertisements of prospective infamy again openly offending the eyes of virtue and intelligence. These banes and pests of society afflict every community, but New York is confessedly the field in which they have held high carnival. It is to be hoped that in our larger towns the good sense and energy of all refined and influential people, who are willing to handle this delicate subject, may lead to the most vigorous crusade against all such malefactors.

Small-pox has recently been much more prevalent in this section of the country than for many years previously. For several weeks past its mortality statistics have been gradually becoming more and more interesting. The number of deaths from this disease in Philadelphia during the past week was 153, which, though apparently a trifling matter in a population of 750,000, is of sufficient numerical importance to create a general uneasiness, mainly on account of the steady weekly increase of mortality. New York is anticipating a visit from it, but thus far only a few cases have been reported. If it should once become firmly seated there, in localities which respond but feebly to the exigencies of sanitary laws, its ravages will doubtless affect seriously a class of the community which modern philosophers and scientists are in the habit of regarding as the "surplus population." They may learn a lesson from our own local experience, however, that in its visitation here it has made but little distinction as to social lines. It is amusing to note the various suggestions offered by the ignorant and unlearned to obviate variolous influences, or to render their incursions non-effective. From carbolic acid amulets to simple brown sugar seems a long step, which the enthusiast in small-pox curatives may take confidently, and pick up abundant material on the way for the relief of the disease, if he can but once repose his confidence in all the popular contributions to the small-pox literature of the times. These are, of course, generally passed by as the idle breath of the hour; but vaccination and revaccination have become the prevailing fashion. It has been remarked that the usual salutation among friends is now, "How is your arm?" but this is somewhat of an exaggeration. It is amusing, however, to note the manner in which the faces of fellow-passengers in our city railway-cars and of pedestrians on the street are scanned to detect the now familiar marks of the disease; how carefully its subjects are avoided; and how even those with more than a legitimate allowance of innocent papule are looked upon with suspicion. When we reflect upon the treatment of the disease in previous centuries, we feel grateful at the prospect of receiving the more gentle, soothing, and unobtrusive medication of the present day, and not being compelled, with our ancestors of the fifteenth century, to swallow the "attenuating and sudorific things" spoken of by an old writer as included in a single decoction prescribed in the early stages of this disease—viz., "liquorice, mallows, borrag, politrichium, maiden-hair, sweet prunes, sunchus, woodbine or honeysuckle flowers, seeds of cucumber, flowers of corn-poppies, and bark of bean-stalks." Such as were "more gross and pituitous" fared no better, for they were obliged to drink a decoction in whey of goat's milk made up of "brans, wheat, beans, liquorice, hyssop, juniper wood, white tartar, barley, sunchus, roots of white lilies, grass, scabions, sweet prunes, etc."

The strong arm of the law is sometimes interposed rather unpleasantly in the affairs of Medical men. Its aid is not judiciously evoked or gratefully appreciated, especially when it is hastily appealed to in anticipation of the action of a society against one of its own delinquent members. As a general rule, the inference would be fairly deducible, that the appellant, under such circumstances, afraid to incur the public odium, was willing to take refuge in any means, however unusual or unwarranted, to escape the penalty. Whether this was the real motive power in a case which excited a good deal of discussion in New York a few weeks since, I cannot say; but the honourable gentlemen constituting the Comitia Minora of the New York County Medical Society, prominent among whom were Drs. Austin Flint and L. A. Sayre, who were immediately affected by this Medico-legal entanglement, must have been very indignant, and not a little sensitive, at the interference of a learned judge in that city in the form of an injunction restraining them from taking any further action against a recusant member. This is probably the first case of the kind

in the history of our Medical Societies; the Court having here intervened previously to the report of the Comitia, before it was known what was the nature of the verdict, whether favourable or otherwise. The member had been charged with a violation of the code of ethics, and it was clearly the duty of the Society to investigate the matter thoroughly.

The Committee of prominent Physicians and Pharmacutists appointed in May, 1870, by the National Convention for the Revision of the Pharmacopœia are actively engaged in the prosecution of their duties, and expect to publish the results of their labours next spring. Of course, in these decennial intervals, many new remedies and novel modes of preparation must suggest themselves; but it is to be hoped that more than even the usual amount of skill and common sense may be called into requisition by these gentlemen, so that we may be able to offer to the world at large a valuable contribution to literature. It is desirable that there should always be every practicable uniformity in the Pharmacopœias of Great Britain and the United States; but each country seems to be jealous of the innovations of the other. I may not be wholly correct in my assumptions, but I am disposed to think that some of the framers of these official guides have a greater satisfaction in striking out into paths of originality than in blindly following the changes suggested by even the best informed pharmacutists and chemists of other lands. One thing must be borne in mind, however, and that is the absolute necessity in a country like our own of adapting a Pharmacopœia, within justifiable limits, to the habits, requirements, and local peculiarities of climate and population of those who are to use it. The great danger is that the *Materia Medica* list, which forms an important portion of it, may be expanded, rather than contracted, under the views entertained by the majority of those present at the Convention. It seems unfortunate that such should be the case at a time when the Medical Profession is already suffering from an *embarras du richesses*, and would gladly part with several score of useless drugs which help to swell out the long list of remedies. If the Pharmacopœia could once be reduced, however, within the limits desirable for mere practical routine purposes, it would constitute a volume mainly remarkable for its insignificance; and it is therefore, perhaps, just as well that it should contain all the remedial agents which may at the present time or in the future be found convenient or useful for the Practitioner. These remarks apply quite as forcibly to the Pharmacopœias of other nations as to our own. May your own Professional men, who speak one common language with those of this country, never be placed in the same straits as those of Switzerland, who, in addition to the erudite Latin, are obliged to issue their Pharmacopœia in three other languages—French, German, and Italian—to adapt it to the understanding of the variety of nationalities represented within its borders.

The virtues of the new reputed cancer cure, condurango, will hardly have been fairly tested in time for its insertion in the new edition of the work just referred to. It attained a temporary notoriety a few months since, from the fact that a quantity of it had been sent from South America to our Government at Washington, to be experimented on by naval and other Surgeons in syphilis and cancer, in consequence of the local reputation it had acquired in regions in which it grew, when administered in these diseases. Soon after this, a few cases of cancer were reported as improved, or cured, I forget which, by a Physician of Washington, who had been quite prominent in the Medical history of our late civil war. Thus far, very little corroboratory testimony has been published in favour of its efficacy, and the impression is gaining ground that this has been greatly overrated. Submitted to analysis, it was found to contain nothing in its composition either wonderful or therapeutically valuable. It sells now at only 2 per cent. of its original cost, which was, I believe, 100 dollars a pound, and the early purchasers are naturally sensitive at this change in its pecuniary valuation. One of them has recently found that he had not even bought the genuine article.

“THE IRISH ELEMENTS.”—We can have no desire to depreciate our Medical friends on the other side of the Irish Channel—far from it. We allude to “the Irish element” in the united services merely with a view of showing that it preponderates; we shall not inquire into the cause. “According to statistics,” says one of our contemporaries, “since the opening of Queen’s College, Galway, in 1850, forty Army Medical, seventeen Naval Medical appointments have been made from this College alone.”

GENERAL CORRESPONDENCE.

ON THE MEDICAL DECLARATION RESPECTING ALCOHOL.

LETTER FROM Dr. MOXON.

[To the Editor of the Medical Times and Gazette.]

SIR,—The document bearing the above title has such a weight of great names subscribed to it as must insure for it everywhere respectful consideration.

There are, however, certain aspects of it which, one fears, its authors did not deliberately stay to observe. May I show one or two of these aspects?

The protest purports to be an address by (I did not count) very distinguished named, and 230 also distinguished but unnamed, Medical authorities, in which the “inconsiderate prescription” of alcoholic liquors by “Medical men” is declared to be a considerable cause of drunkenness.

Sir, there is now a general feeling that the supply of liquor is too free, and that this is the reason why drunkenness prevails so deplorably. If we remember how unlikely legislative assemblies are to act upon divergent views of any subject before them, we may well ask this question: “Now that we have the Legislature ready to curb the grocer and gin-dealer, why does this imposing body of Doctors step in between, and say to us, ‘No! look here at our people! Here are the culprits; your Medical men have incited you. It is done on inconsiderate Medical advice!’” Did these gentlemen see that thus to put the family Doctor in competition with the gin-palace and the grocer as creators of diffused insobriety, if it be complimentary to the Profession, will nevertheless tend to divert public attention from those who were very near having a proper share of restraint laid upon them? What if we find the Legislature staving off its troubles with the grocer, while the family Doctor is exorcised by the incantations of his superiors?

“Look!” they will say; “these people accuse themselves of it; who can doubt their insidious, irresistible influence?—it is throughout every house in the land. Let these inconsiderate prescribers cease persuading the people. We well remember that we had good grounds for creating the family gin-grocer, and created he shall be.” Two years, at least, are required for this experiment of the penitent Doctors.

If the Doctors do by inconsiderate advice create drunkenness, then it is as well they should confess it—or, at least, quietly amend their ways. This document will be accepted as a confession. The public will say, “The Doctors are confessing!—let us listen!” Now, confession is proverbially a good thing for our responsible part, or soul—that is, however, if it be *frank*, and if it be *directed to the right quarter*.

But look at this document. It says, “The acts of Doctors lead to drunkenness in patients.” Now, this might be said in two ways. Either the Doctors might say, “Good people, we, the Medical Profession, have just risen to a general sense of a misdirection in our advice to you, which has been covertly producing very ill issues on your part”—this would honestly take the blame to themselves; or they might say, “You are no sooner set free to take a moderate quantity of wine than you go on a deal too far, to our very great discredit”—this would lay the blame on the public, for their wrong apprehension. But the present affair is neither a frank confession of the Doctors, nor an admonition to the public of their excesses. It is a sort of vicarious confession of everybody for everybody else. It reminds one of that bitter complaint a young lady made to me the other day of her delirious sister—“She confessed all *my* sins.” Truly, Sir, the tendency to confess other people’s sins and weaknesses appears deeply rooted in human nature, especially in those extra-individual parts of our nature that constitute us gregarious. We can always easily be got together for a mutual confession of each other’s sins. Look at the document, and trace it down. It begins with the very distinguished men with names, etc., who say, “We believe Medical men inconsiderately prescribe”; then it comes down to the 230 less distinguished men without names, etc., who repeat, “We believe Medical men inconsiderately prescribe.” Now pray, Sir, why should not every one of us totally undistinguished ones go on and say, “So do we in ours, too; we believe Medical men inconsiderately prescribe”—each set of us thus catching the stone thrown at us from above, until the whole becomes a game of “pass it round.”

I believe, Sir, that this will, however wrongly, be regarded as in the beginning a disingenuous confession, which, begun by

one confessing for his neighbour, will go on raising a reverberation of disingenuous echoes that will die off in *vox et præterea nihil*.

But stay; I see we may be going a little too far. Look at it again. Yes. No, it need not be a confession; perhaps it is not a confession. Yes, it may be quite a different thing—an accusation! Those whose names are signed below may be claiming that they are free from blame in their advice, so that they may turn round and charge their brethren with it!

But it has lately been a very generally prevalent belief that the leading members of our Profession are in favour of sustaining the strength of patients by a supporting, and perhaps stimulating, plan of treatment. Surely the leading members of the Profession have, in their places as teachers, been the very means of spreading this kind of practice.

Now, are those, who have signed, the leading members in question, or are they some other body? Here is a dilemma. For, if these are the leaders and teachers who have been the means of inducing in their followers and pupils the practice they condemn, and if their views have revolved, so that they now think differently of stimulants, surely it is scarcely fair and dignified on their part to turn round and accuse their former pupils in terms that claim for themselves a purer practice (at least, if they don't, it might be more plainly said).

But, if these are not to be regarded as the teachers and leaders—if they do not include all the higher thought in the Profession—then the public, after it has got over the first impression of Medical unanimity which the title "*Medical Declaration*" assumes, will ask, "If these are but a moiety of the leaders, why do they cry thus upon all the followers? why not deal fairly with the camp on their own and the other side, and cry their cry as against a camp of opponents led by equals?" For, indeed, the Declaration by no means purports to come from a division only of the Medical world against another division. The public will say, "If these are the teachers, they induced the practice; why do they turn and accuse it in their followers? and why should we trust these second thoughts? Are repentants such trustworthy guides? But if these are not the teachers, then, after all, it is only the old story of a difference among the Doctors. But why do part speak for all, when the other part (who did teach the stimulation) would, for all we know, oppose them?"

Surely, Sir, if a declaration was required—and I think a declaration might do real service—the proper course would have been for the Medical Profession to have set forth their convictions before the public for the benefit of society. Without confessing for each other, or accusing each other, or doing a nondescript something, neither the one nor the other, which one might call admonishing at each other, the Profession might have risen and said, "Good people, we have lately been informed, and we believe that our well-meant advice is misconstrued by certain among you to your serious detriment. It has been our practice to commend to you a little wine for the stomach's sake, but you go on to take a little more for the sake of the heart. We urge you, good people, to refrain from such injurious indulgence. Pray understand that any pleasurable results of wine on the feelings are not even allowed to influence us in advising you, but are superinduced in spite of our wishes, which are better typified to you in the taste of bottled physic. Remember, each one of you, that whoever drinks wine, beer, or spirits to keep up to his work is in reality sinking capital to pay interest."

These need not be the exact words. I would rather leave the composition to the gentleman who drew up the Declaration. But I believe, if something of such a meaning as the above were placed before the Profession, all would be glad to sign; for, though I believe the numerical result is insignificant, there perhaps are instances of persons taking advantage of a liberty of stimulating allowed them by Medical men.

I am, &c.,

W. MOXON, M.D., F.R.C.P.

BLOODLETTING IN CONGESTIONS AFTER FEVER.

LETTER FROM DR. J. B. WILMOT.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have been led to send you the details of the following case, partly from reading in your number of the 23rd ult. the following extract from the Registrar-General's weekly return of deaths. I trust it will not be inferred that I presume for a moment to question the treatment that may have been adopted in these fatal cases:—

"Aged 38; typhoid fever, ten days; congestion of lungs,

four days. Aged 53; typhoid fever, thirteen days; pneumonia, four days. Aged 37; typhoid fever and bronchitis, thirteen days. Aged 3; pneumonia and enteric fever. Aged 7; typhoid fever, three weeks; congestion of lungs, eight days. All people in a well-to-do class of life."

K., aged 42, a stout athletic man, a village grocer and tenant-farmer of 200 acres, was attacked by scarlet fever, communicated by his children, one of whom had imported it from London.

About twelve days after his attack—viz., on July 28, 1871—the Surgeon in attendance asked me to accompany him, as the man was desperately ill, and the family wished me to see him. His state was deemed so precarious that his will had been prepared on the previous day, and the lawyer was to attend with it this day and get it signed and witnessed if possible.

For five nights he had been delirious, in the day-time excited, rambling, and often incoherent, but yesterday had been sufficiently composed to furnish the lawyer with the necessary instructions for drawing up the will.

We found him on his back, with a somewhat wild expression and anxious agitated countenance, but able to reply rationally though hurriedly to questions. His breathing was short and hurried, his skin cool and dry. There was desquamation of the hands and wrists, and a purplish hue of the extremities. The tongue and fauces were quite clean and moist; the latter exhibited no traces of the cyananche which had accompanied the earlier stage of the attack. In fact, as regards the scarlet fever, he might be said to be convalescent. His pulse small, frequent, unsteady; the heart's action tumultuous, struggling. No thirst, no headache, nor could he complain of the slightest pain in any region of the body. He had no cough; could turn himself in bed on either side without the least difficulty, but preferred the supine position. Urine clear, in fair quantity; the bowels had been sufficiently opened. He was living on beef-tea and brandy.

On setting him up, and listening to the respiration, we found that the right lung was impervious to air, and that this side was quite dull on percussion, while on the other side the resonance was distinct and the respiration puerile. Here, then, was the mischief: congestion of one lung, through which the heart was struggling to force the blood, while the venous blood was kept back in the more remote vessels. My colleague could not doubt the fact.

Having admitted the lawyer to read the will, and satisfied ourselves that it was perfectly understood—that the man was what I believe the law terms "of disposing mind"—he signed it, and we attested.

It was then agreed that the only means of relieving him was by the abstraction of blood, and, as the readiest mode of effecting this, as well as of regulating the quantity, a vein was opened, first in one arm, then in the other; but whether owing to the viscosity of the blood, or to the clogged and powerless condition of the right heart, or to the want of the *vis a tergo*, not a drop could we get, either by stroking the arms or plunging them into hot water. Twelve leeches were therefore sent for, to be put upon the side, with directions to encourage the bleeding by poultices and flannels. The brandy was discontinued, and a saline draught prescribed, with one-sixth of a grain of tartar emetic every three hours.

On the following day, after twenty hours, I found him cheerful—having passed a night of quiet sleep, the first for six nights. The purple hue of limbs had disappeared, the pulse was soft and steady, the heart's action restored to its equilibrium. He continued the tartar emetic for twenty-four hours longer, and made a rapid recovery. I saw him no more until three weeks after, when, passing through the hamlet, I found him busy in his shop.

Of the four children, one died, who seems to have had cerebral symptoms when the specific fever had abated; another escaped with a deposit of matter on the eyelid and surrounding cellular tissue, relieved by lancing.

I do not put forward this case as anything unusual, nor the recovery as remarkable. I could furnish many more instances of successful interference of this nature; but this would be tedious, and might savour of egotism. I would not willingly publish the cases of those in whom the moment for such interference had expired.

The sequelæ of these distinctive fevers—variola, scarlatina, measles, typhoid, etc., have long been looked upon as important and dangerous. Local congestion is almost invariably the cause, followed by secondary fever, running into inflammation—disintegration. Sydenham bled successfully in the diarrhœa following measles. I should be sorry to follow Sydenham

blindly in his practice; but it appears to me that in so marked a case of congestion as the above it would be as rational to urge the heart by stimulants as to attempt to relieve a blockade of carriages at Temple-bar by urging on the vehicles in the rear. Some of the ill-fed, half-rotten creatures in the back slums of populous cities may perhaps require this ramming process, but not so the well-conditioned class, and more especially those who breathe a purer air.

I was one of those who signed the "Declaration respecting Alcohol,"—intended for the Medical journals only—from a conviction that a hint from some of the most eminent and experienced was really required by many in the Profession. We are all too prone to fall into routine practice, and I believe that the champagne-and-brandy treatment is often carried out indiscriminately—too early and too far.

With this portion of the Declaration I would have limited my concurrence, had it been possible, for I regard the greater part of the remainder as mere cobwebs to catch flies. I suppose everyone would gladly support *wise* legislation—a wise proviso which pledges us to nothing, or, at the most, to an unknown quantity.

I am, &c., J. B. WILMOT, M.D.
Tunbridge Wells, December 27.

PHTHISIS IN MELBOURNE.

LETTER FROM MR. W. THOMSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—By last mail from this, a month ago, you would receive a short note from me, accompanied by a *Melbourne Argus*, and the Registrar's monthly report of the vital statistics, all containing facts to enable you to form for yourself an unbiassed opinion as to the accuracy of my former statements respecting the prevalence of phthisis in this place, and made necessary by the doubt you naturally were left in by the reiterated denials of my accuracy by the *Australian Medical Journal*.

To show you that the return for the month of July last was in no way exceptional, I again send you the report for the succeeding month of August, by which you will perceive that the total deaths in Melbourne and suburbs from all causes were 275, and out of that number there were from phthisis 49, being 17.82 per cent. The 275 deaths give 1.34 to every 1000 of the population living. This is a small mortality, being only at the rate of about 16 per 1000 annually, making the ratio of phthisis seem relatively high. Yet, if the total deaths had amounted to 395, which would have raised the death-rate for the month to the twelfth part of the London yearly average—viz., 23 per 1000 (*and it has often been as high here as 26 per 1000*)—the phthisis ratio would still show 12.45 per cent., or exactly the yearly London average.

The 49 deaths from phthisis are in the proportion of .24 in the 1000 of the living population of Melbourne and suburbs, or at the rate of 2.88 per 1000 annually. The death-rate from phthisis in England and Wales is about 2.82 per 1000 living, or not quite so high as here. The 49 deaths which occurred from phthisis in Melbourne and suburbs, during the month of August, will probably be found only a little over the average of all the months of the year, when the whole come to be examined; but, much or little, it will in due time be fairly stated.

The fluctuations of the other causes of death do not appear to affect phthisis, which continues steadily at an almost uniform rate—or fixed quantity, so to speak—and indicating the steady persistency of its causes.

It cannot be longer held, as any explanation of this high mortality from that one disease, that persons suffering from it come to town to die in the Hospitals; for, of the whole number of deaths—viz., 49—only 14 died in the Melbourne Hospital, as will be found on reference to the *Argus's* last summary.

I am, &c., WILLIAM THOMSON.
South Yarra, October 10, 1871.

PARAFFINED PAPER AS A DRESSING.

LETTER FROM DR. W. R. McNAB.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the *Medical Times and Gazette*, of Saturday (p. 759), I notice that waxed paper has been recommended as a cheap and light covering for dressings. As paraffined paper is superior to waxed paper for photographic purposes, I believe it would also answer admirably for Surgical use. Thin paper is saturated with melted paraffin, while the excess is removed by placing the sheet between blotting-paper and passing a hot

smoothing-iron over it. As it can be cheaply and easily prepared I think it would be of great use in Surgery.

I am, &c., W. R. McNAB, M.D.
Royal Agricultural College, Cirencester, Dec. 19.

THE LATE WALTER COOPER DENDY.

LETTER FROM MR. JABEZ HOGG.

[To the Editor of the Medical Times and Gazette.]

SIR,—You will perhaps permit me to add a word or two on another point of interest in the life of our departed friend, Walter Cooper Dendy, altogether omitted in the very interesting notice of him by "J. F. C.," and which may serve to explain the somewhat reclusive life he appears to have led during later years. About the time he was missed by his friends, and his attendances at the Medical Society of London entirely ceased, he suffered from frequent attacks of what he described to me as ophthalmia. Four or five years later he was seated in the reading-room of the British Museum, when he discovered, to his horror, that the sight of the right eye was gone. In great alarm he called upon me, and he was very nervous and a good deal depressed. A careful ophthalmoscopic examination disclosed a considerable clot over the foramen centrale; several smaller hæmorrhagic patches were distributed around the inner side of the peripheral portion of the disc. The fundus presented generally a dull-reddish, congested appearance, and sight was so nearly lost that he could scarcely distinguish the daylight. The internal rectus was paralysed, which produced a considerable convergent squint. The left eye was also congested, but, as the capsule of the lens was slightly striated, the fundus presented a hazy appearance, probably due to slight lenticular opacity. He could, however, on forcibly closing the right eye, read ordinary-sized print. In consequence of the paralysis of the rectus internus, he had difficulty and pain in keeping either eye directed to any object for more than a few moments at a time. The urgent symptoms were prescribed for, and in a day or two after I saw him again, in consultation with Mr. Canton. We strongly urged upon him, in conjunction with treatment, immediate and perfect rest. Dendy at once relinquished work of all kind, and in the course of three months I had the satisfaction of seeing the clots disappear and the sight of the eye return. I again begged of him to abandon Professional work, and seek rest and health in some of those beautiful "Islets of Britain," so admirably depicted by his skilful pen and pencil. In about two years from this time he called upon me perfectly restored to health. I once more examined his eyes, and every trace of the old mischief had disappeared, and I believe, although he used eye-protectors—green goggles—almost up to the day of his death, his sight remained as good as that of most men of his age.

I am, &c., JABEZ HOGG.
Bedford-square, January 1.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 6.

Dr. BRAXTON HICKS, F.R.S., President, in the Chair.

THE following gentlemen were elected Fellows of the Society:—Robert Bell, M.D.; Edward F. Brockman, M.R.C.S.; Thomas W. Evans, M.R.C.S.; Thomas C. McConkey, M.D.; John R. Morrison, L.R.C.P.; Frederick Martyn Rickard, M.R.C.S.; and Montague J. Sturges, M.D.

Dr. AVELING exhibited his Gynæcometer, which consists of a number of uterine sounds capable of being combined in various ways so as to form a hystrometer, a vaginometer, a pelvimeter, or a cliseometer. By its means the dimensions of tumours, and the angle caused by the deviation of the uterus from the vertical line, may be accurately ascertained and transferred to paper.

Dr. ALFRED MEADOWS related a case of so-called Ventral or Abdominal Pregnancy. The patient was aged 22, and was admitted under his care into the Hospital for Women, suffering from what had been previously diagnosed as extra-uterine gestation. The abdomen was enlarged to at least the size of pregnancy at full term, though she had only arrived at about the sixth and a half month. The foetal heart could be heard.

At the end of a week symptoms of collapse supervened from internal hæmorrhage, and the patient died. The foetus was found free in the abdominal cavity, its only attachment being by the umbilical cord to a kind of placental mass formed at the fimbriated extremity of the Fallopian tube. Dr. Meadows advocated a more frequent resort to gastrotomy in such cases, not so much with a view of saving the child or of rescuing the patient when collapse had supervened, but in order to anticipate that collapse, and, in fact, to remove the growth as soon as we could arrive at a true diagnosis. He intimated that possibly, in cases such as the one he related, and perhaps in certain others, it might not be necessary to remove the placental mass, as this might gradually be absorbed by a slow physiological atrophy after that for which it existed was removed.

Dr. PROTHEROE SMITH said there was no doubt in his mind about the propriety of performing gastrotomy in such cases, but a difficulty suggested itself in the previous diagnosis. Seeing that almost always cases of extra-uterine foetation were fatal, he thought that even in the tubular form, if we could but improve our diagnosis so as to detect tubular pregnancy in its early stage, any operative interference which would afford the remotest prospect of life to the mother should be regarded as a duty.

Dr. GRAILY HEWITT believed that the operation of opening the abdomen ought to be performed when hæmorrhage from rupture of an extra-uterine pregnancy threatened to be fatal; but the great difficulty was the diagnosis. With reference to Dr. Meadows' proposal to treat such cases, apart from hæmorrhage, by such an operation, that was another matter, and, in considering it, it should be borne in mind that a certain proportion of supposed Fallopian pregnancies, as stated by Kussmaul, were really cases of pregnancy in a bicorued uterus, and such cases often did well if left to themselves.

Mr. SPENCER WELLS said that the propriety of operating when a woman was dying of bleeding into the peritoneal cavity, or of operating when her life was not in immediate danger, although extra-uterine foetation had been ascertained to exist, were very different questions. In the one case it might be the clear duty of the Surgeon to try and save a patient at any risk from inevitable death; in the other case he would give full weight to the consideration that a spontaneous termination of extra-uterine foetation was not very uncommon. The structure might remain in the body harmless for many years, or pass away through the rectum, the vagina, or the abdominal wall. In a case reported by him the sac could not have been separated, though it would have been easy to remove the foetus and treat the sac by drainage.

Dr. GREENHALGH gave brief particulars of seven cases of Extra-uterine Foetation; three recoveries and four deaths. Of the former, in one the foetal bones were discharged through an abscess in the left groin, in another a full-grown foetus in an advanced stage of decomposition was extracted through an incision in the roof of the vagina, and in the third the liquor amnii was drawn off by a small trocar and canula. Dr. Greenhalgh said that, owing to the great fatality in such cases, he was of opinion that gastrotomy, as recommended by Dr. Meadows, might in many cases give the patient a better chance than by permitting the development of the foetus and secundines to progress, leading to the risk of rupture and probably fatal internal hæmorrhage or other grave termination.

The PRESIDENT said his opinion, based on many cases, was that a number recovered from severe internal hæmorrhage, while a greater number gave no serious anxiety to the patient or Medical attendant. If, then, these cases were not so fatal, he should prefer not to interfere till urgent symptoms arose. But, generally, we do not see the patient or recognise the condition till serious symptoms arise, and then the patient is in such jeopardy that we feel afraid lest, by so serious an operation, we should take away the chance of life, which even then may be reckoned upon; so that practically the opportunity for such an operation as that suggested seldom presented itself. If anyone would look over the records of cases in the Society's *Transactions*, he would see the exceeding difficulty which would have attended the removal by gastrotomy—adhesions in all directions, enlargement of the vascular system into sinuses, the hæmorrhage resulting from the rupture of which would be excessively difficult to stop.

Dr. PLAYFAIR thought the difficulty of diagnosis at an early stage almost insuperable. In advanced cases of extra-uterine foetation, from the first abdominal, it seemed to him that there was much less chance of gastrotomy being successful, owing to the extensive adhesions and matting together of surrounding parts. He thought this procedure a much more

doubtful practice than in early cases of Fallopian gestation. (The specimen was referred to a Committee for a report.)

A Tumour, exhibited by Mr. Scott at the June meeting, which he had removed from a patient, who recovered, was reported upon.

Dr. MEADOWS and Mr. SCOTT believed that the growth was ovarian in its origin. Their report stated that it was almost entirely composed of hard dense fibrous tissue, but having in some places a distinctly reticulated appearance. There were visible under the microscope white fibrous tissue, some elongated fibre-cells, and a few rounded granular cells and granules. At one end of the tumour there was found a portion of the ovary, which contained the remains of a ruptured ovisac, half filled with blood. The ovary itself could not be separated from the tumour, and it seemed to the reporters possible that the tumour originated in the fibrous stroma of the ovary, and that its growth in one direction had not interfered with that portion of the ovary which still maintained its normal character and, so far as could be judged, performed its ordinary function. Mr. Spencer Wells, however, appended to the report, that there appeared to be a great number of non-striated muscular fibres in the growth, there being a number of broad-banded fibres not affected by acetic acid (as the surrounding bundles of fibrous tissue were), and containing long fusiform nuclei. The remains of the ovary seemed to him separable from the tumour; and while not denying the possibility of a tumour largely made up of non-striated muscular fibres originating in the ovary, he thought it must be excessively rare, as he had never seen one—whereas such tumours originating from the uterus are among the most common of morbid growths.

A report by Drs. AVELING and EDIS, on the Malformed Foetus exhibited at the last meeting, was read. The sac, which protruded from and communicated with the abdominal cavity, was as large as a foetal head. It was formed chiefly by an expansion of the sheath of the umbilical cord, but partly, also, by the abdominal parietes, which were continued up around its base. The sac contained the liver, the spleen, the greater portion of the small intestines, and a small portion of the sigmoid flexure distended with meconium. No trace of a gall-bladder could be detected.

Dr. EUGENE GODDARD read the particulars of a successful case of Ovariectomy during Pregnancy. The patient was 29 years of age, and in 1870 was found to be the subject of an ovarian cyst, but as there were no urgent symptoms, the consideration of any Surgical treatment was deferred. She then became pregnant, and about the end of the second month of utero-gestation, Mr. Spencer Wells removed the ovarian cyst. Eleven and a half pints of fluid were withdrawn. The clamp was removed, and the bowels acted on the eighth day. Pregnancy went on uninterruptedly, and a living child was born at the full period. Dr. Goddard said that the compound nature of the cyst precluded the idea of tapping, as also did the risk of peritonitis, suppuration of the cyst, and the formation of adhesions. Premature labour was not induced, because the patient was already beginning to suffer constitutional disturbance from the double burden, and it was doubtful whether, by the time a viable child could be born, they would not have assumed such magnitude as to imperil the patient's safety; whereas, if abortion were induced, the child would be lost and the tumour would remain.

Dr. ROSS related a case in which Mr. Wells had operated under more adverse circumstances, as the lady was much broken down in health at the time of the operation. A small ovarian tumour was diagnosed eighteen years ago. The patient subsequently got married, and Dr. Ross had attended her in four labours. In no instance was parturition attended with any serious difficulty. It was observed that during gestation the tumour appeared to become smaller. The tumour rapidly increased about a year ago, and Mr. Wells removed it successfully, the patient being about two months pregnant. Her labour is now daily expected.

Mr. SPENCER WELLS said that the existence of the cyst for eighteen years, and the presence in its walls of hard, bone-like masses, had led to the diagnosis of a dermoid tumour. Mr. Wells had performed ovariectomy four times during pregnancy, and all the patients had recovered.

Dr. BANTOCK said he was present at the operation, and thought great credit was due to Mr. Wells. The diagnosis of pregnancy at an early stage, complicated with an ovarian tumour, was not always easy. In considering the performance of the radical operation in these cases, one fact was worth any number of theoretical objections.

Mr. SCOTT referred to a case of ovariectomy which he had

recently performed. The patient had passed through two labours at term in safety. No beneficial results could have followed tapping, owing to the compound nature of the cyst and the viscidly of its contents. One danger of leaving the cyst to take its chance was exemplified in the same case—viz., the possible twisting of the pedicle by the gradual development of the impregnated uterus.

The PRESIDENT remarked that in the case of a compound cyst, if relief must be given, the choice lay between induction of labour and ovariectomy. Mr. Spencer Wells's cases showed that ovariectomy in these cases may be attended with satisfactory results.

Dr. BRUNTON detailed a case of Fibrous Enlargement of the Uterus, successfully treated by ergot of rye. The patient was unmarried, and aged 47. The uterus was enlarged to the size of a four months' pregnancy. It was pear-shaped, smooth, and hard. No sounds were heard on auscultation. For four years she had suffered from severe metrorrhagia. Dr. Graily Hewitt saw her in consultation, and agreed in the diagnosis which had been formed. Bromide of potash and other remedies were prescribed, but the hæmorrhage became so severe at the menstrual periods that large doses of ergot had to be given. The hæmorrhages were so severe as almost to prove fatal. Three months afterwards the tumour was evidently decreasing, and in six months it had wholly disappeared. During the half-year she took from forty to fifty ounces of ergot.

Dr. TILT said that, in addition to ordinary cases of uterine fibroid tumours, he had met with two cases in which the womb had become fibrous in its totality. In one case the uterus was about the size of an ostrich's egg. The internal and external exhibition of iodine was recommended, and he heard with surprise some months afterwards that the size and hardness of the uterus had diminished, and that the patient had ceased to suffer. The other patient was seen for the first time ten years ago, and was then 27 years of age. The uterus has gradually increased in size, and is now as large as at the seventh month of pregnancy. He could not believe that large doses of ergot would have prevented its increase.

Dr. PLAYFAIR said that this case could scarcely be claimed as one of the class he had spoken of in his paper "On the Spontaneous Absorption of Fibroid Tumours of the Uterus." This case seemed to be a case of general fibroid enlargement of the whole organ—a pathological condition with which he was not familiar. He did not state that fibroids were absorbed in consequence of Medical treatment, but that in exceptional cases fibroids disappeared spontaneously. The process was probably similar to the involution of the uterus after delivery.

OBITUARY.

NATHANIEL HECKFORD, L.R.C.P. EDIN., M.R.C.S.,
L.S.A.

THE subject of this brief memoir was the son of Captain N. Heckford, well known in nautical circles by his works on navigation. He was born in Calcutta on April 24, 1842, and studied at the principal school and college there (taking the first prize in every class) until he was 15, when he came to England, and was apprenticed to Dr. A. Banks, of Western House, Stratford, Essex, in 1857, and entered as a student at the London Hospital Medical College in 1859. His fellow-students will remember his tall, slender form, and handsome, intelligent features, and recall to mind his generous enthusiasm for the Hospital and College, and the singular aptitude he showed in acquiring all sorts of knowledge bearing on his Profession. His career as a Medical student was unusually brilliant. He took both the Hospital gold medals—viz., that for Medicine, as well as for Surgery—and filled in succession the offices of Resident Accoucheur, House-Surgeon, and Medical Registrar and Tutor, in all of which he displayed singular zeal and ability. Besides this, he frequently acted as Resident Medical Officer (House-Physician) to the London Hospital. After this he was for a short time House-Surgeon to the Metropolitan Free Hospital. In 1866 he returned to India, but only for a few weeks; but, before he did so, his fellow-students gave him a silver cup as a token of their esteem. In India several valuable appointments were offered him, but he declined them all, and soon returned in charge of troops. On January 28, 1867, he married the youngest daughter of the late William Goff, Esq. For a short time he had consulting-rooms in Broad-street-buildings, now demolished for the new station of the Great Eastern Railway. The East London Hospital for Children and

Dispensary for Women, at Ratcliff-cross, was founded on January 28, 1868—the anniversary of their wedding-day—ten beds being opened in a warehouse, purchased by them for £2000, the freehold of which they gave to the Committee in July, 1870. It rapidly increased to forty beds, and is now about to be further enlarged and rebuilt on a site selected by Dr. Heckford. How he worked there, how they both worked there, has been described already by the graceful pen of the late Charles Dickens, who "dropped in," as he delighted to do, quite unexpectedly on the little Hospital, and found out for himself what a noble work was going on in those "back slums" of the far East of London. But those who knew him before were not anyway surprised. They remembered what enthusiasm and skill he had displayed when assisting his friend and fellow-student, Dr. Bathurst Woodman, in taking charge of the cholera wards of the newly opened Limehouse District Cholera Hospital at Wapping. One of that noble band of ladies—some Sisters of Mercy in name, but all in fact—who contributed so much to its success, used to say that she thought Dr. Heckford never slept! Alas! he sleeps now. He was a good diagnoser, and a brilliant operator, and performed most of the capital operations at his little Hospital. He revived the operation of paracentesis capitis, with gratifying though partial success. He was a member of the Pathological and Obstetrical Societies, and secretary of the Beaumont Medical Society. When overwork brought on the fatal pulmonary disease to which he ultimately succumbed, he made two brief visits to Italy—too brief, alas! to do him good, but he would not remain longer absent from work. His death took place on December 14, 1871, and he was interred in the family vault of the Goffs, at Woking Cemetery, on the 19th ult. It is difficult to collect all his publications, as he was utterly careless of these children of his pen. Numerous papers in the Indian and English Medical journals attest his powers of clinical observation. Besides these, he wrote a paper on "Acute Rheumatism," in one of the early numbers of the *Medical Mirror*; also (jointly with Dr. Woodman) a "Report of the Cholera Hospital at Wapping," in the third volume of the London Hospital Reports. Papers by him, on "Still-birth, with Post-mortem Observations" (London Hospital Reports, vol. i., p. 237); and another "On Circumcision as a Remedial Measure in certain cases of Epilepsy and Chorea" (*Ibid.*, vol. ii., p. 58); besides some in the Obstetrical Society's *Transactions* (vols. x. and xi.)

It is characteristic of the man, that he gave the fees he took in private practice to the East London Hospital, as he had an almost insuperable objection to practising his Profession for what he used to call "filthy lucre."

PATRICK MILLER, M.D. EDIN., F.R.S. EDIN.

WE have to record the death of Dr. Miller, of The Grove, Exeter, at the advanced age of 90 years. He was senior magistrate of Exeter. He took an active part in the formation of the Bristol and Exeter Railway, and was for many years a member of the directory of that Company, and also of the South Devon Railway. He was a Physician to the Devon and Exeter Hospital, and, when he retired from the active duties of the office, was appointed Honorary Physician. He was a fellow-student with Lord Palmerston under the celebrated Dugald Stuart, at Edinburgh, who was Dr. Miller's uncle. Dr. Miller was honoured with the friendship of Lord Palmerston through life. He presented to the University of Edinburgh, a few years since, a marble bust of his illustrious relative, for which he received the warm thanks of that learned body. Dr. Miller for a long time took an active part in promoting the charitable institutions and the social improvement of the people. He was universally respected.

HENRY M. GRACE, M.R.C.S.,

DIED at his residence, Downend, near Bristol, on the 23rd ult., after a few days' illness, from an attack of inflammation of the lungs, at the age of 63. He was Surgeon to the Royal Gloucestershire Hussars, and was the oldest officer in the regiment, the present Duke of Beaufort's father having given him the appointment in 1841. He held many public appointments. He was a good Surgeon, and very successful in all he undertook. Being a thorough good sportsman, he was passionately fond of hunting. He was a good cricketer, and himself kept up the West Gloucestershire Cricket Club for a great many years, and founded the Gloucestershire County Club. He has left five sons, three of whom he has established in the Profession; the two younger, well known to all lovers of cricket, have almost completed their studies, and will also become members

of the Profession. He has left a widow and four daughters, two of whom are married. He will be succeeded in his practice by Mr. Skelton, who was about to marry the eldest daughter.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, December 28, 1871:—

Bower, Augustus Edward, Nantwich.
Edwards, John Ellis, Aberdare.

The following gentlemen also on the same day passed their first Professional examination:—

Charlesworth, Henry, Middlesex Hospital.
Cooke, John, London Hospital.
Whately, George Frederick, Middlesex Hospital.
Wright, John Frederick, Middlesex Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BAGSHAW, F., A.M. Cantab, M.D., etc.—Assistant-Physician to the East Sussex, Hastings, and St. Leonard's Infirmary.
BRAYE, HARDWICK HUBERT, M.R.C.S. Eng., L.S.A.—Medical Officer for the Fourth District of the Whitechapel Union, *vice* Dr. E. Richardson, deceased.
CROCKER, JAMES, M.R.C.S.E. and L.S.A.—Medical Officer for the Bingley District of the Keighley Union, Yorkshire.
COUPLAND, SIDNEY, M.B., M.R.C.S.—Resident Physician's Assistant at Middlesex Hospital.
JACKSON, SAMUEL, L.R.C.P. Edin., M.R.C.S.E., and L.S.A.—Medical Officer for the Workhouse of the Oldham Union.
LEDGARD, WILLIAM EDWARD, M.R.C.S.E. and L.R.C.P. Edin.—Medical Officer for the Third District of the Ripon Union.
POLLARD, FREDERICK, M.D. Lond.—Medical Registrar to St. Thomas's Hospital.
RIX, W. K., M.R.C.S. Eng.—Resident Medical Superintendent to the Bradford (New) Fever Hospital.
REID, JOHN, L.R.C.P. Edin. and L.F.P.S. Glas.—Medical Officer, Public Vaccinator, and Medical Officer of Health for the Parish of Balfour, Stirlingshire, *vice* Dr. W. Anderson, R.N., resigned.
RENWICK, WILLIAM, L.R.C.P. Edin., M.R.C.S.E., and L.S.A.—Resident-Surgeon to the Kilburn, Maida-vale, and St. John's-wood Dispensary, *vice* Fletcher Beach, M.R.C.S.E., L.S.A., appointed to the Hospital for Sick Children, Great Ormond-street.
ROBINSON, ANDREW, L.R.C.P. Edin., M.R.C.S.E.—Medical Officer and Public Vaccinator for the Nuneaton District of the Nuneaton Union.
RUGG, B. ALFRED, L.R.C.P. and M.R.C.S.E.—Assistant-Medical Officer to the Asylum for Idiots.
TROLLOPE, T., M.D. CANTAB, L.M., M.B., etc.—Physician to the East Sussex, Hastings, and St. Leonard's Infirmary, *vice* Dr. Dunne, resigned.
WEST, JOHN GILBY 'UYEDALE, M.R.C.S. Eng., L.R.C.P. Lond.—Resident Medical Officer at the North Staffordshire Infirmary.

BIRTHS.

BROWNE.—On December 27, the wife of Dr. Thos. Browne, H.M. Dockyard, Devonport, of a daughter.
JEPSON.—On December 26, at the residence of her father, W. S. Burton, Esq., Inner-circle, Regent's-park, the wife of Octavius Jepson, M.D., Medical Superintendent, City of London Lunatic Asylum, Stone, near Dartford, of a daughter, prematurely.
LIVINGSTONE.—On December 11, at St. John, New Brunswick, the wife of R. Hamilton Livingstone, M.D. Edin., of a son.
MIDDLEMIST.—On December 27, at 10, Bedford-place, Russell-square, the wife of Robert Percy Middlemist, M.R.C.S., L.R.C.P. Lond., of a son.
NICHOL.—On December 27, at Denmark-hill, the wife of R. Nichol, M.D., of a daughter.

MARRIAGE.

DICK—ELLIOT.—On November 22, at Dharwar, Bombay, Dr. Forbes Dick, Royal Artillery, to Constance, daughter of T. Elliot, Esq., The Green, Bishopwearmouth, Durham.

DEATHS.

ALEXANDER, LUCY, the beloved wife of John Alexander, Esq., and only daughter of the late A. S. Allen, M.D., R.N., at 16, Eton-road, Haverstock-hill, N.W., on January 1, aged 29.
ANDERSON, GEORGINA GRAHAM, widow of the late Dr. A. Anderson, H.M.'s 92nd Highlanders, at 40, Minto-street, Edinburgh, on December 31, aged 74.
BAKER, JAMES, M.D., late of 66, New North-road, N., and St. Margaret's, Herts, at Cambridge House, Summerhill-road, Tottenham, on December 25, in his 72nd year.
DICKINSON, LAURA, the wife of W. H. Dickinson, M.D., at 11, Chesterfield-street, Mayfair, on December 29.
FERNERLEY, CHARLES, Surgeon Royal South Lincoln Militia, at Grantham, on December 23, aged 61.
HALE, MARY EUGENIA, the beloved child of Robert Douglas Hale, M.D., at 16, Queen Anne-street, Cavendish-square, on December 19, aged 18.

HECKFORD, NATHANIEL, M.R.C.S., M.D., founder of the East London Hospital for Children, Ratcliff-cross, a few days since, at Ramsgate, after a lingering illness.

JEPSON, BESSIE, the wife of Octavius Jepson, M.D., Medical Superintendent, City of London Lunatic Asylum, Stone, near Dartford, at the residence of her father, W. S. Burton, Esq., Inner-circle, Regent's-park, on December 31, in her 28th year.

MILLER, PATRICK, M.D., at The Grove, Exeter, on December 24, in his 90th year.

NYHLETT, Dr. A. N., at Belsize Manor, Hampstead, on December 22, of rheumatic fever and meningitis, in his 37th year.

OLIVER, ELIZABETH, widow of Richard James Oliver, Surgeon, Leicester, at Highgate-road, London, after a short illness of acute bronchitis, on New Year's-day, in her 78th year.

PEARCE, CHARLES WORTHAM, Surgeon, at 99, Ledbury-road, Bayswater, on December 28, aged 43.

POPHAM, WILLIAM HOME, M.D., M.R.C.S.E., and L.S.A., eldest son of the late Robert Honner Popham, Esq., of Bandon, Ireland, at Gawler, South Australia, on October 20, aged 52.

PRYCE, CHARLES, M.D., etc., at Mornington-road, Regent's-park, on December 23, aged 62.

RICHARDSON, LEA, M.D., at Edinburgh, on December 17, aged 49.

RATTON, ALICE MARY (*née* Bellord), wife of James J. L. Ratton, M.D., Madras Army, at Ceylon, on December 30, aged 22.

SMYTHE, ANNA ELIZABETH, wife of the late Arthur Smythe, M.D., of Pau, at 30, Lee-park, Blackheath, on December 29, in her 53rd year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

AXBRIDGE UNION.—Medical Officer for the Eleventh District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. A. Watson Miller, Clerk, on or before January 8. Election the following day.

CALNE UNION.—Medical officer. For particulars see advertisement.

CANCER HOSPITAL, LONDON AND BROMPTON.—Resident House-Surgeon. Must be M.R.C.S.E. Applications and testimonials to the Chairman of the Weekly Board, 167, Piccadilly, on or before January 22.

DARLINGTON HOSPITAL AND DISPENSARY.—Resident Medical Officer. Medical and Surgical qualifications required. Further particulars of the Secretary, to whom applications and testimonials are to be sent on or before January 9.

JERSEY GENERAL DISPENSARY.—Medical Officer. Further particulars of the Rev. P. A. Le Feuvre, Oakwalk, Jersey. The election takes place early in January, and the duties will commence on February 1.

LANCASTER (COUNTY OF) LUNATIC ASYLUM.—Medical Officer. Must be duly qualified and registered. Applications and testimonials to Mr. F. C. Hulton, Clerk to the Committee, on or before January 8.

MANCHESTER GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN.—For particulars see advertisement.

MIDDLESEX COUNTY ASYLUM, HANWELL.—Medical Superintendent of the Female Department. Candidates must possess both Medical and Surgical qualifications. Copies of testimonials to Mr. R. W. Partridge, Clerk to the Visitors, on or before January 6.

NORTH WALES COUNTIES LUNATIC ASYLUM, DENBIGH.—Assistant Medical Officer. Qualifications to practise must be produced. A knowledge of the Welsh language is necessary. Applications and testimonials to Mr. John Robinson, on or before January 10.

QUEEN'S COLLEGE, CORK.—Professorship of Chemistry. Applications and testimonials to the Under-Secretary, Dublin Castle, on or before January 22.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Must be a Member of the College of Surgeons of London, Dublin, Edinburgh, or Glasgow; or a Licentiate of the Society of Apothecaries. Applications and testimonials to the Treasurer, Mr. R. Tweedy, Truro, on or before January 20.

SUNDERLAND INFIRMARY.—Junior House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Senior House-Surgeon, on or before January 20.

WEST RIDING LUNATIC ASYLUM, WAKEFIELD.—Chemical Assistant. For further particulars see advertisement.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Keynsham Union.—The Mangotsfield District is vacant; area 4417; population 5160; salary £55 per annum.

St. Marylebone Parish.—Mr. W. S. Britton has resigned the St. John's District; population 32,540; salary £120; no fees.

Settle Union.—Mr. R. Tatham has resigned the Bentham District; salary £40 per annum.

APPOINTMENTS.

Forest-gate School District.—Alfred Thomas Roworth, M.R.C.S.E., L.S.A., to the *Goliath* Training Ship.

Hexham Union.—Thos. E. Stainthorpe, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., to the Western Division of the Third District.

Smallburgh Union.—Anthony Crisp, M.R.C.S. Eng., to the Horsey District.

Swaffham Union.—John Ewart, B.M. and M.C. Univ. Edin., to the Saham Toney District.

West Derby Union.—Ebenezer Hughes, M.D. St. And., L.F.P. and S. Glasg., to the Walton Workhouse.

DR. TILBURY FOX has been nominated by the President a member of the Leprosy Committee of the Royal College of Physicians.

DR. BELL has been appointed Medical Officer of the St. John's-wood district by the St. Marylebone Board of Guardians.

GENERAL DISPENSARY, EDINBURGH.—Drs. Inglis and Rodger have been elected Medical Officers of this Institution.

AN offer of £100 has been made by the Government of India for a simple Medical manual for the use of officers whose duty takes them far from Medical aid.

A PERMANENT Sanitary Committee has been appointed at Chatham, in consequence of cases of typhoid fever having occurred.

THE mortality of Wolverhampton is now double the average mortality of the chief towns in England.

THE Lambeth Board of Guardians are about to erect a large Dispensary at Lower Norwood, to accommodate the whole of that portion of the parish of Lambeth which is comprised between Westow-hill, Tulse-hill, Rosendale-road, and St. Julian-road.

THE Cheshire magistrates are taking steps to appoint a county analyst. The *Liverpool Mercury* says one argument used in support of the appointment is that it would diminish drunkenness, by preventing the mixture of drink-provoking ingredients with liquor.

EAST LONDON HOSPITAL FOR CHILDREN.—It has been decided to erect a new Hospital, at a cost of about £8000, in which at least 100 beds could be provided, instead of the thirty-two contained in the present building. An eligible site has been obtained for the new building, close to the Peabody-buildings, Shadwell.

THE quality of the waters supplied to the metropolis during the last month, says Dr. E. Frankland in his report, were clear when drawn from the companies' mains. The Thames and Lea waters supplied by the Chelsea, West Middlesex, Southwark, Grand Junction, Lambeth, and East London Companies were of much "better quality than is usual at this season of the year," but as regards organic impurity compare very unfavourably with those supplied by the Kent and New River Companies, which are principally drawn from deep chalk wells and springs.

MR. CORRANCE, M.P., in reading a paper "On Medical Poor-law Relief," at the last meeting of the Framlingham Farmers' Club, said:—"We must thoroughly reorganise our Medical relief system throughout; establish dispensaries, districts sanitary and Medical; and, above all, take care that the functions of the Medical officer are precise and exact. His duty is Medical. To the Dispensary Committee and the Board of Guardians belongs the duty of relief. For persons too pauperised to afford themselves the necessary food, the infirmary in the house is the proper place. But also I call organised charity into this field as its proper place. Under the Dispensary Committee its relief will seldom fall short or be misplaced."

FEVER AND CHOLERA NOTES.—Fever of a severe type, says the *Bombay Gazette*, is very rife in Calcutta. It is, however, strange to say, mostly confined to Toltollah, about the only purely native section of the city to which the new drainage has been extended. Cholera is abating at Lucknow and Delhi.—The whole of the cholera tents on the heights of the Okncidan, says the *Levant Herald* of December 20, have been removed, and with them, we hope, one of the last reminiscences of this year's cholera epidemic in Constantinople.—A recent letter from Aleppo states that the epidemic, after causing a considerable number of deaths at Mardine, had completely disappeared from that town and all the surrounding neighbourhood.—Forty-five persons died last week in London from different forms of fever, of which four were typhus, thirty-three enteric or typhoid, and eight simple continued fever.—The last weekly bulletin gives no case of typhus fever in Paris, but thirty-three of typhoid.

RAPID CURE OF CORYZA.—M. Barrier strongly advocates a modification of the treatment recommended by Mr. Pretty, of London, in 1845—viz., the employment of the nitrate of silver, substituting the powder for the solution. He recommends—1. To sneeze during the whole course of the disease as seldom as possible, keeping the mouth wide open, in order to expel the column of air, which would irritate the walls of the nares. 2. To blow the nose seldom and incompletely. 3. To sniff up strongly a very small quantity of the powder (nitrate one part; sugar, reduced to an impalpable powder, nine parts) three or four times a day.—*Lyon Médical*, December 24.

THE CORONER'S COURT.—The coroner's court appears to receive favour at nobody's hands. The Middlesex magistrates grumble at its expenses, and threaten all kinds of proceedings to keep them down; the jurymen return verdicts of a speculative character, and ignore or reject Medical evidence; coroners hold inquests unnecessarily, and refuse inquiries where they are urgently demanded—but, with all its drawbacks, it was generally admitted that the "crown's quest" still did perform some useful office for the State. The justices of East Yorkshire, however, will not admit this; on the contrary, at the adjourned annual session of the magistrates of Lancaster, held at Preston last week, an extract was read from a report of the justices of the East Riding of Yorkshire, suggesting that coroners' inquests were entirely useless as an institution, and that they not unfrequently obstructed the course of criminal justice and brought the magisterial and coroner's jurisdiction into unseemly and unnecessary collision. The subject was not discussed.

PREVENTION BETTER THAN CURE.—It is marvellous that, in a great city like London, the prevention of disease is regarded, in the main, as a secondary matter. When diseases come in an epidemic form we are all in alarm: we have made such imperfect preparations that all is confusion and mismanagement. Yet we have it in our power, in a quiet way, and without hurry and distraction, to prevent the extension of some of the worst diseases that afflict humanity. It is now believed that cholera, in its origin and its progress, is mainly helped by impurities in our drinking-waters. What have we done to remedy this evil? In some districts all the pumps have been closed; but what of the water supplied by the water companies? At the last meeting of the Vestry of Newington Butts, the Medical Officer of Health drew its attention to the statements contained in the Registrar-General's Report, on the defective quality of the water supplied by the Lambeth, Southwark, and Vauxhall Water Company. Is this water properly filtered? Dr. Cortis remarked that if the Local Government Board, instead of talking of erecting cholera Hospitals for the metropolis, took some steps to prevent the dissemination of cholera-poison by bad water, they would do a great deal more good. It was ultimately resolved to forward a memorial to Mr. Stansfeld, praying for his intervention in the matter; and remedial action is urgently demanded.

THE PRECOCIOUS COLD OF 1871.—The winter of 1871-72, whatever it may turn out to be as to duration, has been, at all events, remarkably precocious; for, according to M. Sainte-Claire Deville, in only four years during a century has a greater degree of cold been observed in November than that of November, 1871. These years were 1774, 1782, 1786, and 1858. It is doubtful whether the thermometer has descended lower than on December 9 of this year, on the morning of which day it stood, at the Observatory of Montsouris, at 23° C. below zero. Indeed, M. Arnoult observed it as low as 24° at Parmain, near Isle-Adam. This precocity of cold has been generalised over all France, the southern portion of the country especially exhibiting it.—*Gazette Méd.*, Dec. 16.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN DECEMBER, 1871.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	21.97	0.048	0.124	0.003	16.2	3.8
West Middlesex	20.40	0.028	0.118	0.001	15.4	3.6
Southwark & Vauxhall	20.80	0.050	0.122	0.002	15.5	3.6
Chelsea	21.83	0.049	0.120	0.003	16.0	3.7
Lambeth	21.21	0.051	0.119	0.004	15.8	3.7
<i>Other Companies.</i>						
Kent	26.83	0.011	0.182	0.000	20.0	6.0
New River	20.60	0.028	0.120	0.001	15.6	3.7
East London	22.31	0.056	0.125	0.001	16.7	4.2

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—namely, in that of the Grand Junction and the Chelsea Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies

to the Association of Medical Officers of Health, 103,055,193 gallons; and the number of houses supplied was 482,719. This is at the rate of 31'6 gals. per head of the population daily.

THE EPIDEMIC OF SMALL-POX IN BERLIN IN 1871.—Between January 1 and November 26 there occurred 14,358 cases, with 4248 deaths. In the four Small-pox Hospitals there were admitted during the same period 6951 patients, of which number 997 died and 666 still remain under treatment.—*Berlin. Woch.*, December 4.

BENZOIC ACID OINTMENT IN ANAL FISTULA.—Dr. Gibbs, of the U.S. Navy, states that this is especially useful in inaccessible blind fistule. He has used it in several cases of commencing fistula, as well as in others more completely formed. It was used every night by digital application, taking care that it covered the whole surrounding ulceration, and entered, under pressure, the fistulous aperture. The following is the ointment, the morphia being added to quiet irregularity of the sphincter, etc.:—Benzoic acid, 2 scruples; acetate of morphia, 4 grains; simple cerate, 1 drachm; softening with glycerine, if required. An immediate feeling of relief follows the application; and the ointment is earnestly recommended to those who dread operation, and when the patient's own finger can be employed. Within a month a fistula of six months' standing has been relieved.—*New York Medical Record*, November 15.

NOTES, QUERIES, AND REPLIES.

De that questioneth much shall learn much.—*Bacon*.

I. F.—15s. The firm in question will send their catalogue when it is ready.

R. P., Lancaster.—Sir Thomas Browne, M.D., died at Norwich, October 19, 1682, aged 76.

Inquirer.—Both. Dr. W. W. Hunter's salary as Director-General of Statistics to the Government of India is £1800 a year, besides travelling and office allowance.

M., Ventnor.—A Licentiate in Dental Surgery of the Royal College of Surgeons has no right to have on his door-plate "L.R.C.S. Eng." (omitting the D.); the title does not exist.

Another Distinction in Lincolnshire!—We last week stated that one of the Lincoln papers had announced the important fact that one Physician only in that extensive county had been elected a Fellow of the Royal Medical and Chirurgical Society. The *Lincoln Gazette* of last week gives us the startling information that "Dr. Mitchinson, L.K. & Q.C.P., Physician to the Lincoln County Hospital, is the only Lincolnshire Practitioner who signed the Medical Declaration against Alcohol, published in another column."

MEDICAL FEES IN NORWICH.

We, the undersigned, Medical Practitioners residing in Norwich, fully endorse the following resolutions, and pledge ourselves heartily to co-operate with our Medical brethren in carrying out the same:—

That the payment for attendance and medicine by each member of a benefit society be not less than four shillings per annum.

That midwifery, vaccination, and dentistry be considered extras.

That no member residing more than three miles from his club-house be entitled to attendance at his own residence.

That no contracts be entered into for attendance on the wives and families of members of clubs in which such an arrangement does not already exist.

That the fee for attendance on the wives of members of clubs in their confinements be not less than one guinea.

That the fee for examination of candidates for admission and re-admission to benefit societies, and for all certificates (except the ordinary certificate of ability or inability to work), be one shilling.

That the fee for a certificate of death for a burial club be two shillings and sixpence.

W. Biansby Francis.

Obstetrician, Truro.—Schultze named Adam as the first accoucheur, by the authoritative voice of necessity: "Laboranti amicæ obstetricis manus adhibuisse, sic que chirurgie primam forte operationem exercuisse." Le Clere contended that our first parent was not only the first accoucheur, but also the earliest Physician and Surgeon in the world.

N. H.—If your son should prove successful at the recent Examination in Arts at the College, he could commence his Hospital studies at once, and obtain credit for half a session—i.e., from January to March. Write to the Secretary for the Regulations.

1. Competitor.—There is no dearth of essays for the Jacksonian Prize "On the Treatment of Wounds after Operations"; as many as six have been received by the Secretary of the College of Surgeons. The dissertations for the Collegial Triennial Prize must be delivered before Christmas-day, 1873.

Surgeon Royal Navy.—The paper by Dr. Bryson, "On the Respective Value of Lime-juice, Citric Acid, and Nitrate of Potash, in the Treatment of Scurvy," you will find in vol. xxi., pp. 212 and 435, of the *Medical Times and Gazette*.

The North Devon Infirmary, Barnstaple.—If the statement made in the letter of "A Subscriber," in the *North Devon Journal* of the 28th ult., be true, then it is important that the Medical staff of the Hospital should be increased. It is alleged that "the poor people, on Fridays, are sometimes kept waiting five or six hours, wearied out, ere they are attended to, and then hastily dismissed to their homes—it may be several miles in the country—after nightfall." If this be true, it is simply disgraceful. We cannot help thinking there must be some great exaggeration in this matter. At all events, a searching inquiry should be instituted by the Governors.

SANITARY SCIENCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

"Ridiculum acri fortius, magnas plerumque secat res."—*Hor. or Juv.*

"Within the last fortnight, we have had a still more striking illustration of the difficulty of getting at the truth on any subject, in connexion with the painful inquiry into the sanitary condition of Londesborough Lodge, and the origin of the Prince of Wales's fever."—*Saturday Review*, December 17—"Historic Doubts."

SIR,—A Medical barometer, considered extremely sensitive to all the "nuances" of Medical opinion, I have been sorely exercised of late by sanitary science, e'en to the point of losing my "ventral" balance. I had been rising gradually to "Set Fair"—or, rather, "Set Foul," sanitary subjects not being particularly savoury—when the doctrines now being "ventilated" upset me again.

A careful study of the Medical Commissioners' Londesborough, Searborough, and Sandringham reports, has induced a "soupçon" that we may have Smithfield market back again in the old home, and graveyards restored to cities and towns!

To increase my perplexity, the *Times* lately published a letter, headed "Typhoid Fever," from Edward Clapton, M.D., most properly deprecating the disturbance of drains, etc., at this season, giving as a reason—*inter alia*—"the existence of fires in almost every room."

On the other hand, Dr. Copland ("Dictionary of Practical Medicine," 1866), in the article "Therapeutics, Special Principles of," writes—"Heated air is the only real disinfectant."

Utrum horum, Mr. Editor? Where does truth lie?—Not, I ween, in the present instance, at the bottom of a well; for are not wells percolated by sewage?—cautioning us to let well alone! (I can never again think the song "All's Well" a sweet air!)

Seriously, after the (inky) flood of light that has been thrown on this subject, I am still driven sorrowfully to ask—Where, when, and how did the Prince really catch typhoid fever? I am, &c.,

December 18.

ANEROID.

Temperance is thanked for calling our attention to the silly article in the *Journal*. The writer of that article appears to think—if he thinks at all—that there is no boundary between temperance and total abstinence. This is the rock on which the enthusiasts against the use of alcohol invariably get wrecked. If "wine" be a "mocker," it has the highest authority for its use, in moderate and proper quantities, when it "cheers but not inebriates." It is to be regretted that the advocates of what they call "temperance" should not give a definition of that word. Their definition, according to the article referred to, is not that admitted to be correct by those who are "temperate in all things."

Scarborough must recollect that some allowance is to be made for the time at which the articles were written. Something "sensational" was expected, and you could scarcely be sensational without some "damning facts" to comment upon. We believe that Dr. Rooke's letter in the *Scarborough Express* of last week gives a fair and truthful account of the sanitary condition of the town. We condemn, and have long condemned, the "system" of fixing upon some health-resort, and "running it down" simply because one or two cases of measles, more or less, have occurred. This kind of proceeding is most unjust, and most injurious to the inhabitants and visitors of the attacked town. But, then, it answers its purpose—the sensational paragraphs are quoted!

PALATABLE COD-LIVER OIL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I wish to call the attention of the Medical Profession to the benefit derived from Fox's palatable cod-liver oil in laryngismus stridulus.

Some time since I was called to see a child, aged 18 months, suffering from a series of severe attacks of this disease, accompanied with convulsions—the child being anæmic, thin, and scrofulous. I prescribed the usual remedies, the spasms coming on at the usual periods, from which it has suffered for at least six months. The debility was considerable, and I ordered two drachms of Fox's oil four times a day with very decided benefit, only two attacks occurring afterwards. This improvement I attributed to a mere coincidence, but curiosity prompted me to try the remedy in three other cases, with singular relief. I may conclude by saying it acted like a charm in spasmodic croup, and is worthy of further trial.

I am, &c.,

J. PRESTWICH, L.R.C.P., &c.

COMMUNICATIONS have been received from—

Mr. BULLEY; Mr. W. RENWICK; Mr. SNEAD; Mr. PRESTWICH; Dr. T. BROWNE; Dr. O'NEILL; Mr. J. BURTON; Mr. J. MOFFAT; Mr. CORFIELD; Mr. HOLMES COOTE; Mr. W. T. GRANT; Dr. KEOWN; Dr. NEILD; Dr. BENICE JONES; Dr. C. J. B. WILLIAMS; Dr. RUSSELL; Dr. CLIFFORD ALBUTT; Dr. LIONEL BEALE; Mr. T. BRYANT; Dr. MONON; Mr. FREDERICK CHURCHILL; Dr. RAMSKILL; Dr. JOHN HARLEY; Dr. JAMES RUSSELL; Dr. PORTER SMITH; Mr. JEBB; Dr. ABRATH; Mr. G. LAWSON; Dr. JAMES PART; Mr. RIX; Mr. HOLMESTED; Dr. LETHBY; Dr. C. HANDFIELD JONES.

BOOKS RECEIVED—

Report of the Registrar-General of Queensland, 1871—Dr. Aldis's Report on the Sanitary Condition of the Parish of St. George, Hanover-square—How to Feed Infants, by Dr. James Jamieson—Waring's Plan for the Collection and Disposal of Sewage on the Separate System—Report of Sanitary Committee to the Commissioners of the City of London on Spurious and Unsound Tea—Report of the Highgate Infirmary—Year-book of Pharmacy.

PERIODICALS AND NEWSPAPERS RECEIVED—

The Salopian—North Devon Journal—Medical Press and Circular—The Doctor—Pharmaceutical Journal—Nature—Australian Medical Gazette—Darlington and Stockton Times—Australian Medical Journal—Journal of Mental Science—Lincoln Gazette—Philadelphia Medical Times—Scarborough Express—Stamford Mercury—Transactions of the American Ophthalmological Society—Monthly Microscopical Journal, January—Quarterly Journal of Science—Popular Science Review.

APPOINTMENTS FOR THE WEEK.

January 6. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, LL.D., F.R.S., "Ice, Water, Vapour, and Air." (Lecture V.)

8. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. First Lettsomian Lecture, by Dr. Habershon, "The Liver and its Nerves."

9. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, LL.D., F.R.S., "Ice, Water, Vapour, and Air." (Lecture VI.)

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Dr. Wm. Ogle, "Complete Recovery after Removal of a Cervical Vertebra." Dr. John Ogle and Mr. Henry Lee, "Case of Tracheotomy; Detachment of Tube from its Shield and Escape into Trachea; Removal by Second Operation fourteen months afterwards."

10. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

EPIDEMIOLOGICAL SOCIETY, 8 p.m. Dr. James Christie (Physician to the Sultan of Zanzibar), "On 'Kidinga Pepo,' a peculiar form of Exanthematous Disease recently epidemic in Zanzibar."

11. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

12. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. Ogle, "On the Temperature in certain Affections of the Nervous System, but especially in Tetanus." Mr. R. Brudenell Carter, "Case of Paralysis of External Rectus cured by Iodide of Potassium, Faradism, and Operations." Mr. Cooper Forster, "Case of Popliteal Aneurism, with Remarks on Treatment."

QUEKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Specimens only.

VITAL STATISTICS OF LONDON.

Week ending Saturday, December 30, 1871.

BIRTHS.

Births of Boys, 993; Girls, 898; Total, 1891.

Average of 10 corresponding weeks, 1861-70, 1791'0.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	823	863	1686
Average of the ten years 1861-70	749'9	744'0	1493'9
Average corrected to increased population	1643
Deaths of people aged 90 and upwards

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Popula- tion, 1871.	Small-pox.	Measles.	Scarlet Fever.	Diphtheria.	Whooping- cough.	Typhus.	Enteric (or Typhoid) Fever.	Simple continued Fever.	Diarrhoea.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29'604 in.
Mean temperature	43'0°
Highest point of thermometer	48'4°
Lowest point of thermometer	36'0°
Mean dew-point temperature	40'0°
General direction of wind	S.W.
Whole amount of rain in the week	0'56 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, December 30, 1871, in the following large Towns:—

Boroughs, etc. (Municipal bound- aries for all except London.)	Estimated Population to middle of the year 1871.*	Persons to an Acre. (1871.)	Births Registered during the week ending Dec. 30.	Deaths Registered during the week ending Dec. 30.	Temperature of Air (Fahr.)			Temp. of Air (Cent.)	Rain Fall.	
					Highest during the Week.	Lowest during the Week.	Weekly Mean of Mean Daily Values.		Weekly Mean of Mean Daily Values.	In Inches.
London	3263872	41'8	1891	1686	48'4	36'0	43'0	6'11	0'56	1'42

Total of 20 Towns in United Kingd'm	7204001	33'8	4906	4125	53'0	30'2	42'2	5'67	0'58	1'47

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29'60 in. The highest was 30'02 in. at the beginning of the week, and the lowest 29'23 in. on Thursday evening.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

+ No returns having been received from Edinburgh or Glasgow, averages of the numbers of births and deaths returned in those cities in recent weeks have been inserted, in order to make up totals for the twenty towns of the United Kingdom.

ORIGINAL LECTURES.

LECTURES ON THE
PRINCIPLES OF THE TREATMENT OF
FEVER.

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE II.

THE PRINCIPLES BY WHICH WE SHOULD BE GUIDED IN THE
TREATMENT OF SLIGHT CASES OF FEVER, AND OF THE EARLY
STAGE OF CASES WHICH MAY AFTERWARDS BECOME SERIOUS
OR DESPERATE.

"The valuable labours now under prosecution in the long-neglected field of treatment of disease . . . have received general recognition, and thus a final blow has been given to the dominion of a disheartening therapeutic nihilism."—*Felix von Niemeyer*.

It would seem almost superfluous to urge that the admission that there are cases of fever which will get well without any Medical treatment whatever, and cases that cannot be saved by any mode of treatment yet discovered, does not involve the inference that nothing is to be gained by treatment, and that fever must be left to itself, or the natural course of the disease merely watched with care, and the efforts of Nature assisted. But yet, from some of the remarks made of late years, many a student has been led to suppose that it was really doubtful whether the patient suffering from fever was placed in a more favourable condition as regards his chances of recovery if he was subjected to treatment, than if the course of the malady was attentively watched by his Medical attendant. Some, indeed, seem to cast doubt upon the utility of all treatment, and the art of Medicine seems to be almost reduced to the art of consoling the sick and their friends. Scientific doubt concerning the action of remedies, encouraged by general scepticism or disbelief in the remedial influence of measures, many of which were believed in by our predecessors, has paved the way for the reception of that most interesting and highly intellectual form of philosophical credulity, "nihilism." Such a result, however, can hardly be fairly accounted for by the advance of knowledge, as has been erroneously intimated; but seems rather to be an obstinate determination on the part of some to insist that all shall look at things from that particular side upon which they have taken *their* position; and that only certain facts, which are of importance by reason of having received *their* imprint, are to be regarded as facts at all. On the other hand, all phenomena which seem to be inconsistent with the predetermined conclusion, which is alone to be accepted, are to be ignored or denied. But, notwithstanding all these advantages, therapeutic nihilism has happily not yet been generally acted upon in this country—nay, it is not always acted upon where it is encouraged as a therapeutical theory. Practitioners will not soon be brought to admit that between the remedies prescribed by them and certain results which follow soon after the remedies in question have been introduced into the body there is no relation—and this although the same sequence of phenomena is noticed in case after case. Nor is it an easy matter to convince oneself that a medicine which produces certain quieting effects in health is useless in disease in which restlessness is painfully manifested and may be certainly relieved without any harm resulting from the administration of the remedy in question. No one will deny, for example, that opium acts upon the system in a special manner, but many talk as if they doubted whether this action of opium was of the slightest advantage, or was desirable, in disease. Nay, they seem to argue that, although opium and other remedies do undoubtedly allay pain, it by no means follows that such drugs are of any advantage, or ought to be given, in certain morbid conditions accompanied by pain, distress, and suffering, notwithstanding these very remedies have been given, and have been believed to have been of use, by many successive generations of Practitioners.

Of all forms of scepticism, therapeutic scepticism is the most extraordinary, seeing that many of the questions upon which doubt is cast are matters of everyday experience, and some of them can even be determined by a very simple experiment being made upon the organism of the sceptic himself. As a fact, however, sceptical philosophy is invariably supported by dogmatic teaching of a very decided character, promulgated by authority that cannot err. It is this that enforces

conviction and wins disciples. But surely no one who has studied the phenomena of the body in health and disease will be in danger of being misled either by those who, professing to be able to *cure*, seem to be proud of their ignorance concerning the *nature* of morbid changes, or by those melancholy therapeutic nihilists who profess to base their scepticism upon the inferences arrived at by philosophical speculators who demand acquiescing reverence on the ground that they have devoted themselves to pure science, and have left the pursuit of practice to less highly trained intellects.

Up to this time we have always had amongst us not a few Practitioners who have studied science as earnestly and as successfully as any who have devoted their lives exclusively to scientific labours. Scientific theories have been studied and criticised upon their own merits, by men well conversant with their bearing upon disease, and in this way Medicine has gained no small advantage. But within the last few years more than one authority in some special section of scientific investigation, armed with the power of popularity alone can give, has thought fit to assume an attitude dictatorial rather than persuasive, towards us and towards the members of another Profession—which, like ours, is sometimes attacked by sneers, and its working members accused of being unphilosophical and something worse. With arrogant condescension and pomposous seriousness, we are made acquainted with the last new hypothesis and its bearing upon the views it is desired we are to entertain concerning the nature and treatment of disease; but the truth of the hypothesis we are called upon to accept is not to be demonstrated until some time after we have ceased to live. We are expected not only to receive without inquiry and with enthusiastic respect the wildest conjectures, but to regard them and employ them as if they had been established and were incontrovertible facts. And yet it must be obvious to everyone who considers the matter, that the position assumed by the teachers and followers of conjectural science is opposed to the spirit of science, and antagonistic to the principles entertained and taught by every scientific body throughout the world. But it unfortunately happens that some members of our Profession, who have accepted without examination some of the newest dogmas, have been led, unintentionally, no doubt, to sanction and support this arrogant system, which is based upon intolerance, and is most damaging to liberty of opinion, if, indeed, it is not utterly inconsistent with that freedom of thought and work without which true science cannot progress or even exist. Practitioners, persuaded by philosophers that Practitioners cannot pursue science to advantage, or scientific men practise, and ignorant or forgetful of all the scientific work that has been done by members of their Profession in the time past, seek to inaugurate a new system which shall discourage in the Profession the very work by which the high position now held by Medicine has been gained, and by the continuance of which it will alone deserve to retain the place among the sciences it has occupied, and still holds, at least in England. Let us learn from the work and lives of Harvey and Hunter, and Bell and Astley Cooper, and Brodie, and many more, what is our duty as well as our true interest. If we would serve Medicine as we ought, with all the great advantages we now possess and which were not enjoyed by those who preceded us, we should follow the example they so nobly set, by thinking and studying and investigating, as well as by doing all we can to relieve suffering and prevent or alleviate present disease.

It is impossible to discuss the treatment of fever or any other form of disease, as it ought to be discussed, without considering the bearing of many facts which might appear at first sight to be of scientific interest only. It seems to me, therefore, that all students should be well educated in science, so that when they come to be Practitioners they may be able to form an opinion upon the views that are put forward, and may be in a position to pursue certain branches of scientific investigation, if opportunity offers, and thus extend our knowledge of the nature and treatment of disease.

THE TREATMENT OF SLIGHT FEVER.

We may learn something concerning the treatment of the feverish state, if we study carefully the changes which go on in our own bodies when we ourselves are suffering from a slight feverish cold, and observe carefully the effects of the remedies we think well to take for the alleviation of the symptoms. The instinct which prompts a patient suffering from the feverish condition to seek warmth, and to prefer plenty of blankets and the neighbourhood of a good fire to a cold bath or the free application of cold air to the surface, is probably preservative, and experience justifies the adoption of

such a course. All the unpleasant feelings experienced by anyone who has a feverish cold disappear for the time if he takes a warm bath. If the skin can be made to act freely, by keeping the surface warm, internal heat is got rid of very quickly, and thus the temperature of the body kept down. Mr. Garrod has proved by experiment that by simply removing the clothes from the healthy body the temperature of the blood rises as much as two degrees of Fahrenheit's scale, while, very soon after the skin has been again protected by a badly conducting artificial covering, the temperature falls to its normal standard. The explanation is simple. By exposure to cold the radiation of heat from the cutaneous surface is reduced, the vessels are caused to contract, and the blood driven *from* instead of *towards* the surface of the body. Hence, if we want to cool the blood and internal tissues in ordinary fever, we must keep the skin warm and protect it from currents of air. If, however, the temperature is already very high, indeed near the point at which, if reached, death must soon occur, the decided external application of cold is probably the only way of keeping the patient alive (see page 732); but we are now discussing the principles of treating slight degrees of fever only. By external warmth, then, the blood is determined to the surface, the glands are excited to act, and by free perspiration the blood is relieved of certain constituents which were accumulating in it to the detriment of the organism. The tension of the vessels of the secreting organs is lessened, and the removal from the blood of water holding in solution various soluble excrementitious substances soon follows. We all know how pleasant is the sensation produced when moderate perspiration is established in the early stage of a common feverish cold. Even placing the feet in very hot water relieves, in a few minutes, the unpleasant feeling of tension about the head, nostrils, throat, and neck which, doubtless, we have all experienced. And there is no doubt that in promoting perspiration by those simple plans known to all, and by the introduction of sudorific remedies, the feverish attack may be shortened and its intensity lessened. By free perspiration, not only are various materials removed from the blood, but thirst is excited, the gratification of which insures the solution and subsequent elimination of more material which might otherwise be devoted to the abnormal nutrition of bioplasm, leading to those serious consequences which have been already referred to. The moderate perspiration excited by exercise conduces to health in this way, and renders needless the occasional use of the warm bath. If free sweating be artificially induced at the right moment, it is not improbable that a feverish attack may sometimes be altogether averted. Moreover, free excretion from one surface is not unfrequently followed by free action on the part of the other excreting organs, and in this way a quantity of material, the presence of which in the blood would be detrimental, is got rid of before any harm has resulted.

But a slight feverish attack may be *cured* by simple rest and warmth. Very often twelve hours' uninterrupted rest is the only remedy that is required to cut short many an attack of feverishness—indeed, healthy constitutions frequently "sleep off" their feverish ailments, and many children who go to sleep in a highly feverish state, wake up twelve hours afterwards perfectly well.

I have often been led to suppose that a sharp attack of diarrhoea, occurring during the period of incubation of virulent fever-poison, has mitigated the subsequent attack of fever, consequent upon the multiplication in the body of the special fever-germs. This conclusion is supported by the fact that in many cases all the symptoms of commencing continued fever have suddenly ceased upon the occurrence of free action of the skin, kidneys, and bowels. Of course, no one can say that the symptoms were really due to the actual presence of contagious poison in the blood, which was destroyed or removed in consequence of the rapid outpouring of soluble materials and water; but a number of considerations render it probable that such an inference is really correct—at least, in some instances.

In many of those struck down by contagious fever there has been for some time previously imperfect action of the eliminating organs, during which period the blood was acquiring a state favourable to the growth and multiplication of disease-germs. When the excreting organs do not act properly, certain substances, which ought to be eliminated, get reabsorbed by the blood, and then the composition of the circulating fluid becomes altered, and its properties modified. Nor is it astonishing that excrementitious substances, perhaps modified in character, and circulating freely among the most delicate tissues of the body, should derange their action. Sick-headache, certain muscular and nerve pains, aching of the limbs, and the sensation of general discomfort which pervades

every sensitive part of the body (and parts, even, which in health afford us no evidence of their existence), are probably due to the presence of those noxious matters which ought to have been eliminated. Such considerations lead us to a plausible explanation of the influence of methods of treatment, the utility of which has been conclusively proved by experience. Thus, we see how purgatives act beneficially in the early stage of the feverish state; and, of all purgatives, calomel and other mercurial preparations. These promote free action of all the glands which pour their secretions into every part of the alimentary canal, from the mouth to the anus. By this free excretion quantities of peccant substances are removed from the blood which otherwise would have remained there. Similarly we may explain the beneficial action of diuretics and sudorifics, of a course of German waters, of the frequent use of the warm bath and of the Turkish bath in many forms of disease. Those living in cities, taking little exercise, and imbibing the warm air of rooms, will do wisely if they excite artificially the free action of the skin, kidneys, and bowels from time to time. In this way, and by care in eating and drinking, they may keep the body in fair health under disadvantages, and diminish, I believe, to a very great extent, their liability to troublesome febrile attacks, to contagious fevers, and to inflammatory disorders.

(To be continued.)

ECZEMA PALPEBRARUM.

CLINICAL LECTURE DELIVERED AT ST. MARY'S HOSPITAL

By HAYNES WALTON, F.R.C.S.,

Surgeon to the Hospital, and Surgeon in Charge of the Ophthalmic Department.

(Reported by Mr. Moir.)

GENTLEMEN,—This is the most common affection of the eye. It is usually, but incorrectly, called *tinea tarsi* and *ophthalmia tarsi*.

The characteristics are the same as those of eczema of the trunk or of the limbs, a little modified by position, to which are added certain effects arising out of the conformation of the edge of the eyelid, the part of the lid in which the affection is most developed.

The whole thickness of the eyelid with its many textures are involved.

The skin is the texture most palpably implicated. It is inflamed, and there are marked changes in its structure, as well as derangement in its functions. Its sensibility is augmented. It is thickened by serous infiltration, and, as a consequence, is oedematous and sometimes fissured. It exudes at times a serous lymph. Sometimes papules, sometimes vesicles, sometimes pustules, form on it. The commonness of the last entitles the disease to be placed under the pustular form. There is nothing peculiar in this from an ophthalmic point of view, because the pustules prevail in hairy situations. Cuticle, which, thus raised, may be entirely thrown off and replaced by a soft, lardaceous-looking material, which is merely unhealthy cuticle attended by muco-purulent secretion, or by a thick crust formed by the drying of the morbid secretions which are poured out from the skin itself, the Meibomian glands, the cilia follicles, and the conjunctiva—most, or all, of these eruptions may co-exist.

The usual appearance of the disease when we are consulted is that of crusts on the edge of the eyelid by which the cilia are glued together in groups. In children there is usually an overflow of tears, and the cheek is excoriated or roughened.

The subjective symptoms are itching or tingling, but neither of these is well marked in this region, and the patient escapes much torment; or soreness; or stiffness of the eyelid; or a sensation of roughness in the eyeball, or of grit in the eye, which necessitates the eye being kept partially closed; and nearly always agglutination of the eyelids during sleep.

The usual variations in eczema are met with here. The inflammation, or the pimples, or the pustules, or the exudation, or the infiltration may predominate. This includes mildness or severity of such symptoms. Thus, there may be present but the least redness or swelling, with only a little scurf between the cilia; or most of the eczematous features in the fullest intensity.

The upper eyelid suffers more than the under.

The disease may be partial, affecting only a portion of the edge of the lid, or completely occupy it, and involve besides a considerable portion of the rest of the palpebra.

Both eyelids are usually diseased, and of both the eyes.

Effects of Eczema.—Beneath incrustations which adhere to the

cuticle, there is always excoriation from which serum and thin pus exude. The ulceration may be sufficiently deep to destroy much of the skin, and even some of the tarsal cartilage.

The cilia follicles seldom escape damage, from which the cilia grow abortively (and trichiasis is induced) or are lost from suppuration in their follicles.

The fibro-cellular tissue of this situation becomes thickened and dense. This is the chief source of the thickening of the ciliary region, which may be very marked.

The tarsal cartilage becomes thickened and hardened, and contracted from side to side.

The Meibomian glands become altered in function, pour forth a viscid secretion (the chief source of the agglutination of the eyelids), and are ultimately destroyed, and their outlets closed by cicatrisation. Some of them may suppurate.

The conjunctiva undergoes the morbid changes usually produced in it by inflammation.

Entropium may ensue.

Slight ectropium is more common. This is associated with damage to the punctum lacrymale, together with displacement of it and loss of the inner and part of the outer edge of the eyelid, with cuticular degeneration of the surface, by which a glazed red margin is left, constituting what is called lippitudo.

The whole of the palpebral and most of the ocular conjunctiva may inflame.

Intolerance of light may be produced, irrespective of cilia irritating the eyeball.

Eczema is essentially, in the eyelid, a chronic affection, without any specific course, although there are stages or periods of irregularity of the several morbid phenomena. It may last for years, and even for life, with intermission to the more prominent symptoms, all the while spoiling the eyelid more and more. It generally lessens in severity, and may even cease, when the cilia follicles and the Meibomian glands are destroyed.

Cause of Eczema Palpebrarum.—Struma, or poor nutrition, is so frequently an accompaniment of the eczema, that it must be regarded as the remote or predisposing cause. There is frequency of the disease among the children of very poor people. In nearly every case there are evidences of an inherited or an acquired scrofulous constitution. There are enlarged lymphatic glands, or a swollen upper lip, or sore ears, or a tumid belly, or derangement of digestion; or strumous conjunctivitis, or paleness, with looseness of the skin. There are immediate or exciting causes, such as small-pox, measles, scarlet fever, smoke and filth in bad dwellings, impure air.

General Treatment.—I regard the constitutional remedies as the most essential. If the eczematous diathesis be subdued—that is, if the poor nutrition, or the debility from whatever origin, which is the predisposing cause of the affection be removed—the local manifestation of the disease will soon vanish; yet sooner, if assisted by local measures.

The secret of the cure consists, then, essentially in discovering the nature of the debility—whether it be assimilative, nutritive, or nervous—and subduing it. This includes attention to the disordered function of any internal organ. I have known of several severe examples of the affection which have been completely cured by change of residence—and nothing else—from this to a warmer country.

Local Treatment.—In every instance the cilia should be closely cut. Any of them that are irregular or abortive should be plucked from their follicles. For the eczema itself, the remedy must be shaped according to the condition of the eyelid when the patient is seen, subject to the principles of reducing the inflammation, stimulating to a more healthy action the exuding surface, removing accumulated secretions or crusts, and healing excoriations or ulcerations.

When the inflammation is acute rather than chronic, the use of an evaporating lotion to reduce any unnatural heat is advantageous. When it is chronic, warm applications, as fomentations, are preferable. With the reduction of inflammation, the case is materially better.

When the disease is in an early stage, and the surface-accumulation is scanty and of the lighter form (chiefly from serum), and the inflammation is subdued, or where it is so slight as not to be a prominent symptom, stimulation is called for.

Lotions are not applicable, on account of their liability to irritate the conjunctiva and the cornea. Ointments answer better, and they serve the double purpose of enabling the drug to be definitely and persistently applied, while they prevent the eyelids from adhering. They are demanded of varying strengths, according as irritability or sluggishness of the skin prevails; the stronger being for the latter state. They should be applied twice or thrice daily, with a sable brush, after the

part has been cleaned with warm water and Castile soap, and any secretion washed off. The merest smearing of the surface will suffice. After trying various substances, I have settled down to the use of the hydrargyri oxidum rubrum. My weakest formula is one grain of this to a drachm of the unguentum cetacei; my strongest, two grains to the same.

The greater the strength of the ointment, the more sparingly and neatly must it be used, lest it should get within the eyelids and inflame the eye. Should either seem to irritate, it must be used less strong or less often.

When the disease is of old standing, and the incrustations are dense and adherent, being made up of dried pus, epithelium scales, sebaceous matter, carbon and dust from the atmosphere, beneath which there is sure to be excoriation and ulceration, other treatment is needed. The incrustations must be removed without damaging the eyelid. My plan is to keep them oiled with almond oil for a couple of days, and then to sop them for a long time with hot water and a rag until they are sufficiently softened to be wiped off or picked off; oil the lids, and on the following day wash them and dry them thoroughly, and touch all the excoriated or ulcerated parts with nitrate of silver. For years I used strong solutions of this drug, but now I apply it solid, scraping the stick to a point, and touch the parts lightly and definitely, taking the greatest care not to let any of it enter the eye. I keep a piece of blotting-paper at hand to soak up any moisture which may be about the edge of the lid. Should any of the caustic accidentally enter the eye, in spite of all caution, the eye should be very freely washed at once in a basin of tepid water, to relieve the burning. This plan may require to be repeated. An interval of a week at least should be allowed, during which the eyelids should be washed and oiled twice or thrice daily.

From time to time the cilia should be re-cut, or re-plucked.

Or, again, the application of the nitrate of silver is required when there are pustules on the lid, with little or no incrustation.

Any excoriation or roughness of the cheek should be attended to. Eczema palpebrarum will readily yield to the methods which I practise and recommend. Certain damage which may have been inflicted on the cilia follicles is capable of much repair, and tolerably healthy cilia may grow in the place of abortive ones, or of many which have dropped. But many, or all of them, may be destroyed. The Meibomian glands are always more or less destroyed in all prolonged or severe cases of the affection. When treatment is undertaken before the glandular apparatus of the lid suffers, every trace of the disease may be removed.

The injury which the disease inflicts, and which is so apparent, must not be mistaken for the disease itself, or else treatment will be continued when it is unnecessary, and often undertaken when the eczema is cured.

The trichiasis, the entropium, or the ectropium which may be induced, demands special treatment, of which I shall not speak to-day.

ORIGINAL COMMUNICATIONS.

NOTES

ON THE PATHOLOGY OF MALIGNANT NEW GROWTHS.

By HENRY ARNOTT, F.R.C.S.

Assistant-Surgeon to St. Thomas's Hospital, and Joint Lecturer on Morbid Anatomy in the School.

IV. (a)

SARCOMA.

Distinction from Carcinoma—Divided into Spindle-cell, Round- and Oval-cell, and Myeloid Sarcoma, together with Glioma and Psammoma—Spindle-cell Sarcoma.

In the last paper of this series those varieties of carcinoma which have acquired distinct names, as fungus hæmatodes, colloid cancer, and the like, were discussed, but a large number of malignant growths yet remain for consideration, which in their intimate structure are essentially distinct from carcinoma, although generally coupled with it by English Surgeons under the comprehensive title cancer. The most important of these may be divided into two groups—the sarcomata and the epitheliomata—and of these sarcoma claims our first

(a) These remaining "Notes" should have appeared some months back, but their completion was postponed by unavoidable causes.—H. A.

attention, as the more malignant and, from a clinical point of view, the more nearly allied to carcinoma.

It is probable that by far the greater number of "soft cancers" recorded in English publications are really sarcomas; and if we were to limit the term "cancer" to "carcinoma" as anatomically defined in a previous article, we should probably be surprised to find how very rarely true primary medullary cancer is met with by the Surgeon. Nearly all melanotic growths, for instance, and all the primary soft cancers of bone, would probably be more correctly classed with the sarcomata, whilst a fair proportion of "villous cancers," and at least a third of the cancers affecting the uterus and rectum, would find a place amongst the epitheliomata. Allusion has been already made to the clinical importance of recognising these distinctions, and it will be sufficient to repeat here that, although all three varieties of new growth are truly and formidably malignant, they exhibit this property in very different and definite degrees.

Thus sarcoma, although in certain of its forms nearly as prone as carcinoma to infect remote parts, very rarely invades lymphatic glands, and probably seldom appears as a secondary tumour until a comparatively late stage in the disease: hence the greater hope of successful issue of any operation attempted for the removal of a sarcomatous growth, provided that the affected limb be divided at a safe distance from the tumour. Where this is not possible, as in certain cases of mammary sarcoma, although the patient may live for long with no visceral or glandular complications, yet the local growth itself will be very apt to return with great pertinacity; the reason being, that sarcoma is as essentially an infiltrating or tissue-invading growth as carcinoma, and equally difficult to extirpate without a freer use of the knife than is commonly deemed necessary. Mr. De Morgan (b) has suggested a valuable rule for operative interference with these malignant tumours of the limbs. After narrating two cases of sarcoma of the lower limb before the Pathological Society of London last year, he remarked—"Are there any means of diagnosing these sarcomatous tumours from true cancerous encephaloid growths, if such exist? There can be no doubt that in the latter disease amputation should be performed through the joint, not in the continuity of the bone. I do not think it is so necessary in a case of sarcoma. At any rate, I have amputated through the bone in some of these cases without return of the disease after many years." In the same contribution it is suggested that "generally the veins are less defined, and the growth is much more rapid in a sarcoma than in an encephaloid cancer." Whether this last observation is constantly true or not, I have no means of judging, for I confess to having myself very rarely seen primary soft carcinoma of a limb; and as I have seen very many malignant growths in such positions, I am led to believe that primary soft carcinoma of the extremities is seldom met with by Surgeons. In the form of secondary growths in the viscera I know of no distinguishing naked-eye character of sarcoma save the absence of umbilication. Very few carcinomatous nodules, however soft, fail to exhibit more or less dimpling of the surface from contraction of the fibroid stroma upon the cells which, in the centre of the growths, so soon fattily degenerate; but I believe that secondary sarcomatous nodules have usually no such sign distinguishing them. For the rest, these sarcomata vary in consistence from tough, fibrous tissue to a creamy softness, yield to the knife scraping the cut surface an abundant milky juice, blend intimately with surrounding healthy tissues, very rarely being encapsuled, although occasionally shelling out from such a tissue as the lung, as though they were so limited, and in all respects bear the closest resemblance to genuine soft carcinoma.

The main distinctive characters of sarcoma, therefore, are to be sought for solely in the form and arrangement of its microscopic elements; and a sarcoma may be described as a tumour made up of embryonic tissue, which may tend towards development into a perfect tissue. Hence a sarcoma is almost entirely a cellular growth, with more or less of visible intercellular substance, and the cells are usually of a spindle or fusiform type.

Although the prevalence of one form of cell in each tumour is the rule, it is not uncommon to meet with considerable variety in the size and shape of the component cells in a single tumour; and in classifying the sarcomata, therefore, one must have regard rather to the prevailing form of cell than to the exclusive presence of any one form. Thus, one may meet with fine oat-shape, large plump spindle, small or large oval, small round, and huge myeloid cells; and, according to the proportion in which any one of these forms

preponderates, sarcomatous tumours are subdivided into—(1) spindle-cell, (2) round- or oval-cell, and (3) myeloid sarcomata. Besides these general varieties, sarcoma takes a special form, and receives a special name when affecting the neuroglia or fine connective tissue of the nervous system—*Glioma*,—and when springing from the membranes of the brain, and enclosing corpora amyacea and "brain sand"—*Psammoma*. In all these several varieties, however, the one character remains—viz., that the bulk of the tumour is built up of simple cells, bound together by a scanty homogeneous or granular semi-fluid substance. Hence a marked distinction from carcinoma, in which the cells are, as a rule, quite free from any visible intercellular material, and float in the meshes of a fibrous stroma. A further difference is seen in the form of the component cells. It has been already said that the cells of carcinoma are of an epithelial type. Now, cells of this kind are very rarely met with in sarcoma. One does, indeed, occasionally meet with a formidable variety of sarcoma, in which huge angular and many-tailed cells are interspersed with the spindle cells forming the bulk of the tumour; and a scraping of such a growth might readily mislead an observer. But, in the great majority of cases, the cells of sarcoma, when they are not simply elongated and disposed in regular tracts, are plump and round or oval rather than angular, for they are imbedded in a soft fundamental substance, and are so not subjected to the changes of form brought about by mutual pressure in the case of the cell-elements of carcinoma. The semi-solid intercellular substance also accounts for the comparatively scanty juice yielded on scraping any but the softest sarcomas. This juice is also less freely miscible with water than that of carcinoma, the cells cohering in little flakes; and, in examining thin sections, very few detached cells float out into the water or glycerine in which the section is immersed, instead of the large number of cells so detached in carcinoma.

SPINDLE-CELL SARCOMA is by far the most common of all these tumours. Springing from connective tissue, and assuming the form met with in the development of granulation tissue into the fibrous texture of a scar, one meets with considerable differences in the size and appearance of the cells, which may vary from an extremely slender fusiform shape, barely distended in the centre by a small elongated nucleus, to a plump cell with large oval nucleus and delicate tapering extremities. Whichever variety be present, a certain definite arrangement of the cells prevails, their axes being parallel to one another, and broad waving tracts of such parallel cells crossing and recrossing through the tumour. A scraping generally shows sufficiently the type of cell present (see Fig. 12), but viewed in

FIG. 12.

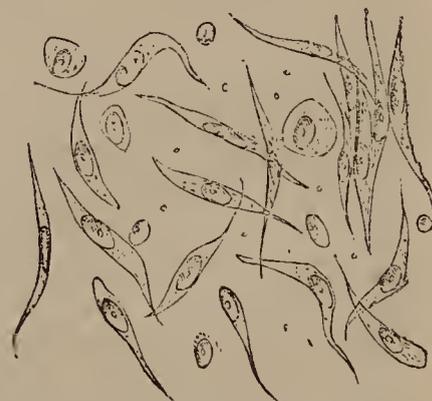

FIG. 12.—Scraping from a spindle-cell sarcoma. Magnified 220 times.

section the shape of the individual cells is by no means always so easily made out. The regular arrangement of oval or elongated nuclei, and the occurrence here and there of patches of apparently small round cells enclosed by these others—in reality similar bands running at right angles to the first, and so cut across transversely—is tolerably suggestive; but at the edges of such a section one may generally see the fine tails bristling out, if indeed there be not a free cell or two showing yet more distinctly their precise form (Fig. 13). In some parts of these tumours the spindle-cell growth gradually passes into ordinary connective or white fibrous tissue, in such a manner as to render it impossible to say whether the spindle-cells are developing into the formed tissue or whether they are themselves derived from this by a retrograde metamorphosis to an embryonic condition. Besides this common admixture of connective tissue, spindle cells usually form the basis of other sarcomatous tumours, occurring in small number, indeed, in the round- and oval-cell growths, but rarely wholly absent. A curious feature of this growth is the tendency shown by its elements to assume a larger, plumper form with each recurrence, and, together with this alteration in the size of the component cells, to exhibit an increased rapidity of growth and proneness to infiltration.

Spindle-cell sarcoma (including, as it does, the tumours long recognised as "fibro-plastic," "recurrent fibroid," "fibro-

cellular," and many of the "medullary sarcomata") exhibits very different degrees of malignancy in different cases, so that

FIG. 13.

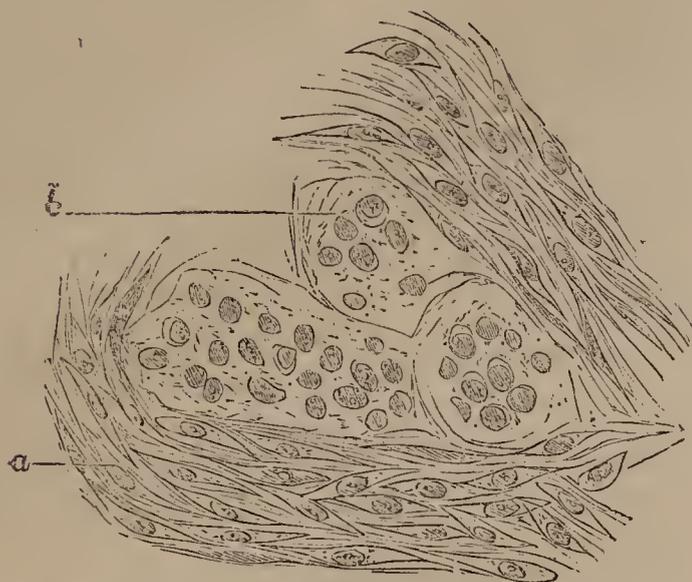

FIG. 13.—Thin section of a spindle-cell sarcoma, showing in the centre groups of similar cells divided transversely.

a prognosis is specially uncertain in the case of this growth. Local recurrence may in almost all cases be predicated where the knife has not gone quite clear of the affected tissues; for this form of tumour, usually described as encapsuled, or spreading only in the connective tissue, occasionally exhibits distinct infiltration of other textures. I have myself seen instances of spindle-cell growth invading muscular tissue, and breaking up the striped fibres in quite as destructive a manner as any carcinoma. Infection of remote parts is also not very uncommon. I have met with spindle-cell growths in the liver, lungs, and mesentery, but such secondary growths are very rarely found in the lymphatic glands.

It is probable that a careful consideration of the microscopic structure offers valuable indications for a prognosis, those tumours being more apt to show true malignancy whose elements are plump and interspersed with large, irregular, and multinucleated cells. Special regard must, of course, be had to the rapidity of the growth, its consistence, and its seat. Where, for instance, the tumour is distinctly encapsuled, and even pedunculated—as in certain fleshy nasal polypi—the prognosis would be infinitely more favourable than where the growth infiltrates a soft, moist part, subjected to constant movement—as I have twice seen it in the uterus, simulating, in all respects, ordinary uterine cancer, and running a similarly fatal course.

(To be continued.)

THE PATHOLOGY AND TREATMENT OF CHOLERA.(a)

By GEORGE JOHNSON, M.D., F.R.C.P.,

Physician to King's College Hospital, Professor of Medicine in King's College, London.

My experience of cholera began during the epidemic of 1849. I had been taught, and I firmly believed, that the main object of treatment in the earlier stages of the disease is to arrest the discharges by opiates and other astringents, in order to prevent that drain of liquid from the blood which was assumed to be the cause of choleraic collapse. Acting upon this theory of the disease, I soon found reason to question its truth. The first case which painfully excited my doubt was that of a woman about 40 years of age, who had what appeared to be a mild attack of choleraic diarrhoea. She had vomiting, purging, and cramps, but she had a warm skin, a good pulse, and no symptoms of collapse. I prescribed five grains of Dover's powder to be taken every hour; and when I saw her again, after three doses had been taken, I found that the vomiting, purging, and cramps had all been abruptly checked by the opium, but, to my dismay, she was in full collapse, and in a few hours she died. These facts appeared to me to be inconsistent with the theory which I had accepted and acted upon. If collapse results from the drain of liquid, it was difficult to understand the occurrence of extreme collapse im-

mediately after the sudden arrest of the discharges. It was years before I obtained the clue to the mystery; but this case greatly excited my interest, and made me watchful and observant of the phenomena of the disease, and in particular of the influence of various and opposite modes of treatment. During the course of that epidemic I had the opportunity of witnessing the effects of two very different modes of treatment in King's College Hospital. At one period all the cases were treated by liberal doses of brandy and opium, and about two-thirds of the cases thus treated died. The treatment was then entirely changed; brandy and opium were discontinued, and unlimited quantities of salt and water were given. The effect of this treatment was to excite frequent vomiting, and certainly not to check, but rather to increase, the purging; yet, under this rough and apparently unscientific treatment, the recoveries were as numerous as the deaths had been under the brandy and opium treatment—about two-thirds of the cases treated by salt and water recovered. The larger proportion of recoveries under this method of treatment was not accounted for by the milder character of the disease—the cases were of equal severity.

In the year 1854, as the Junior Assistant-Physician, I was left in sole charge of the Hospital during nearly the whole period of the epidemic, and I entered upon the work with feelings of anxiety bordering upon dismay. Bearing in mind the results of my experience during the previous epidemic of 1849, I also learnt what I could of the effect of what is called the saline treatment of the late Dr. Stevens, and of the treatment by repeated small doses of calomel with cold water, as recommended and practised by the late Dr. Ayre, of Hull. It is very difficult to make an exact comparison between different modes of treatment, at various times and places, by different Practitioners, but it appeared to me that the results of the saline and the calomel and cold water treatment were decidedly more favourable than the opiate and stimulant treatment. The effect of the salines and the calomel would be rather to encourage than to check the discharges. It might be, so I argued, that the discharges were the means by which a morbid poison is eliminated, and if so, they may be as much an element in the natural process of cure as the cutaneous eruption of the acute exanthemata.

By this train of reasoning I was led to make trial of the treatment by castor oil and cold water, and the results were such as to convince me that, at any rate, we were on the right track. The experience of a very few cases sufficed to show, with unmistakable clearness, that the drain of fluid from the blood, by the discharges from the stomach and bowels, is certainly not the main or essential cause of choleraic collapse. This was proved by the fact that patients who were admitted in collapse, recovered from that condition while profuse discharges by vomiting and purging still continued, and that no recovery from collapse occurred without a continuance of the discharges; while, on the other hand, it was found that a complete arrest of the discharges during collapse is a sign of fatal import.

At that time I knew nothing of the pathology of cholera, and I made some serious practical mistakes, one of the greatest being that of giving a needless amount of medicine. On the whole, however, the results were so satisfactory that I determined to publish the cases in detail. Meanwhile, stimulated to unusual exertion by the unreasoning outcry which had been raised against my practice, I determined to do my utmost to solve the problem of the pathology of cholera. I began to read, and carefully to analyse and annotate, the works of those men who had seen most of the disease, especially in India. I found in the works and reports of the earlier Indian writers on cholera—Scot, Bell, Orton, Twining, Annesley, Christie, Kennedy, etc.—a rich storehouse of facts, and it soon became apparent that these facts were quite irreconcilable with the theory which had gained almost universal acceptance; I mean the theory which explains the collapse of cholera by the discharges from the alimentary canal. By degrees, and by dint of hard work during the winter of 1854-55, I arrived at what I believed to be the true physiological explanation of the phenomena of choleraic collapse, and in the spring of 1855 I published in a volume (on "Epidemic Diarrhoea and Cholera") the results of my labours, with a detailed report of all the cases treated by me during the epidemic of the year preceding. From that time to this I have seen no reason materially to alter my views, either as to the nature of the disease or the principles of treatment.

If I had foreseen to what an extent the publication of my doctrines on the nature and treatment of cholera would involve me in painful, profitless, and time-consuming controversy, I

(a) A paper read at a meeting of the West Kent Medico-Chirurgical Society at Greenwich, January 5, 1872.

am not sure that I should have had the courage to undertake the duty. I have always been thankful to receive candid and unprejudiced criticism, but it is not pleasant to have to defend oneself against such a weapon as deliberate, unscrupulous misrepresentation. This, unfortunately, I have had to do quite recently, as on more than one occasion before. Having once, however, committed myself to this work, I have never felt the slightest inclination to withdraw from it. Moreover, the labour has not been without its reward. The investigation which it has involved has led me to the interesting discovery of hypertrophy of the muscular walls of the minute arteries in many tissues throughout the body; and in this fact to find the explanation of the hypertrophied left ventricle in cases of chronic Bright's disease. (b) In prosecuting these researches, I have had the satisfaction of knowing that I have been working to promote the interests of mankind as well as the credit of my own Profession, which is deeply concerned in the solution of the problem as to the nature and the correct treatment of cholera. While the opposition which I have met with has certainly not been free from prejudice, and has, for the most part, been more noisy than rational or argumentative, I have obtained the public support of men of great eminence, distinguished alike for the extent of their knowledge and the soundness of their judgment. And last, but not least, you, Mr. President and gentlemen, have done me the honour to invite me here to-night to discuss with you the pathology and treatment of cholera.

In the brief history which I have given of the manner in which I was led to take up this question, and to prosecute the inquiry, my main object has been to show that I did not begin by theorising on the subject of cholera; on the contrary, I loyally accepted the current theory, and proceeded to give it a practical application. It was not until I discovered that, when thus applied, it was misleading and mischievous, that I felt bound to examine the grounds upon which the theory was based. I now propose to bring distinctly before you, in the fewest possible words, the main points relating to the pathology and treatment of cholera which I believe to be probably true, and upon each of these points to invite comment and criticism.

Cholera is the result of a material and portable morbid poison, which is capable of being conveyed from place to place and communicated from person to person. The poison may enter the system either with the air through the lungs, or with the food and drink through the alimentary canal. It is probable that the rapid spread of the disease over a limited district is mainly due to atmospheric agency during an epidemic season; it is still more probable—nay, it is certain—that sudden local outbreaks have been caused by the drinking of impure water, and especially of water contaminated by choleraic discharges. Mr. Charles Maenamara, of Calcutta, records the fact that nineteen healthy men, upon one occasion only, drank water with which cholera stools had been mixed. In the course of the next three days five of these men were seized with cholera. At the time of this remarkable occurrence there was no cholera in the neighbourhood, nor had there been for years. The poisonous discharges employed in the performance of this experiment were brought from a distance.

It is probable that, during an epidemic season, water containing fæulent matter, even though not contaminated with the specific choleraic discharges, may communicate the disease directly; or it may act as a predisposing cause, concurring with some unknown specific atmospheric agency.

In connexion with the subject of impure water as the vehicle of the cholera poison, the name of the late Dr. Snow deserves most honourable mention. It is to his persevering efforts, in spite of ridicule and opposition, that we are mainly indebted for our knowledge of this important agency in the causation of cholera.

In whatever way the poison enters the system—whether with the air through the lungs, or with water through the alimentary canal, it is absorbed, and enters the circulation before it gives rise to its characteristic symptoms. The chief facts and arguments upon which is based the doctrine of a blood infection in cholera are these:—

It is a general law of physiology that the absorption of a poison into the circulation precedes the occurrence of the constitutional symptoms to which it gives rise. The cholera poison, if it were not absorbed, would form an exception—and, I believe, the only known exception—to this general law. When the poison enters the system by the lungs, the blood is obviously the only channel by which it can reach the alimentary canal. In like manner, when the fœtus in utero (as has fre-

quently happened) is found to have been infected by cholera, its intestines containing the characteristic rice-water fluid, it is obvious that the morbid poison must have traversed the blood of both the mother and the fœtus before it could reach the alimentary canal of the latter. There is usually an interval, varying from one to three or four days, between the absorption of the poison and the onset of the characteristic symptoms. During this period of incubation there is, in some cases, a general feeling of *malaise* and depression—the result, probably, of blood-poisoning and a consequent disturbing influence upon the nervous system. It would be a very interesting point to determine whether, as is highly probable, there is a febrile elevation of temperature during this initiatory stage of the disease.

In a large proportion of cases, not only of collapse, but of choleraic diarrhoea, the urine which is first passed after the height of the disease is over is found to be albuminous. This affords the same kind of evidence of blood-poisoning as is afforded by the same symptom in cases of diphtheria, scarlatina, and other diseases which are unquestionably associated with a specific blood-poison.

Lastly, the most probable explanation of the formidable symptoms which have often followed the abrupt arrest of the choleraic discharges by opium is that the poison, being thus retained within the circulation, had caused the collapse or the fever, as the case may be.

The discharges from the alimentary canal are the means by which the poison and its products are expelled from the system. In this respect they are analogous to the eruption of small-pox and the intestinal discharges of enteric fever. That the discharges in a certain stage of decomposition do contain a specific poison, is conclusively proved by such experiments as that of Mr. Maenamara, before referred to; and the doctrine is implied in the practice of disinfecting the cholera stools, the importance of which is almost universally acknowledged.

The discharges, when abundant, are obviously a source of great exhaustion, and they may be so copious as to kill; but that they are neither the sole nor the chief cause of choleraic collapse, is evident from the following considerations:—They bear no direct relation to the degree of collapse; in the worst class of cases an inverse relation appears to prevail. Collapse and death may occur without discharges, and with but a scanty secretion into the alimentary canal; while, on the other hand, recovery from collapse is always associated with a continuance of the discharges, which gradually cease as reaction occurs. The state of collapse is evidently different from that of mere exhaustion by profuse discharges; it has often been relieved by venesection, which would certainly aggravate a state of mere exhaustion; on the other hand, it is not beneficially influenced by the remedies for exhaustion—such as alcoholic stimulants, for instance. The onset of collapse has often been too sudden to be satisfactorily explained by exhausting discharges; and recovery from extreme collapse is sometimes so rapid as to form a striking contrast with the necessarily slow recovery from the exhausting effects of profuse discharges. Neither the amount of the discharges nor the rapidity with which they are poured out affords a satisfactory explanation of the state of collapse, which, as I have said, gradually diminishes and passes away, while the liquid flux continues until reaction has been established.

Dr. Edward Goodeve admits that symptoms similar to those of collapse may result from poisons without purging. He says: "I have seen people under the influence of the malarious poison, in Calcutta, lie for hours as cold and pulseless, and as embarrassed in the breathing, as in cholera." (Reynolds's "System of Medicine," vol. i., p. 712, second edition.)

There is reason to believe that *the main and essential cause of choleraic collapse is an impeded flow of blood through the lungs, and a consequent defective circulation throughout the whole system.*

The proofs of this impediment *during life* are—1st. The comparative emptiness of the systemic arteries; the pulse being small and feeble, or even imperceptible, at the wrist. 2nd. The fullness of the systemic veins and the consequent lividity of the surface. *After death*, anatomical evidence of impeded circulation is found in the condition of the heart and lungs. The left side of the heart is empty, or nearly so, while the right cavities of the heart, the pulmonary artery, and the large systemic veins are distended; the lungs are anæmic, light in weight, and either dark- or light-coloured, according to the presence or absence of a retrograde passive engorgement of the bronchial veins and capillaries.

When collapse has been very prolonged, the lungs may be œdematous, a result of serous exudation from the passively engorged bronchial capillaries.

The hæmorrhagic spots commonly seen beneath the peri-

(b) See *British Medical Journal*, April 16, 1870.

cardium and the pleura are analogous results of engorged systemic veins and capillaries. Similar hæmorrhagic spots are often found in cases of valvular disease of the heart; and these, again, are similar to the ecchymoses beneath the skin and conjunctiva which sometimes occur during an epileptic fit.

The most complete and accurate record of the post-mortem appearances is that contained in the fourth volume of the London Hospital Reports.

The only probable explanation of the arrest of the circulation during collapse is that which refers it to contraction of the minute pulmonary arteries excited by the poisoned blood. A similar arrest of the circulation occurs in cases of acute apnoea. The anatomical condition of the heart and lungs after death from sudden suffocation is identical with that which is found in cases of choleraic collapse. So, during a severe fit of spasmodic asthma a state of collapse occurs very similar to the collapse of cholera. The main difference between choleraic and asthmatic collapse consists in this—that in asthma there is a primary apnoea, the result of bronchial spasm, and a secondary asphyxia or pulselessness, consequent on contraction of the minute pulmonary arteries; on the other hand, in cholera collapse there is a primary asphyxia and a secondary apnoea, consequent on the arrest of the circulation.

The rapidity and the duration of arterial contraction in different diseases vary exceedingly, from the sudden spasm of the cerebral arteries, which is now generally believed to be the immediate cause of an epileptic fit, to the persistent contraction of the minute systemic arteries, which results in hypertrophy of their walls, and causes the hypertrophy of the left ventricle in cases of chronic Bright's disease.

It is evident that an impeded flow of blood through the lungs does explain the phenomena of collapse.

I have references to several cases of embolism of the pulmonary artery, the symptoms of which have borne a striking resemblance to those of the collapse stage of cholera. The most completely recorded case of this kind is one published by Dr. Alfred Carpenter (*Lancet*, September 23, 1871). In that case, as Dr. Carpenter remarks, "the only symptoms wanting to make it apparently one of cholera were alvine discharges and cramps in the limbs." The symptoms actually noted were blueness of the surface, icy coldness of the uncovered parts of the body, cold clammy perspiration, coldness of the breath, sinking of the eyes, feebleness of the voice, a feeble thready pulse, with quick breathing, excessive thirst, and almost complete suppression of urine (two ounces of urine only being passed one day, and on another day less than two ounces). (c)

(c) Reference may be made to the following cases in which fibrinous plugs in the pulmonary artery caused symptoms of collapse:—A case briefly mentioned in my "Notes on Cholera," p. 54; one recorded by Dr. Martyn (*Pathological Trans.*, vol. xvi., p. 71); another by the same author (*Obstetrical Trans.*, vol. x., p. 266); one by Dr. Playfair (*Obstetrical Trans.*, vol. x., p. 23); and a case by Mr. Worley (*British Medical Journal*, May, 1870, p. 459).

(To be continued.)

NOTES ON AN INSTANCE OF THE
CO-EXISTENCE OF THE
EPICONDYLOID AND EPITROCHLEAR
FORAMINA IN THE HUMAN SUBJECT;

AND THE PERSISTENCE OF THESE FORAMINA IN THE MAMMALIA.

By J. BESWICK PERRIN,

Demonstrator of Anatomy at King's College, London.

In a female subject, age 95, recently (a) dissected at the Royal College of Surgeons, I met with a specimen of the epitrochlear foramen co-existing with an epicondyloid foramen (Fig. 1). Professor Flower, with his characteristic liberality and kindness, has allowed me to describe this specimen; (b) also to examine the extensive collection of skeletons of the mammalia contained in the Hunterian Museum, with the view of determining the persistence of one or both of these foramina.

Both of these foramina were absent on the right side of the female subject above mentioned. The epicondyloid foramen was partly formed by bone and partly by ligamentous tissue (Fig. 1, *Ep CF*). The bony part consisted of a well-developed conoid-shaped process, which projected downwards and inwards from the inner border of the humerus, about half an inch above the inner condyle. From the summit of the process a small tendinous arch stretched to the inner condyle, joining there the internal intermuscular septum which formed the posterior wall of the canal leading to the osseo-tendinous foramen. The pronator radii teres took its origin from the bony process and the tendinous arch. The median nerve and the radial artery passed through it, the latter being given off from the brachial opposite the middle of the humerus. This arrangement closely accords with some instances met with by Professor Gruber, of St. Petersburg, except that the radial is substituted for the ulnar artery. The latter eminent observer has already placed on record no less than forty-seven instances in which the epicondyloid foramen was present in the human subject. This is the only specimen, however, which I have met with in the human subject, although I have carefully examined all that have come under my notice in the dissecting-room for several years, as well as every accessible skeleton. Professor Wood's large dissecting-room experience coincides with that of my own, that the epicondyloid foramen is of rare occurrence in the human subject of this country. As regards the epicondyloid foramen co-existing with a high division of the brachial artery, the foramen is decidedly the exception, and not the rule. I have oftentimes met with a high division of the artery, but in no instance, except the prementioned, has it been accompanied by an epicondyloid process or foramen. (c)

(a) April Examinations, 1871.

(b) Now in the Museum collection.

(c) This foramen has been described by Dr. Knox, "Great Artists and Anatomists"; by Professor Struthers, *Lancet*, 1863; and by Mr. Mivart, *Transactions of the Philosophical Society*, 1867.

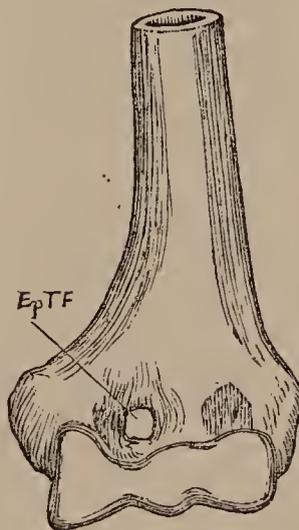

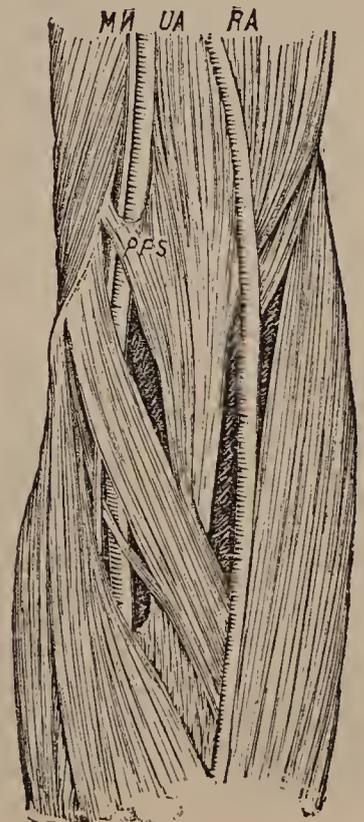

FIG. 4.

Explanation of Figures.

FIG. 1.—Lower end of left humerus, female, aged 95. *Ep TF*, epitrochlear foramen; *Ep CF*, epicondyloid foramen; *RA* (radial artery), *MN* (median nerve), passing through the foramen.

FIG. 2.—Humerus of Wombat (after Flower), showing epicondyloid foramen.

FIG. 3.—Lower end of left humerus of gorilla (male), showing epitrochlear hole.

FIG. 4.—Left arm of female subject, aged 19. *PPS*, an abnormal additional slip of origin of the pronator longus, perforated by the ulnar artery (*UA*) and median nerve (*MN*).

Figs. 1 and 3 Professor Flower kindly allowed to be drawn from the specimens.

Besides the epicondyloid foramen, there was on the same (left) side only a well-marked epitrochlear foramen.

More recently, in a female subject, aged 19, I met with a very interesting specimen which throws much light on the metamorphosis which this foramen undergoes between an entirely osseous foramen on the one hand, and its complete abortion on the other. The pronator radii teres was normal so far as its humero-condyloid and its ulnar coronoid attachments were concerned. It had, however, associated with it a strong muscular slip (Fig. 4, *PPS*) arising from the internal humeral inter-muscular septum, about a quarter of an inch above the large and ordinary condyloid pronator origin. This slip was entirely muscular, about an inch wide at its origin, separated from the pronator longus by an areolar interval. It gradually tapered to its termination, where it joined the middle of the condyloid head of the pronator longus on its upper aspect. This supracondyloid pronator addition was perforated at its base by the ulnar artery and median nerve (Fig. 4, *UA, MN*), the former arising from the brachial opposite the coraco-brachialis insertion (exactly simulating the specimen already described). Below this point the artery and nerve preserved their average arrangements—namely, the nerve passing between the condylo-coronoid heads of the pronator, and the artery behind both. This specimen I consider to be an important link between the completely osseous epicondyloid canal, and an almost aborted one as exemplified by merely muscular perforation. It has, also, an additional interest in bearing out the views of Professor Busk, that the epicondyloid process gives increased attachment to the pronator longus. It was present on the left side only. In the same arm there was an inverted palmaris longus. The right arm was normal in every respect.

Wishing to find out whether one or both of these foramina were present in the humeri of skeletons of the ancient Britons, dug up from the cromlechs or barrows, I wrote to my friend, Mr. Lukis—the venerable and experienced Guernsey archæologist, whose collection, and personal knowledge, of everything pertaining to the ancient past, derived from the abundant materials which the Channel Islands have afforded him, are second to none in the United Kingdom (d)—for information on this point. He informed me that perforations of both human and mammalian bones were common enough; but, as a rule, these were artificially made, for the purpose of passing a string through, so that they could be worn round the neck as amulets. Mr. Lukis, however, forwarded me a sketch, copied from one in his collection, of a savage warrior with an inverted humerus suspended to his neck, the string passing through a foramen exactly in the position of the epitrochlear foramen. Whether this is artificial or not, it is difficult to say; but the fact is very suggestive, even if the foramen is artificial, inasmuch as it may readily be surmised that the shrewd minds of the aborigines of this or other countries were not slow to avail themselves of the ideas which they derived from the isolated instances of perforated humeri presented to them. What, indeed, could be a more emblematical trophy than a human bone? and what could be so little an encumbrance with equal effect? and, providing that the bone had done its duty as a trophy, by a transition of ideas it may be readily imagined that the possessor preserved it as an amulet. In the celebrated Bateman collection, Dr. Barnard Davis informs me that there is not a single specimen of perforated humerus.

It would seem, then, that the presence of an epicondyloid process in the humerus of the human subject is of rare occurrence, and the existence of a complete osseous epicondyloid foramen still more so. But the co-existence of an epicondyloid and epitrochlear foramen in the same individual is a condition less frequently met with than either of the preceding. The epitrochlear foramen exists in about 12 per cent. of the human skeletons which I have examined. (e) In those specimens in which this foramen was present the ulnar proximal processes were in no way better developed than in those in which the foramen was wanting. Again, the foramen is not always equal when present on the two sides; neither does it always exist on the

(d) Mr. Lukis' collection of flint implements, etc., and other curiosities of the aborigines of the Channel Islands, Brittany, etc., would alone amply repay a visit to Guernsey—that is, to anyone interested in these matters.

(e) According to Professor Busk, quoted in Darwin's "Descent of Man," page 28, "Professor Broca noticed this perforation in $4\frac{1}{2}$ per cent. of the arm-bones collected in the Cimetière du Sud, at Paris; and in the Grotto of Orrony, the contents of which are referred to the Bronze period, as many as eight out of thirty-two were perforated. M. Dupont found 30 per cent. in the caves of the Valley of the Lesse belonging to the Reindeer period. M. Lequay observed 25 per cent. perforated in a sort of dolmen at Argenteuil. M. Pruner-Bey found 26 per cent. in bones from Vauréal. The latter state that it is common in Guanche skeletons."

two sides of the same subject—e.g., in the skeleton of the female Boschisman in the Hunterian Museum it is present on the left side only, while in a native male Polynesian skeleton it was present on both sides, but much larger on the left than on the right side. Now, it is very singular that this condition should almost exactly correspond with that which prevails amongst the gorillas. In the three skeletons of the gorilla in the Hunterian Museum the epitrochlear foramen is present only on the left side, being very large and circular. The minute perforation on the right side can scarcely be called a foramen, corresponding more in character with that of a nutritious canal than a decided epitrochlear foramen. Of the five skeletons of the chimpanzee it was entirely wanting in three; present, but small, on both sides in one, and only on the right side in the other. In the silvery gibbon (*Hylobates luciscus*) it was present on the right side only, and small; while in the *Hylobates lar* it was wanting on both sides. Of four specimens of the orang (*Pithecius satyrus*) the epitrochlear foramen was present in three on both sides; in the fourth skeleton—a young female—it was wanting on both sides. In the skeletons of the old-world monkeys the prevailing disposition is the absence of the epitrochlear foramen. It is present on the left side only, and very small, in the sacred monkey of the Hindoos (*semnopithecus entellus*). In the *colobus velerosus*, on the right side, small; proboscis monkey, right side. In two skeletons of the pig-tailed monkey it was present in one, and only on the right side. In four specimens of the short-tailed monkey it was present, but small, on both sides in one; in another on the right side only; and in the remaining two it was wanting. In the skeletons of the following monkeys in the Hunterian collection the epitrochlear foramen is wanting:—The *cercopithecus*, *cercopithecus ruber*, *macacus*, negro monkey (*lagotherix Humboldtii*), Siamang or Unqa ape, pig-tailed monkey (*macacus menestrimus*), bonuet monkey (*macacus radiatus*), and three specimens of the mandril (*papio mormen*). And the following new-world monkeys:—The red howling monkey (*myectes ceniculus*); four specimens of the marmoset (*hapale jacchus*); two specimens of the spider monkey (*ateles arachnoides*, et *ateles paniscus*); the white-bodied spider monkey (*marimonda*); and the awantibo.

In some instances the epitrochlear foramen is found co-existing with the epicondyloid foramen—e.g., in the squirrel monkey (male) *callithrix sciureus*, on the left side there is an epitrochlear foramen. (f) Besides the epitrochlear, there is an external and internal epicondyloid aperture on the right side; on the left side the radial epicondyloid foramen is wanting. In the female of the same species there is, on both sides, an epicondyloid and an epitrochlear foramen. In one of the two skeletons of the slender lemur (4633) there is a corresponding condition to the above-described, also in the galeopithecus and cebus. This peculiarity is met with again in the ichneumon (*mangusta ichneumon*) in which both foramina, epitrochlear and epicondyloid, are found; and in the wombat (*phascotomys vombatus*). In the Virginian opossum the epitrochlear is present on the left side only, and the epicondyloid on both sides.

We find the epitrochlear foramen next amongst the dog-like carnivora; it exists on both sides in the following:—The *proteltes cristatus*, Italian greyhound, St. Bernard's dog, Newfoundland, Esquimaux dog, dingo, Arctic wolf (on right side larger than on left), common fox, and long-eared fox. It is also present on both sides in the civet (*viverra civetta*). In the French bloodhound and badger the foramen is wanting.

Amongst the ruminants it is found in the musk-deer (*moschus moschiferus*) on both sides. In the female and male napu chevrotain (*moschus napu*), in the Javan chevrotain (*traquillus Javanicus*), and in the meminna chevrotain (*moschus meminna*), on both sides, but small. Amongst the ungulate the epitrochlear foramen is found in the white-lipped peccary (*dicotyles labiatus*), the collared peccary (*dicotyles torquatus*), the Indian wild boar, and the wild boar. In one specimen of the wild boar, this epitrochlear foramen was wanting on both sides. It exists on both sides in the *hyrax dorsalis* and *hyrax Capensis*.

In the capybara, the porcupines, crested and crestless, the coypu, the paca, the acouchy, the viscacha, chinchilla, guinea-pig, jerboa, and occasionally in the rabbits and hares, amongst rodents, it is present on both sides.

In the Virginian opossum (*didelphis Virginiana*) the epitrochlear foramen is present on the left side only.

The epicondyloid foramen is not generally found in the higher quadrumana. It is wanting in the gorilla, chimpanzee, orang, etc., etc. It is present only in the following monkeys

(f) On the right side of this specimen (4666) the ligaments are left, so it is impossible to say whether the foramen is present on that side or not.

(excepting those prementioned where the two foramina coexist simultaneously):—the douroucouli, the pithecia monachus, potto, Tarsier, Capuchin monkey, grand galago, and aye-aye.

It is more persistent among the lemurs, being present in the black- and white-fronted lemurs, the indri, the slender and ruffled lemurs, and galeopithecus—in the last-mentioned co-existing with an epitrochlear as already described.

Amongst the carnivora it is present in the cheetah, wild cat (three specimens), tiger, lion, Indian tiger, luricate (*ryzana tetradactyla*), racoons, *coati mundi*, badger, ailurus, Javanese skunk, pine marten, sable, ermine (male and female), kinkajou weasels, Alpine polecat, otters, genet (or young *paradoxurus*), and *paradoxurus typus*, binturong, sea otter, common and harp seals on both sides. In the musang, or palm civet, an epicondyloid perforation exists on the outer side of the humerus only; there is no ento-epicondyloid foramen. It is wanting in the black, polar, and sloth bears, and in the elephant and saw-toothed seals.

Passing over the ruminants, etc., comprising the zebu, *nahura Argali*, Nepaul goat, sheep, Saiga antelope, four-horned antelope, gazelle, goat, padu deer, roe, fallow-deer, reindeer, fawn, African chevrotain, vigugna, young pigmy chevrotain, llama, paco, wart hog, ass, zebra, equus, it is not met with in a single specimen. The *sirenia* and *cetacea* have not a vestige of any perforation.

It is large and well developed amongst some of the sloths—*e.g.*, the two-toed (*cholæpus didactylus*), and in the armadillos (*chlamyphorus truncatus*—the nine-banded), and the great armadillos (both sides and large), *tutusa hybrida*, weasel-headed armadillo (*dasyurus sexcinctus*), the Tamandua ant-eater (*myrmecophaga Tamandua*), great ant-eater (*myrmecophaga jubata*), the Cape ant-eater (*orycteropus Capensis*), *manis longicaudata* and *pentadactyla*, Siberian marmot (very small), great squirrel of Malabar, and common squirrel, Cape jumping hare, and Australian brown-footed water rat (in the latter animal it is present on both sides, but small). It is wanting in the following:—Flying squirrels, Australian water rats, white-footed rats, great Cape mole rats, Norway rat, black rat, beaver, *spigurus insidiosus*, hares, and rabbits. In one specimen of the hare, the epitrochlear foramen was present on both sides.

In the Alpine marmot the epicondyloid foramen is present on the left side only. In the *eyclothuris didactylus* the epicondyloid perforation occupies the middle of the outer border of the shaft of the humerus.

In the thylacine (two specimens) the epicondyloid foramen is present on both sides.

In the true and great kangaroos it is wanting. In the ursine *dasyurus* it is present on the left side only. In the long-tailed *dasyurus* it is wanting. In the *phoscogale flavipes* it is present on both sides, also in the banded *myrmecobius* and *bandicoot*; in a skeleton of a species of *didelphis*, Virginian opossum, Cook's phalanger, long-tailed petaurist, and koala. In the flying opossum there was only an epicondyloid process, as in the female human subject already described. In the following animals the epicondyloid foramen is present on both sides, namely:—Rat-tailed potoroo, rat kangaroo, Bennett's kangaroo, vulpine phalanger, echidna, platypus, and mole.

Inferences to be deducted from the foregoing.

1. That the epicondyloid foramen is, as a rule, peculiar to the lower monkeys, the carnivores, etc. Its presence in the human subject is strange.

2. That the epitrochlear foramen, though occasionally found in the higher quadrumana and man, yet its existence in these animals is evidently nothing more than accidental tracings of a bygone condition. This view is strengthened by the fact that in the two specimens of the lower types of human individuals it is present exactly as in the gorilla. It is not present in the skeletons of the chimpanzees in the Hunterian Museum; but on examining some of the bones belonging to the separate series, the epitrochlear foramen was present in one (5083 D) on the left side only (female chimpanzee), and in another specimen on both sides; the left perforation being; however, much larger than on the right side. In the humeri of five other specimens there was not a trace of this epitrochlear foramen.

It is also subjected to irregularity in the gibbons (*vide* before) in the separate series. The epitrochlear hole was present on both sides in one, and wanting in two others.

In the humeri of three orangs in the separate series the epitrochlear hole was present in one, and only on the left side. My object in this paper is simply to give an account of the variations which these foramina exhibit in the mammalian skeletons contained in the Hunterian Museum. Professor Flower's admirable work on osteology contains a thorough and

accurate description of the bones of all the mammalia. It has not been the intention of that author to describe irregular, but average osteology, and in that he has more than amply succeeded. (g)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

ANEURISM OF POPLITEAL ARTERY—FAILURE OF PRESSURE—CURED BY LIGATURE OF FEMORAL.

(Under the care of Mr. WOOD.)

[FOR notes of the following case we are indebted to Mr. Roche.]
JOSEPH D., aged 26, bootmaker, admitted June 22. Has been in present occupation eight years, and has been accustomed to sit for several hours a day on a low stool, with the legs acutely flexed upon the thighs, and having a boot (upon which he was working) fixed between the knees. His health has always been good. The swelling in the popliteal space, for which he is admitted, came gradually; first noticed it shortly before Christmas, 1870, when it was about the size of a bean. He felt it beating, but suffered no pain nor inconvenience in walking. The swelling slowly increased till three months ago, when it had reached its present size. About that time the calf began to swell, and there was numbness of the leg, and any long walk caused a feeling of weakness in it. Only one month ago actual pain was felt, and only within the last week has there been serious difficulty in walking. On admission a pulsating tumour about the size of a Tangerine orange was observed. It was abrupt in its upper outline, while below it shaded off more gradually. The tendon of the semi-tendinosus crossed over it internally. It was very tense, and the impulse very marked, ceasing on compression of the femoral artery, when the sac became flaccid. There was one inch difference in the circumferential measurements of the two knees, while the calf of the affected leg measured two inches more than the other. The veins of the affected leg were noticed to be more conspicuous than those of the other, and there was slight œdema over the tibia. No sensible difference in the pulsations of the posterior tibial arteries was observed.

June 26.—Pressure applied to the femoral artery by means of a Signoroni's tourniquet fitted with double compressors. The patient only bore it for one hour.

28th.—Pressure applied for four hours and a half.

29th.—Pressure applied for two hours.

July 1.—Pressure applied for three hours.

2nd.—Pressure applied for four hours. The patient suffers considerable pain from the use of the tourniquet.

3rd.—A broad strip of washleather, spread with soap plaster, was applied along the course of the artery, which gave a better surface for pressure, the pads slipping less when once adjusted. Compression about four hours and a half.

4th.—Compression for six hours and three-quarters.

5th.—Compression for eight hours. The tumour feels firmer. The patient can bear the pressure much better since the washleather was put on.

8th.—The patient manages the compression himself—alternating the pressure. He averages nine hours a day. Ice-bags applied to the tumour, but discontinued on account of the pain produced.

10th.—Compression eleven hours.

20th.—Compression on an average ten hours daily. The tumour feels firmer, and a cure appeared very probable.

21st.—In the evening it was noticed that a portion of the tumour was more prominent, and the pulsation was felt to be increased. The tumour had evidently at one point forced itself through a split in the fascia. The skin over this point was of a dark colour.

22nd.—Patient was placed under chloroform, and the artery rapidly ligatured. Mr. Wood pointed out the very slight disturbance to which he had subjected the tissues, and, having washed out the wound with a solution of chloride of zinc to

(g) It is a great pity that this admirable book is not introduced into all the schools as the text-book on osteology for Medical students, rather than the mere reviews of human bones described in books on human osteology. The latter are good so far as they go, but the student ought to know something more than human osteology; in fact, he cannot know the latter without some knowledge of the osteology of mammals generally.

stop oozing, brought the edges of the wound carefully together with three sutures; pads were placed on each side of the wound, and over all a carbolic putty poultice.

23rd.—Leg wrapped in cotton-wool. Toes warm. Slight pulsation in sac. Dressing not disturbed.

24th.—Wound has healed in nearly its whole extent by the first intention. There is some tenderness of the glands below Poupart's ligament. Slight redness over the painful part. Wound dressed with unguentum simplex. Poultice over painful spot.

26th.—Pain and redness increased, and there is slight swelling. Wound healthy.

29th.—On pressure, about three ounces of healthy pus made its way by the track of the ligature, and the patient was much relieved. Toes warm.

31st.—Pain, swelling, and tenderness have quite subsided. A little pus by the side of the ligature. Sac firmer and diminished in size.

August 4.—Ligature came away without any traction. An oozing of pus in its track.

9th.—The sinus left by the ligature does not heal rapidly. Granulation flabby. Nitrate of silver applied.

14th.—The sac is less. The knee cannot be straightened, any attempt to extend it being attended by pain. The tendon of the semi-tendinosus stretches very tightly across the sac.

21st.—The sac is diminishing and getting firmer. The leg can be extended better. There is some difficulty in healing the sinus left by the ligature.

September 13.—The wound perfectly healed, and the leg, having been gradually straightened, the patient was this day discharged, walking with a stick. Had the patient been able to extend the leg, he might have been discharged three weeks ago.

LONDON HOSPITAL.

DISEASE OF SPINAL COLUMN—PRÆVERTERBAL ABSCESS—PRESSURE ON TRACHEA—TRACHEOTOMY WITHOUT RELIEF.

(Under the care of Dr. RAMSKILL.)

[Reported by Mr. STEPHEN MACKENZIE, Resident Medical Officer.]

W. S., AGED 6. When the child was brought to the Hospital, it appeared to be dying of suffocation. It was gasping for breath, and the epigastrium and intercostal space were greatly retracted at each inspiration. The sister who accompanied the child stated that it had had an injury to its spine, that it had had a wheezing at the chest for the last few days, and that there were no other children ill in the house, or, that she knew of, in the neighbourhood.

As the child was evidently dying from air being unable to enter the chest, tracheotomy was quickly and skilfully performed by Mr. Arthur Moore, the House-Surgeon. When the trachea had been opened, and a tube introduced, it was still found that air did not enter the chest properly. The child breathed a little better when the tube was removed and the edges of the tracheal opening were held open, but even then but little air entered. Previous to the operation, the intercostal muscles did not act at all, and it is doubtful if they did at all after it. The diaphragm acted very powerfully. The patient survived the operation about an hour.

The mother subsequently stated that about a year previously the child had fallen and injured its spine. It had been under treatment at the Orthopaedic Hospital and elsewhere for this ever since. It wore a deal board down the back as a support. It had had attacks of difficulty of breathing for the last fortnight, and these had been more severe the last few days.

The autopsy was made on the following day by Mr. McCarthy. The body was well nourished. There was a large abscess with very thick walls extending from the seventh cervical to about the tenth dorsal vertebræ. Secondary sacs had developed just above the bifurcation of the trachea. There was extensive absorption of the bodies of the upper dorsal vertebræ. One was completely absorbed, and the spinal canal opened into thereby. There was lymph on the anterior surface of the dura mater, and extreme congestion of corresponding part of pia mater. The lungs were emphysematous, and there were patches of collapse at the bases. The left kidney was much congested, and contained a calculus. The incision in the trachea where tracheotomy had been performed was just below the isthmus of the thyroid gland. The left subclavian artery was given off from the innominate, and crossed the trachea but very little below the incision.

SUDDEN DEATH FROM FATTY AND DILATED HEART.

W. H., aged 45, was brought dead to the Hospital. At the inquest it was elicited that the patient went out in search of work on the morning of his death, to all appearances in his usual health. During a shower of rain he took shelter in the lobby of a coffee-house. Whilst there he was seen to fall. When picked up he was insensible, and died on his way to the Hospital.

Autopsy.—Body spare; rigor mortis but slightly marked. Heart: The aortic valves were incompetent, and contained plates of calcareous matter; other valves healthy. Mitral orifice admitted the tips of four fingers; tricuspid orifice, the tips of five fingers. The left ventricle was dilated, its walls slightly thicker than natural; the muscle was soft and not contracted. Right ventricle dilated. The whole of the muscle of the heart was soft, but it did not appear to the naked eye to be fatty. Under the microscope, however, the transverse striæ were in many parts obliterated, whilst in other parts, though the striæ were distinct, fatty granules could be seen running in a linear form along the muscular fibrillæ. The pleuræ were much thickened, and the lungs emphysematous throughout. The kidneys were of moderate size, and their surfaces very granular, and studded with numerous cysts; the cortical substance was diminished. The capsules of liver and spleen were thickened, and the latter organ very small. Dura mater thickened and adherent to the bone. The arachnoid was thickened, the convolutions of brain wasted, and there were cysts in the choroid plexuses.

SATURDAY, JANUARY 13, 1872.

PRACTICAL HISTOLOGY.

THERE have been few subjects on which nonsense has been more persistently buzzed about of late than on the practical teaching of physiology. The authorities at the College of Surgeons very properly passed a resolution enforcing attendance on a course of practical physiology on all students entering the Profession after a given date. But they refused to give any definition of what they considered a proper course of practical physiology, and so each teacher was left to his own devices and to the advice which was so lavishly bestowed on him by those most ignorant of the practical wants of the student.

In conducting a class of practical physiology, it is quite plain that a portion of the course must consist of demonstrations given by the teacher, and that part ought to be committed to the hands of the student under due supervision. It has been found difficult to tell where the one should begin and the other end; but there has been to our minds one clear rule for general guidance, and it is this: students are sent to us to

make them fit to practise the Profession whereby they are to earn their bread. We are not expected to turn out *savants*. The period assigned for the study of this arduous Profession is rarely over three years, and in this time they have to learn everything relating to it, of which physiology constitutes but a small part. It is, therefore, more important to teach men how to learn for themselves than to try to teach them everything. Throughout the course of study a practical end should ever be held in view; and to spend time in teaching men how to perform elaborate experiments with expensive mechanism is to waste time.

In a course of practical physiology, putting for the moment applied physics on one side, there are two great divisions—histology and physiological chemistry. Neither should be allowed to usurp the place of the other, but, as far as possible, each should occupy a due proportion of the student's time, though it is of one only we now desire to speak. Practical histology is one of the most important branches of Medical education, but it is just one of those which may readily be carried too far, and may easily be converted into a pursuit rather than into a subservient study. A well-thought-out scheme of study must therefore be of the greatest importance to both teachers and taught, but especially to those who are striving to educate themselves after having acquired the smattering which was wont to be taught in many schools. Such a scheme from the well-skilled pen of Professor Rutherford appears in the present number of the *Quarterly Journal of Microscopical Science*. This journal, under the editorship of Dr. Frank Payne, of St. Thomas's Hospital, has just sprung into new life, and the present number contains so much valuable matter, especially to the student, that we strongly counsel him to make himself the possessor of it as speedily as possible.(a)

The two articles to which we now especially refer are that by Professor Rutherford, already alluded to, and one by the editor, on "Students' Microscopes." In the latter Dr. Payne gives a tabular comparison between the microscopes of the various English and the chief Continental makers which are likely to be available for students. Now, on this subject we confess to have very strong opinions—perhaps prejudices. Our rule, both in working and in teaching, is to study simplicity. Now, with one of the larger microscopes of British make—models of solidity, strength, and finish—it takes so long to get to work that with one of simpler construction it is possible to finish an observation before, with the other, one would be ready to begin. Our favourite instrument is a little thing of Hartnack's, which costs but three pounds, and almost resembles a toy, but to whose character we can testify as an efficient and, in every respect, reliable instrument. To this class Dr. Payne does not allude—the Hartnack he refers to is larger, and has two eyepieces; but for ordinary work we can confidently recommend the smaller model. And it has this advantage: with a tall English microscope one requires to incline the tube at an angle, to study with comfort. This implies an inclined stage, and, if one is working with wet preparations, the fluid surrounding them—serum, salt solution, or what not—is apt to run; but these are so short that one may sit at the table and work with comfort, having all the time a level stage. They have no joint; and, should the illumination most readily available be unsuited for an upright microscope, an inclined plain, with a socket for the foot made of heavy wood, may be got for very little.

A word or two more on the subject of Professor Rutherford's "notes" and we have done. It would be hardly possible to epitomise the paper here, seeing that it is already as condensed as may be; so that we are fain to refer the reader to the article

itself. In it he will find directions for a complete course of microscopical study, so far as histology is concerned; and we are bound to say that the course is neither too diffuse nor too contracted—it fairly meets the wants of the student. And though in some respects this course does not correspond with that we are wont to adopt, we are content to let it pass without criticism, only trusting that it may be generally followed.

COMPARATIVE ANATOMY AS A MODE OF FORCE.

THE rarity in our columns of a paper bearing on Comparative Anatomy has forcibly suggested itself to us on looking over Mr. Perrin's article in our present issue; indeed, there is not a single branch of Medical education which is so inadequately taught as Comparative Anatomy. The greater the importance which this sublime science attains to in the minds of the general public, and the more eager those outside the Profession are to acquire a thorough knowledge of this subject, the more it is ignored by the Profession. As if a teacher had the power of working miracles, he is expected to embody all that a student is required, not to know—but to hear—in a three months' course. The result is simply that Comparative Anatomy is the most disregarded of all the branches of a student's education. While the history of man is tottering upon the brink of a revolution founded upon this science—while the whole educated world are studying the many admirable works readily comprehended with a little labour—the Medical Profession seem to attach less importance to its study than ever. Our old forefathers in the Profession disgrace us in this respect. They had a profound love for Comparative Anatomy; they resorted to it as a pastime—a pleasure, fraught with the deepest interest. But what discoveries resulted from working in this prolific field even then? What has resulted since it has been more extensively worked by earnest-minded men, from the time of the foundation of the Jardin des Plantes under the bold genius of Buffon and his gifted assistant Daubenton, to those of our own time—Owen, Goodsir, Huxley, Darwin, Flower, Haughton, Turner, Rolleston, Humphreys, and many others in this country, not to mention the vast labours of Continental naturalists? It has become the mistress of all sciences, because it embodies the intimate world of living beings which are playing their parts in each and every sphere of existence. By the knowledge already accumulated, old ideas are being rapidly swept away; the position in nature of man is no longer a mysterious problem. Till now an unknown quantity, it has been—in the opinion of many—resolved at last. Is it not, therefore, imperative that the cultivation of this science should occupy a more prominent part in the Medical student's education? Is it not high time that the threadbare and time-worn method of teaching exclusively human anatomy should become a thing of the past; that the long-discovered human and comparative study should be united and taught as one great whole? The significant facts long ago promulgated as *usus naturæ*, of variations occurring in almost every human subject—extensively worked out by Professors Wood, Turner, Macalister, and others—find explanation only in animals lower in the scale than man. They tell their own tale of the urgent necessity which there is for students to devote more time to the cultivation of Comparative Anatomy. The time wasted in descriptive lectures on bones—which even a second year's student is compelled to attend, although supposed to know his bones as well as his A, B, C—could be much better employed; nay, the bones of the whole of the vertebrata could be taught and learned in the time that it now takes to dawdle through a course of lectures on human bones alone. The present method of teaching Anatomy to the student is like building a house by beginning with the roof. If the student could attend a course of theoretical and practical instruction on the invertebrata during his first summer

(a) *The Quarterly Journal of Microscopical Science*. Edited by Joseph Frank Payne, M.B. Oxon., B.Sc. Lond., Fellow of Magdalen College, Oxford, Assistant-Physician to and Lecturer on Morbid Anatomy at St. Thomas's Hospital; and E. Ray Lankester, B.A. Oxon., F.R.M.S. London: J. & A. Churchill. Price 4s. January, 1872.

(and let the summer be his commencement of study), and then during his first winter attend a regular course of practical demonstrations on the vertebrata, from a fish to man, he would acquire a basis then worth considering as such. In the meantime, rather than let his first essay be a crude attempt at dissecting a human being, let him first thoroughly master the anatomy of the fish, then the bird, then a dog, then a monkey; and he would be in a better position to understand the anatomy of the human being. But the present method is a relic of a muddled past; it is much like the old way of teaching a language—a few years' cramming of grammar before any knowledge of the materials which the grammar governs!

HEALTH OF THE NAVY.

(Concluded.)

ON the home station the proportion of admissions from primary syphilis was 42·1; from secondary syphilis 12·8; from gonorrhœa, stricture, and orchitis, 55·5 per 1000, giving a total from venereal diseases of 110·4 per 1000. Compared with the preceding year, there was an increase in the ratio from primary syphilis to the extent of 5·0, and from gonorrhœa of 7·3 per 1000; and a reduction of 3·1 per 1000 from secondary syphilis. It is observed that probably some amount of this increase may be referred to the numerous obstacles that have been thrown in the way of the efficient working of the Contagious Diseases Act. The ratio per 1000 constantly sick, from primary and secondary syphilis, was 5·6, and from gonorrhœa 1·9 per 1000. The average duration of each case of primary syphilis was about thirty-seven days, and of secondary syphilis about forty-one days. It is observed that the majority of the cases were contracted in places to which the action of the Contagious Diseases Act does not extend, and that the Medical officers, without exception, bear testimony to the value of legislation in this direction, and, as a rule, advocate its extension. Deputy Inspector-General Domville, C.B., of the Royal Naval Hospital, Chatham, states "that although an increase in the number of admissions from primary syphilis, as compared with 1868, occurred at that station, it is attributable to increase in the number of men, consequent on the transfer of the Woolwich Division to Chatham; and that comparison with the numbers admitted during the four previous years shows a marked improvement." Staff-Surgeon W. T. Wilson, of the *Duke of Wellington*, expresses the opinion that the arrangement of the Lock wards of the Landport Hospital is defective, both as regards the treatment and examination of the patients, and that the rule of assigning two Lock wards to each of the Medical officers of the Hospital did not appear to him to conduce to the efficiency or discipline of the establishment. Surgeon T. Haran, of the *Pembroke*, states that the cases of syphilis and gonorrhœa under treatment in that ship were furnished by protected towns, as compared with the unprotected, in the proportion of 15 to 14—an anomaly which he explains by observing that prostitutes moving from unprotected places very often succeed in communicating disease in quick succession to several persons before they are detected. Men also contracting disease in unprotected places, extend it in a similar manner; the only remedy for such a state of affairs being, in Mr. Haran's opinion, the application of the provisions of the Act to every town in the United Kingdom. Staff-Surgeon Lilburne, of the *Sheerness Reserve*, remarks that, "as a rule, the disease contracted in Sheerness was of a more tractable character than formerly, being more amenable to treatment."

The highest proportions of admissions from venereal diseases occurred on the China and Pacific stations; at the former, primary and secondary syphilis respectively caused the admission of 91·4 and 47·4, and at the latter 75·9 and 42·4 per 1000 of the strength. The admissions from gonorrhœa and allied affections on the two stations were respectively 93·6 and 63·9 per 1000.

These rates, as compared with those observed during the preceding year, show a reduction in syphilitic disease of 9·1 per 1000 on the China station, attributable, in great measure, to the preventive system adopted at Hong-Kong, and at Yokohama in Japan; while, on the other hand, there was a great increase in this class of disease on the Pacific station, consequent upon more extensive intercourse with Valparaiso, which is a perfect hotbed of disease, no system of surveillance whatever being in existence there. With reference to the results of the preventive system in force at Hong-Kong, there appears to be some difference of opinion among the Medical officers who visited the port. Staff-Surgeon A. Watson, M.D., of the *Galatca*, attributes the great decrease in the number of venereal complaints, when contrasted with his former experience whilst serving on that station, some twelve years previously, to the fact of the Contagious Diseases Act having for several years past been rigidly enforced by the Colonial Surgeon. He also mentions the facility and efficiency with which that Medical officer, with instruments invented by himself, can accomplish vaginal introspection. On the other hand, Surgeon D. Wilson, of the *Juno*, reports Hong-Kong as being still a hotbed of venereal disease, and of the very worst kind. He considers the police regulations for prostitutes to be insufficient, and, in most cases, incapable of being carried out against the women who are diseased. He states, also, that at Yokohama, and other Japanese ports, venereal disease is very rife, notwithstanding the regulations enforced by the Japanese authorities to prevent its spread. Dr. John Breakey, Surgeon of the *Scrapis*, is an advocate of general inspections of the men, as a means of detecting disease, as also of inducing the men to apply for treatment during its early stages. He inclines to the opinion that the examinations are not offensive to the men, and says that during two years only one man objected, and that, when examined, he was found to be suffering from gonorrhœa.

Although it is generally admitted that, as respects intemperance, the habits of both sailors and soldiers have of late years considerably improved, Dr. Balfour, in his recent paper before the Statistical Society, has shown that delirium tremens is more frequent among sailors than soldiers. It is a significant and far from gratifying fact that in the Report before us we find it stated that, of the forty-two cases of this degrading form of disease on the home station of the navy, six, or 14 per cent. occurred among commissioned officers. Considering the proportion of officers to men, this preponderance among them of self-induced disease is very striking. The Army Returns do not include the diseases of officers, consequently no comparison can be instituted on this point between the two services.

For the first time, the Statistical Report of the Navy contains separate returns of the marine force stationed on shore. There are considerable difficulties in collecting correct information as to the prevalence of disease among the marines. Some of these are, we believe, attributable to the peculiar nature of the service. The arrivals of marines from foreign stations in varying states of health are very frequent. Those who are in bad health are placed in one of the naval Hospitals, and the others get a furlough in proportion to their length of service abroad. At the expiration of six weeks the sick men are transferred to the books of the nearest battalion, although still in Hospital; and it may so happen, and, indeed, frequently does happen, that they die or are finally discharged without having ever actually joined the battalion on shore. Such a system cannot but complicate and obscure the vital statistics of the force. In the Army Returns, as we understand, the sickness of invalids from foreign stations is entirely excluded from the statistical records of troops serving at home, their invaliding and mortality being entered to the charge of the stations at which the diseases have been contracted. In this manner only can a fair estimate be formed of the relative health of troops serving at home and abroad. The report of each marine

battalion in the volume before us is given separately, and without any uniformity of plan; it is, therefore, only after the expenditure of some trouble and time that one can effect a comparison between any two battalions. We would suggest that, with this object in view, the returns of the marine force serving on shore should be compiled in a tabular form. That this plan would considerably facilitate investigation, and afford means of comparison between the various corps of marines, as well as with troops of the line, will be apparent from the two following tables which we have constructed, showing the comparative prevalence of diseases of the circulatory system and venereal diseases among the two bodies during 1869:—

Diseases of the Circulatory System.

	Ratio per 1000.			Total loss per 1000.
	Admitted.	Died.	Invalided.	
Royal Marine Artillery—				
Eastney, Portsmouth	51.5	2.57	24.45	27.02
Royal Artillery in the United Kingdom	13.9	3.16	7.20	10.36
Royal Marine Light Infantry—				
Forton, Portsmouth... ..	23.6	...	8.52	8.52
Plymouth	34.061	.61
Chatham	30.0	1.33	10.86	12.19
Infantry of Line in the United Kingdom	12.3	1.17	4.47	5.64

Primary Venereal Sores.

	Ratio per 1000 admitted.		
	Royal Marine Artillery, Eastney.	Royal Marine Light Infantry, Forton.	Troops of the Line.
Portsmouth	102	110	62
Plymouth ...	—	85	74
Chatham ...	—	74	41

The remarkable excess of admissions and invaliding, from diseases of the circulatory system, among the Royal Marine Artillery at Eastney, appears to call for investigation and explanation. Staff-Surgeon Jenkins, M.D., C.B., the author of the Report on the Royal Marine Artillery, considers the causes of the greater prevalence of certain classes of disease under three heads—labour, dress, and prostitution. But it appears to us that, however great may be the effect of such influences, they are by no means peculiar to the Royal Marine Artillery and quite fail to account for the results given in the above tables. There can, however, be no doubt that the addition of the diseases of invalids from abroad must have had a considerable share in increasing the apparent amount of disease among the various corps of Marines.

The system of weekly returns of sickness and mortality, which has been in force in the army—both at home and abroad—since 1859, has, we believe, been found to act admirably, and we would strongly urge its adoption by the Medical Director-General of the Navy, among the Marine force at home. We would also advise that in the Naval Returns there should be less divergence from the new nomenclature of disease. We observe, for instance, that diseases of the eye, ear, and nose are included with those of the nervous system and special senses; that diseases of the urinary and generative systems are massed together, and that no distinction is made between gonorrhœal epididymitis and orchitis from other causes; that delirium tremens is returned among unclassified diseases, instead of among the results of poison; also that there is no classification of wounds and injuries, as accidental, self-inflicted, homicidal, etc.; that in one instance, at least, hanging is returned as a cause of death, without mention as to whether it was judicial or suicidal; and that Surgical operations do not appear under a distinct heading as causes of admission to Hospital.

We regret being compelled, by want of space, merely to allude to some of the excellent reports by individual Medical officers, particularly those of the Marine divisions, dockyards, naval Hospitals, the Asylum at Great Yarmouth, and the notes and statistics relating to the boys under training for the Royal Navy in 1870.

THE WEEK.

TOPICS OF THE DAY.

THE convalescence of the Prince of Wales may be said to be now established. His Royal Highness has been able to change his apartment, and weekly bulletins are now substituted by his Medical advisers for daily. The statement which appeared in this journal last week—that the local affection which has retarded the Prince's recovery was "the result of the protracted *decubitus*, and of the long stages of exhaustion and debility through which his Royal Highness has passed"—was made on very high authority, and was presented to us with evidence which left no reasonable doubt as to its truth. We have seen that a contradiction has been given to it in some of the daily papers, but on what authority has not been stated. One morning paper "understands" that there is no foundation for the statement; another writes of it as an unjustifiable invention, although it had just stated that the Prince's local affection was believed by his attendants to be the result of pressure, which is what we said. And here we would emphatically disclaim any intention of throwing a shadow of a doubt on the excellence of the nursing in the Prince's case. We are certain that everything which affection and loyalty could prompt, and art accomplish, was done. The inference we drew last week, however, is a just one—that if all the care and skill bestowed on his Royal Highness could not shield him entirely from this sequel of fever, the occurrence of the same sequel in other cases should not be made the ground of complaint, as it often has been against Medical men and nurses.

The scheme for a Conjoint Board between the Royal Colleges of Physicians and Surgeons and the four Universities, to which we adverted last week, is the same in its general features as that on which we remarked last year. The cumbrous and unnecessary machinery of a Committee of Reference for the nomination of examiners is retained. The fee for the conjoined diplomas is to be not less than thirty guineas, to be paid in two or more payments; and students who have matriculated at the English Universities, and have been examined at their Universities in the subjects of the primary examination or examinations, will only have to pass the final examination, and to pay a fee of five guineas, which, however, will not entitle them to the Licence of the Royal College of Physicians or the Membership of the Royal College of Surgeons. To obtain either or both of these diplomas, twenty-five guineas more must be paid. It is unnecessary again to point out that this scheme is open to all the objections of being a partial one, that it systematically excludes the general Practitioner from taking any part in the examination of his own class, and that, so long as the Acts of 1815 and 1858 are in force, it will utterly fail of erecting one portal to the Profession in England.

At the Comitia Majora of the Royal College of Physicians, held on Wednesday last, the opinion of Sir Roundell Palmer, Mr. Denman, and Mr. Bevir was read in favour of the legality of the scheme for the Conjoint Examinations submitted to them by the Royal Colleges. It is understood that the Royal College of Surgeons will have to make some alteration in its by-laws in order to carry out the provisions of the scheme.

The discussion which the ill-advised Medical Declaration on Alcohol has raised continues in the columns of the *Times*. It was begun by Mr. Skey and Dr. Risdon Bennett, and it has been maintained by Mr. Skey, Dr. Bree (of Colchester), Dr. Forbes Winslow, Dr. Wilks, and Dr. Lionel Beale. The editor of the *Times* very properly heads the discussion with the old question of "Who shall decide when Doctors disagree?" The history of the Declaration has yet to be written. Dr. Burrows has assured Dr. Bree that he was asked to sign it, but that he does not know how the other signatures were obtained. Elsewhere we have seen that it was produced, on the instigation of an official of a temperance association, by the editor of a Medical contemporary. We should think that the Medical Profession are

obliged to these gentlemen for the mire through which they are being dragged. Not only does the Declaration itself give countenance to an untrue and undeserved libel on the Medical Profession, but it holds up our differences of opinion before the gaze of an amused public, and justifies the keenest satires that have ever been launched at the fallacies of Physic. When will the Medical Profession learn the respect due to itself in its corporate existence? When will its members learn that the columns of a public newspaper are the last place in which their controversies should be aired? One of the latest and most striking outcomes of this unlucky Declaration is, that a proposal is afloat, and several thousands of pounds have been collected, for the erection of a new Hospital, where patients in acute disease are to be treated without alcohol. The Profession, we presume, is to be divided into "Œnopathists" and "Œnophobists," and the great art and science of healing to be made the arena for the combined forces of a new quackery and an old fanaticism.

By the retirement of Dr. Goodfellow, one of the Physicians to the Middlesex Hospital, there is a vacancy for an Assistant-Physician.

DR. DALRYMPLE, M.P.

DR. DALRYMPLE, M.P., has failed to obtain a hearing at an open meeting of his constituents at Bath. Dr. Dalrymple has been at the pains and expense of travelling to America to obtain information respecting the best means of curing habitual drunkards of a vice akin to insanity; and, notwithstanding the unexceptionable character of his motives, he returns to his native land only to find himself a victim to the alcoholic element. The constituency of Bath seem to think that one who, from purely philanthropic motives, endeavours to rescue his fellow-creatures from the effects of a miserable habit, partly by a compulsory system of cure and partly by facilitating their own desire to enter an asylum where they may be removed from the temptation of their besetting sin, is, if not an enemy to his species, at all events a destroyer of the "vested interests" of those who profit by inciting to such a state of bondage. Such a spirit might be readily characterised, but its condemnation is too obvious to require any further notice. The publican interest at Bath will not, it is to be hoped, have the honour, at the next general election, of unseating a very useful Member and a liberal-minded philanthropist.

Apropos of the subject of drunkenness, at a quarterly meeting of the magistrates of the borough of Liverpool, the Chairman of the Watch Committee stated that there were in that town ninety-five public-houses, the resort of thieves, prostitutes, and disorderly characters. The names and addresses of the occupiers were, together with instructions for the abatement of such houses, in the hands of certain discreet and intelligent officers of police, who would for the future use every possible means to ascertain whether they could not be brought under the law. Mr. Still, one of the magistrates, said that Liverpool contrasted unfavourably in respect of drunkenness with other towns. There were 14,000 persons charged with drunkenness taken up and incarcerated in the cells of the Liverpool Bridewell in the course of a year; but, as the bulk of them were dismissed upon becoming sober by the head constable, without being brought before the magistrates, no record of their having been there appeared. Mr. R. Gladstone, another magistrate, wished that publicity should be given to the numbers discharged, so that the extent of the evil might be seen, and the facts better known; and, for that purpose, he had come to the determination, individually, to attend at the various gaols on Sunday, during some part of the day, for the purpose of releasing those who had come under the denomination of drunkards, but who had not been guilty of any other breach of the law; and he should endeavour to obtain a

list of the names and addresses of the persons so apprehended, and who thus contributed to the heavy taxation to which the ratepayers were liable, with a view to their publication, and thus see whether they could not lessen the evil of which they complained. Either they were dealing with a grievous evil, or not; either they were sincere and anxious to put down drunkenness, or they were not. He professed to be sincere, and would test his sincerity by doing what he proposed. Other magistrates thought Mr. Gladstone's suggestion a good one, and some proposed to follow him in that course. Mr. Robertson Gladstone is a brother of the Premier.

ROYAL COLLEGE OF SURGEONS.

WE hear with a regret in which many will share that Mr. Partridge and Mr. Adams are so ill as to be unable to take part in the examinations commencing this day (Saturday); and owing to the vacancy occasioned by the retirement of Mr. E. Cock, the number of members of the Court will thus be reduced to seven. The candidates are much in excess of those in the corresponding period last year. We just learn that the illness of Mr. Partridge is causing great uneasiness.

M. LIEBREICH.

M. LIEBREICH has been to Paris to see M. Thiers's eyes. According to a telegram, M. Liebreich states there is no cause for uneasiness. We hope that our skilful *confrère* will enable the President to see his way to the settlement of the French political difficulties.

A FALSE ECONOMY.

DISSATISFACTION has been felt by a section of the Hackney Vestry with the resolution passed by the District Board of Works in favour of increasing the salary of Dr. Tripe, Medical Officer of Health for the parish, and a discussion on the subject took place at the last meeting of the former Board. Strange as it may appear, after the important services rendered by Dr. Tripe, after the public acknowledgment of those services, and the saving of the rates by his energetic conduct in reference to the last epidemic, the liberal Vestry of Hackney passed the following resolution, by a majority of 26 to 22. Anything more inconsequent than such conduct, and shabbier on the part of a public body, it is impossible to conceive:—"That, considering the high rates in the parish of Hackney, this Vestry views with regret and alarm the continued increase of official salaries by the District Board of Works. In particular, they think the increase recently voted to the Medical Officer of the Board has been determined upon too hastily, and without sufficient inquiry, and they request the said Board to suspend the increase till further information can be obtained as to the duties, emoluments, and stipends of the Medical Officers of Health in other metropolitan parishes."

THE CORONER'S COURT.

THE agitation against the coroner's court continues, and at Salford has assumed a very serious aspect. How far the determination of the magistrates to override, as it were, the duties of the coroner may be practicable remains to be seen. Some legislative proceedings must be taken, we believe, before the magistrates will be empowered to determine what are and what are not suitable cases for a coronatorial investigation. However this may be, on Monday last the Salford magistrates had submitted to them a report, drawing the attention of the Court to the holding of unnecessary inquests, and giving notice to coroners that, in future, such cases will be investigated with a view of recommending the Court to disallow payment for inquisitions which in the opinion of the Committee had been held unnecessarily. It is contended that, unless there be reasonable ground for suspicion that the deceased came to his death by violent and unnatural means, there is no

occasion, except in the case of a person dying in gaol, for the interference of the coroner. We venture to say that the dictum of the magistrates would be overruled by an application to the Court of Queen's Bench. The function of the coroner is much more extensive than the Salford magnates seem to believe.

AN UNHEALTHY SCHOOL.

THAT able and indefatigable public Medical Officer, Dr. Liddle, of Whitechapel, has had his attention directed to the condition of the Roman Catholic Schools at Hammersmith. He reports that the building is wholly unfitted for the purpose to which it is applied, and that the arrangements made for the accommodation of the children are altogether inadequate. The health of the inmates has consequently suffered to a considerable extent, and we are glad to find that several Boards of Guardians who have sent their children there to be educated have determined to remove them without delay. A public supervision of many private schools would, we doubt not, be attended with most beneficial results.

THE WOMEN MEDICAL STUDENTS.

ON Monday the University Court of Edinburgh considered the proposals in reference to the Medical education of women. The Court rejected the proposals, on the ground that two of them involved action beyond the power of the Court, and that the third involved the question of graduation, which the Court did not feel competent to decide. The Court is nevertheless desirous to remove as far as possible any present obstacle in the way of a complete Medical education being given to women, provided that Medical instruction to women be given to strictly separate classes. If the present applicants could be content to seek the examination of women by the University for certificates of proficiency in Medicine such as are granted by the London University, instead of for University degrees, the Court thinks that arrangements for accomplishing this object would be within the powers given to it by Act of Parliament, and would consider any arrangement which might be submitted to it. The University Court is evidently in a difficulty, and proposes a solution which will satisfy neither party.

PRESENTATION TO DR. TURNBULL.

ON Friday last an interesting ceremony took place at the Huddersfield Royal Infirmary, on the occasion of a presentation to Dr. Turnbull of a splendid testimonial, as an evidence of the high esteem in which that gentleman was held by the subscribers. The testimonial consisted of a timepiece, épergne, and salver. The timepiece is of black marble, with external silver pillars and fittings, and surmounted by a representation of the Good Samaritan, in oxidised silver. The épergne, which was decorated with fruit and flowers for the occasion, is of solid silver, seventeen inches in height, and beautifully chased. The salver is twenty inches in diameter. There was a very large and influential gathering of the subscribers, and Mr. J. C. Laycock, President of the Institution, was in the chair. The presentation was made, accompanied by a neat speech from the chairman, and acknowledged, in a very eloquent speech, by Dr. Turnbull.

"THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE."

THE proprietors of this ably conducted journal have, in accordance with an intention which they have long had under consideration, altered their arrangements, so that the journal shall appear for the future as a monthly, instead of a quarterly publication, under the name of the *Dublin Journal of Medical Science*. The first number in the new form is now before us, and bids fair to preserve the character it has maintained since its commencement in 1832. The editorship is still in the hands of Dr. James Little, who has conducted the

journal for the last three or four years. The present number contains "Notes on the Treatment of Small-pox," by Dr. Stokes, which, during the present prevalence of that disease, will be found of much value, particularly the remarks on the employment of local means—such as poultices for the exclusion of air; the maintenance of a moist state of surface, and the lessening of local irritation, as a means of preventing pitting; the influence of local depletion, in some cases, in modifying or even aborting the pustular eruption; and the beneficial effect of the warm bath, as recommended by Hebra. Dr. Stokes states that no danger attends the employment of the bath, and in asthenic cases stimulants can be freely used. In the Vienna Hospital, patients have been kept continuously in the bath for 100 hours with good effect. The Reviews and Bibliographical Notices of Works on the Diseases of Children will convey much information to the busy Practitioner who has not leisure to study the original works. Dr. George H. Kidd contributes an erudite and practical "Half-yearly Report on Obstetric Medicine and Surgery"; and the number closes with a report of the proceedings of the Dublin Obstetrical Society, containing Dr. Kidd's opening address as President, and two papers on "Transfusion," by the Drs. Kingland, junior and senior, the great intrinsic value of which is materially increased by the subsequent discussion, in which the ingenious and effective method of transfusion devised by Dr. Robert McDonnell was fully explained by that gentleman, and commented on by several others. We wish the *Dublin Journal of Medical Science* a continuance and increase, during the new and many following years, of the success which under its previous name and form it had already attained.

THE ROYAL INFIRMARY, LIVERPOOL.

AT the annual meeting of the trustees of the Liverpool Royal Infirmary, held on Monday, the 8th inst., the law which limited the term of service of the Physicians and Surgeons to twenty-one years was so altered as to admit of their continuing in office until the age of 65.

SMALL-POX JOTTINGS.

TEN new cases of small-pox in the Medical relief district of Islington were reported during last week; there were no deaths from the disease during the week.—In the past five weeks there have been in St. Pancras twenty-three deaths from the disease.—In Chelsea, during the last three weeks, three deaths from small-pox have occurred.—At Belfast, last week, fifty-four small-pox cases had entered the workhouse Hospital, against fifteen discharged. Throughout the town generally the disease has prevailed, and amongst the upper as well as the lower classes the deaths by it have been numerous.—The small-pox epidemic rages in Edinburgh with undiminished virulence.—Ten persons from Bradbury were summoned at the Stockton County Sessions for neglecting to have their children vaccinated. Most of the parties belong to the Anti-Vaccination League; six of them were, however, fined, one in 20s. and costs, and five in 10s. and costs, the other six summonses were withdrawn on paying costs, the parties promising to comply with the law at once.—The small-pox epidemic still prevails in Aberdeen to a somewhat alarming extent. The accommodation at the Infirmary is quite occupied. December, as compared with November, showed a large increase of cases in the town, but it is hoped the epidemic is now at its worst.—Small-pox is very prevalent in the New Brompton district, Chatham. Several cases have already occurred in the families of some of the women employed in the spinning department of the Dockyard, and orders have been issued that the whole of the women and girls are to be vaccinated.—Nine deaths are reported to have occurred in the Poplar Union last week from small-pox, and eight new cases brought under notice. There were at that time seventeen small-pox patients under treatment

in North-street Infirmary.—It was reported that at Homerton the Vaccination Act did not appear to be any better enforced now than formerly, for a great part of the cases admitted to that Hospital were found to be unvaccinated persons.—In the Limehouse district twelve deaths had occurred from small-pox during the past four weeks, and ten fresh cases had been reported.—At Berlin, from the 3rd to 4th inst., thirty-seven persons took the small-pox, and twenty-one died.—At Plymouth, in consequence of the spread of small-pox, the South Devon Hotel has been prepared for the reception of patients. This was opened on Saturday last, and fourteen persons suffering from the disease were taken into it. There are altogether twenty-five beds; thirteen new cases are reported, and three deaths.—Small-pox is on the increase in Dublin; upwards of twenty telegraph clerks are suffering from the disease. An application has been made to the Lord Mayor, and a deputation to the Lord Lieutenant, to procure the unoccupied portion of Grangegorman Prison, for the purpose of a home for convalescent small-pox cases.—Thirty-one deaths from small-pox occurred at Wolverhampton during last week, which is a decrease of four on the previous week.—At Milton-next-Sittingbourne small-pox continues to increase. The infected district is in close and constant communication with Chatham and Sheerness. There is no building in the town capable of being adapted for a Hospital for the sick.—There are some cases of the disease at Sittingbourne, but no fresh cases have occurred in the past few days.—In the Holborn district Dr. Gibbons reported to the Board, on Monday, that twelve fresh cases of small-pox had occurred in the district since their last meeting, three of the patients being unvaccinated. Eleven were removed to the Hampstead Small-pox Hospital.—Ninety-one deaths from small-pox occurred in the metropolis last week, against ninety-seven the week before.—It is stated on authority that at present there are 600 cases of small-pox at Halifax.—Charles Washington Nye, of Chatham, was fined 20s. and costs by the Rochester magistrates, on Tuesday, for about the sixth time, for neglecting to have his child vaccinated. Mr. Buchanan, who prosecuted, said Nye always went to prison, and his family were sustained by the Anti-Vaccination Society. It was, however, very necessary for the guardians to attend to this matter now, as he would be afraid to say how many people were suffering from small-pox in New Brompton, which is within the district.—Dr. Aldis, of St. George's, Hanover-square, reported two cases of small-pox—one of a child, aged 2, vaccinated in the inwards, removed to the Hospital; the other vaccinated in the outwards.—Small-pox has been steadily increasing in Scotland during the last four months. The last monthly report of the Scottish Registrar-General states that in the eight principal towns there occurred 47 deaths from small-pox in September, 88 in October, 157 in November, and 354 in December. The small-pox deaths for the month, therefore, constituted 11.4 per cent. of the total mortality. In Dundee 38.8 per cent. of the deaths arose from this disease, which was especially fatal in the Lochce district; in Leith, 31 per cent.; in Edinburgh, 17.3; in Aberdeen, 7.6; in Perth, 7.1; and in Glasgow, 1.6 per cent.; while in Paisley and Greenock no deaths from that disease were registered. Thus it will be observed that the disease has been most prevalent in the towns on the east coast of Scotland.

VITAL STATISTICS OF QUEENSLAND, 1870.

THE Registrar-General of Queensland has just issued a volume which almost bears comparison even with the reports of the United Kingdom. It is an able and exhaustive document, and is creditable to the public officer who has issued it. From an immense amount of information contained in it, we select the following facts, which are interesting as showing the vital progress of a colony which one day promises to be amongst the foremost of the "jewels of the British crown":—The popula-

tion of the colony on December 13, 1870, was estimated, after careful consideration, at 115,567, of which 69,629 were males and 45,938 females, showing an increase over 1869 of 5670 persons, or 3058 males and 2612 females. The total number of deaths in 1870 was 1645, or 1060 males and 585 females. Compared with the deaths in 1869—viz., 1761—this gives an absolute decrease of 116. Of these, 416 died of zymotic diseases, 188 of constitutional diseases, 539 of local diseases, 246 of developmental diseases, 212 from violence, and 44 from unascertained causes.

FROM ABROAD.—SPECTRUM ANALYSIS APPLIED TO PRACTICAL MEDICINE.

DR. WATERMAN recently delivered an admirable address before the New York Academy of Medicine upon "Spectral Analysis applied to the Practice of Medicine." It has since been published in the *Medical Record*, and we make a few extracts. Speaking of the minuteness to which the analysis can be carried, Dr. Waterman supplies the following illustration:—

"One word regarding the extraordinary delicacy of the spectrum test, which far surpasses every other test previously known to us. To give you an idea of its sensitiveness, let us take one pound of common salt, and divide it into 500,000 parts. One of these minute atoms of matter is called a milligramme. The experienced chemist is enabled to weigh such a minute particle only with the most delicate scales and with extraordinary care and acquired dexterity. But with this performance he has arrived at the limits of possibilities. And now let us divide again one of these minute particles into 3,000,000 parts, and we obtain an atom of matter so minute that the human mind is unable to form any conception of it. Yet we can demonstrate its presence by the spectrum test with the utmost certainty and ease. The dusting of a book in the remotest corner of this room will immediately cause the sodium to dart forth with its brilliant yellow line, and thus reveal the presence of this metal. This delicacy of reaction is not confined to sodium. Lithium gives a reaction with a $\frac{1}{1000000}$ th part of a milligramme; strontium with a $\frac{1}{100000}$ th part of a milligramme. In the ash of a cigar moistened with hydrochloric acid and held in a flame we obtain simultaneously the spectra of sodium, potassium, lithium, caesium, rubidium, and calcium."

Dr. Waterman pursues the subject of the spectrum analysis of the blood at considerable length, and, after detailing some of the properties of hæmato-crystalline or hæmo-globine, goes on to say,—

"The possibility to measure the vital force is certainly a matter of the greatest importance. True we can measure the temperature, count the pulse, and by practice learn to appreciate its oscillations, its volume, and other peculiarities. But are the pulse and thermometer absolutely reliable? What experienced Physician has not witnessed in inflammatory conditions—such, *i.e.*, as peritonitis, meningitis, and others—a compressed, small, wiry pulse, which would lead the unwary to administer stimulants to the imminent danger of the patient, when after a moderate abstraction of blood the pulse would quickly rise to great strength. Let us confess that we are often in doubt whether a case is truly the result of anæmia or otherwise, forcing us to temporise when the fleeting moments are extremely precious. How welcome to us is in such moments the information which the spectrum test is so well able to impart.

"Spectrum analysis is suggestive as to the proper treatment of abnormal conditions depending upon permanent or temporary alteration of the blood-crystals. We understand now how it happens that when a man has inhaled the poisonous fire-damp he may be brought to the surface alive, may linger on for days, and yet is beyond the possibility to recover, even if he were plunged into an ocean of oxygen. Such was the condition of many of the victims of the late accident in the collieries of West Pittston. In these cases the crystallisable ingredient of the blood had been affected. We know now that the act of breathing is not a mechanical but a chemical act; that hæmato-crystalline alone possesses the marvellous capacity to attract and fix the oxygen, loosely indeed, so that it may as easily be exchanged for carbonic acid. . . . We know the strange and fatal affinity of hæmato-crystalline for carbonic oxide and other irrespirable gases, which, once attracted to it, form inseparable alliances held in deathly embrace, use up all oxygen, so necessary to the animal economy, to satisfy their own wants, as is the

case when sulphuretted hydrogen is inhaled; or the deathly messenger deprives the hæmato-crystalline of its power and capacity to absorb oxygen, and to convert the hæmato-crystalline into oxyhæmato-crystalline, as is the case when carbonic oxide is inhaled; or both effects occur at once—when, for example, prussic acid has been brought into the circulation. . .

“I have spoken of transfusion in these and other cases, where the vitality of the hæmato-crystalline has been suspended or destroyed. This operation is not free from danger. It requires proper mechanical means, not accessible to all, and neither the instruments nor the blood may be at hand when wanted. It also requires experience which not every Physician may be able to gather. In view of this, I propose to give the hæmato-crystalline internally, not alone in poisoning with gases, but also in cholera and typhus, which affect the integrity of this life-sustaining substance. Solutions of this salt may be substituted where transfusion is practised, or a small quantity may be hypodermically injected. It can now be purchased in quantity, and experiments should be instituted to test the correctness of my proposition, which is at least logically and philosophically correct. As this substance also possesses the respiratory power, it may prove superior to transfusion. Its indestructibility would secure its reaching the circulation in an unaltered condition. But, even if it should undergo a chemolytic change under the influence of the gastric juice, its only possible transmutation would be into hæmatine, which substance, in common with hæmato-crystalline, also possesses the breathing power of the blood, although, perhaps, in an inferior degree.”

After describing the spectral appearances produced by hæmato-crystalline, hæmatine, and cruentine, Dr. Waterman continues—

“Being in possession of all the modifications to which blood can be brought by chemical agencies, we are now prepared to understand how this analysis can be applied to Medicine. First and foremost, its adaptation to Forensic Medicine is to be considered. No matter in what manner *bloodstains* have been tampered with—be it by maceration, boiling, acids, alkalies, or alcohol—the spectroscopist can tell us all about them. Where no change has been attempted, we can show the well-known blood bands; where boiling has been resorted to, we know that the hæmato-crystalline has become coagulated, and we must obtain the hæmatine tests; so, where acids and alkalies have been employed, we do well to use the cruentine reaction, with its characteristic bands. We have already adverted to the fact that hæmato-crystalline preserves its integrity almost for ever, and that we can always demonstrate it spectroscopically. You may interrupt me by claiming that a good microscope will demonstrate blood equally well. To this, however, I demur. I am no stranger to the microscope, and know, in the first place, that the defining power of the best instruments falls far below the response of the spectrum test. But it is entirely useless when blood has been acted upon by the various chemical agents above enumerated, and where the corpuscles have been disintegrated and destroyed, leaving no characteristic by which the microscope could definitely demonstrate blood.

“Spectrum analysis has thrown light upon the nature of *bile* in disease, and made us acquainted with many of its results of decomposition. Normal bile is nearly devoid of power to affect the spectrum, and this negative quality becomes a matter of great diagnostic value. . . . Satisfactory results have been obtained from spectral analysis of the *urine*. The presence of hæmato-crystalline or hæmatine is, of course, easily detected. In diseases in which an extensive destruction of blood corpuscles takes place, I have repeatedly discovered a beautiful band near F, at the commencement of the blue part of the spectrum. When this band becomes visible in the urine, it indicates gravity of disease, and is a landmark to the Practitioner, informing him that the vital powers of the patient are fast breaking up and passing away. . . . The spectral appearances of urine in *cholera* deserve our special notice. The early urine of patients under the influence of this terrible malady contains a peculiar principle, which, under the action of certain chemical agents, has the property of generating a blue and a red colouring-matter. These pigments give peculiar absorption-bands. The blue pigment differs in a most decided manner from the blue pigment which is derived from indican. It differs also from the blue pigment derived from bile; but bears resemblance to the alkaline alcoholic solution of hæmatine. The spectrum test may therefore be applied to diagnosticate true endemic cholera from the urine of cholera patients. We have also peculiar absorption-bands characteristic of cholera stools—the so called ‘rice-water’ dejections. The spectrum resembles

that of blood, but differs from it sufficiently, so as to distinguish one from another for practical purposes. These bands are not produced by any other evacuations known, and we have therefore in them a diagnostic sign of the highest value to distinguish in doubtful cases sporadic cholera from the true Asiatic disease. The source of this pigment in cholera is probably the hæmato-crystalline, split up and morbidly charged by the destructive chemolytic power of the cholera poison.

“The spectrum has also thrown considerable light upon the cause of some of the symptoms in *Bright's disease*, hitherto little understood. We all know that uncontrollable retching and vomiting is often a constant symptom in chronic renal disease. This is probably produced by two new bodies, discovered by Dr. Thudichum. They are decomposition products, derived from urochrome,—viz., omicholine and omicholic acid—and are formed within the economy in certain diseases of the kidney. They possess highly nauseating and emetic properties, and probably cause that uncontrollable irritation of the stomach, especially in cases where, by an irrational treatment, salutary evacuations have been repressed, and the task to relieve the system of this noxious product has been thrown upon the stomach. These bodies can be readily demonstrated by the spectrum test. Uromelanine, a decomposition product from urine, can also be easily detected. It is often coincident with melanotic disease, and points at grave disordered assimilation and imperfect decarbonisation of the blood. A substance always found in connexion with it is paramelanine. This is an interesting body, as it yields to the spectroscopist characteristics of cruentine, thus revealing its true origin from the blood.

“Spectrum analysis has recently been employed in experiments to demonstrate minute quantities of *vegetable poisons* and their alkaloids—such as strychnine, veratrine, atropine, and others. The experiments, although not completed, are promising very interesting results. Metallic poisons—such as arsenic, copper, antimony, lead, thallium, and barium—can be most readily detected by bringing them into a state of incandescence, when each will show its own peculiar modification of the spectrum. Many of the tinctures and solutions of narcotic poisons give characteristic absorption bands; and by the aid of the spectroscopist we can detect adulterations of wine and fermented liquors, as also the age of wines and the quality and purity of fixed and volatile oils.”

SMALL-POX AT WOLVERHAMPTON.

THIS frightful disease is raging at Wolverhampton. The first death from it, says the *Wolverhampton Chronicle*, was registered in the week ending June 10. By the end of August six deaths had occurred. During the month of September eleven deaths occurred, making a total, to that date, of seventeen. In October, twenty-nine deaths from small-pox were registered, and the epidemic spread rapidly. In November, eighty-four deaths were registered, and in December 154, making a total of 284 deaths since the commencement of the epidemic. The deaths from ordinary causes are much above the average. If we deduct the 267 deaths from small-pox during the last quarter, the death-rate from other causes is 31 per 1000; the usual average being about 21 per 1000. In other words, the number of deaths registered during the last quarter of the year was fully one-third more than the average, exclusive of the mortality from small-pox.

It is satisfactory, however, to know that in the week ending January 6 the small-pox was fatal in only thirty-one cases, against thirty-five and thirty-seven in the two preceding weeks. It seems that the Town Council of Wolverhampton (spite of the fact that small-pox had raged in Paris, then in London, and that it was sure to spread to other neglected towns) had done little to protect their fellow-citizens till, in December last, they passed a resolution authorising all Medical men in the town to vaccinate and revaccinate all comers, and offering payments of eighteenpence and one shilling respectively for such operations. This brought down a letter from the Medical Officer of the Privy Council, and a visit from Dr. Ballard, one of the Government Inspectors, who was present at a meeting of the Town Council on Monday last. Mr. Simon tells them that—

“Sufficient provision is made by the Vaccination Acts for gratuitous public vaccination and revaccination by officers

appointed by the guardians of each union, and that public vaccination is not likely to be facilitated, or made more useful, but rather, on the contrary, to be hindered, in Wolverhampton by the Town Council also undertaking to provide it; that the interests of the public health will be better secured by the entire arrangements for public vaccination being left to the guardians, while the corporation exercises its powers of providing Hospital accommodation, and seeing to the disinfection of houses and things."

The debate that followed was curious, and, on the whole, creditable:—

Councillor Turton, after showing that vaccination at the hands of a public officer was expressly defined not to be a receipt of poor-law relief, said that out of 2360 children vaccinated in Wolverhampton last year more than 2000 were vaccinated by the public vaccinators, to whose stations the children were taken. Seeing that the organisation for the performance of vaccination was perfect, he did think the action of the Council in giving a general order to the Medical men to vaccinate at the expense of the Corporation was indiscreet, and calculated to injure the cause of vaccination and bring it into disrepute. He believed that during the past week there had been more reckless vaccination performed in Wolverhampton than for a long period. He himself had seen children of three, four, and five years old, who, though bearing the marks of efficient primary vaccination, had been revaccinated, which experience taught was quite unnecessary, and therefore a simple piece of wanton cruelty. During the small-pox epidemic in Wolverhampton there had been no case of a child vaccinated in infancy suffering from the disease before the age of puberty; yet he knew scores of children of the tender ages of four, five, and six, who had been revaccinated at the cost of the Corporation. There seemed conclusive evidence to prove that one successful revaccination afforded almost absolute protection against small-pox, yet he knew people who had been vaccinated for the third time at the expense of the Corporation. Another objection to the resolution of the Council arose in this way. If private Medical Practitioners were called upon to do revaccination to any extent, they had not a sufficient supply of children primarily vaccinated to enable them to practise vaccination from arm to arm, and the use of stale lymph was calculated to bring vaccination into discredit. In connexion with the public vaccinators there were officers to send unvaccinated children to their surgeries, so that they were able to keep up arm-to-arm vaccination, but the private Medical men were not in this favourable position, and he would assert that much of the vaccination performed during the past week had been reckless, panic-stricken work, which, if continued, was likely to do more harm than good. One of the public vaccinators, during the past week, had vaccinated something like 1000 people, for whom he would be paid by the Board of Guardians and he would also charge the Corporation.

Councillor Dr. Smith, one of the public vaccinators, said that although a bill which had been issued showed that people who had been revaccinated would not take the small-pox, yet numbers of persons who had been revaccinated flocked up to the surgeries to be done again. The offering of a fee by the Council was not necessary, because the public vaccinators were paid by the Board of Guardians, and if the notice had been issued without the resolution as to payment by the Corporation, the good effect would have been the same. The public vaccinators alone had the supply of lymph necessary in this time of emergency, and the authorising of all the general Practitioners to vaccinate at the public expense did no good, because they had no fresh lymph, except what they got from the public vaccinators.

Councillor S. Lloyd said he considered that the remarks of Councillor Turton reflected much on the Medical men in Wolverhampton; but he would appeal to the conscience of any honest man, whether Medical Practitioner or not, to decide whether a Medical man, if a child were taken to him to be revaccinated and it did not want doing, would not say so plainly. For a long time the public looked coolly upon revaccination, though it was recommended from the pulpit and in other ways, but, in one week after the issuing of the Corporation handbills, 1000 persons were revaccinated by one Medical man. He should like to ask Mr. Turton how many were revaccinated in the same time before the notice was issued.

Councillor Willcock expressed his surprise at the arguments with which Councillor Turton had supported his motion.

In the first place, he had reflected on the Medical Profession. Now, although he (Mr. Willcock) had not the highest opinion of them, he had never gone half so far as Mr. Turton had done that day. What would be the effect of his speech? Tell him that the working-man would go and be revaccinated after an authority like Mr. Turton had stated that the manner in which the operation had been performed during the past week was a disgrace to the Medical Profession! That statement he (Mr. Willcock) ventured to say would do away with the good which the Corporation had been endeavouring to inculcate.

Alderman Fowler could not but express his surprise that Mr. Turton, of all men, should have uttered what he (Mr. Fowler) could not help calling a libel on the Medical Profession; for if any man, for the sake of a paltry shilling, would vaccinate or revaccinate a person who did not stand in need of it, and thus risk a child's or an adult's health, he was not only a disgrace to an enlightened, educated Profession, but also a disgrace to our common humanity. He did not believe there was such a Medical man in Wolverhampton; he did not believe there was such a scoundrel—for such he would be who, for such a remuneration, would trifle with the public health; and he threw back the insinuation that there had been any reckless vaccination and revaccination. He believed the Medical men generally of Wolverhampton were as competent as Mr. Turton or as any public vaccinators were to determine these questions; he believed they were desirous of acting honourably and to the best of their ability, and he thought the Council were not entitled in that public room to fix such a stigma on them as one of their own body had done when he imputed to them that they were acting in the manner described for such a paltry consideration. Suppose there was a raging fire in the town, and there was a large number of inflammable buildings around, but before the fire brigade arrived some bold sensible man screwed a hose on the first fire-plug and commenced playing on the flames, but someone said, "Oh, that's not proper—the fire brigade are the proper authorities to extinguish fires, wait till they arrive," and in the meantime let the fire go raging on, and threatening the town! It was something the same with small-pox and vaccination in Wolverhampton. Small-pox was raging, and there were men appointed to do vaccination, but they were not doing it to the extent required.

Dr. Ballard then addressed the Council in explanation of the letter of the Local Government Board. He pointed out that by law the carrying out of vaccination was in the hands of the Board of Guardians, and that the Local Government Board were desirous not only that the quantity of vaccination performed should be large, but that the quality of it should be unexceptionable. Now, to secure a high quality of vaccination, the Local Government Board held it to be necessary that the operation should be performed from arm to arm. Apart from the irregularity which he might be permitted to say the Corporation had committed in passing the resolution, he might state that the arrangements of the Board of Guardians were such as to admit of all vaccination and revaccination being done from arm to arm, whereas the resolution of the Council, while making provision for revaccination by Medical men generally, at the public cost, did not make sufficient provision for primary vaccination, and therefore the Medical men would be unable to obtain primary lymph for use in their operations. Dr. Ballard gave the Council credit for acting from the most humane motives in passing the resolution, but suggested that, as the arrangements of the Board of Guardians are complete, the resolution should be rescinded. Dr. Ballard then spoke of the importance at the present time of the isolation of the sick, and the disinfection of infected houses and things, and pointed out that the law cast upon the Town Council, as the sewer authority, the duty of making the necessary arrangements in these instances. He expressed a hope that all the Medical men in the town would send notice of small-pox cases to the Medical Officer of Health. He learned that at present there was no disinfecting apparatus in the town, but he had no doubt the Sanitary Committee would carry out the recommendation of the Medical Officer of Health on the subject. He had seen the Small-pox Hospital which the Corporation had provided, but he could not say that the arrangements were altogether satisfactory to his eye, and he thought it desirable to have a place ready at all times where they could isolate the first case of infectious disease. Dr. Ballard said he believed that if they had had such a Hospital when the first case of small-pox was imported; if the case had been removed there and isolated, and the earlier cases which occurred by infection had also been removed there; if they could have disinfected everything, and so crushed out the first sparks, there would

not have been the fearful mortality of nearly 300 deaths which had followed. It also devolved upon the Council to provide a proper carriage for the removal of the sick to the place of isolation.

Councillor Major, as a member of the Sanitary and Sub-sanitary Committee, said there was not a single recommendation that Dr. Ballard had made which the Committee had not already carried out. He complained that the request of the Committee to the Medical men to furnish information of small-pox cases had been met with the reply in many instances that "they had something else to do," and stated that the disease would probably have been stamped out at the beginning, but for red-tapeism and the clashing of the powers of the Council and Board of Guardians, the latter declining to receive into the infectious wards of the workhouse the first case of small-pox which appeared in the town because the person was not a pauper, although the Committee offered to pay the expenses. The Town Council were the authority to whom the Local Government Board looked for the maintenance of the health of the town, and were the first to whom they sent threatening letters, yet their hands were tied in this manner. Dr. Ballard had not told them whether a third vaccination was necessary.

Dr. Ballard: Let me answer that question at once. It is the opinion of the general Medical Profession, and it is my personal opinion, that a third vaccination is perfectly unnecessary.

Councillor Major contended that it would be a most mischievous thing to rescind the resolution, which had evidently done a great deal of good.

Councillor Walsh also defended the resolution of the Sanitary Committee, and said that many middle-class people who could not afford to pay for vaccination, and were not willing to go to the public vaccinators, were ready to be vaccinated at the expense of the Council. About 100 people had been to his Medical man to be vaccinated, and that gentleman had referred them to one of the public vaccinators. Their reply was, "We don't care to be vaccinated by the pauper-Doctor."

Councillor Turton stated that though it was said that the public had a great objection to being vaccinated by the public vaccinators, yet it would be found that the great bulk of the vaccination done in the past week had been done by the public vaccinators. He would observe that the large number of revaccinations performed last week could not have been performed without a large supply of lymph obtained from other sources. Where it came from nobody knew. What he advocated was vaccination of good quality. He contended that they would do better by steadily revaccinating, according to the supply of lymph from children, selecting the persons to be revaccinated first from districts where small-pox prevailed, than by vaccinating in a panic-stricken manner. Mr. Turton then withdrew his resolution.

REVIEWS.

Lectures on the Principles and Practice of Physic. By Sir THOMAS WATSON, Bart., M.D., F.R.S., etc. etc. Fifth edition. Two vols. London: Longmans, Green, and Co., 1871.

[CONCLUDING NOTICE.]

THROUGHOUT the lectures on the Diseases of the Nervous System we meet with numerous proofs of the careful and conscientious revision the author has bestowed on his work; the eye, as it runs over the familiar paragraphs, being frequently arrested by the names of the most recent writers on the several subjects, and finding full acknowledgment of their labours. The admirably graphic pictures of Delirium Tremens remain, of course, as they were, but the subject of the treatment of the malady has been in considerable part rewritten, so as to bring it more into accordance with the less vigorous method of treatment of the day; though we can easily imagine that it may still seem to some writers on the subject to place too much reliance on drugs. The observations of Dr. Ware, of Boston, Dr. Peddie, of Edinburgh, Professor Laycock, Dr. W. T. Gairdner, and others, as to the *self-limiting* character of the disease, are noted; the "felicitous method of injecting the salts of morphia (or other medicinal substances) into the subcutaneous tissue," is acknowledged and appreciated, and the latest drugs used instead of opiates are spoken of. Of large doses of the tincture of digitalis, Sir Thomas says, "I confess to you that, though I have no fear of opium in uncomplicated

cases properly watched and regulated, I do not dare to prescribe digitalis in that way. That it has served to effect a speedy cure I do not question; but, in my judgment, it is a hazardous remedy. Its successes we hear of; its ill-fortunes are not so likely to be told." The bromide of potassium, in half-draehm or draehm doses, he considers to be a "perfectly safe remedy," and very efficacious "in restoring the lost blessing—sleep," and he would not hesitate to make trial of it in cases "where the sleeplessness was obstinate, and the use of opiates precluded or ineffectual;" and in the epilogue to the work Sir Thomas says, "Had I known (when preparing the first of these volumes) what I now know about the effects of chloral in procuring sleep, I should have recommended it as preferable to opium in the treatment of delirium tremens."

Speaking of coma, the author, after noticing observations by Dr. G. Johnson, Mr. Jonathan Hutchinson, and the late Dr. Snow, sums up thus: "While sometimes coma is a result of the arrested circulation of the blood, sometimes of defective oxygenation of blood, and sometimes, again, of the addition of some narcotic to the blood, the proximate cause is in every instance identical—namely, a defective oxidation of the nervous tissue." We had nearly forgotten to remark that the author has not omitted to mention the use of the ophthalmoscope as "an avenue to the diagnosis of brain diseases, which is of recent discovery, and of great importance." He says, "Mr. Bowman has assured me that the ophthalmoscope has contributed nothing less to our knowledge of the diseased conditions of the interior of the eye than the stethoscope has to those of the chest; and Dr. Hughlings-Jackson makes a similar estimate of its comparative value for unravelling the complex symptoms of diseases of the brain." And after describing shortly some of the morbid changes observed in the conditions of the *optic disc*, he advises his hearers "to lose no opportunity, while you are *in statu pupillari*, of making yourselves familiar with the sound and the unsound aspects of this significant disc. It is an advantage new to the present generation."

The lectures on Apoplexy and Hemiplegia have been very largely added to and rewritten, and Sir Thomas accepts Dr. Broadbent's theory to explain the fact that, in hemiplegia, the only muscles decidedly palsied are those that move the limbs; while, "those which minister to the special senses, and those which subserve the organic functions of the body, are unaffected"—the "real verdict" being, in Dr. Broadbent's words, that "the muscles which escape are those which act only bilaterally, or in concert with the corresponding muscles of the opposite side." As a specially admirable example of the author's desire to note all recent information, to give due credit to all labourers in a subject, and of his characteristic power of working up the knowledge and views of various authorities into a full, lucid, and graphic statement, we recommend to our readers the lecture on Aphasia. The theories of Broca, Gratiolet, and others are noticed, and the observations and writings of Drs. Sanders, Bateman, William Ogle, Maudsley, Hughlings-Jackson, Wilks, Lockhart Clarke, Charlton Bastian, and Moxon are so laid under contribution as to produce an admirable exposition of the present state of knowledge on the subject. Sir Thomas says, "I refrain from pronouncing any judgment of my own upon these various speculations and opinions, of which I desire to be considered as being, however imperfectly, the mere expositor;" but he does decline to accept or put faith in "the theory upheld by M. Broca and his followers, that the part of the brain specified by him—namely, the posterior part of the inferior frontal convolution of the left cerebral hemisphere—is the seat or organ of language." Nor does he believe "that there is any special seat or organ of language in the brain."

We find that Sir Thomas has somewhat modified the view he formerly held concerning the relation between cerebral hæmorrhage and hypertrophy of the left ventricle of the heart. It may be remembered that in the fourth edition of his "Lectures" he said, "Do not fall into the mistake which has been made by pathologists of eminence, of assigning to apoplexy and hypertrophy of the heart, when they meet in the same person, as they frequently do, the relation of effect and cause;" and, after stating that Dr. Hope held that this relation "is one of the best-established doctrines of modern pathology," and that Andral, Bouillaud, and Cruveilhier had expressed similar opinions, he added, "I believe them to be entirely erroneous." Now, after showing that in a large number of cases no such relation does exist, and stating the proposition "that whenever hypertrophy of the left ventricle results from valvular or other disease of the heart itself, or from obstructive disease of the larger arteries, it is not to be considered the cause of cerebral hæmorrhage, should that also happen," he goes on to say—

"Yet there is a form of hypertrophy which is very likely to prove a direct cause of cerebral hæmorrhage. Of Bright's disease of the kidney, when chronic, hypertrophy of the left ventricle, without valvular or other disease of the heart or great arteries to account for it, is an almost constant accompaniment and consequence. How is this?" And then, referring to Dr. George Johnson's paper on the *stopcock* function of the minute arteries, and adopting the theory by which he explains how and why the muscular coat of those arteries is liable to become hypertrophied, Sir Thomas explains how in some cases a real relation of cause and effect does exist between hypertrophy of the left ventricle and cerebral hæmorrhage. "In Bright's disease the blood is unpurified, and while the minute arteries in various tissues, the skin, the muscles, the brain, and other parts, oppose its passage, the left ventricle beats with increased force to drive it onwards. The result is hypertrophy of the muscular fibres of the arteries, and of the left ventricle of the heart. Apply this doctrine to the brain. The arterial stopcocks resist the passage of the unpurified blood into the capillaries. The strong left ventricle strives to force on the blood. The resulting distension of the systemic arteries is indicated by the full and hard radial pulse, and by the evidence of increased arterial pressure afforded by the sphygmograph. There is thus excessive pressure on the whole of the arterial pipes between the stopcocks and the forcing-pump; and in the struggle between the two contending forces, a minute artery in the brain may be broken, and so cerebral hæmorrhage may occur."

Heat-Apoplexy, or Sunstroke, Locomotor Ataxy, and Wasting Palsy are subjects which appear for the first time in these lectures, and are clearly and instructively, though but briefly, treated of.

Among the novelties to be found in the first volume of the "Lectures," we may also mention Exophthalmic Goitre, and Mesmerism. Speaking of the latter, Sir Thomas says, "You may desire to know, and you have a right to know, my creed upon this vexed and much-abused subject;" and he points out that of the brain and nerves there are many and various strange conditions which occur, as it would seem, spontaneously, or during the progress of some better-known malady, such as hysteria, catalepsy, ecstasy, trance, *double-consciousness*, and *sleep-walking*. "Now," he states, "whatever condition of this kind may arise thus spontaneously, may also, I believe, be produced in some persons under the mesmeric practisings. Not, however, through any material or occult influence emanating from the mesmerism; but subjectively from the mental attitude (if I may use that expression) in which the person mesmerised is led to place himself.

. . . . The phenomena are subjective phenomena. The determining influence is from within as much as, or even more than, from without. Derangements, such as sometimes occur thus in disease, may also sometimes occur under the mesmeric atmosphere, but no other or more mysterious derangements. Thus much I perfectly believe. I believe, too, that sleep may sometimes be conciliated by the monotonous biddings of mesmerism, where drugs might fail to procure it; and that such sleep may become sometimes, and in certain diseases, a mode and instrument of cure. But I go no further. All the transcendental phenomena—the miraculous diagnoses and revelations, the clairvoyance, the prophecies—I class with the spirit-rappings and the table-turnings, as evidences of imposture on the one side, and of miserable credulity on the other, and as alike scandalous in an age and country which vaunt themselves to be enlightened."

The lectures on Tetanus have been revised so as to include the microscopic observations of Dr. Lockhart Clarke and Dr. Howship Dickinson, but not so far as to make any mention of the use of the Calabar bean as a remedy—nor, of course, of either chloral or the nitrite of amyl.

The subject of Neuralgia has hardly, we venture to think, been revised with the care and attention bestowed on so many other subjects, and which it so fully merited.

Sir Thomas charms so well and wisely, that we have been seduced into lingering over his lectures on the Diseases of the Nervous System till we have but very brief time and space left to devote to the rest of the lectures. This we may regret the less, however, as subjects treated of in the second volume will have passed more lately under the author's revision than those in the first, and are therefore still more sure to have been brought up to the present state of knowledge and theory.

It will be observed that in this edition of his "Lectures" Sir Thomas has discarded the terms *cynanche trachealis* and *diphtheritis*, in favour of *infantile laryngitis* and *diphtheria*, or *diphtheritic laryngitis*. This latter malady, which in the last previous

edition was very briefly noticed, is now fully described and discussed, large use being made of the writings of M. Trousseau, Sir William Jenner, and the late Dr. Hillier on the subject. "Although the complaint," says Sir Thomas, "includes diphtheritic laryngitis, it has a wider scope, and is more especially and more often, in the outset at least, a *pharyngeal* affection in its local as distinguished from its general manifestation. The proper place for diphtheria in any methodical nosology would be among the specific fevers;" and after full consideration of it he remarks—"We are now prepared for the consideration of a most important question. Is the disease, which has for so many years been called, in this country, the *croup*, and which is attended with a membranous exudation in the larynx, anything else than diphtheria? He believes that it is not, and goes on to explain that, "ever since Dr. Horne's pamphlet on 'Croup' was published in 1765, our writers on the subject have given us the history, the symptoms, and the treatment of acute catarrhal laryngitis, of what I have been describing as infantile laryngitis, with the morbid anatomy of diphtheria; thus confounding together two diseases very different in themselves, and requiring very different treatment." He quotes Sir William Jenner's verdict against the opinion that diphtheria and croup are not essentially the same disease, but accepts the arguments of the late Dr. Hillier against Sir William's belief, and concludes thus: "You will understand that I give in my adhesion to the opinion that croup, accompanied by false membranes in the larynx and trachea, is always diphtheria—whether in the child or in the adult; and that simple laryngitis is never associated with the exudation of false membrane." We must confess to thinking that, unless the term "croup" is to receive a new definition, the majority of English authorities will agree with Sir William Jenner rather than with Sir Thomas Watson in this matter.

When speaking of the treatment of Pleurisy, Sir Thomas gives a decided opinion against the early performance of paracentesis in "simple pleurisy," but no reference is made to Dr. Bowditch's teaching on the point, nor to the fact that methods of performing the operation have been discovered by which entrance of air into the pleural cavity may be effectually prevented.

When discussing the subject of Pulmonary Hæmorrhage, mention is, of course, made of the observations of Niemeyer and his revival of the views of Morton, Cullen, and other older writers; and Sir Thomas Watson observes—"If *tubercular* disease is ever a direct consequence of retention of blood effused into the lung, there must, in my judgment, have been a constitutional predisposition to tubercular deposit."

The subject of Phthisis Pulmonalis is preceded by an inquiry into the morbid anatomy of tubercular phthisis, in which the most modern doctrines concerning tubercle are clearly, though of course briefly, set forth, and our author concludes that, "upon the whole, we must believe, with Laennec, with Niemeyer, with (I think) Drs. Sanderson and Fox, that the yellow opaque tubercle is often merely an advanced stage of the grey semi-transparent granule; but we must also believe that it may occur independently of the granule, and even become its parent." The views of Dr. Andrew Clark also receive due attention; and, when speaking of *fibroid phthisis*, Sir Thomas says, "Upon the whole I think, with Dr. Andrew Clark, that it will be well, for the future, to define phthisis pulmonalis generically, as comprehending all progressive consolidations and circumscribed suppurative degenerations of the lung."

Sir Thomas Watson's history and description of Epidemic Cholera are, as is well known, most interesting and admirably clear, and he has added largely to his lectures on the subject; but we cannot help expressing our regret that he has so unreservedly adopted Dr. George Johnson's views on the pathology and treatment of the disease. However able they are, and attractive from their simplicity, they have not met with anything like general acceptance as yet, and are, we venture to think, still far from proven. At the last meeting of the British Medical Association, Inspector-General John Murray, M.D., stated that of the 505 Medical officers in India whose opinion he collected in 1864, "there were only eight who did not consider the administration of purgatives in the early stage as dangerous. In the reports received from America, similar views of the dangers of purgatives—even castor oil—were entertained."

The lectures on Worms and the Human Parasites have been in great measure rewritten and extended. Notice is taken of *acute or yellow atrophy* of the liver; and with regard to the relation between hepatic abscess and dysentery, it is shown

that, though the connexion between them suggested by Dr. George Budd does undoubtedly obtain in some cases, yet both in this country and in tropical climates abscess of the liver and dysentery may, and frequently do, occur without being connected together as cause and effect.

The lecture on Diabetes appears to us hardly up to the general standard of excellence and completeness of Sir Thomas Watson's work; and we venture to think that the subject of Addison's Disease is too briefly treated.

We might, no doubt, point out more deficiencies in this work, as we might easily point out many more excellencies and beauties; but, take the work as a whole, we have no work on Medicine equal to it in limpid beauty of style, power and vividness of description, and high-minded healthiness of tone. In his graceful little epilogue, Sir Thomas Watson speaks of "working with many interruptions, and the slowness of old age." We are sure that no one can take up the volumes without feeling deeply grateful to him for having, at his time of life, undertaken such laborious work as the revision of his "Lectures" must have been, even though most readers may think it a "labour of love."

NEW BOOKS, WITH SHORT CRITIQUES.

General Report, with Statistical Tables, of the Patients under Treatment in the Highgate Infirmary (Central London Sick Asylum District). By THOMAS STRETCH DOWSE, M.D., Medical Officer.

* * * This unfortunate building, which has been the cause of so much heart-burning, is now fairly floated as one of the institutions of the Sick Asylum Board, and, we are pleased to see by the Report, under what seems very satisfactory management. We are well pleased with Dr. Dowse's Report; it is a plain, straightforward, honest statement, strictly confined to the matters which refer to his own immediate sphere, and trenching not, as is too often the case, on the stewards' department. His notes on the varieties of disease which came under his notice are interesting, and they show a tendency which we wish we more frequently saw manifested, to make some use of the vast mass of material at the disposal of officers of such institutions.

Transactions of the American Ophthalmological Society: Eighth Annual Meeting, Newport, July, 1871. New York: Appleton.

* * * This brochure contains a good deal that is of interest to the Ophthalmic Surgeon, and the "Report on Ophthalmic Surgery," by Dr. Joy Jeffries, of Boston, is above the average of such *collectanea*. Two of the most interesting papers to the general Practitioner are that on "Gunshot Wound of the Brain, followed by Fungus Cerebri, and Recovery, with Hemiopsia," by W. W. Keen, M.D., and William Thomson, M.D.; and another on "Paralysis of the Trigemini, followed by Sloughing of the Cornea," by William F. Norris, M.D., Philadelphia.

GENERAL CORRESPONDENCE.

THE MEDICAL PROFESSION IN VALPARAISO.

LETTER FROM DR. J. HOLMES JOY.

[To the Editor of the Medical Times and Gazette.]

SIR,—I learn by the public papers of Valparaiso, November 30, that it is the intention of the Intendant of this province to endeavour to induce, through the agency of one of the Chilean Ministers in Europe, several properly qualified Medical men to come to Valparaiso to settle. The terms which he offers are these: A free passage, and 200 dollars (about £40) a month for three months after their arrival. They are to give their Professional services for a period of not less than three, four, five, or six years, with the express condition of submitting to all the laws, decrees, and ordinances which control [*reglamentar*—to lay down regulations for] the exercise of their Profession. By a recent "decree"—October 11—of the present Intendant of Valparaiso, it has been made compulsory for all the Doctors to submit to a weekly "turn," when they are to hold themselves in readiness to serve the public whenever called on, from 12 p.m. to 7 a.m., for an entire week, and this without any remuneration whatever in case of the applicants being personally unable to pay them—in brief, to be what Poor-law Doctors are at home, but without *any* payment! Among sixteen of us, this weekly turn would recur once in two months, and I need not allude to

the impossibility of fulfilling it and at the same time doing justice to our own private practice. The utterly arbitrary character of the ordinance, and its entire illegality in a free country, need no comment from me. Holding no public appointment whatever—being simply a Physician in private practice—of course there can be no power but the physical power of police authority which can compel me to any such course. That this is the universal feeling here, is amply proved by the fact that, in consequence of the decree alluded to, fourteen out of the sixteen who constitute all the properly qualified Medical men here actually made a public renouncement of their Profession, and remained "on strike" for ten days, rather than comply with it. They have now resumed their practice, under a private promise of the Intendant not to enforce the turn; but he believes he will be able to get Doctors from Europe, on the terms above stated, to come and settle here for three months' salary, and to conform to such utter violations of their personal liberty, or any other which he may subsequently think fit to decree. Be that as it may, an article has been forwarded by to-day's mail to the editor of the *London Times*, by one of our English Medical men (Dr. Duffy), to put young men on their guard against being inveigled into signing *any* contract. They could not practise here without passing an examination before the Medical Board in Santiago (the capital)—an examination conducted entirely in Spanish. Nor then have they any guarantee of earning a farthing (except by what private practice they can secure) beyond the three months' pay already alluded to, which the Intendant would secure to them. Translations of the article I herewith accompany (translated by myself, for insertion in the Medical journals of Great Britain if you approve it) are being forwarded by the German and French Physicians here to their several Universities for publication, and will be widely disseminated thereby the general as well as Medical press. I also forward to you the *Mercurio, Patria*, and *West Coast Mail* (English), which contains an account of this subject.

I am, &c.,

J. HOLMES JOY, A.M., M.D., Ch.M. Univ. Dub.
Valparaiso, December 2.

(Translated from the *Valparaiso Mercury* of November 30, 1871.)

"ILLUSTROUS MUNICIPALITY;—Considering that Congress will shortly end its duties, leaving no opportunity to promulgate a law which shall define the extent of the obligations which the members of the Medical Profession owe the public, and it being suitable to compile, for the benefit of the said public, the several existing regulations, not only in regard to that Profession, but also with respect to those others which render daily and indispensable services to the locality, I have thought it opportune to formulate a regulation about this matter, not doubting that the illustrious Municipality, availing itself of the power (or right) which Act Number 4, Article 103, of the 'Organic Law' concedes it, will favourably approve it:—

"Art. 1. The Physicians, Surgeons, Phlebotomists, Chemists, Druggists, and Midwives who desire to practice their Profession in the department of Valparaiso, shall previously manifest it in writing, presenting at the same time their diplomas to the Intendencia.

"Art. 2. To comply with the preceding Article, a register for matriculation shall be opened at the Intendencia, in which the name and profession of each individual separately shall be written down, and the date of their inscription.

"Art. 3. Every matriculated individual who wishes to absent himself from the department, or suspend the practice of his profession, shall make it known in writing to the Intendencia, in order that his inscription be cancelled, or the time noted down during which he wishes to be absent, that the proper steps may be taken accordingly.

"Art. 4. Twice a year—in the months of January and July—all those actually engaged in practice shall hold one or more meetings, to be presided over by the delegate of the 'Protomedicato,' in which the prevailing diseases shall be considered, and the most simple means which their individual experience suggests in the treatment of them; the proper measures of hygiene which it is expedient to adopt for the greater health of the town; articles of food and drinks which are injurious to health; and, in conclusion, all measures tending to the improvement of the public health, be set forth and detailed. An extract of the result of these conferences shall be forwarded to the local authorities, who shall cause it to be published in the papers, in order that the indications suggested may be known to all, and that the authorities, in so far as they may think proper, may adopt the proper measures.

"Art. 5. Besides these periodical meetings to which reference

is made in the preceding Article, the Medical men in practice shall hold extraordinary meetings whenever the authorities shall require it, in case of plagues or epidemics, and in any other grave circumstances which affect the public health.

"Art. 6. Every Physician practising his Profession is compelled to assist the sick at whatever hour of day or night he may be called, excepting during the hours of his 'turn,' referred to in the following Article, under a penalty of \$40 [about £8 sterling (note of translator)], for each occasion on which he fails in this respect.

"Art. 7. There shall be two Doctors on 'turn,' in order to attend to the extraordinary calls that may be made on them during the advanced hours of night—i.e., from 12 p.m. till 7 a.m. The Doctors on 'turn' shall not be allowed to excuse themselves from rendering these services, except on account of some cause made good to the satisfaction of the authorities, and on leaving in their place another Medical man to do their duty. In this case they must give timely notice to the Intendencia. The Doctors on 'turn' shall be exempt from the obligation of assisting any patients during those hours not comprehended therein. Those who fail in whatever is contained in this article incur a penalty of forty dollars.

"Art. 8. In order to avail themselves of the services of the Doctors on 'turn' during the advanced hours of night alluded to, the public will observe the following:—1. Whoever has need of the Doctor on 'turn,' must go to the police-office and have his name and address in writing. 2. This done, an agent of the police will accompany the applicant to the house of the Doctor on 'turn,' and from thence will escort the Doctor to the patient's residence. 3. If the Doctor desire it, the policeman will await him while he makes his visit, and then accompany him home.

"Art. 9. Every Doctor shall be obliged to give whatever information is officially required of him by the authorities in urgent or special cases, or at the demand of the 'City Doctor.'

"Art. 10. The Doctors shall also be obliged, taking it by turns amongst them, to attend daily at the dispensaries, or other public places pointed out by the authority, in order to lend his Professional services to the poor, and give them the prescriptions which their cases may require.

"Art. 11. Any apothecaries' shops which shall be established in future, must be situated at least 300 metres distant from any other already established. The same rule applies to those already existing, in case of their removal.

"Art. 12. There shall be apothecaries' shops in 'turn,' to supply any medicines required by the sick during the night. These shops, their situation, and numbers shall be determined by the authority, as may best befit the public requirements. They shall keep their door open and have a light inside, and have a competent person to make up the receipts demanded. They shall also have bells in a convenient place at the entrance, in order to render it easier to call up the *employés*.

"Art. 13. Each apothecary's shop shall be kept by a qualified apothecary, and the same individual cannot preside over more than one, nor be absent from it without previously advising the authority, and nominating some competent person to take his place.

"Art. 14. There shall also be phlebotomists and midwives on 'turn' for the service of the public in their respective departments. The 'turns' of these professions shall be also regulated by the local authority in the form best adapted for the good service of the public. Those persons who practise these professions shall have at their doors, besides the plate which tells their name and calling, bell-pulls, to facilitate those who need to summon them.

"Art. 15. Those who need assistance from the apothecaries, phlebotomists, or midwives, may require the aid of the police in charge of the district, who shall be obliged to give it, in order to obtain promptly whatever is required for the patient's need. The same aid shall be rendered by the police, in order to obtain ice from the ice-depôts, for those sick who may need it, during the said advanced hours of night.

"Art. 16. The infringers of any of the 'dispositions' contained in this ordinance (who do not incur some special punishment) shall pay a fine of not less than 10 or more than 40, without prejudice to the execution of whatever else the laws of the country may impose. The fines imposed in accordance with this ordinance shall be collected by the police.

"Art. 17. This shall be in force from the moment of its promulgation; all former regulations on this subject becoming null and void.

"N.B.—This means that when accepted by the Municipality

it will be at once published, and at once have the effect of a local law."

* * * We have received a letter from Dr. Duffy, of Valparaiso, embodying the same facts as the letter of Dr. Joy.

"ANOTHER DISTINCTION IN LINCOLNSHIRE."

LETTER FROM MR. G. MITCHINSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—Thanks for the opportunity you have afforded me of repudiating any complicity with the paragraph which recently appeared in the *Lincoln Gazette*. Until I saw the statement in the *Gazette* I was entirely ignorant how many Lincolnshire Medical men had, or had not, signed the memorial alluded to. Immediately after reading the paragraph I wrote to Mr. Garnham, President of the Lincolnshire Medical Society, and informed him that neither directly nor indirectly had I anything to do with its insertion. I also wrote to the same effect to Mr. Broadbent, Senior Surgeon to the Lincoln County Hospital, and, during the day, mentioned to several Medical and other friends how much annoyance I felt on seeing the paragraph in question. In addition to this, I communicated with the editors of the other Lincolnshire papers, and requested them not to copy it. I am, &c.,

Castle Hill, Lincoln, Jan. 10. GEORGE MITCHINSON.

P.S.—Would it not have been more generous if your correspondent had communicated with me, before placing me under your active treatment?

ALCOHOL INCONSIDERATELY PRESCRIBED.

LETTER FROM MR. J. W. TURNER.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a letter from Dr. Lionel Beale, in your "General Correspondence" of December 9, under the head of "Alcohol Inconsiderately Prescribed," he states—"No doubt many people would live longer if they drank less alcohol," and then asks—"Can we, by signing an expression of opinion, however strong and unanimsously, hope to influence them?" and—"What is likely to be gained by some of us coming forward to protest against habits which all people know to be wrong?" To his first assertion, there cannot be a doubt that people would live longer. Speaking from my own experience, after thirty years' practice, I positively declare my opinion that half the untimely male adult deaths (innate phthisis excluded) are owing to the abuse of alcohol; and I judge it incumbent on the Medical Profession, as guardians of public health and well-wishers of their fellow-mortals, to make this evil of alcohol-drinking better known to the said public, more especially at this particular time, when some mode of reform in the liquor trade and licensing system is a matter causing much anxiety and discussion. What an assertion!—half the untimely male adult deaths (innate phthisis excepted) to be put down to the abuse of alcohol!

Let me ask my Professional brethren the cause of a vast amount of kidney and liver diseases, diseases of the brain and nervous system, insanity, paralysis, and idiotcy? From what cause more than half the accidents which fill our Hospitals? What number of suicides occur in the depressing stage following over-excitement of alcohol? How many murders in the non-natural state produced by it—not to mention the many cases of assault which appear before our police courts and crowd our prisons. How many miserable alcoholic dyspeptics apply daily to the Profession for aid, and too often confirm their ill-health by persisting in the use of stimulants that have brought them to their wretched condition? Can we imagine that the public is fully aware of these facts? and that from alcohol, or spirits of wine in small doses, a person is quickly placed in such a non-natural condition as will excite him or her to commit such acts as in their normal state they would shudder to think of? and that such excitants are permitted to be vended at every corner to any empty-stomached or empty-headed customer with a few pence about them? Do the people know that the habit of spirit-drinking grows like a dire disease upon the drinker? Do they know that brandy, gin, whisky, hollands, rum, etc., can be made artificially from alcohol or spirits of wine, and flavouring or seasoning like "Dickens's" far-famed pies; also cheap dinner sherries and palatable port wines? If the English public must have stimulants (and it will), we ought to try and educate the palate to natural ones—namely, the products of fermentation *versus* distillation (the former, when

pure, being non-injurious, save in quantities such as only a very deliberate toper would take)—and then they would but bring him loss of self-respect, and, maybe, render him offensive and ridiculous *pro tem.*, and make him suffer for his excess (headache, indigestion, and *malaise*), from which he would gain a practical lesson, teaching him moderation and sobriety; whereas let him be overcome with the strong products of distillation, then his nervous system has received such a shock, and his delicate organisation such direct injury, that he does not quickly or entirely revert to a normal state. So great a craving and horrid depression possesses him that he almost always resorts to the enemy for relief to his symptoms. Then begins the indigestion of spirit-drinkers, and the varying conditions of animal spirits called “ups and downs”—all the false excitement of the “ups,” and all the morose ill-temper and brutality of the “downs.” A short course of this kind brings the nervous tremors and that incapacity for sustained mental or bodily exertion without the false prop. This soon tells upon the finances, if not immediately apparent upon the health, and all kinds of shifts and schemes are resorted to for supplies of stimulants and evasion of work, inducing irregularities, often resented by employers; and the spirit-drinker is thus thrown out of his situation or work. Still, he will get his stimulants! and then, if not before, the home has to suffer. Wife and children are made miserable, and his home becomes a silent and bitter rebuke, at best, when the drunkard returns to it. Debt, degradation, disease, and destitution soon follow, and this pest of society throws himself and surroundings upon the funds of the charitable, or charitable institutions, or upon our hard-working, heavy-ratepaying nation. Not a day passes without such sad evidences of the dire evils of spirit-drinking being brought to the direct knowledge of Medical men; and they, of all classes, I think, should give utterance to their opinions on this subject.

We have of late heard the social, judicial, political, moral, and mercantile opinions freely given upon this subject; now let our Profession speak as to restrictions on the sale of the products of distillation—namely, spirits in general, and, what is nearly as bad, fortified wines, or spirits in disguise. Let our Profession express its opinion on the use of Nature's gift—the products of fermentation on the one side, and the evils of the products of distillation by art and man's device on the other.

The exciting principle is the same, you will say—isomeric, the chemist assures us. But is alcohol in natural combination, resulting from fermentation, identical in action with alcohol educted from fermented compounds? and can a mortal quench thirst, or escape the risk of injury, by imbibing spirit or strong spirituous compounds stronger than those produced by the fermentation of the most saccharine juices of fruits, etc.? I judge it is not for us to do more than declare the evils; the remedy must come from another quarter. We can only do our duty to the public in the matter; and when we know that alcohol is a fertile source of so much evil in our land, we ought to speak, and even pray, that some strong measure may be adopted to restrict the sale of ardent spirits, but not the products of fermentation; although happy is the man who can do with or without even these latter. The end to be gained—and I trust Dr. Lionel Beale will with his able pen and ability advocate it—is this, the amelioration of our fellow-creatures, maybe by placing some very heavy licence duty upon those permitted to sell ardent spirits and fortified wines; and, if the lovers of alcohol will have it in full force, let them pay dearly for it, and at least relieve the milder drinkers from the onus of having to be heavily taxed and rated for their selfishness. I suspect, looking at it merely as a matter of finance, the Government gets about ten millions from the spirit duty, and the ratepayers are paying ten times this amount in compensating the evils produced by spirit-drinking, whilst the whole nation is groaning under a sense of moral degradation, and mental as well as physical degeneration.

I am, &c., J. W. TURNER, F.R.C.S.

31, Lower Phillimore-place, Kensington.

N.B.—I have just read the excellent letter of “F.R.S.” in your number for December 16, with whose sentiments I entirely agree.

A RAILWAY BOON TO THE SICK.—Lord Lyttelton, Lord Leigh, and other noblemen and gentlemen, are trying to induce the railway companies in the district of Redditch to grant to the holders of out-patients' tickets for the Birmingham Hospital, residing six miles and upwards from Birmingham, the privilege of riding on their lines to Birmingham and back at a single fare for the double journey.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, DECEMBER 19, 1871.

Mr. HILTON, F.R.C.S., President, in the Chair.

MR. SPENCER WATSON exhibited an Ulcer of the Eyelid, removed by Dr. Swift Walker, from a male aged 68. The man had long suffered from a pimple in that vicinity, which he picked till it began to ulcerate. When the ulcer was removed the glands were not affected, and no deformity followed. The growth seemed epitheliomatous.

Dr. CHOLMELEY considered the growth was so small it was useless to discuss its characters till it had been described microscopically. (Referred to Committee on Morbid Growths.)

Mr. A. T. NORTON exhibited a specimen of Ulceration of the Trachea undergoing repair, and a sloughing cavity in its vicinity. The patient had been ill four months, and had brought up blood. On examination by the laryngoscope, the trachea was seen to be ulcerated, and the voice was rough. The breathing was also hoarse; but he improved under treatment. He died quite suddenly. The other parts were healthy, and there was no history of syphilis.

Dr. SOUTHEY narrated the case of a female patient who came to St. Bartholomew's Hospital, cachectic and losing flesh. Two years previously she had been stout. By-and-bye she began to vomit and suffered from flatulence. She had some scars on her leg which were pigmented, but not more than usual. In August she took to bed, and had some diarrhoea; then persistent vomiting began. A diagnosis of ulcer of the stomach was made. She was very taciturn, and was delirious at night. She was fed by nutritive injections, but sank from exhaustion. The viscera were healthy except the lungs, which contained some patches of tubercle. The supra-renal capsules were also enlarged and caseous. The right was the larger. There was no pigmentation of the skin.

Dr. POWELL asked if the capsules had been examined microscopically, as disease of the supra-renal capsules of this kind, without bronzing, was rare.

Dr. SOUTHEY, in reply, stated that they had been carefully examined: they only gave signs of caseous degeneration.

Dr. DICKINSON considered the change here was not identical with that found in Addison's disease where there was a cellular growth. Sometimes the capsules were altered without any bronzing of the skin. (Referred to Drs. Greenhow, Cayley, and Southey.)

In reply to the President, Dr. SOUTHEY said the solar plexus was involved, but the semilunar ganglion was not examined.

The PRESIDENT remarked that in one case, where there was no bronzing, he had made the post-mortem for Dr. Addison, and found the semilunar ganglion fatty.

Dr. PEACOCK narrated the following case:—A man, between 40 and 50 years of age, was admitted into St. Thomas's Hospital, under the care of Dr. Peacock, on December 11, 1871. It appeared that immediately before his admission he was observed to be holding himself up against the railings of a house, and when admitted, though he could not speak, and had apparently lost the use of the right side, he was sufficiently intelligent to be able to protrude his tongue. At first great difficulty was found in getting the bowels to act, but after a day or two, when free evacuations had been obtained, he rallied somewhat, though he never recovered the power of speaking, and his intelligence continued impaired. On the 17th he was evidently sinking; both pupils were small, but the left rather the larger of the two; his eyelids dropped, but paralysis of the left was less than the loss of power of the right; the mouth deviated to the left side; he had entire loss of power over the right limbs, and the right side of the chest moved less freely than the left. There was no distinct stertor, but he was disposed to moan, and his breathing was embarrassed, and there was loud rhonchus in the chest, which entirely masked the cardiac sounds. He could not evacuate the bladder, and the urine removed by the catheter was at first albuminous, and subsequently contained blood. The stools were passed unconsciously.

Dr. PAYNE narrated the post-mortem appearances. He found a clot in the middle cerebral, and the brain was softened at the middle temporal convolution; the frontal lobe was not so. The softening passed inwards to the corpus striatum. The clot seemed to have been mainly formed *in situ*. The heart was

large, and the pericardium adherent. There were no vegetations on the valves, and the kidneys were granular.

Dr. MURCHISON said the case was of importance with regard to diagnosis. He had seen paralysis from plugging of the middle cerebral without loss of consciousness, though some say that loss of consciousness is frequent.

Dr. PAYNE said in this case the man was hanging on to a railing, and could not speak. When loosened from the railing he fell.

Dr. WHIPHAM said that in such cases the accession of symptoms was sometimes gradual, loss of speech coming on a day or two before loss of power.

The PRESIDENT asked what were the effects of plugging of the middle cerebral as compared with vessels of other parts.

Dr. SCHULHOFF had a case of plugging of the posterior cerebral with similar symptoms to those produced by plugging of the middle cerebral.

Dr. DICKINSON said, with regard to the resemblance of the symptoms of plugging to those produced by extravasation, he had met with several cases where the symptoms were exactly similar. When the basilar artery was plugged, both sides of the body were paralysed, and death speedily followed.

Dr. GOODHART inquired if this was due to arterial disease.

Dr. DICKINSON: No; rather to condition of the blood.

Mr. HULKE thought this explanation was insufficient, as coagulation ought to be general if due to condition of blood.

Dr. MURCHISON said that, nevertheless, it was so in point of fact.

Dr. DICKINSON said in one case the basilar was atheromatous; in the others it was not.

Dr. MURCHISON had reported a case of relapsing fever where gangrene of the lower extremities came on from coagulation in the femoral vessels. There were also plugs in the renal and splenic vessels. The patient died from plugging of the middle cerebral.

Dr. SEPTIMUS GIBBON doubted if there was true loss of consciousness here.

Dr. PEACOCK had often seen less loss of consciousness with extravasation of blood.

Dr. PAYNE next exhibited an altered Bloody Mass from among the Muscles of the Thigh. The patient had heart disease, and the leg had begun to swell. Then a tumour appeared in front of the thigh. It was punctured, but only a little clear serum came away. The mass turned out to be a blood-clot. On examination, after death, it was found that this had altered, just like a clot in a vessel. Outside was a whitish film or membrane; in the middle was a white and crumbling mass. This showed that the influence of epithelium was not needed to induce these changes.

Dr. PEACOCK said this occurred in a boy with aortic and mitral disease. Some vegetations were found in the auricle. There was also renal disease.

Dr. MURCHISON asked if the patient suffered from uræmia, and if the muscle was altered. Did the plugging seem to follow blood-poisoning, as in fever?

Dr. PAYNE said the vessels seemed natural. The muscles were infiltrated, and there was some hæmorrhage into the sub-arachnoid. The kidneys were in a state of acute nephritis.

Dr. PEACOCK said intelligence was impaired, but there was no distinct uræmia. He was better just before death.

Mr. HULKE narrated the case of a girl who came to King's College Hospital with what was supposed to be a medullary cancer. The skin broke, a bloody mass came away, and the girl got quite well. He had, however, seen medullary cancer simulating these extravasations.

Dr. PEACOCK had often seen extravasations in the rectus abdominis in typhus.

Dr. GOODHART showed a Cast of the Intestine from a Woman who had suffered from Constipation, and passed these casts from time to time. They consisted mainly of columnar epithelium.

Mr. ARNOTT gave an account of the structure of a Scrofulous Testicle, as a sequel to a former contribution. The growth was almost entirely fibro-corpuseular, like that of a gummy tumour. In the later stages of several forms of diseased testicle the appearances were alike. Either the corpuseles degenerated or they were squeezed aside by the fibrous tumour.

Dr. PAYNE had noticed the same similarity of appearance.

Dr. CAYLEY said that in tubercle there were no vessels, so that the tissue could not develope.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, DECEMBER 15, 1871.

Dr. WOODFORDE in the Chair.

AFTER the usual preliminary business, Dr. STEVENSON brought up a report from the General Purposes Committee on the subject of the unsatisfactory state of the Water Supply, embodying a resolution to the effect that this Association requested the Government to institute an early inquiry into the quality of the metropolitan waters by an independent skilled analyst, in consequence of the probable approach of an epidemic of cholera, and of the uneasiness produced in the public mind by the Registrar-General's reports, especially as all investigation led to the conclusion that there existed a connexion between drinking-water and cholera. The report was adopted.

W. H. MICHAEL, Esq., then gave his views "On Future Sanitary Legislation." After glancing at the unaccountable phenomena of the metropolis being carefully excluded from various sanitary inquiries and reports, he proceeded to ask what were the proper limits of legislation in regard to sanitary measures. Property must, he said, have some laws respecting sanitary matters. It was evident that something more than individual supervision was necessary. One of the greatest difficulties in the future lay in neglect in the past. People had formerly been allowed to do as they liked with their property, and defaulters were often men of influence on the local boards. These men were a great obstacle in the way of sanitary improvements throughout the country. Moreover, after people had been allowed to build houses in a certain way, it was hard to call upon them now to put their houses in a certain condition. The question then arose as to how far sanitary legislation is to be compulsory. Hitherto, he argued, it had been—practically, at least—permissive. The infliction of a small fine was ineffectual. It was plain that the public had a right, in the interests of their own pockets, to say to an owner, "*Sic utere tuo, ut alienum non lædas.*" Besides the difficulty arising from the past, another one also arose where there was only a sparse population, as in country districts. Taking the law (1) as it is, and (2) as it ought to be, Mr. Michael said nothing was more unsatisfactory than the present state of things. There were Acts within Acts, so complicated and so embroiled that even learned judges confessed that they could make no sense out of the enactments on this subject. The Government itself had proved unable to give advice to local boards. The consequence was that in some districts boards had been broken up, and in others action had been paralysed. Act contradicted Act, district overlapped district. Consolidation of sanitary authority had long been urged, and in the last session a great step had been made in this direction. The next thing to be aimed at was the establishment of one local power. Then areas would need rectification in such a way that not political exigencies, but the wants and physical conditions, should be considered. As to sanitary officers, Medical Officers of Health were at present mostly men in private practice, and dependent on the very men against whom they ought to take action. Therefore, except in times of panic arising from an epidemic, their hands were tied, and they limited themselves to removing the more obvious nuisances. It was necessary, then, that there should be one general statute embodying all the various sanitary enactments, and a central authority to supervise their execution. While he approved of what had been done last session in this last respect, he did not think sanitary measures ought to be confined to the houses of the poor; every house in the country ought to be included within their scope. He was also averse to their having any connexion with Poor-law relief. As to the divisions of areas, a fast line could not be drawn; they ought to be determined by their physical condition, their drainage necessities, and the watershed. The areas ought to be large enough to support thoroughly efficient officers. As to the constitution of local boards, and the difference between urban and rural populations, Mr. Michael maintained that a difference, not in matter, but in manner, was needed. There ought to be only one authority in each area, and that authority thoroughly representative. He proposed, also, an intermediate authority of a higher character to hear any appeals on the spot—such as the Metropolitan Board of Works was to the London vestries, whose duty should be to step in when local boards failed to do their duty. He was sorry that in the Bill brought in by Sir Charles

Adderley, based upon the report of the Royal Commissioners, there was no such provision. The deficiency could not be adequately supplied by inspectors sent down from London; their action would come when it was too late. An authority was needed on the spot to prevent in time. Boards of Guardians would not do for this; they had shown their incompetency in the past. The sanitary officers must be thoroughly educated Medical Officers of Health. They must not be, as in times past, merely ornamental adjuncts; they ought to be the moving powers in sanitary matters. They must be men of high intellect, and the area large enough to give them a salary that would enable them to give their whole time to their office. The registration of death and of sickness ought to be under their control instead of being in its present unsatisfactory state. Mr Michael likewise proposed that there should be a Minister of Health as the head of the central authority; that there ought to be a compulsory power for joining districts for drainage purposes; that additional borrowing powers should be given; that the incidence of rates should be modified in accordance with the benefits accruing; that Medical Officers of Health should be armed with increased powers to prevent overcrowding, and to deal with infectious diseases; and that private Practitioners should be compelled to give all necessary information,

Dr. STALLARD objected to many points raised by Mr. Michael. He maintained that it would be impossible for any authority to carry out what was against the public opinion of a district. The people must first be educated. He defended boards of guardians from the charge of failure; for how could they act effectually when the law itself was so contradictory? As to an intermediate authority, he thought that unless it had the power of taxation, it would never do. He had not more faith in the sanitary enlightenment of country squires than of boards of guardians. He thought it would be better to go on progressing steadily as they were at present doing. If the central authority could contribute or withhold a certain quota of the expense, that would be far more effective than compulsion. With the latter part of Mr. Michael's remarks he quite agreed. He warned them against centralisation and functionarism. In England it would prove a failure.

Mr. HOLLAND deprecated harsh compulsion. He was in favour of inspectors under the central authority, as being free from all suspicion of partiality and from all local prejudices. Such men would be able to carry their experience from one district to another, and enlighten the sceptical by adducing what was in actual operation. He thought that the difficulty of adapting sanitary measures to various districts arose in great measure from the determination of Parliament to do everything itself, even things it was incompetent to do. He quite agreed that Medical Officers of Health ought not to be in private practice.

Dr. HARDWICKE agreed with most of the proposals advanced by Mr. Michael, but did not think it likely Parliament would give that extension of power to Medical Officers which he proposed. He thought they ought to work things as they stood, rather than invent a new cut-and-dried system. If these county boards could be obtained, it would be a great step. The illness of the Prince of Wales would, no doubt, have its effect upon the House, at least during the early part of the session. Mr. Michael might tone down some of his views, and then they might bring these matters before the notice of Government. He thought judgment and tact were among the most necessary qualifications of a Medical Officer of Health.

Dr. BARCLAY agreed with Mr. Michael in many respects, especially as to the position of Medical Officers of Health. He thought he ought to have under him a number of deputies; and the Poor-law Medical Officers were the best in the world for this. He differed from Dr. Stallard as to legal compulsion. Without it in the background they could never have succeeded, although he advised a scanty use of it. Judgment and moral suasion were among the best qualifications of a Medical Officer. Men specially trained for the duties would not succeed so well as a man of large and practical experience. He was therefore in favour of Medical Officers of Health having some field of practice if they were independent of the districts in which their powers lay.

The CHAIRMAN said that the mere possession of compulsory powers was mostly all that was necessary. He was in favour of large areas of operation, and of the registration of deaths and sickness being under the control of the Medical Health Officer.

After some little further discussion, the meeting concluded.

NEW INVENTIONS.

APPARATUS FOR APPLYING HEAT OR COLD TO DIFFERENT PARTS OF THE HUMAN BODY.

(Designed by Dr. ALEXANDER ROBERTSON, of Glasgow.)

THESE apparatus are constructed for the application of regulated temperatures, from that of ice to the highest that can be borne. They consist of two or more compartments, and have an inlet- and an outlet-pipe from three to four feet in length, through which water is admitted and discharged. The current is regulated by a tap on the discharge-pipe, and may be either constant or intermittent. There is no difficulty in maintaining the temperature of the circulating water to within three or four degrees of a given point. They may be worked either in connexion with a vessel of water which has a tap at the bottom—the end of the inlet-pipe being attached to the top—or on the principle of the syphon, in which case no special vessel is required.

HEAD BAG.—It consists in some of eight, in others of ten, compartments, each a little more than an inch in diameter. These are arranged in parallel lines over the head, those at the sides being much shorter than the central ones. The whole set of compartments are cemented along part of their under surface to thin vulcanised cloth, which fits the head smoothly, and they are covered externally by thin woollen or waterproof cloth, to which thin vulcanised cloth is stitched or cemented along the margin. The cap is secured to the head by straps under the chin. When sufficiently distended it contains only about eight ounces of water; and if a free current be allowed to circulate, this will all be displaced by a fresh supply, admitted by the inlet-pipe, in less than half a minute. Dr. Robertson states that by circulating ice-water, or a solution of ice and salt, cold is more conveniently and efficiently applied to the head than by the ice-bag; and he hopes that by the use of water at definite degrees of heat a soothing influence may be produced on the brain in certain forms and conditions of disease.

CHEST OR ABDOMINAL BAG.—It consists of six compartments, which are enclosed in the same way as in the head bag. When sufficiently distended the weight both of bag and contents is less than that of an ordinary poultice. It may be used alone, or on the outside of a light poultice or fomentation. The heat of the two latter agents may be renewed without in the least disturbing the patient, by simply admitting warm water at the inlet-tube, which displaces what is in the bag when the tap on the outlet one is open. Dr. Robertson says that besides preventing patients from being exposed and annoyed by the renewal of the poultice or fomentation, this bag is useful in certain cases of disease when a uniform high temperature is maintained for one or more hours continuously, and he expects that it will reduce hyperpyrexia through the circulation of ice-water.

UTERINE BAG.—It consists of two compartments. On the outer surface is a small pouch for a director to assist insertion; and at the sides and ends are little loops, to which a piece of lint may be tied. It is rolled up lengthways, and can then be pushed up behind the neck of the uterus with the greatest ease. After its introduction, water is allowed to flow into the bag, expanding it, and then passes away by the outlet-pipe. Should a moist or sedative fomentation be desired, the lint is previously soaked with water or other suitable liquid. According to the height of the column of water in the inlet-pipe, the bag may, or may not, be fully distended internally.

Dr. Robertson states that this instrument is useful in inflammatory conditions of the uterus, in certain states of uterine cancer, etc., when warm water is circulated; and that in menorrhagia the cold of ice-water, with the pressure of the distended bag, usually stops the bleeding.

SPINAL BAG.—This bag is about a foot in length, but it may be longer or shorter, and consists of two compartments which communicate freely below. Along their inner margin they are connected closely together, at intervals, by bands. At the top, the one terminates in an inlet-, the other in an outlet-pipe. As in the other apparatus, the current through this bag may be either constant or intermittent. Besides its obvious use in applying either a low or high temperature to the spine in ordinary inflammatory and painful affections, Dr. Robertson thinks that the effect of maintaining an equable high temperature in such diseases as tetanus, locomotor ataxy, etc., is worthy of being tested.

THROAT BAG.—This instrument exists only in pattern. It is anticipated that it will be found useful in laryngitis, etc.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, January 4:—

Butler, William John, Delamere-crescent, W.
Thompson, Francis Henry, Tenbury, Worcestershire.

As an Assistant in Compounding and Dispensing Medicines:
Hockenhull, Philip Hall, Macclesfield.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BAGSHAWE, FREDERIC, M.A. M.D. Cantab., M.R.C.P.L.—Assistant-Physician to the East Sussex, Hastings, and St. Leonard's Infirmary.

BAYLIFFE, ALWORTH M., M.R.C.S.E. and L.S.A.—Medical Officer for the Eleventh District of the Axbridge Union.

ORMSBY, L. H., L.K.Q.C.P.I., L.R.C.S.I., Demonstrator of Anatomy in the School of Surgery, Royal College of Surgeons of Ireland—Surgeon to the Meath Hospital and County Dublin Infirmary, *vice* Robert St. John Mayne, L.K.Q.C.P.I., etc., deceased.

O'SULLIVAN, STEPHEN, M.D. Queen's Univ. Irel., C.M., L.R.C.S. Edin., etc.—Medical Officer for the Blackrock Sub-district of the Cork Dispensary District.

SWEENIE, W. F., M.B., L.R.C.S.—Medical Officer for the Killea District of the Londonderry Union.

MILITARY APPOINTMENTS.

19TH FOOT.—Staff Assistant-Surgeon Henry Hummerston Burford, to be Assistant-Surgeon, *vice* John Leader, who exchanges.

50TH FOOT.—Staff Assistant-Surgeon John Murray, M.B., to be Assistant-Surgeon, *vice* Jonas Richard Leake, placed upon half-pay; Staff Assistant-Surgeon Brodie Cruickshank, M.B., to be Assistant-Surgeon.

MEDICAL DEPARTMENT.—Assistant-Surgeon James Landale, M.D., from the 6th Dragoon Guards, to be Staff Surgeon, *vice* Staff Surgeon-Major Thomas Frederick Wall, who retires upon half-pay; Assistant-Surgeon John Leader, from the 19th Foot, to be Staff Assistant-Surgeon, *vice* Henry Hummerston Burford, who exchanges; Assistant-Surgeon Christopher John Weir, M.B., from the 75th Foot, to be Staff Assistant-Surgeon, *vice* Arthur Wellesley Roche, appointed to the 48th Foot; Assistant-Surgeon Jeremiah James O'Grady, from the 104th Foot, to be Staff Assistant-Surgeon, *vice* William Armstrong, placed upon half-pay.

BREVET.—Staff Surgeon-Major Thomas Frederick Wall, who retires upon half-pay, to have the honorary rank of Deputy Inspector-General of Hospitals.

BIRTHS.

BATEMAN.—On January 7, at 32, Compton-terrace, Highbury, N., the wife of Henry Bateman, F.R.C.S.E., of a daughter.

BLYTH.—On December 27, 1871, at Worcester, the wife of A. W. Blyth, M.R.C.S., L.S.A., A.K.C., of a son.

THOMSON.—On December 28, 1871, at Greenock, N.B., the wife of James Thomson, Surgeon Royal Navy, of a son.

WATSON.—On January 2, at Little Huthwaite, Wortley, near Sheffield, the wife of Alfred M. Watson, M.D., of a daughter.

WILLEY.—On January 6, at Winchester, the wife of Henry Willey, M.B., of Heathfield, Bromley, Kent, of a daughter.

MARRIAGES.

AMBROSE—McMURDO.—On December 5, 1871, at St. James's Church, Delhi, J. D. Ambrose, M.D., Assistant-Surgeon 58th Regiment, to Katherine Emily, eldest daughter of Major-General W. M. S. McMurdo, C.B., commanding the Rawul-Pindee Division.

BARRIE—D'URBAN.—On January 10, at 30, Gilmore-place, Edinburgh, Andrew David Barrie, M.B., C.M., and L.R.C.S., of Dumfries, to Emily, relict of Thomas William Findlay D'Urban, of Natal, and youngest daughter of the late John Stiven, of Glasgow.

HULL—OGLE.—On December 4, 1871, at St. George's Cathedral, Cape of Good Hope, George Askew Hull, M.R.C.S. and L.M., eldest son of Dr. George Hull, 102, Warwick-gardens, Kensington, to Isabel, fourth daughter of John Connell Ogle, Esq., of Kensington.

HUNTLY—JONES.—On January 2, at Holy Trinity Church, Sydenham, the Rev. B. C. Huntley, M.A., to Jessie Augusta, eldest daughter of Edward Jones, M.D., Sydenham-park.

WRAITH—DUCKLE.—On January 2, at the Church of St. Mary, Reading, Lawrence Hargreaves Wraith, Esq., third son of the late S. H. Wraith, F.R.C.S., J.P., of Over Darwen, Lancashire, to Eliza Marian Burton, elder daughter of the late H. C. Duckle, M.D., of Pilham Hall, Lincolnshire.

DEATHS.

BESEMERES, WILLIAM, M.D., F.R.C.S., formerly of the Old Kent-road, at Dole, near Aberystwith, on December 29, 1871.

BROWN, SARAH, the beloved wife of Lundin Brown, M.D., at Malvern Wells, on December 21, 1871, aged 34.

DEBENHAM, ELIZABETH MOSS, wife of Robert Debenham, M.R.C.S., at Heath House, Stepney, on January 3, aged 40.

EDWARDES, JOHN, M.R.C.S.E., at his residence, Uppingham, Rutland, on January 8, aged 54.

FERNLEY, CHARLES, Surgeon of the Royal South Lincoln Militia, on December 20, 1871, at Grantham, aged 61.

MINOAYE, CHARLES PAGET, Surgeon, late of Twickenham and Dedham, at 215, Brompton-road, on January 6, aged 48.

MUNDAY, CHARLOTTE, widow of Dr. Charles Munday, formerly of King-street, Snow-hill, E.C., at 7, Fortress-terrace West, Junction-road, N., on January 5, in the 59th year of her age.

ROBINSON, HENRY CHARLES, M.R.C.S.E., L.S.A., many years senior Medical Officer of Mile-end Old Town, and formerly of St. Pancras, at his residence, 156, Stepney-green, on January 8, aged 64.

WARE, ELIZABETH JESSIE, daughter of the late Dr. Hibbert Ware, at Torquay, on the 8th inst.

WELD, ELIZA ANN, wife of William Walter Weld, Staff Surgeon H. P., at Eastgate, Rochester, on January 3, aged 45.

WOLSELEY, CHARLES BERTIE, third son of the late William Augustus Wolseley, M.D. Edin., of Rothesay, Isle of Bute, supposed to have been lost in the ship *Arco*, on her last voyage from Calcutta, in the 19th year of his age.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BATH ROYAL UNITED HOSPITAL.—Medical Officer. Must be M.R.C.S., and either L.R.C.P.L. or L.S.A. Applications and testimonials to the Secretary, on or before January 22. Election February 6.

CALNE UNION.—Medical Officer for the entire Union. Candidates must possess the qualifications prescribed by the General Orders of the Poor-law Board. Applications and testimonials to Mr. H. S. Heath, Clerk, on or before January 30.

CANCER HOSPITAL, LONDON AND BROMPTON.—Resident House-Surgeon. Must be M.R.C.S.E. Applications and testimonials to the Chairman of the Weekly Board, 167, Piccadilly, on or before January 22.

CHESTER GENERAL INFIRMARY.—Visiting Surgeon. Double qualifications required. Further particulars to be obtained of Mr. T. Jones, Secretary, on or before January 22.

CHRISTCHURCH UNION.—Medical Officer. Candidates must be qualified in accordance with the General Orders of the Local Government Board. Applications and testimonials to the Clerk to the Guardians, on or before January 22. Election the same day.

CROYDON UNION.—Medical Officer for No. 3 District. Candidates must be duly qualified to practise. Applications and testimonials to Mr. A. G. Blake, Clerk, on or before January 15. Election on the 16th.

GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, 16, BRIDGE-STREET, MANCHESTER.—Resident Medical Officer. Candidates must be duly qualified and registered. Applications and testimonials to the Secretary, on or before January 23.

JERSEY GENERAL DISPENSARY.—Medical Officer. Further particulars of the Rev. P. A. Le Feuvre, Oakwalk, Jersey. The election takes place early in January, and the duties will commence on February 1.

MIDDLESEX HOSPITAL.—Resident Obstetric Assistant. Must possess one legal qualification. Applications and testimonials to the Secretary, at the Hospital, on or before January 30.

QUEEN'S COLLEGE, CORK.—Professorship of Chemistry. Applications and testimonials to the Under-Secretary, Dublin Castle, on or before January 22.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Must be a Member of the College of Surgeons of London, Dublin, Edinburgh, or Glasgow; or a Licentiate of the Society of Apothecaries. Applications and testimonials to the Treasurer, Mr. R. Tweedy, Truro, on or before January 20.

ST. GEORGE, HANOVER-SQUARE, DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE.—Physician-Accoucheur. Must be M.R.C.P.L. Applications and testimonials to the Honorary Secretary, on or before January 30.

ST. PANCRAS, MIDDLESEX, N.W.—Medical Officer for No. 7 District. Candidates must possess the qualifications prescribed by the General Orders of the Poor-law Board. Forms on which applications are to be made may be had of Mr. D. Fildeu, Clerk to the Guardians, on or before January 15. Election on the 18th.

SUNDERLAND INFIRMARY.—Junior House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Senior House-Surgeon, on or before January 20.

TONBRIDGE UNION.—Medical Officer for the Fourth District. Candidates are required to possess the qualifications prescribed by the General Orders of the Poor-law Board. Applications and testimonials to Mr. F. Stone, Clerk, on or before January 18. Election the following day.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

New Winchester Union.—Mr. Frederick Eldridge has resigned the Third District; area 18,500; population 2359; salary £92 per annum.

St. Asaph Union.—The Rhuddlan District is vacant; area 7478; population 4151; salary £78 per annum.

St. Pancras Parish.—Mr. J. Wickham Barnes has resigned the Seventh District; salary £100 per annum.

APPOINTMENTS.

Biggleswade Union.—Thomas H. Barues, M.D. St. And., M.R.C.S.E., L.S.A., to the Sandy District.

Oldham Union.—Samuel Jackson, L.R.C.P. Edin., M.R.C.S.E., L.S.A. Lond., to the Workhouse.

Wolverhampton Union.—Francis J. Griffiths, L.F.P. & S. Glasg., L.S.A. Lond., to the Bilston District.

Woodbridge Union.—Henry R. Ruckley, L.R.C.S. Ire., L.R.C.P. Edin., to the Fifth District.

THE next examination of candidates for commissions in the Medical Department of the Army will be held in London, on February 12. It is stated that there will be about twelve vacancies.

ROYAL COLLEGE OF SURGEONS.—At a meeting of the Council on the 11th inst., Mr. John Buck Stedman, of Godalming, Surrey, having been elected a Fellow at a previous meeting of the Council, was admitted as such, his diploma of Membership bearing date March 5, 1841. At the same meeting a vacancy at the Dental Board was declared, caused by the retirement of Mr. Edward Cook.

ARTS EXAMINATION.—The 300 gentlemen who underwent their preliminary examinations for the diplomas of Fellowship and Membership of the Royal College of Surgeons a few weeks since, will be glad to know that the result will be sent to them in the ensuing week.

PROFESSOR FLOWER, F.R.S.—This gentleman has consented to deliver a lecture on the "Structure and Habits of Fishes," at the *soirée* which will take place this (Friday) evening in the Aquarium of the Crystal Palace.

A MEDICAL OFFICER OF HEALTH is about to be appointed at Oxford during the progress of the drainage works.

The mortality of Paris is still decreasing; the numbers last week were 768, against 832 the week before.

BY the resignation of Dr. Bond the Regius Professorship of Physic in the University of Cambridge has become vacant. Dr. Bond has held the office since 1851. The names of Professor Humphrey and Dr. Latham have been mentioned as likely to succeed Dr. Bond.

A MOVEMENT has been started to establish a Hospital in London "for the treatment of diseases apart from the ordinary administration of alcoholic liquors."

MONDAY, February 12, and following days, have been appointed for a competitive examination of candidates for the Naval Medical Service, at the University of London, Burlington Gardens.

A SWISS society has offered two prizes of 400 fr. and 200 fr. each, for an essay on the best means for moderating the excessive consumption of ardent spirits in Switzerland.

Dr. BALLARD has been sent down by the Local Government Board to Wolverhampton, to make an official inquiry into the cause of the excessive death-rate which has prevailed for some time in that town.

CHOLERA has reappeared in Western Mekron, and intermittent fever is prevalent in the town of Gwadir. Several villages in the immediate neighbourhood of Calcutta are suffering from a severe visitation of fever. A few cases of cholera are reported to have occurred at Decca.

THE Metropolitan Board of Works, with a view of ascertaining whether there is any connexion between typhoid fever and sewage emanations, have requested all the metropolitan vestries to send in returns of the number of men and boys employed in flushing and other sewer work, and the number (if any) that may have been attacked with typhoid fever.

HEALTH OF SHIPS' CREWS.—The Board of Trade has decided to substitute chloralum for the solution of zinc at present included in the scale of medicines and medical stores issued and caused to be published by the Board.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—On Friday, January 5, 1872 (J. M. Burton, Esq., F.R.C.S., President, in the chair), Dr. Geo. Johnson read a paper "On the Pathology and Treatment of Cholera," in which he ably enunciated his now well-known views of that disease, and defended himself from attacks that have recently been made upon him. Drs. Clapton, Carr, Dixon, Venables, Gooding, and Moon, and Mr. Mitchell, took part in the discussion which followed.

CHAIR OF PHYSIOLOGY AT THE PARIS FACULTY OF MEDICINE.—For this there are two candidates—M. Béclard, well known for his treatise on Physiology; and M. Vulpian, the present Professor of Pathological Anatomy. The latter candidate, being considerably the younger, and remarkably well versed in all the investigations of the more modern schools, would probably stand the better chance, had not the Faculty some time since pronounced against the "permutation of chairs" by a large majority.

UNIVERSITY COLLEGE, LONDON.—At a Session of Council on the 6th inst., Mr. J. Booth, C.B., in the chair, after the reading of the School Committee's report, in which the Committee represented the urgent necessity of an extension of the school buildings, in order to accommodate the rapidly increasing number of pupils, Mr. Samuel Sharpe, a member of the Council and of the Committee, announced his intention to present the College with the sum of £4000 as a contribution to the cost of the required buildings. The cordial thanks of the Council

were at once voted to Mr. Sharpe for this most generous gift, the gratitude evoked by which was enhanced by the recollection of former liberal donations to the College from the same gentleman, who had previously given two sums of £1000 each to the School-Building Fund, £1000 to the Retired Professors Fund, £600 to the Fine-Art Building Fund, and several other lesser sums for various college purposes. The College has recently received from another liberal friend, Mr. J. Pemberton Heywood, a donation of £1000 to the School-Building Fund, to which he had contributed a like sum a few years ago, besides £500 to the Fine-Art Building Fund. At the same Session a communication was read from the late Mr. Felix Slade's executors, in which they stated that, having been informed that further assistance was needed to defray the cost of the fine-art buildings at the College, and to provide casts and other appliances for the use of the students, they had determined to place in the hands of the Council the sum of £1600, to be applied for the purposes above mentioned. It may perhaps be remembered that about two years ago the executors gave to the College £5000 towards the Building Fund, in addition to the large endowments for the Slade Professorship and Scholarships founded at the College, in pursuance of the directions contained in Mr. Slade's will. The best thanks of the Council were voted to Mr. Slade's executors for this further proof of the desire which they have on every occasion evinced to promote the interests of the Fine-Art Department of the College. A resolution was adopted at the same Session to admit ladies attending the class of political economy, to compete for the prizes and the Hume and Ricardo Scholarships, awarded for proficiency in that science.

TESTIMONIAL TO J. W. KAY, M.R.C.S.E., ETC.—On the 4th inst. a public dinner was given at the "White Hart," in Abchurch-lane, for the purpose of presenting a testimonial to Mr. J. W. Kay, which consisted of a malachite clock, together with a silver tea- and coffee service, claret-jug, etc., and bore the following inscription:—"Presented to J. W. Kay, Esq., M.R.C.S.E., by members of the Medical Profession, and others, his neighbours and friends, in testimony of their esteem and very warm regard."

AN ORDER OF MERIT AND HEREDITARY HONOURS.—Much discussion has taken place on the question, What is the most fitting distinction to bestow upon eminent Medical men? It may be interesting to trace the origin of hereditary dignities. That of Baronet is the most modern of all such dignities. Its creation in England dates from the year 1611; but, in 1619, James I., being desirous of replenishing the Royal coffers, and at the same time of colonising the province of Ulster, in Ireland, extended this new order of hereditary knighthood to that part of the kingdom, and offered it, together with a grant of land in the above-named province, to anyone who paid £1000 into the Royal exchequer. The oldest baronets are, therefore, for the most part, representatives of a purchased honour. The blood-red hand, emblazoned on the escutcheon, and borne as an honourable augmentation on the coat-armour of all recipients of this order, constitutes, in fact, the arms of Ulster. There are no ancient historical associations connected with this innovation upon the Equestrian Order. The baronets of Scotland (A.D. 1625) owe their origin to a like scheme for colonising Nova Scotia. The order has never altogether lost its plebeian, or, rather, venal origin; and as the number of its members is now unlimited, mere wealthy *parvenus* have so frequently gained admission into its ranks, that it has become the constant theme of ridicule, together with its twin-brother, the City Knight. Thus, in the words of a once-popular song—

"Next came a baronet whose blood-red hand
Was emblazoned in chivalry;
But as he'd been known behind a counter to stand,
Why, he would not do for me."

As no political or personal privileges attach to the position, unlike the peerage, there is no court that can decide a disputed claim to this title. Hence, there are at the present day many contemporaneous claimants, all asserting their right, and assuming the title which this dignity confers, to the great confusion of genealogists and heralds. The title may be, therefore, almost as readily assumed as that of Esquire, which, strictly speaking, no amount of property or of courtesy can bestow. Knighthood, at all events, is at least personal, and there can be no mistake about the individual so honoured; but after two or three generations it is sometimes hopeless to attempt to decide upon the succession to a baronetcy. So much for the hereditary principle. Again, the judges of the land are, for the most part, satisfied with a simple knighthood, and certainly reflect as much honour upon it as it confers upon them, although occasionally they are raised to the peerage,

rather to assist in its appellate jurisdiction, and to preserve the character of that time-honoured attribute of the institution, than as a matter of personal favour to themselves, or even as the reward of merit. No title, in fact, enjoys a greater *prestige*, or is more associated with historical reminiscences and chivalrous devotion than that of knighthood. For a man to "win his spurs" by merit is proverbial. The Equestrian Order has always commanded respect and claimed consideration. At one time it constituted even an international, if not a cosmopolitan fraternity, and the "*chevalier sans peur et sans reproche*" expresses the very quintessence of knightly honour. The craving for hereditary honours is certainly a marked feature of the present age. Such a yearning was unknown to the ancient barons of the realm, whose honours were solely personal, and for some centuries conferred no hereditary rank or privileges. Indeed, hereditary nobility was unknown in Europe till the year 987, when Charlemagne introduced it into France; but it was not recognised in England till some four centuries later, as is attested by many cases of writs of summons to Parliament never having been renewed to the descendants of the barons so summoned. The term "baron" was not originally, as now, synonymous with "noble," but rather with "freeman." The knight's fee in land was, in fact, the reward for distinguished services, and the fortunate possessor of several such fees was usually summoned, as one of the greater barons, to the general council of the nation; but the honour was merely personal, although, as lands could not be alienated without the king's permission, nor yet disposed of by will at all, the succession to knighthood frequently continued in the same families, the renewal of the honour being voluntary on the part of the king, but, at the same time, accompanied by a pecuniary acknowledgment on that of the recipient. At the present day an Equestrian Order of Merit of a purely personal character seems needful to reward distinguished men.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. J. E. Gross, Gibraltar.—The letter has been received, also an enclosure.

Dr. F. D. Edgerton, Middletown, U.S.A.—Your letter, with enclosure, has come safely to hand.

Q.—We do not know the preparation, nor do two leading chemists whom we have asked.

R. W.—The case is recorded in vol. xxix. of the *Transactions of the Royal Medical and Chirurgical Society.*

R.'s request has been attended to. We should be glad to receive further descriptions and statement of results.

Ishmael.—M'Call's, Houndsditch. For tongues write to Mr. Renshaw, Medical bookseller, 356, Strand, London, W.C. The latter are excellent and cheap.

An Experimenter.—The A B C process of the "utilisation of sewage" has been reprinted in the form of a pamphlet from the *Standard* newspaper, and may be obtained at E. Newman's, Devonshire-street, Bishopsgate.

Lambeth.—"A Guardian" informs us that notice of the following motion has been given, to be brought forward at the next meeting of the Lambeth Vestry:—"That, having regard to the resignation of their late Medical Officer, Dr. Puckle, they desire to record their high appreciation of his valuable services during the time he has held the office, and to express their hope that his health, impaired in the exercise of his Professional duties, may soon be restored."

Impudence and Cant.—A "London Physician" has called our attention to a pamphlet published by a quack doctor near Bedford-row, containing an account of some universal medicines which are to cure all diseases. That which distinguishes the work of this "Professor" is the abundance of greasy allusions to the Bible, from which the Professor professes that his system of cure is derived; and besides this, the impudence with which he forges quotations from Hippocrates, and testimonials from respectable Physicians. He asserts that the Queen's Physicians always prescribe his medicines in dangerous cases; he forges a testimonial from the late Mr. Beale, Medical Officer of Health to St. Martin's-in-the-Fields, and takes the same liberty with the names of many other eminent Practitioners lately deceased. Thus, amongst the alleged patrons of his quack pill and ointment, he gives the names of Count Wollowicz, Dr. Thomas Mayo, Dr. Symonds, of Clifton, Dr. James Jones—for he has the cunning to choose those who are lately dead, and whom he thinks he can misrepresent without being molested. We cannot help thinking what a profound and widespread ignorance of the Bible must prevail, when anyone can appeal to it successfully in favour of quack pills; and we wish that some Medical Corporation would have the spirit to indict the quack for libel in making this impudent use of the names of deceased members.

Materfamilias suggests that policemen should be armed with lactometers, and with authority to use them in testing the quality of the milk carried through the streets for delivery, and they will soon put a stop to the malpractices of dairymen. One man thus employed in each district would quickly work a reformation.

Worcester.—The Guardians were clearly wrong. The facts of the case may be stated briefly. It appears that on October 12 last Dr. Woodward certified that one William Jones, residing in the parish of St. Clement, was insane, and the usual certificate was handed over to the assistant-overseer, W. Walker. He duly visited the patient, and left with the intention of returning to him accompanied by a magistrate. Instead of doing so, however, he took with him Mr. Minchin, a Guardian, to the house of the lunatic. The circumstances were communicated to the Guardians on their next board day, and they gave a verbal order to Marshall "to suspend the usual proceedings for the removal of the lunatic to Powick." In the course of a few days the lunatic died, before his removal to any lunatic asylum. Now, who is responsible for this grave interference with the law? It may be answered, The assistant-overseer, Walker; and so, technically, he undoubtedly is; but surely the Guardians are solely *de facto* to blame. What right had they to interfere with the wholesome and necessary provisions of an Act of Parliament? Whatever the Guardians may think—and it would appear, from the report of the proceedings at their last meeting, they imagine they are to determine whether a certified lunatic is or is not to be removed to an asylum—we take the liberty of informing them that they are not the judges in the case, and that they are forced to obey the law. We understand, from the *Worcestershire Chronicle*, that the case is not the first of the kind that has happened at Worcester. We trust that the Local Board will take such steps as will, at all events, make it the last. Common humanity, as well as the interests of the public, demands that such outrages against decency and common sense should cease.

The Medical Declaration respecting Alcohol is treated with much ability and acumen in the last number of the *Camden and Kentish Town Gazette*. We extract the following as the views of a "Layman" on the subject:—

"It is patent, therefore, that, both in health and disease, the "Faculty" in this Declaration strictly adheres to the doctrine of temperance *versus* abstention, and merely urges the weight of its authority and opinion against *excess*. So far, it is a very conscientious document, and the hardest "pill" that teetotalers ever had to swallow. When the declarants, however, travel beyond the region of their Professional opinions and experiences, they are evidently beyond their depth. While they are to be commended for throwing their whole weight into the scale in favour of moderation, they have no right to stigmatise their own Profession as criminally addicted to the promotion of intemperance.

"As a Medical document, pure and simple, the Declaration is a very creditable and valuable performance; but as a political instrument and an indication of a demonstrable fact, it is as unreliable as the most romantic statement of a Robertson Gladstone or a Recorder Pope. The subject has been already, to use a vulgarism, 'run to risings.' In a physiological point of view the scientific treatment of alcohol is really subservient to the knowledge of the secret higher influences that operate upon the material of our existence, and of these learned men know little. . . . The Medical declarants were perfectly right in 'speaking by the card,' and advocating the medium. They shook their heads and looked wise, Professionally, over their patients' pulse, and characteristically and safely struck the 'happy medium.' So let us all do likewise, and advocate moderation and wisdom in all things, and thank our Heavenly Father, who does not allow a 'sparrow to fall to the ground' without his beneficent care, even for the blessing bestowed upon us in the shape of alcohol, remembering that its *abuse* in some cases does not lessen by one grain the value of its *use* by the majority."

C. H. W. P. has forwarded to us the following cases for publication.

Certainly, if an inquest was required in these instances, Medical evidence was essential to determine the real cause of death. No wonder the coroner's court "is becoming a by-word" when such cases occur:—

Case 1.—I was summoned at eight o'clock one morning to go five miles into the country, to see a woman—a primipara—who had been confined of twins by a midwife between 1 and 2 a.m. The old woman waited from that time until 7 a.m. for the expulsion of the placenta, and then despatched the husband to fetch a Doctor. About 9 a.m. I found the woman had been dead half an hour. The corpse was very much blanched, and the abdomen distended. The woman present stated there had been hæmorrhage going on more or less all the time, and that about an hour after the messenger started slight convulsions came on, speedily followed by death. I ordered the corpse to be left as it was, and on my return gave information to the authorities. In this case no inquest was held, and, as I refused a certificate, the death was returned "Uncertified," and the body buried by the clergyman.

Case 2.—J., a young man, about 30, a farm labourer, in robust health, came home from his work complaining of "toothache." He obtained some stuff from a chemist to apply to the tooth. About 3 a.m. a person sleeping in the next room heard a noise, came into the room, and found him struggling somewhat and gasping for breath. Sent in for me immediately—(two miles). On my arrival I found the man had died within half an hour, without speaking or much struggling. There was nothing particular about the appearance of the body. In this case an inquest was held; no Medical evidence was called, and no history of previous disease elicited. Verdict—"Died by the visitation of God."

Case 3.—Mr. W., aged about 40, had been suffering for some time from extensive organic disease of the heart, liver, and kidneys. About a week before he died I was sent for to see him, as he had been very delirious. I found the delirium had passed off. The secretion of urine, which had been gradually getting scanty, had then almost ceased. There was great anasarca of the lower extremities, slight jaundice, ascites, a distressing cough from congestion of the lungs, and the characteristic aortic pulse. He was so weak that he could not bear to be moved to have his bed made. (I mention his condition at that time to show that it was impossible for him to

have gone from his house to the place where he was found dead, unless under the influence of delirium produced by uræmic poisoning.) From this time a man slept in the house, to assist his wife in the event of the delirium returning. He seemed a little better, and there was no return of the delirium until the night preceding that on which he died. On that next night, his wife, worn out with watching, fell asleep, and the poor man must then have got out of bed in his night-shirt, gone down-stair, opened the door, passed through the garden, and walked a good hundred yards, and then have thrown himself into a small pond (not more than six inches deep, mud and all), where he was found dead, lying on his face. An inquest was held; no Medical evidence was called—although the necessity for it was pointed out to the coroner—and an open verdict of "Found drowned" was recorded.

COMMUNICATIONS have been received from—

Dr. W. P. HARRISON; Mr. BLYTH; Dr. CARNEGIE; Mr. J. H. SCOTT; Mr. PALMER; Dr. FAYRE; Dr. WADHAM; Mr. PURVIS; Mr. C. S. EGARR; Dr. G. JOHNSON; Mr. W. CARTER; Dr. SUCKLING; Dr. ALDIS; Mr. BULLLEY; Mr. OXLEY; Mr. BURROWS; Mr. J. W. DUFFY; Mr. G. GASKOIN; R.; Rev. J. M. VAUGHAN; Mr. MITCHINSON; Dr. CAYLEY; Mr. G. GROVE; Dr. HANDFIELD JONES; Mr. H. ARNOTT; Mr. HAYNES WALTON; Dr. J. W. OGLE; Dr. GEORGE JOHNSON; Mr. J. CHATTO; Dr. WHITMORE.

BOOKS RECEIVED—

An Earnest Appeal for a New System of Astronomy—Deschanel's Natural Philosophy, Part 3. Electricity—Spiritualism Answered by Science—Parisiana, new edition—Report of the Sanitary Commissioners with the Government of India, 1870—Nelson Hardy on Hospital Out-Patient Reform—Transactions of the Odontological Society—Concerning Spiritualism, by Gerald Massey—Approved Plans and Specifications for Post Hospitals, War Department, U.S.A.—Report of Surgical Cases in the U.S. Army.

PERIODICALS AND NEWSPAPERS RECEIVED—

Dark Blue, January—The Doctor—Medical Press and Circular—Quarterly Journal of Microscopical Science—British and Foreign Medico-Chirurgical Review—Journal of the Gynaecological Society of Boston—Braithwaite's Retrospect, vol. lxi.—Practitioner, January—Pharmaceutical Journal—Huddersfield Daily Examiner—Huddersfield Chronicle—Scarborough Express—Camden and Kentish Towns Gazette—Birmingham Medical Review—Westminster Review.

APPOINTMENTS FOR THE WEEK.

January 13. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

15. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.
MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. Chapman, "On the Pathology and Treatment of Neuralgia and its kindred Disorders."

16. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Mr. Arnott's Case of "Tumour of the Testicle" (Report). Dr. Southey's Case of "Disease of Supra-renal Capsules" (Report). Mr. A. Norton, "Malignant Growths of Femur." Mr. Lawson, "Sequel of a Case of Blood-Cyst." Dr. Leared, "Renal Calculi of Cystic Oxide." Dr. Thorowgood, "Salivary Calculus." Dr. Greenhow, "Excavation of Lung, with Arrest of the Disease; Complete Destruction of one Lung by Non-tubercular Excavation." Dr. King, "Embolism of the Middle Cerebral Artery associated with Aneurism of the Aorta." Mr. C. Heath, "Fibro-cystic Tumour of Lower Jaw."

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Nervous and Circulatory Systems."

17. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

SOCIETY OF ARTS, 8 p.m. Meeting.

18. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Mr. Fairlie Clarke, "Syphilis as it affects the Tongue."

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

19. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 9 p.m. Prof. Odling, F.R.S., "On the New Metal, Indium."

VITAL STATISTICS OF LONDON.

Week ending Saturday, January 6, 1872.

BIRTHS.

Births of Boys, 1249; Girls, 1203; Total, 2452.
Average of 10 corresponding weeks, 1862-71, 2207.7.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	829	790	1619
Average of the ten years 1862-71	793.7	804.8	1598.5
Average corrected to increased population	1758
Deaths of people aged 90 and upwards

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29.539 in.
Mean temperature	41.5°
Highest point of thermometer	51.4°
Lowest point of thermometer	33.0°
Mean dew-point temperature	37.0°
General direction of wind	S.W.
Whole amount of rain in the week	1.19 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, January 6, 1872, in the following large Towns:—

Boroughs, etc. (Municipal bound- aries for all except London.)	Estimated Population to middle of the year 1872.*	Persons to an Acre. (1872.)	Births Registered during the week ending Jan. 6.	Deaths Registered during the week ending Jan. 6.	Temperature of Air (Fahr.)		Temp. of Air (Cent.)	Rain Fall.		
					Highest during the Week.	Lowest during the Week.		Weekly Mean of Mean Daily Values.	In Inches.	In Centimetres.
London	3312591	42.5	2452	1619	51.4	33.0	41.5	5.28	1.19	3.02

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.54 in. The highest was 30.06 in. on Sunday evening, and the lowest 28.75 in. on Friday morning.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

† Through an error which has been discovered on the revision of the enumerated numbers at the Census Office, the correct population of Manchester at the middle of 1871 was 351,488, and not 356,099, as published in recent Weekly Returns. The number for the middle of 1872 (352,759) shows, therefore, an increase of 1271 upon the corrected number for 1871.

NOW READY,

In Two Volumes, 8vo, 2300 pages, bound in cloth, with Steel Plate, Map, and nearly Two Hundred Woodcuts, price 38s.

THE SIXTH EDITION

OF THE

SCIENCE AND PRACTICE OF MEDICINE.

By WILLIAM AITKEN, M.D. Edin.,

Professor of Pathology in the Army Medical School; Corresponding Member of the Imperial Society of Physicians of Vienna, of the Society of Medicine and Natural History of Dresden, of the Imperial Society of Medicine of Constantinople, &c., &c.

This "REPRESENTATIVE BOOK OF THE MEDICAL SCIENCE AND PRACTICE OF THE DAY" ("Lancet") has been out of print more than a year, in consequence of the great care exercised by the Author in the preparation of the New Edition.

The Additions and Improvements (among which may be mentioned the adoption of the order of Classification, as well as the new Nomenclature, of the College of Physicians) are too numerous and extensive to be specified in detail; but it may be sufficient to state that they are in reality equivalent to a THIRD VOLUME, a special font of type having been cast to enable the printer to preserve clearness without adding to the bulk of the work.

Every part has been thoroughly Revised, especially the details of Temperature in each Disease, for which new Diagrams have been cut after a better method.

CHARLES GRIFFIN and COMPANY, 10, Stationers' Hall-court, London.

CHLORODYNE.

SPECIAL NOTICE.

The absurd statements that have recently appeared in Medical and other Journals respecting the constituents of CHLORODYNE (each analysis differing widely), J. T. DAVENPORT is compelled to further CAUTION the Profession against using any Compound under the name of Chlorodyne but the genuine, which alone has gained such extraordinary celebrity.

J. T. DAVENPORT appends Medical testimony in confirmation of the above.

The wonderful efficacy of Chlorodyne being universally acknowledged, it must be evident to all that the assumption of the name to any other Compound than the Genuine is not only improper, but unprincipled, as it is liable to injure the health of the Patient and cause discredit to the Physician. Even death has resulted from the use of spurious Chlorodyne when benefit had been previously experienced from the genuine; and this melancholy circumstance has no effect in restraining these heartless proceedings.

From Dr. J. WILSON, Castleton, Yorkshire.

"I require to use a considerable quantity of Chlorodyne in cases where no other medicine is of the least avail; and my object in wishing a supply from your own establishment is that I am frequently deceived by getting a *Spurious* article from other places, although I never order anything but the genuine Browne's Chlorodyne."

From JAS. ATKIN, M.D., Medical Officer, Fever Hospital, Oldcastle, Co. Meath.

"Having ordered from our Druggists "Chlorodyne," I was not only *disappointed in its effects*, but annoyed when I received a spurious compound. I have been in the habit of using your Chlorodyne with great advantage to my patients and satisfaction to myself."

From F. E. BARTON, Esq., Surgeon, Dover.

"I have now used your Chlorodyne in numerous cases, and have much pleasure in adding my testimony to its very great efficacy as an Anti-spasmodic and Anodyne, having found it especially valuable in those cases in which Opium does not agree well with the patient."

From Thomas F. Hale, Esq., Surgeon, Saundersfoot, Pembrokeshire.

"Sir,—I should be much obliged by your forwarding three bottles of Dr. J. COLLIS BROWNE'S CHLORODYNE, which I have found most useful in allaying pain. I have used twelve ounces of it, and, in nearly every case in which I have employed it, have every reason to be satisfied with the result; and although I object, as a rule, to use any preparation of a secret nature, and whose composition I am not fully acquainted with, still, having once tried the Chlorodyne, and found that it really did produce the effects stated, I do not think I should be justified in withholding such a preparation from my patients, when I see the value of the remedy."

From Lord FRANCIS CONYNGHAM, Mount Charles, Donegal, December 11th, 1869.

"Lord Francis Conyngham, who, this time last year, bought some of Dr. J. Collis Browne's Chlorodyne from Mr. Davenport, and has found it a most wonderful medicine, will be glad to have half a dozen bottles sent at once to the above address."

"Earl Russell communicated to the College of Physicians that he received a despatch from Her Majesty's Consul at Manilla, to the effect that Cholera has been raging fearfully, and that the ONLY remedy of any service was CHLORODYNE."—See "The Lancet," 1st December, 1864.

CAUTION.—Vice-Chancellor Sir W. Page Wood stated that Dr. J. Collis Browne was undoubtedly the Inventor of CHLORODYNE, that the whole story of the Defendant was deliberately untrue, which, he regretted to say, had been sworn to.—See "Times," 13th July, 1864.

The Sole Manufacturer of Dr. COLLIS BROWNE'S Chlorodyne is

J. T. DAVENPORT, 33, Great Russell-street, Bloomsbury-square,

Who alone received the Recipe, and who is the Only Authorised Maker.

ORIGINAL LECTURES.

SKETCHES OF
SUCCESS AND FAILURE IN MEDICINE,

BEING THE SUBSTANCE OF THE

LUMLEIAN LECTURES AT THE LONDON ROYAL COLLEGE OF PHYSICIANS
IN 1862.

By CHARLES J. B. WILLIAMS, M.D., F.R.S.(a)

(Concluded from page 2.)

ANOTHER example of signal success in the prevention of disease and death may be found in the statistical returns of the British army during the last ten years. The writings of Sir John Pringle and others had directed the public attention, a century ago, to the necessity of sanitary regulations for the preservation and efficiency of the lives of soldiers and sailors—men thrown together in large numbers under circumstances in various ways trying to the health; and the well-known fact that the history of our armies generally comprised also the history of various pestilences, which they carry in their train, could not be disputed. Those best acquainted with the details of past sieges and campaigns knew also that the ravages made by these foes within the camp were often tenfold—nay, more than a hundredfold—greater than those inflicted by the arms of the enemy.

But the destructiveness, not merely of war, but of military life during peace also, was never fully felt until made known by the searching statistical records first devised by Sir James MacGregor, afterwards digested into reports by Dr. Graham Balfour and Lieutenant (now Major-General Sir A.) Tulloch, and finally extended and completed by the Royal Commission of 1857, of which Lord Herbert was president. Who could have supposed that the annual mortality of the army in this country in time of peace was more than double that of the general male population of the same age?—and, still more, that the Footguards, consisting of picked men, selected for their healthiness and robustness, should annually die off at the rate of 20·4 per thousand, whilst the ordinary mortality does not exceed 9·8? Yet these were disgraceful facts, arising from official carelessness and ignorance through a series of years, until hundreds and thousands of valuable lives were sacrificed, an incalculable amount of public money wasted, and a stigma of obloquy was cast on a noble branch of the national service. In vain did many of the more intelligent and enlightened Medical officers endeavour to make their representations at head-quarters why such mortality occurred, and how it could be corrected. In such appeals to those in authority they generally only *got snubbed*, and were told to hold their tongues and mind their own business!

If such were the fatal results of the criminal indifference and ignorance of the governing classes during peace, can we wonder at the harvest of disaster, disease, and death which resulted in the trying times of war? The horrors of the Crimean campaign are still fresh in our memories. And who is there among us that has not heard of the prominent features of that eventful period which bear on our present subject?—of the unheeded warnings of the Director-General and other experienced Medical men?—of the hasty equipment of the expeditionary force, and its foretaste of suffering from the neglect of sanitary precautions on the voyage and in the camp before Varna?—of the inadequacy of the supplies for the sick and wounded at Alma?—of the perils and privations of Balaklava, aggravated as they were by desolating storms, intense cold, and still more by the blundering of officials, through which the troops were kept without food and clothing, and were consequently soon decimated by starvation and disease?—of the further ravages of zymotic pestilence in the Crimea and at Scutari, from almost total want of proper sanitary arrangements on board the transports, in the camps, and in the Hospitals?

The amount of mortality from disease alone was something appalling during the first seven months of the Crimean campaign, rising to the rate of 60 per cent. per annum of the

whole army—a mortality greater than that of the great plague of London in its population! And observe, all this awful sacrifice of life was from preventible causes, as you may judge from the sequel, which will serve us as a present illustration of the successes of Medicine.

During the last five months of the Crimean campaign the mortality among the troops did not exceed 11·5 per thousand per annum, which is considerably below the average mortality of the army at home in time of peace. And that this remarkable improvement was really due to better management, and not to increased healthiness of the climate, is obvious, from the fact that at this very period in the contiguous French army fever and other zymotic diseases were still making fearful ravages.

The reform thus accomplished at last, was brought about through much tribulation. The British nation was aroused to sympathy and indignation at the sufferings and destruction of its army, denounced by one of the Ministers in the Government as “horrible and heartrending.” The public, through the agency of the “*Times* Commissioner,” vied with the now earnest and lavish War Minister in sending abundant supplies to the Hospitals and to the camp, where the more enlightened Medical officers, now freed from the trammels of red tape and official obstructiveness, and aided and strengthened by able special commissioners,^(b) were carrying on their sanitary measures with the vigilant superintendence of that guardian angel of the British army, Miss Nightingale, with her band of devoted assistants. Thus was the residue of the army saved, and the reinforcements sent out were preserved in health and efficiency. So prosperously ended the Crimean campaign.

But where was the security that the lesson thus taught would be remembered any more than those to be learnt from former wars, which had to struggle through similar disasters—those of Walcheren and the Peninsula, for example? There was none; and if no further change had been made in the system, in all probability the results of experience and the dictates of science and common sense would have soon been set aside by the spirit of official obstinacy and military arrogance which would surely prevail in the War Department as hitherto administered.

But, thanks to Sidney Herbert’s Royal Commission of 1857,^(c) a change was made in the system—the administration of the army has been put on such a footing as to secure a constant attention to sanitary matters in future; and the short period which has since elapsed enables me to record such satisfactory results, both in peace and war, as to fully entitle them to a foremost place among the successes of Medicine.

Thus, during the last three years, since the reformed system has been in operation, the annual mortality of the Footguards at home has been reduced from 20 to 9 in 1000, and that of the infantry of the line from 17·9 to 8·5, and even so low as 5 in Aldershot and Shorncliffe.

And in proof of the success in war, I will quote a passage from one of Miss Nightingale’s summaries:—“The crowning testimony of the great national importance of the new system of sanitary administration inaugurated by Lord Herbert is to be found in the last Chinese expedition, when his reforms were first practically tested. An expeditionary force was sent to the opposite side of the world, into a hostile country, notorious for its epidemic diseases. Every required arrangement for the preservation of health was made, with the result that the mortality of this force, including wounded, was little more than three per cent. per annum, whilst the ‘constantly sick’ in Hospital were about the same as at home. Let us contrast this great success with what happened during a former war in China. The 26th Cameronians, a ‘total abstinence’ regiment, and one of the finest and most healthy in the British service, was landed at Chusan 900 strong, and left to its fate without any sanitary care. In two months only twenty men could be got together.”

I claim for Medical science the chief credit in supplying the foundation for these successes; and had the voices of the more enlightened and intelligent Medical officers of the army been listened to long ago, much good might have been done, and much evil averted sooner. But, as before said, these voices

(b) Two commissions were sent out to the Crimean army at this date—one respecting supplies for troops and sick, presided over by Sir John MacNeill; the other under Dr. Sutherland, for carrying out sanitary improvements in the Hospitals and camps of Scutari and before Sebastopol.

(c) The members of this Royal Commission were—the Right Hon. Sidney Herbert, M.P.; Augustus Stafford, M.P.; Major-General Sir H. Storks; Dr. Andrew Smith, Director-General; Mr. Alexander; Sir J. Phillips; Sir Ranald Martin; and Dr. Sutherland. After the Royal Commission issued its report, several commissions were appointed to give practical effect to its recommendations.

(a) Various circumstances have delayed the appearance of these Lectures, of which no authentic report has yet been published. Their delivery was undertaken at the urgent and repeated request of the late Dr. Mayo, then President of the College. He went out of office in the following year, and the usual custom of appointing the same Lumleian Lecturer for two successive years was discontinued; therefore, the latter parts of these papers, although prepared for the lectures, were not delivered.

were silenced by military despotism and official indifference; and it was not until, strengthened and re-echoed by new and awful experience, they reached the ears, touched the heart, and convinced the understanding of one high in rank and authority, that they became strong enough to bear down the opposition and obstruction that beset them on every side. Lord Herbert had already considerable experience in War-Office administration, when the disasters of the Crimea occurred and opened his eyes to its utter inefficiency. From that time forward, both in office and out of office, in public and in private, he devoted his whole life and best energies to the examination of the details of every department, to searching out all defects, and to finding and providing adequate remedies. At the head of that before-named Royal Commission of 1857, supported by competent Medical and other advisers conversant with the various subjects to be examined, he summoned the most eminent or best-informed witnesses, and in replies to upwards of ten thousand questions, with voluminous appendices, was amassed an enormous amount of information on all connected topics; the results of which were embodied in a most masterly report, concluding with a series of practical recommendations, which have since been in great measure adopted and carried out with a success exceeding the highest expectations. Prominent among these recommendations was that to place the Medical officers on a proper footing as guardians of the health of the army, to be consulted and deferred to for the prevention as well as for the cure of disease; and thus for the first time the Medical service became a power in the army, efficient and successful in some proportion to its dignity and deserts.

This great work Sidney Herbert conscientiously and nobly accomplished; but, alas! at the sacrifice of his health and life.

Note added in 1871.—Another great loss, which occurred about the same time, was that of Mr. Alexander, the Director-General, who, with great personal labour, first brought the new sanitary regulations into operation. Happily Lord Herbert's successors, in conjunction with Dr. Sutherland and other surviving members of the Barrack and Hospital Improvement Commission, have continued the arrangements under the authority of the present Army Sanitary Commission, which comprises representatives of the War Office, Royal Engineers, Office of Works, Local Government Act Office, and India Office, together with the Army Medical Department.

The most important field of operation of this Sanitary Commission at present is in India, where it was introduced under the direction of Lord Stanley, now Earl of Derby. Here it has already begun to achieve great successes in the prevention of disease, and bids fair to accomplish still greater triumphs hereafter. An annual report of the measures adopted is now published by the India Board; and the following extract from the last report will serve as a sample of what may be done.

In the year 1857 Sir Ranald Martin addressed two letters to the Chairman of the Court of Directors, recommending that all British soldiers available from the duties of the plains should be permanently cantoned in the hill regions of the country to diminish the high mortality then prevalent among them—amounting during fifty-six years of this century to 69 per 1000 per annum. In a letter dated March 27, 1870, alluding to the adoption of Sir R. Martin's recommendation, Dr. Cuninghame states that Dr. Bryden had sent in a table showing the results for working parties in the hills during the past seven years. (d) The result is that the death-rate per annum is only just over 4 per 1000. "That the removal to the hill ranges, everywhere to be found throughout India, should reduce the death-rate from 69 to 4 per 1000 is, indeed, a most patent and wonderful fact. It is the greatest triumph ever achieved over the external causes of disease everywhere prevalent in the plains of Hindostan."—Report, etc., p. 5.

But there was one other chief agent in the commencement and completion of the great and successful work (of the Crimean campaign) whose name I cannot pass over, although, being neither Medical, military, nor even masculine, her share in the matter is little known or even suspected.

In all that relates to nursing and providing for the sick army in the East, the name of Florence Nightingale is as a household word; suggestive of devotion so noble, of self-sacrifice so chivalrous, that it might seem romantic if it had not been so substantial and practical in its beneficence. But the army and the country owe to Miss Nightingale much more than the devoting of years of day and night toil in watching, nursing, and superintending in the Hospitals and camps of Scutari and the Crimea. With a vigilance untiring, a rare intelligence,

and a memory never failing, this gifted lady saw and comprehended all the multitudinous wants and requirements of the army, in Hospital, in camp, and in barrack; in war and in peace, in sickness and in health. She noted the complete failure of the existing system of administration, and how much was necessary to reform it in every department. At the end of the campaign in 1856, when Miss Nightingale returned home with weakened frame and broken health, her Queen and her country were ready to welcome her back to honour and to repose.

But no, Miss Nightingale had a further mission to fulfil; and instead of accepting titles or honours for herself, the boon which she asked was for the issue of that Royal Commission, with Sidney Herbert at its head, which has been the means of bringing about those reforms which she knew to be so much needed. Instead of seeking her own ease and rest after labours almost superhuman, she ceased not to work on for this end by taking a chief part in suggesting the course of the inquiries, and in obtaining the requisite evidence in ways and to an extent which her vast experience and knowledge enabled her alone to do.

Well, therefore, may we rank the name of Florence Nightingale with that of Sidney Herbert, foremost among the authors of the great sanitary regeneration of the British army, which has now made it, beyond comparison, the best-provided and the healthiest army in the world.

Note added in 1871.—Miss Nightingale's labours did not cease here: through all the intervening time, in spite of much bodily suffering and failing strength, numerous proofs of her superior intelligence and experience may be found in the workings and reports of various Government Commissions and public institutions connected with the army, Hospitals, and sanitary science. Even in the last Annual Report of the Progress of Sanitary Measures in India, Miss Nightingale's words of criticism, direction, and encouragement are deservedly brought forward as those of the highest authority and importance.

ORIGINAL COMMUNICATIONS.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,
Student of Guy's Hospital.

No. I.

The Origin and Construction of the Sphygmograph—Regulation of Pressure—Mode of Application—Adaptation to form a Cardiograph.

EVER since the art of healing has been practised, the pulse has been one of our two most prominent symptoms; probably the rudest of our forefathers in Medicine—the very aborigines, so to speak, of the world of physic—"looked at the tongue and felt the pulse" of their patients. From that time till the present day, this index of the centre of life has been the aid and adviser of the Physician or the Surgeon; no remedy is administered, no operation ever performed without consulting it. That silent tale-bearer tells us how life is ebbing or flowing in our patient; whether that wonderful organ, whose never-ceasing action is so necessary to life, tires or faints at its work; whether it requires assistance, and, when that assistance has been given, whether life or death will be the result. Even in these later years, when our means of ascertaining the condition of the hidden machinery of life have been so greatly multiplied, still our old ally, the pulse, ranks the first among our guides; no Surgeon can despise its counsel, no Physician shut his ears to its appeal. Since, then, the information which the pulse affords is of so great importance, and so often consulted, surely it must be to our advantage to appreciate fully all it tells us, and to draw from it every detail that it is capable of imparting. Our sense of touch, however highly educated, is manifestly liable to error, and it is to our more reliable sense, that of sight, we appeal, when possible, for confirmation. It is by the aid of this more accurate sense we should study the pulse, in its marvellous changes of character and form, as recorded by the sphygmograph.

This instrument, though it has now been used in England for several years, has not yet received that general attention which its great value demands from us, and which will, I trust, before long be paid to it. Taken up by many at its first intro-

(d) It may, however, be questioned whether the greater salubrity of "working parties" may not be in some measure due to their exercise in the open air as well as to the altitude.

duction, it was speedily cast aside, partly on account of its own imperfections, but chiefly from our want of knowledge of how or when it should be employed. Since then its use has been confined either to the physiological laboratory or to a few advanced Physicians, who foresaw the wide field of knowledge to be opened up to them by a more perfect acquaintance with the instrument and its more extended use. Still, by far the larger number of our Profession have continued almost in ignorance of its existence, and completely so as to its clinical value. The continued absence of any guide to its clinical use has tempted the writer to lay before the readers of the *Medical Times and Gazette* a few of those results which he has obtained from the practical study of the sphygmograph during the last few years; but, before we proceed to the investigation of its clinical use, it will be necessary first to obtain a knowledge of our instrument, and then of the physiology peculiarly attached to it. Those who wish for a more philosophical treatise on the subject than it is in my power to give, I would refer to Dr. Burdon-Sanderson's interesting book, entitled "Handbook of the Sphygmograph;" but we have to regret the absence in our literature of any adequate guide to its everyday clinical use. Drs. Balthazar Foster, Anstie, and Grimshaw have each contributed to our knowledge of sphygmography. Working, however, only on the outskirts of this field of inquiry, they have left the interior still unexplored.

It has been the aim of many physiologists and Physicians in times past to be able to register accurately and visibly the characters of the pulse. Galileo was perhaps the first to be struck with the idea. It occurred to him while watching the great

swinging lamp in the central nave of the Cathedral of Pisa; and, after much trouble, we are told that he constructed an instrument, which he called the "pulsilogia." It created great interest among the Physicians of the day, though it was very imperfect, and soon fell out of use. Many succeeding attempts were made having the same object; but Vierordt was the first to contrive an instrument laying claim to the name of *sphygmograph* (σφίγμος pulse, γραφω I write); but this, though of ingenious construction, was full of fallacies and of no practical value. It is therefore unnecessary to describe it, and we may pass on to the more perfect instrument invented by Marey, bearing the same name.

This instrument as made by M. Brequet, of Paris, or some modification of it, is the one now in general use. The great objection to Marey's instrument, in its original form, was the very limited and imperfect manner in which the pressure of the spring applied to the artery could be controlled, and this was speedily discovered by all who used it to be a most important source of fallacy and imperfection in the results obtained. Dr. Sanderson and Dr. Foster have each invented more or less efficient methods of discovering the pressure employed, and of regulating it; both of these have been published in the Medical journals, and are described in their respective books upon the subject. I do not propose, therefore, to discuss their merits here, but we will proceed to the examination of the instrument that has been employed in making the observations which I propose to publish in these papers. Fig. 1 represents a sketch of the instrument, from which some idea of its general outline and framework may be

FIG. 1.

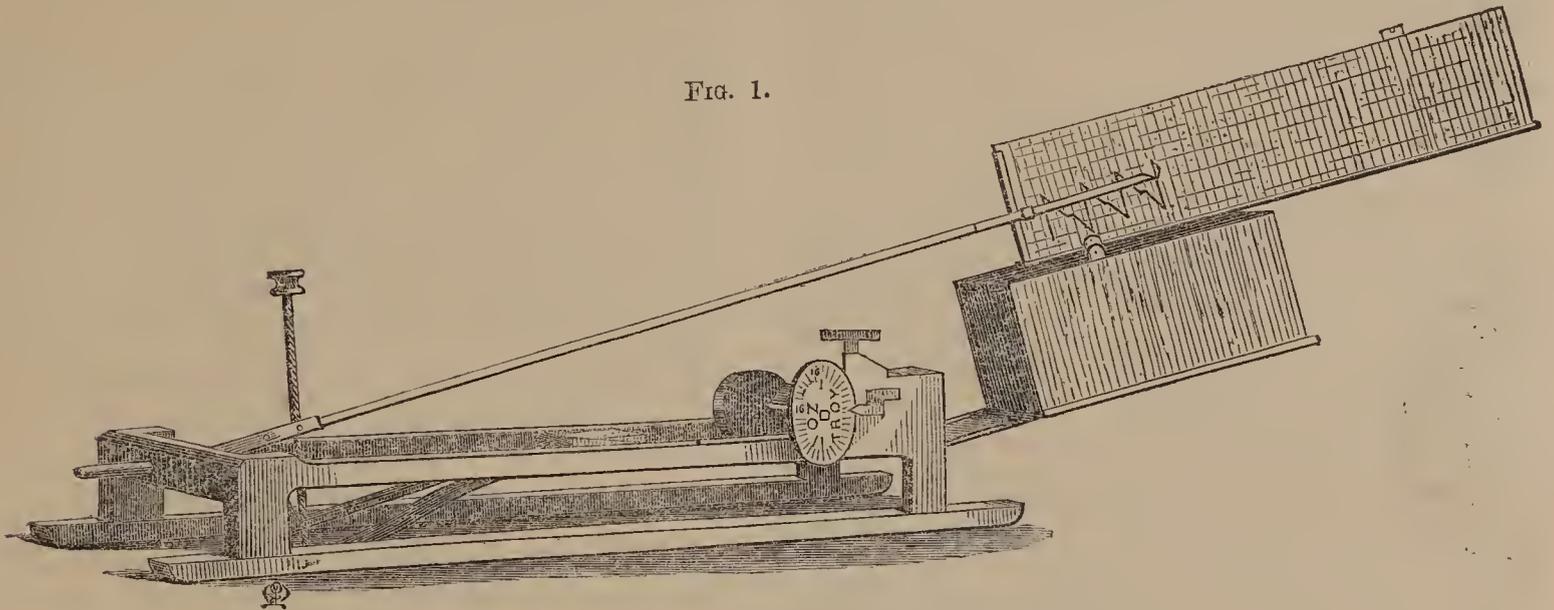

FIG. 1.—Perspective view of Mr. Mahomed's modified Sphygmograph.

obtained. It is to the arrangement of the levers by which the pulse-wave is transmitted and increased in size, as depicted in Fig. 2, that I would call attention. The mainspring, marked in the diagram A, is attached to the framework of the instrument by a hinge joint, H, which permits

FIG. 2.

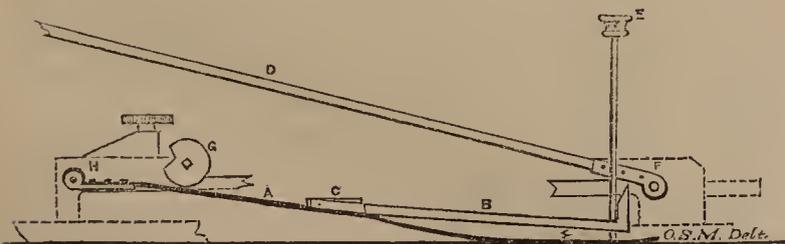

FIG. 2.—Diagrammatic section, showing arrangement of levers and eccentric.

free vertical, but no lateral movement. Its free extremity, which is covered by an ivory pad, rests upon the artery (usually the radial) from which it is proposed to obtain a tracing. To this spring is attached a block, C, which forms the centre of movement for a lever of the third order, marked B, which encloses it by the bifurcation of its extremity, a pin projecting from either side of the block, and passing through each extremity of the bifurcation, thus insuring a perfect vertical movement free from lateral oscillations. The free extremity of this lever is turned

up at a right angle, and terminates in a sharp knife-like edge, which is kept in contact with the writing-lever, D, by the regulation of the screw, E. This screw passes through the lever, B, and rests upon the spring just above the ivory pad; every movement of the pad is therefore transmitted by means of the screw to the lever, B, and, by its sharp upturned extremity to the writing lever, D, the length of the screw below the lever, B, being increased or diminished according to the variation of the distance between the spring, A, and the writing-lever, D. Passing through the end of the writing-lever, D, is a hollow bar, receiving two fine pins which project from either side of the framework of the instrument; in this case, also, perfect vertical movement is obtained. The lever is made of a delicate slip of extremely light and flexible wood, and its free extremity is armed with a pen or fine steel point, by which its movements are recorded on the slide moved past it by means of clockwork, travelling at the rate of about four inches in ten seconds. In Marey's original sphygmograph the mainspring was rivetted to a sloping platform; a considerable amount of pressure was therefore unavoidable under all circumstances. This was increased by the use of a screw passing through the spring and pressing it closer to the platform; the variation was not great, and the pressure employed quite unknown.

The principal point, then, to attain is the ability to apply the sphygmograph with the smallest possible amount of pressure upon the artery, the tension of the spring being equally slight, to accommodate itself to the feeblest pulse, and then to gradually increase the pressure to the necessary extent,

increasing at the same time the tension of the spring in the same ratio. This I have been able to arrive at by unrivetting the spring from the platform, and suspending it by a pin passing through a hollow tube attached to the spring, and rivetted in each side of the framework, perfect vertical movement being again attained. A strong bar passes through the framework above the spring, about half an inch from its attachment. Around this bar, over the centre of the spring, is an eccentric, *g*. External to the framework the bar forms the axis of a strong cog-wheel, and still more external to this it bears a circular index-plate. Fitting into the teeth of the cog-wheel is an endless screw, turned by the thumb-screw shown in the drawing, which thus causes the eccentric to revolve above the spring. When the ivory pad of the spring is pressed up level with the framework of the instrument, the spring is brought in contact with the eccentric. The pressure required to do this—which is, in other words, the pressure applied to the artery—is regulated by the length of the radius of the eccentric in contact with the spring. This can be altered at will by turning the thumb-screw. The pressure applied to the artery is indicated by the figure engraved on the dial-plate, to which a fixed index points. This plate is marked in ounces of Troy weight. The pressure may be varied from one to eighteen ounces—a range which will be found wide enough to meet every requirement. The side-wings, by which Marey's instrument was laced to the arm, have been dispensed with, and ivory bars attached to the brass framework in their stead. The instrument in this form, with other minor improvements, was made for me by Mr. Clark, of 3, Windsor-cottages, High-street, Lower Norwood, who displayed in its construction the greatest ingenuity and the most perfect workmanship; I need not say that both these qualifications are necessary for the production of a reliable sphygmograph. Mr. Clark, I believe, is prepared to supply sphygmographs at the very reasonable price of five guineas.

The arm of the patient of whose pulse a tracing is required should be placed on a double inclined splint, bent to an angle of about 135° . I have used a plain wooden splint, with a hinge-joint, having on its under surface a brass bar fixed at one end by a hinge, and at the other by a pin into a block, which can be removed at pleasure, to allow of the splint being folded up, and thus making it more portable. Attached to the splint are two strong bands, which pass, one over a pin projecting from the end of the sphygmograph, the other over part of the framework connecting the box containing the clockwork to the other part of the instrument, and are held firmly on the other side of the splint by two pairs of sharp hooks, having their points directed downwards. By this means the ivory stand of the instrument is kept in perfect and firm apposition with the arm, and insures the spring being pressed up to its proper level. The hand is thus bent slightly backwards at the wrist, the fingers being passed below a strong elastic band stretched across the splint, and the patient directed to slightly flex the fingers round the band, but not to grasp it. If the wrist be flexed strongly backwards to the extent of a right angle—as directed by some sphygmographers—the parts are too tightly stretched, and the walls of the artery (included in this stretching) are made somewhat tense. Again, if the hand be firmly closed on anything given the patient to grasp, the tendons of the surrounding muscles are made tense, and are liable to interfere with the perfect application of the instrument, or in weakly subjects to vibrate. The ivory pad of the spring should be applied to the radial artery, as it lies on the inner side of the styloid process of the radius and is crossing the anterior ligament of the wrist-joint, for in this situation the artery can be most perfectly examined; and here it can be compressed against bone—a most important point when we desire either to obtain a perfect tracing or to measure the compressibility of the pulse.

The operator, feeling certain that the spring is perfectly applied to the artery, the sphygmograph may be strapped firmly upon the arm, as directed above; no fear need be felt of compressing the artery, which will lie, if the instrument be properly applied, between the ivory rods. The pressure of the spring must now be varied till we ascertain by which pressure we obtain the greatest movement of the lever, and a tracing may be taken, during which the slide should be stopped two or three times, and the pressure altered, so that we may discover at which pressure we obtain the greatest upstroke—that is to say, at which the spring follows most perfectly the expansion of the artery, and with which the apex is most sharply marked and free from rounding, and the various notches best defined. Experience alone can teach us when the tracing we obtain is perfect, and the pressure used the correct

one. The use of incorrect pressure is perhaps the most common source of error in sphygmography, and the greatest care is necessary in deciding upon the amount of pressure to be employed. This, when ascertained, should be carefully recorded, as it is one of the most important characters of the pulse. Notice should also be taken of the amount of pressure required to totally extinguish the pulse, so that the lever remains perfectly motionless; for by this means an estimate can be formed of the force with which the heart is contracting. The tracings may be taken either on glazed white paper with ink; or smoked glass, the writing lever being armed with a fine steel point; or on smoked paper—each method has its supporters. I have tried all, but find the smoked paper by far the best. When ink is used, great difficulty is often experienced to induce the pen to mark, and it frequently occurs that the arm of the patient and the face of the operator are freely bespattered with ink. If glass be employed, its want of portability forms the chief objection, and also the space required to store the tracings when obtained, and inability to preserve them in books or on reports of cases. I have from these and various other reasons found it best to employ paper enamelled on both sides, which can be obtained of Messrs. Woolley and Co., 210, High Holborn. It reduces the amount of friction to a minimum, and can be easily smoked, without burning, over an untrimmed paraffin lamp; it is then stretched on the slide. After the tracing has been obtained, and the name, age of the patient, the pressure employed, date, and other particulars written upon it by a fine point (such as a needle mounted for microscopic use), it may be passed through a varnish made of gum benzoin and methylated spirit, about one ounce of the gum to six fluid ounces of spirit; it will rapidly dry, and be found both portable and permanent.

I may here mention that the sphygmograph may readily be adapted to form a cardiograph or polygraph. For this purpose I have used two small indiarubber bags, connected by tubing; one bag is placed over the apex of the heart, and retained in position by a piece of bandage with a buckle attached; the other, under the spring of the sphygmograph; the patient is then directed to hold his breath, so as to fix the chest-wall, in order that the bag may be affected by no movement except that of the heart, each pulsation of which presses the air out of the bag placed over it, and distends that to which the sphygmograph is applied; this movement is transmitted to the writing lever, and very satisfactory tracings of the heart's action, or of pulsating tumours, may be obtained.

With this brief description of the instrument and its application, we may pass on to the study of the normal pulse.

(To be continued.)

CASES OF INTESTINAL OBSTRUCTION.

By C. HANDFIELD JONES, M.B., F.R.S.

(Concluded from page 4.)

Case 4.—E. S., aged 64, admitted January 26, 1865. Has been ill more than a year, suffering from diarrhoea, the stools being often coloured with blood; was taken worse fourteen days ago with constipation and pain all over the front of abdomen and in the back. Bowels have not acted at all since January 13, and that was after an injection. Abdomen is globularly distended; resonant everywhere, except far back in the left flank; the highest percussion-note is given about the middle. No tumour to be felt. No marked tenderness of abdomen. Distended coils of intestine are evident through the parietes. Says she has much rolling, grumbling, "wobbling" sensation in the belly, attended with pain. Last summer her stools were small, like a worm. Has no vomiting; brings up sour water at times, but is not particularly sick. No appetite, but great thirst. Tongue red and dry, not much coated. Urine pretty free, high-coloured. Skin cool. Pulse weak and quiet. Expression of face tranquil. Pupils of medium size. Low diet; milk, beef-tea. Enema terebinth, stat. Extract belladonnæ, gr. $\frac{1}{2}$ + opii gr. $\frac{2}{3}$ in pil. ter die. The injection returned as it was thrown up; it did not penetrate above a little way. Rectum, on examination, found perfectly empty.

February 1.—Passed a fair amount of urine of natural appearance in twenty-four hours. Bowels still much distended.

On 30th passed a hard piece of faecal matter about the size of a hazel-nut. Much flatus escaped. Tongue moist and natural. Much thirst. Pupils rather large. Extract. nucis vomica gr. ss. + aloes gr. jss. in pil. quater die.

4th.—Bowels acted well on night of 2nd; acted all night long; the belly became softer; but next morning she was partially collapsed. Pulse above 100; appetite lost; tongue dry. The abdomen still showed marks of distended coils of bowel. During 3rd she became weaker, and vomited in the afternoon; the pulse failed, and she sank at 3 a.m. of 4th. The pills were omitted, and she had brandy, etc.

Post-mortem.—On opening the abdomen the peritoneum was found everywhere much reddened. In the left flank the coats of the small intestine were deeply reddened, and there was a notable amount of puriform fluid; the right flank contained only some serous fluid, but there was puriform matter in the ileo-cæcal fossa, and a good deal in the true pelvic cavity. The large intestine was greatly distended; the small was little, if at all. The cæcum was very large. The transverse colon descended from the right hypochondrium to the top of the hypogastrium, and ascended again to the left hypochondrium. The descending colon was moderately, the rectum greatly, distended, and occupied most of the pelvis. On examining the front of the rectum, fecal matter was seen escaping from a minute orifice. It seemed probable that this escape had only occurred after death, and that it had no share in setting up the peritonitis. On laying open the small intestine, extensive traces were found of former ulceration of Peyer's patches. They were of a bluish-grey colour, and the mucous membrane was in great part destroyed. The large intestine appeared healthy internally until arriving at the stricture, which was situated six or seven inches from the anus. Here there was considerable thickening of the coats of the bowel, for the space of about an inch—the tissue being firm, and creaking under the knife. On laying open the rectum, the stricture was found to admit the middle finger pretty easily; the canal of the strictured part was red, and the mucous membrane appeared wasted and destroyed. At the upper and lower orifices of the canal the mucous membrane appeared as if pervaded by a whitish-grey growth, which formed a wavy, sinuous prominence, encircling the canal. None of this growth existed within the canal of the stricture. The coats of the bowel in the strictured part were weak, and readily yielded to traction, so that the part tore in removing. This was not the case at the seat of thickening. Microscopic examination of the swollen part of the rectal mucous membrane showed the tissue apparently infiltrated with epithelium-like particles—in fact, it seems to be made up of these and a fibroid stroma. The growth is no doubt an epithelial cancer, which has invaded the coats of the intestine. Heart: The right auricle was much distended. On cutting the cavities across carefully, the right ventricle was found much distended and filled with soft black coagula; the left was rather widely open, and contained similar black coagula. The walls of the ventricles were flaccid; the valves appeared healthy. The size of the heart was rather small. Rigor mortis was slight. Body was rather emaciated. The large intestine contained a prodigious amount of feces of healthy appearance.

The chief points for remark in this case are the chronicity of its course and the (consequent) mildness of its symptoms. They came on, in fact, so gradually that the system in a measure became accustomed to them, and no stormy reaction ensued. It is clear that it is not the circumstance of the large intestine being the seat of lesion which determines the mildness of the symptoms; for in Case 1, where the cæcum and ascending colon were affected, they were severe, and proved rapidly fatal. The small amount of injection which the bowel could receive showed that the obstruction must be low down. The worm-like appearance of the stools pointed strongly in the direction of stricture. The statement that she had long suffered from diarrhoea might have been misleading to a young hand, if he had not been aware how commonly patients designate any rectal irritation by that name, or how often fecal impaction is attended with actual watery mucous discharge. The efficacy of the aloes and nux vomica in enabling the large intestine to evacuate in part its contents, in spite of the obstruction to their passage, is noteworthy, though some suspicion may be entertained as to this provocation of intestinal activity having had something to do with the onset of the peritonitis. It is also very remarkable how the existence of a ring of morbid growth, which had destroyed at any rate the mucous coat, but had not by any means blocked up the canal, sufficed to cause such very considerable opposition to the onward passage of the contents. No doubt, however, the width of the channel after death would appear somewhat greater than it was during life. Abercrombie considers that mere paralysis of the muscular actions of a tract of intestine may suffice to interfere very seriously with the progress of the fecal contents.

Case 5.—J. D., aged 17, carpenter's labourer, admitted October 23, 1871. A tall, laxy-made youth. Ill since October 20 with pain in abdomen, most severe on right side; was first sick on night of 21st. No sleep for several nights. Bowels acted on 20th and 21st, but not since, though he has had oil and enema. The action was slight on 21st. No blue line on gums. At present: Pulse 124, of good size; temperature 99.7°. Urine is rather full-coloured, acid, clear, sp. gr. 1036. Lies at full length; abdomen motionless; upper chest moves freely. No hernia can be discovered. Abdomen tender, dull at both flanks; pain is constant all over it. When he is going to vomit, it grips him, he says, about the navel. Low diet; ice; poultice to abdomen. Opii gr. j. 2dis horis. Baln. calid.

October 24.—Much relief from warm bath; pain ceased for one hour, and he was not faint. Countenance anxious. Pulse 102; temperature 98.8°. Complains of twisting and bruising pain about navel. Repeat bath; a large enema.

25th.—About a quart of enema was thrown up; it returned without the least appearance of fecal matter. Pain very bad; very little sleep; aspect distressed and sad. Temperature 99°. Has vomited copiously green semi-stercoraceous matter. Pulse 104. Pt. pil. opii, strychniæ gr. $\frac{1}{20}$ + acidi nitrici mj. + aq. zss. quater die.

28th.—On night of 26th he had very copious vomiting, in consequence of yielding to his craving thirst. Since then the amount of ingesta has been limited, and the sickness is much less. Says he feels better, but has had no stool yet. Temperature 97.8°; pulse 93. Pulse on 27th compressed by 366 gr.

31st.—Has been doing well since last report; has had very little pain or sickness. Beef jelly and a little milk and ice have been his chief support. The opium has been given less frequently; about six grains in twenty-four hours. Pulse 84, good. No stool has been passed till 2 p.m. to-day, when he had a large fairly natural evacuation, chiefly solid. Omit opium.

November 2.—Has had several copious solid stools; no sickness; takes more food. Pulse small and weak; right radial compressed by 120 gr., left by 135 gr. Two eggs.

4th.—Up and dressed; doing very well. After this he went on well, except that some diarrhoea and pain made it necessary to confine him to bed for some days; but he soon improved, and went out November 15.

The precise condition causing the obstruction in this instance was (happily) not ascertained. It seems tolerably certain that it was not a cancerous stricture, a gall-stone, nor an intussusception; but it may have been a local palsy, a twisting of the mesentery, a sharp flexure of the bowel on itself (as in Case 1), or possibly an incarceration. At all events it was some condition which was removable by nature or art, or by both together. The good effect of limiting the amount of fluid taken was very conspicuous, and bears out fully Dr. Brinton's remarks on the subject. Two remedies were employed, both in pretty full doses: that first given, the opium, produced no decided good effect in two days, and subsequently it was given at a diminished rate along with the strychnia. This did not, either, accomplish much until the amount of ingesta was restricted, but afterwards the patient passed four days with great mitigation of the symptoms, and in a fairly satisfactory state, before decided recovery commenced. Were this the only case in which I have seen strychnia administered with apparent advantage, I should lay no stress upon it. But, apart from direct experience, I think there is good reason for regarding it as a hopeful remedy. If, as Dr. Brinton avers, distension (paralytic) is still the *bête noire* of the story, a drug which can reanimate failing nerve-power is surely appropriate to such a condition. Again, strychnia is notoriously of virtue in arresting the vomiting of an irritable stomach, and quieting its excessive, irregular, and exhausting muscular action; and this is also just what is wanted in most cases of intestinal obstruction. Here we have to cope with pain, irregular and abnormal nervo-muscular action, and exhaustion. Now, all these we may reckon as modes and degrees of paralysis, and to all the same kind of medication is appropriate. Whatever be the cause of the obstruction, whether it be removable or not, our success in saving or prolonging life will be just in proportion as we can obviate these evils. The slight extent to which they were present in Case 4 accounts sufficiently for its long continuance.

For pain, opium is generally the best remedy. By it we save the nervous system the wear and tear of agony, we obtain sleep, and we shield the cardiac nervous centres, more or less, from the paralyzing inhibitory impressions conveyed from the irritated districts. Opium, moreover, in some conditions

certainly promotes peristaltic action powerfully; so that it seems capable of acting as a conservator of force to both sensory and motor departments of the nervous system. Strychnia, on the other hand, is efficacious chiefly in re-creating motor nerves, and in this respect is greatly superior to opium. In these two remedies, then, we possess valuable agents for counteracting the pain and paralysis by which so much of the evil attendant upon intestinal obstruction is worked out.

The action of belladonna is not fully ascertained; it appears in small doses to allay pain (like opium), and in larger to increase the energy of intestinal motor nerves. Brinton, however, speaks of its reducing (in small doses) peristalsis to a zero. It does not seem impossible to conciliate these apparently opposite opinions.

To speak of these drugs as stimulants or sedatives, describes, I believe, their action imperfectly; they are rather *re-creators of nerve-force*, and the primary result of their successful action will not be any evident exertion of force, but the return of a capacity for exerting force efficiently on the application of suitable stimuli. What a feed of corn, a draught of ale, or a dose of opium is to an exhausted horse, the drugs above-mentioned are to exhausted intestinal muscles and nerves. When, as Abercrombie says, a case of intestinal obstruction yields to a full dose of opium after the most active purgatives have been tried in vain, is not the explanation that the latter were simply an unnecessary and injurious stimulus, which gave no force, while the opium did? So, also, in a case given at p. 691 of my work, symptoms of intestinal obstruction subsided under the use of strychnia, but no evacuation took place until a mild aperient was administered. Here it seems pretty evident that the strychnia restored *nervo-muscular force*, but did not call it into action.

The nervine remedies alluded to commend themselves still more to our attention, if we consider that in the great majority of cases of obstruction the mischief is brought about by some derangement of the nervous apparatus regulating the intestinal movements. Given, a normal working of this apparatus: and intussusceptions, twistings, incarcerations, and paralysis could hardly occur.

OBSERVATIONS ON

DR. C. B. RADCLIFFE'S THEORY OF THE GENESIS OF PAIN.

By JOHN CHAPMAN, M.D., M.R.C.P., M.R.C.S.,
Physician to the Farringdon Dispensary.

(Concluded from page 765, vol. ii., 1871.)

HAVING adduced the pathological facts just discussed in support of his position, that pain is antagonised by an over-active condition of the circulation, Dr. Bland Radcliffe then goes a step further, and declares that "*there is reason to believe that pain of a neuralgic character is antagonised rather than favoured by inflammatory excitement of the nervous system.*" In order to prove this remarkable proposition, he appeals to facts of a nature very similar to those already discussed. He says that, when he himself was suffering from neuralgia, the pain subsided when "local tenderness, redness, and swelling, with general feverish reaction" set in; that it is "the rule rather than the exception for toothache to come to an end when the face becomes swollen and inflamed"; that the stabbing pains, which so generally precede the inflammatory eruption of herpes, scarcely ever remain after this eruption is fully developed; and that in three cases of sciatica which he mentions, "the plain fact was that the severe neuralgic pain, which had existed for some time previously, was at an end when the swelling and tenderness gave evidence of the establishment of inflammation in the course of the sciatic nerve." These cases are in no respect essentially different from those which I have already discussed, and which I have shown to afford no real support to the theory in favour of which they are put forward; but when an attempt is made to adduce facts in proof that pain is antagonised by inflammatory excitement of the brain and spinal cord, the facts have to suffer a tremendous strain.

Dr. Radcliffe says—"Even in inflammation of the membranes of the brain, severe pain in the head cannot be looked upon as a symptom of this inflammation. Three or four years ago I had a youth in the Westminster Hospital with well-marked symptoms of acute cerebral meningitis. When I first saw him he complained of frequent rigors, and of a constant agonising pain in the head, and at this time his face was pale and

perspiring. His ears and his head generally were below the natural temperature, his pupils somewhat dilated, and his pulse contracted and feeble. Eight hours afterwards, when I saw him the second time, his face was flushed, his head burning hot, his pupils contracted, his eyes ferrety, his skin hot and dry, his pulse strong and full, and fierce delirium had taken the place of pain—and this, so far as my experience goes, is the regular history of pain in this disorder." In short, while the cerebral inflammation was being developed, the pain was so intensely acute as to result in the loss of normal consciousness, which was replaced by "fierce delirium"—a state when the brain, in respect both to feeling and thinking, is functioning with such tumultuous and overwhelming rapidity as to prevent either any thought or any feeling from making an abiding impression, and hence, most fortunately for the sufferer, no consciousness or memory of pain endured during the delirium is retained.

In cases of inflammation of the membranes of the spinal cord, Dr. Radcliffe admits that "pain along the spine," as well as in the extremities, "must be regarded as the most prominent symptom; but," he says, "it is brought on by any movement of the trunk, and in great measure, at least, it may be prevented by avoiding such movement. It is often brought on, also, by moving one of the extremities—the pain in this case beginning in the limb, and extending thence to the spine. It seems to depend—in part, at least—upon the same cause as the pain of pleurisy—viz., the dragging of an inflamed and, therefore, exquisitely tender serous membrane."

The presence of pain in cases of uncomplicated inflammation of the spinal cord itself cannot, unfortunately, be referred to "the dragging of an inflamed and, therefore, exquisitely tender serous membrane"; and, as such pain is stubbornly irreconcilable with his theory, he questions its existence in such cases. It is admitted that Dr. Brown-Séguard describes "a constant pain in the part of the spine corresponding to the upper limit of the inflammation of the cord," as a characteristic symptom; "but," says Dr. Radcliffe, "I question very much whether this statement is in accordance with well-sifted clinical facts. . . . At any rate, it is certain that there is not in uncomplicated myelitis that severe pain in the back and limbs which is brought on or aggravated by movement in spinal meningitis." He frankly states that "in three cases of well-marked spinal congestion, and in many cases of partial congestion," he has observed "dull aching along the spine increased by warmth," and then, unfortunately for his theory, he makes this additionally damaging admission—"I have also noticed the same symptom in myelitis and spinal meningitis . . . in fact, so far as my experience goes, I can say that this symptom is likely to be met within congestive or inflammatory disease of the cord." In regard to each of the spinal affections mentioned, he says—"Absence of spinal tenderness I believe to be the invariable rule"; and yet, further on, when adverting to "spinal irritation," he says—"Spinal tenderness would seem, indeed, to deserve to be regarded as the pathognomic symptom of spinal irritation; for in the few cases of spinal meningitis, myelitis, or spinal congestion, in which it is met with, there is reason to believe that its presence may be accounted for by the association of the phenomena of irritation with that of inflammation or congestion."

But, in truth, the facts observed by the great body of impartial and competent Professional witnesses, confute Dr. Bland Radcliffe's assertions, that "even in inflammation of the membranes of the brain severe pain cannot be looked upon as a symptom of this inflammation"; that the pain of spinal meningitis may be, "in great measure, at least, prevented by avoiding" movement of the trunk; and that "there is not in uncomplicated myelitis that severe pain in the back and limbs which is brought on or aggravated by movement in spinal meningitis." In Dr. Copland's definition of cerebral meningitis, the first words are—"Acute pain in the head," and, in describing the symptoms of the disease, he says—"Acute meningitis of the convexity of the cerebral lobes is attended with violent pain, which is exasperated at intervals." (a) This description is endorsed by Aitken. (b) Dr. Watson says—"speaking generally, this complaint is marked by pain of the head"; and, referring to a case by way of illustration of the disease, he remarks—"There was no symptom to mark the extensive mischief within the head, except the *pain*"; and then, having described another case, he says—"There again pain was the most prominent symptom." (c) Dr. Wood

mentions that—"along with the usual febrile phenomena which usher in acute inflammation, are conjoined intense headache, redness of the face, suffusion of the eyes, an excited or wild expression," etc. (d) Testimony to this effect abounds, in fact, in the writings of every author who has given especial attention to the subject; and though it may be admitted that cerebral meningitis and cerebritis generally co-exist, the existence of pain in cases designated cerebritis, while confuting—so far as the meningitis, supposed to accompany it, is concerned—Dr. Radcliffe's assertion of the absence of pain in that malady, confutes at the same time his broader proposition that, as a general rule, pain is antagonised by inflammation. "In cases of cerebritis," says Dr. Flint, "a pretty constant premonition [of coma] is *persisting cephalalgia*, referred to a particular spot or limited to one side of the head, that is unilateral." (e) Even Dr. Hammond, who, to a considerable extent, is a follower of Dr. Radcliffe, dissents from his statement concerning the facts in question. Of "the stage of invasion" of acute cerebritis, Dr. Hammond says—"The most prominent initiatory symptom is headache"; and of "the stage of excitement," he adds—"The pain in the head augments in violence, and is increased, by pressure on the scalp, or even the slightest movement." (f)

Again, the evidence on all sides in respect to spinal meningitis, as well as myelitis, proves indubitably that the actual facts have a totally different aspect from that in which, tempted by his hypothesis, he has been induced to present them. Speaking of the two chief and most constant symptoms—"symptômes qu'on pourrait considérer en quelque sorte comme signes pathognomoniques de l'inflammation aiguë des membranes de la moelle"—Ollivier says one of them is "une douleur plus ou moins vive dans la région du dos: elle semble partir en général du point où l'inflammation a la plus d'intensité, et là elle est aussi toujours plus aiguë." (g) "Acute pain in the course of the spine" are the first words of Dr. Copland's definition of spinal meningitis. He adds—"the pain is severe, and although beginning in a particular part or region, generally extends more or less along the spine." And, in like manner, he observes—"Acute myelitis commences with or without chills, or rigors, with acute deep-seated pain in some portion of the spine that is much aggravated by motion." (h) "The commonest symptoms of inflammation of the meninges of the cord," says Dr. Watson, "appear to be pains, often intense, extending along the spine, and stretching into the limbs, and aggravated usually by motion, and simulating, therefore, rheumatic pains." (i) Dr. Aitken says, meningitis "is characterised by pains in the back. . . . A greater or less degree of pain of the back, proceeding from the point of greatest intensity of inflammation, is one of the most prominent symptoms." (k) And, again, concerning myelitis, he says, "the patient complains of pain in the back corresponding to the seat of greatest intensity of the inflammation." (l) Concerning spinal meningitis, Dr. Hammond affirms that "there is intense pain in the back, which is aggravated by every movement of the patient"; and, referring to the symptoms of acute myelitis, he says, "Among the first, pain in the back at the seat of the lesion is prominent. It is not, however, so intense in character as that attendant on meningitis. The limbs below the seat of the inflammation are likewise affected with pains, which are mainly confined to the trunks of the nerves coming from the affected portion of the cord. A pain is also experienced, in the great majority of cases, at the upper limit of the inflammation, and which extends round the body at that height." (m) In respect to each of these affections, the testimony of Dr. Flint (n) wholly confirms the truth of the authoritative statement just quoted, and I am sure the great body of Physicians, who are not committed to any theory on the subject, will recognise them as accurate representations of the facts in question. My own experience of these maladies assures me that those statements are true, but in this case I prefer to rest my arguments on the evidence of the most widely

recognised Medical authorities; and, as I have now shown, they warrant me in asserting that, as a general rule, pain is not only among the chief symptoms, but is the predominant symptom of inflammation both of the cerebral and spinal membranes, and of the brain and spinal cord themselves. I say as a general rule because occasionally, though rarely, cases of myelitis occur in which little or no pain in the back is complained of. In these exceptional cases it is probable, I think, that either the inflammation does not extend to the sensory elements of the cord, or that they are so swiftly and so completely congested—possibly disorganised—at the very outset of the disease as at once to prevent them, at the seat of inflammation, from functioning at all; in either case, as is easily conceivable, there may be little or no pain.

Such being the facts of the case, according to the authoritative observers whose evidence I have just quoted, I was somewhat surprised to find that the classical work of Ollivier is appealed to by Dr. Radcliffe in support of his doctrine. Referring to the alleged "absence of pain in the spine and extremities" in cases of myelitis, he says, "Pain, either in the spine or elsewhere, is not mentioned, for example, in the nineteen cases, acute and chronic, given by Ollivier, except in three, and of these three the myelitis was complicated with meningitis in two, and in the one remaining the symptoms justify the presumption that the same complication existed." But though this statement is literally true, it is not the whole truth. Regarded as it stands in the context of Dr. Radcliffe's article, it certainly impresses his readers with the conviction that he has the great authority of Ollivier in support of his doctrine that inflammation of the spinal cord is unaccompanied by pain at the seat of inflammation. As about fifty years have elapsed since the reports in question were written, any explanation of their silence concerning the presence or absence of pain is unverifiable now, and therefore useless. I believe, however, that a complete explanation of that silence is derivable from a due consideration of the sources and character of those reports, and that if Ollivier were still in the flesh he would be more surprised even than I was on finding his cases appealed to in support of a doctrine diametrically opposed to the one he taught, the latter being concealed in silence meanwhile. In his explicit description of the symptoms of myelitis, Ollivier says, "The patient complains of a deep and, more or less, intense pain at some point along the spine—pain which corresponds to the part of the nervous centre which is the seat of inflammation. This pain may extend itself along the whole length of the back." He adds, "According to Klohs [who wrote on myelitis], the pain is augmented by lying on the back, especially if the patient lies on a feather bed, and not on a mattress." (o)

Dr. Radcliffe's assertion that, in cases of cerebral meningitis, the pain precedes but does not accompany the stage of inflammation, receives no countenance from any Medical writer I am acquainted with; and though it is generally recognised that, in cases of inflammation of the membranes of the spinal cord, the accompanying pain is increased by movement either of the trunk or of the limbs, none of the authorities mentioned give the faintest intimation that the pain of spinal meningitis does not exist unless when induced by movement. In maintaining this novel position, that the pain is almost wholly due to movement of the trunk or extremities, and may, therefore, be almost wholly prevented by avoiding such movement, Dr. Radcliffe stands alone.

On the subject of spinal tenderness, Dr. Radcliffe does not seem to me to have defined his views with sufficient clearness: anxious as he is to demonstrate that in cases of congestion of the spinal cord and of inflammation of both the cord and its membranes, absence of spinal tenderness is the "invariable rule," he announces, as a distinct proposition, that "pain, the result of tenderness, would seem to be associated with a state of inflammatory excitement in the nervous system." But if it is, why is he so ready as he is to recognise the presence of spinal tenderness in cases of so-called "spinal irritation," which, as he declares, denotes "a deeply depressed condition of circulation in the spinal cord"? and why does he seek to prove that spinal tenderness is invariably absent in cases of inflammation of the cord and its membranes? I may of course misunderstand him; but, after carefully considering all he has published on the subject, it seems to me that in his writings "tenderness" plays two parts differing completely from each other in character. According to his theory, "spinal irritation" is an especially characteristic feature of the neuralgic constitution which, as he says, is associated with a depressed condition of the circulation; therefore, if I understand him

rightly, he adduces "tenderness" of the spine in cases of spinal irritation as evidence of that neuralgic diathesis or extreme nervous excitability which he regards "as a sign of defective vital power in general, and of defective nerve-power in particular." Having presented "tenderness" in the character just mentioned, he makes the utmost possible effort, and even ignores well-authenticated facts, in order to ensure the absence of that symptom, as well as of spine-ache, whenever meningitis or myelitis are on the stage of discussion; for the introduction of tenderness of the spine as a sign both of a depressed circulation in the spinal cord and of that extremely exalted condition of the circulation constituting inflammation would be glaringly contradictory. Dr. Radcliffe believes that the nature of the proximate cause of pain of a neuralgic character differs fundamentally and essentially from that of the proximate cause of "pain the result of tenderness;" accordingly he thinks it necessary for the sake of his theory to insist on that difference, and apparently does not perceive that the co-existence of pain, even "when the result of tenderness," with "a state of inflammatory excitement in the nervous system," invalidates that theory. For what is the pathological significance of "pain, the result of tenderness"? I venture to affirm that it is excessive excitation of the sensory nerve-centres consequent on excessive excitation of the peripheral ends of the sensory nerves within the area of the tender region. The tender region is tender for one or both of the following reasons:—(1) Because its sensory nerve-centres are in a state of excessive excitability (due, as I affirm, to hyperæmia of those centres); or (2) because it is the seat of inflammation of some grade of intensity. It is tenderness of the second kind to which, as I apprehend, Dr. Radcliffe refers. Now, if the tenderness of this kind be produced by inflammation pure and simple, the existence of such tenderness seems to me to be a fact wholly at variance with the requirements of his theory. Tenderness means a great susceptibility of the tender part to external impressions which are capable of exciting pain in it with preternatural facility; and while this great susceptibility is a condition which, as Dr. Radcliffe assures us, is peculiarly favoured by a depressed condition of the circulation, pain itself, he says, is associated with a reversal of the normal state of electricity in the nervous centre in which the painful nerves converge—a reversal consequent, as he also says, on a deficiency of arterial flood in that centre. In recognising that "pain, the result of tenderness, would seem to be associated with a state of inflammatory excitement in the nervous system," he virtually recognises that at least half of the whole region of pain is in a state of unconquerable insurrection against his theory, for he has given no explanation of the existence of this vast exception to it—and it may be safely presumed that if he could have given one he would have hastened to do so. After placing myself in imagination by his side in the "region of abstract theory," and scrutinising the entire area of the pathology of pain through his theoretical telescope, I can discover no vestige of a reason by which the existence of that vast province of pain associated with a state of inflammation is so explicable as an exceptional phenomenon as to be reconcilable with the doctrine in question.

But while dissenting from Dr. Radcliffe's conclusions, and noting his occasional straining of facts in order to make them support his hypothesis, I feel compelled to express my admiration of the general excellence of both the method and spirit of his investigations. His work is a remarkable example of unwearying labour, patient ingenuity, and skilful selection, arrangement, and interpretation of facts seemingly subservient to the theory they are designed to support; it also displays unwavering loyalty to the theory espoused, logical acumen in the advocacy of it, and, throughout, a spirit of modesty which causes him to preface almost every one of his numerous propositions—even the most dogmatic of them—with the formula, "It would seem." It may be true that, in practice, a man who is guided by a false theory is a dangerous man, and the more especially dangerous, the more thoroughly he is faithful to it; but in the region of ideas, the man who attempts the solution of hitherto unsolved problems of great practical concern, by means of a comprehensive, ingenious, and more or less logically coherent hypothesis, and who exhibits a persistent and practical allegiance to it, is a public benefactor, even though that hypothesis should prove untrue—for, whetting the appetite for facts in confirmation and in confutation of it, it awakens, stimulates, and guides observation, provokes discussion, and, by the friction of thought with thought, develops that intellectual light which ultimately leads to those sound generalisations speedily recognised by all investigators as really representative of truth itself.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

CASES UNDER THE CARE OF MR. ERICHSEN.

[For the notes of the following two cases we are indebted to Mr. Curtis.]

Fracture of the Nasal, Superior Maxillary, and Malar Bones—Recovery.

A. B., aged 30, was driving a waggon on the day of admission, when the horses took fright, and he was thrown out. The two wheels passed over the back of his head, as he was lying with his face to the ground. When admitted, immediately after the accident, there was unnatural mobility of the whole of the palate and upper teeth, so that, when the finger was placed behind the upper incisors, the two upper jaw-bones, the nasal bones, and the hard palate very easily were moved in one mass in an antero-posterior direction. There was considerable ecchymosis of both sets of eyelids, and of the upper portion of the face. There was some bleeding from the nostrils, which was readily checked by plugging. On the back of the occiput was a cut two inches in length, but no sign of concussion of the brain or fracture of the skull. He was quite conscious, and gave a coherent account of his accident. No fracture or irregularity could be felt from the inside of the mouth, nor was there crepitus on moving the upper jaw; but, after careful examination, it seemed that the nasal bones were fractured transversely at the root of the nose; also, the malar bone on each side, close to the articulation with the superior maxillary bone; and the ascending plate of each palate bone and the pterygoid processes must also have been fractured, otherwise there could not have existed such marked mobility.

Carbolic dressing was applied to the wound at the back of the head, and the head bandaged in such a way as to give some support to the fractured bones. He continued to do well, and on the thirteenth day after the accident could bring his teeth together with a distinctly audible snap. On the twenty-fourth day he was discharged.

Fracture of Superior Maxillary, Nasal, and Ethmoid Bones and Zygoma on each side—Rupture of Liver—Death.

F. B., aged 22, a potman; believed to be sober at the time of the accident. All that was known of his accident was that he fell over the banisters of a staircase—a height of thirty feet—on to a boarded floor. When picked up he was bleeding profusely from the nose and mouth, and three of his teeth were found near him. On admission crepitus was felt about the whole of the face. He was partly conscious, but complained loudly of pain. There was a small wound near the bridge of his nose, and another through the lower lip. He continued groaning and apparently in great pain, until his death, two hours after admission.

At the post-mortem examination, conducted by Mr. Marcus Beck, the nose was found completely smashed, and all the front teeth of the upper jaw were gone. The skull was opened, but no fracture of the bones existed. The brain was uninjured. The lower jaw was broken on the left side, immediately behind the last molar tooth. The whole of the alveolar part of the upper jaw, with the teeth, the hard and soft palate, and the pterygoid plates of the sphenoid, were detached from their connexions, and could be removed in one piece, after separation from the soft parts. Another fracture, vertical in direction, ran through the upper part of each superior maxilla, into the orbit, and backwards into the spheno-maxillary fossa, so as to separate the part of the bone to which the malar bone is articulated. On the right side the zygoma was fractured close to the malar bone, and on the left close to its root. On this side the fracture was not quite complete; the compact tissue on the surface, not having given way, the bone was bent. Thus, on each side was a fragment consisting of the malar bone, with parts of the superior maxillary bone and zygoma; and on raising these the cavity of the antrum on either side was fully exposed, filled with clotted blood. The nasal processes of the superior maxillary bones, the nasal bones, the os unguis, the ethmoid, and the vomer were broken into innumerable fragments, of which no exact description is possible. The lungs were found congested, and the bronchi full of frothy, blood-stained fluid.

and a few patches of subpleural extravasation of blood of variable size; the largest about an inch in diameter. The third and fourth ribs on each side were fractured about their middle, and the seventh cartilage of the left side was fractured. In each mediastinum, but more especially in the posterior, was found a quantity of clotted blood, the source of which could not be traced. The abdomen contained a small quantity of fluid blood; and several subperitoneal extravasations were observed; one especially large one was over the cæcum. The liver, which was large and fatty, was superficially ruptured in several places upon its surface. The wounds extended through the peritoneum, but not deeply into the liver tissue. On the under surface were two patches, about one inch in diameter, in which the hemorrhage had separated the peritoneal covering, and formed two small bags of blood.

[For notes of the following case we are indebted to Mr. Barfoot.]

Acute Necrosis of Tibia—Pyæmia before Abscess was opened—Death.

A. C., aged 4, described as always delicate, and as having suffered from bronchitis on more than one occasion. Present illness began, three days before admission, with a severe cold, and two days ago the leg began to swell and become red; the next day the child remained very ill and feverish, and on the following she was admitted. There was no history of any injury. On admission the child was evidently seriously ill; pulse and respiration very rapid. A red swelling existed over the upper part of the tibia, which was brawny and hard, and very tender. A poultice was applied to it, and some aconite was given internally ever hour, but as it seemed to depress her it was discontinued after a few hours. On the day after admission the child was worse. She screamed frequently at intervals. On examination of the thorax, there was found dulness over both bases, with abundant crepitant and sub-crepitant râles. The respirations were very rapid, the pulse was 140 and weak, and the skin hot and dry. Towards evening she became very stupid. In the afternoon of the following day an abscess was opened over the front of the leg, from which some non-offensive pus escaped, and about five hours afterwards she died. A post-mortem examination was made eighteen hours after death, and the following is an abstract of the report of Mr. Marcus Beck:—"Rigor mortis well marked. The body was well nourished. Some purplish patches were scattered over the limbs and chest in front. On opening the chest the pericardium was found distended with nearly a pint of fluid. The whole surface of the heart was covered with a layer of lymph one-eighth of an inch in thickness; it was soft, and yellowish in colour. The valves of the heart were healthy. The posterior parts of the lower lobes of the lungs were of a dark red colour, looking at first like pneumonic consolidation. On making sections into them a large part of each lobe was found partially collapsed, but did not sink in water. The upper lobes and anterior part of the lower lobes were healthy. Scattered over the surface of both lungs, close under the pleura, were about a dozen dark-coloured spots, some breaking down in the centre into cavities containing purulent fluid. These deposits were typically pyæmic in character. All the other viscera, including the brain, were examined, but nothing abnormal was found. The throat was examined for ulceration. There was no sign of discharge from the ears. On dissecting the right leg the upper end of the tibia from the epiphysis to about the middle of the shaft was found necrosed; the periosteum was separated from it over the whole of this part, and the pus had lain between it and the bone; below, the periosteum was adherent, and the bone healthy. On section the specimen showed clearly that the disease stopped at the epiphysis. The medulla of the bone was red, but nowhere suppurating. The knee-joint was intact; no other joints were diseased. The fibula was healthy. On examining the veins of the limb the posterior tibial was found adherent to the surrounding tissues so firmly that it could not be dissected out from them; but on laying it open it was found to contain a broken-down clot. This was perfectly decolorised, and had the appearance of thick pus."

ROYAL INFIRMARY, EDINBURGH.

CASE OF PROCIDENTIA UTERI—OPERATION FOR RESTORATION OF THE PERINEUM PERFORMED.

(Under the care of Dr. MATTHEWS DUNCAN.)

[Reported by Dr. J. R. HARDIE.]

M. T., aged 21, has had one child. She was admitted to Ward XVI., November 6, 1871, complaining of falling down

of the womb, pain in the back, pain during micturition, and a yellow-coloured discharge. Eighteen months ago she was delivered of her child; six months subsequently a feeling of weight in the lower part of the belly—accompanied with bearing down—set in, and five months later the womb came down between her thighs. It was replaced at this time, but in a few days prolapsed as badly as before, and has remained so up to the present time. Her monthly periods have been regular for the last six months, but had been absent during the previous five months. A yellow-coloured discharge, occasionally tinged with red, has troubled her during the same period.

On a physical examination being made, the uterus is found to be procident, enlarged, inflamed, and ulcerated to the extent of the size of a half-crown piece around the os uteri. On passing the sound the uterus is found to measure fully six inches in length; and on introducing a sound into the bladder it is found to pass upwards, backwards, and then downwards into a pouch which forms part of the procident mass anteriorly. A finger inserted into the rectum detected no pouching of that piece of gut. The protruding organs were reduced with ease, and patient ordered to keep her bed.

November 14.—Patient has lain in bed since last report. The bladder and uterus have remained in position; the latter organ now measures only four inches, and no ulceration is to be seen, but a copious muco-purulent discharge is present.

18th.—T. was put fully under the influence of chloroform, and the operation for elongating the perineum was performed. During the operation there was a good deal of venous oozing, which was arrested only partly by applying cold water, and more fully on bringing the cut surfaces in accurate apposition by means of sutures composed of silver. This oozing could easily be seen to proceed from enlarged veins. The parts operated on were then dressed with lint steeped in carbolic oil (1 in 8); patient was put to bed, and orders were given that if she could not make water conveniently by herself it should be drawn off with a catheter. She was ordered a grain of opium at night, or oftener if necessary, and to have fluid nourishment.

25th.—The stitches were taken out to-day. The wound was found to be completely united throughout its extent. The vaginal orifice, which was previously gaping and would have admitted the fist, was now found to be only large enough to allow a single finger to pass into it.

27th.—Yesterday half an ounce of castor oil was administered, and this morning patient's bowels were freely moved without injury to the parts operated upon.

December 12.—Patient continues quite well, and only awaits the fitting on of a proper baudage before being dismissed. Uterus measures a little less than four inches; the discharge is much diminished in quantity, and she makes her water without pain or any effort.

Remarks.—The procidentia in the case related followed closely on childbirth, an interval of only six months elapsing between the symptoms which first indicated an impending prolapsus and the birth of the patient's child, five months intervening between these premonitory symptoms and the complete descent of the parts between her thighs. Although in most cases of prolapsus we have a history of previous childbearing, yet many instances of it are on record in which such had not existed. In virgins even it is not extremely rare. Its occurrence in the humbler ranks of life is well known. This is probably owing to want of proper care during the puerperal state—too early getting up, disturbing the process of involution, and premature return to the ordinary duties of household life, lifting weights, and the like, favouring the production of this complaint. Under these circumstances, the uterus may be larger than usual, the passages more relaxed, and the woman's general health somewhat feeble. It is a process which goes on gradually and insidiously, often without attracting attention until the whole mischief has been accomplished. Much has been written and said concerning the causes of prolapsus or procidentia, and although undoubtedly we know a great deal about co-existing states which may be also among the causes of this disease, still there are important points in its causation—perhaps the most important—which are ill-understood. A study of it in this direction, from a mechanical point of view, promises to bear fruit in the same manner as labour itself has been elucidated. Pain in the back and during micturition, and a discharge, were present. The pain during micturition was probably owing to an irritable state of the mucous membrane of the bladder. The other symptoms are of pretty frequent occurrence, but we often see cases of complete procidentia where all that is complained of is the physical

inconvenience caused by the protruding organs. The component parts of the procidentia were the bladder, the uterus, and the vagina, the rectum being in its natural position, as was ascertained by introducing the finger into it, and finding that there was no pouching of the anterior wall. Owing to the more intimate anatomical relations of the bladder to the uterus, you never meet with a complete case of procidentia into the formation of which the former viscus does not enter; the rectum, on the other hand, is not so closely connected with the uterus, and, therefore, not so liable to be affected in its position by changes in that of the uterus. It not uncommonly retains its normal position when both bladder and womb are wholly procident. The rectum may be alone procident through the vagina, and remain so for a considerable time; but if the bladder be so affected, it gradually pulls the uterus with it. The length of, and the changes in the length of, the uterus is a point of noteworthy importance in the case of M. T. On the uterine sound being introduced, on November 6, it was observed to pass fully six inches; in this state it was replaced, and allowed to remain in position undisturbed until November 14, when it was re-examined, and found to have diminished considerably in size—to measure only four inches. On examination again, on December 12, a still further diminution in size was seen to have taken place. This gradual diminution in the size of the uterus was accompanied by disappearance of the inflamed look the parts presented on admission, likewise by the disappearance of the patches of ulceration. This is a point of considerable importance in practice, and indicates that proceedings sometimes resorted to in order to diminish the size of the procidentia, such as amputating a portion of the cervix uteri, poulticing, etc., are at least unnecessary. The ulceration around the os uteri was pretty extensive, and appeared to possess more of the characters of true ulceration than what is found in most cases of this nature. In many instances a diphtheritic membrane is present, which, on being peeled off, brings into view an abraded condition merely of the mucous membrane, not real ulceration. The ulceration mentioned disappeared, however, with amazing rapidity by keeping the uterus in its place, no local application whatever being used. The only mode of treatment applicable with any prospect of relief or cure in a case like that related, is the performance of the operation of restoration of the perineum where it has been ruptured seriously, or elongation of it where no rupture worthy of the name exists. When the operation of restoration of the perineum is had recourse to, an amount of elongation is also practised. The operation, although well known, is worthy of a short description here. Preliminary arrangements: These consist in selecting the time for the operation, which should be as soon as possible after a monthly period, in having the bowels freely opened shortly beforehand, and in having the stomach free from food. The patient is placed on a table in the ordinary lithotomy position, the operator sitting on a low stool arranged so as to reach the parts without effort. Chloroform, or a mixture of it with ether, is administered, so as to produce anæsthesia and keep the patient quiet. A piece of integument, about half an inch broad, is then removed, so as to make raw the separate margins of the perineum so far forwards as to be on a level with the orifice of the urethra on either side. By this mode of procedure a horseshoe-shaped wound is produced. During the operation several arteries require to be secured; these are generally situated in front of the sphincter on either side, and further forwards, near the upper end of the wound. Sometimes oozing from veins is present; this is generally arrested by the application of cold water. If not entirely stopped in this manner, the next step in the operation—namely, the closing of the wound by means of silver-wire sutures—generally suffices. In introducing the sutures care must be taken to bring the parts into accurate apposition. The urine is now drawn off, the parts carefully washed and dried, and the wound dressed with a piece of lint steeped in carbolic lotion. Opium, to the extent of a grain at bedtime (or oftener, if need be), is given, so as to prevent any passage of the bowels, and the patient is ordered fluid nourishment. Care must be taken to keep the wound clean by changing the dressing daily. The urine is drawn off by the catheter, if it cannot be readily voided by the patient herself. The stitches are taken out on the seventh or eighth day after the operation, and next day the bowels are evacuated by means of castor oil. After the parts are in a fit state to bear pressure, a T bandage accurately fitted is used. On the under strap of the bandage a sliding pad, so adjusted as to press on the perineum, is placed; this is covered with patent leather. In making the bandage, an accurate fit round the haunches is indispensable, otherwise it is useless. If the perineum were not supported in this manner,

the procidentia would probably recur in the course of time, gradually stretching the new perineum. This is prevented by the means described. In some cases, however, the bandage is not found necessary. If these measures combined fail, then a pessary of the kind called disc and stem pessary, varying in size with the requirements of the case, may be introduced.

SATURDAY, JANUARY 20, 1872.

THE STOCKWELL MURDER.

THE trial of the Rev. John Selby Watson for the murder of his wife has, according to general expectation, ended in a verdict of guilty, and his condemnation to death. The jury added a strong recommendation to mercy, on account of the advanced age and previous good character of the prisoner. Everyone will agree with the learned judge who tried the case in his remark, when passing sentence of death, that nobody who has heard this trial can regard the case of the prisoner otherwise than with the greatest compassion.

The facts of the case must be in the minds of all our readers, and it will be necessary to recapitulate them only with the greatest brevity. The Rev. J. S. Watson, a clergyman of the Established Church, about '67 years of age, was, till the end of the year 1870, head master of the Stockwell Grammar School. He was a man self-educated in the main, yet of great classical learning and culture, and an author of considerable merit. He had always led a blameless life, and had lived for many years apparently on terms of affection with his childless wife. In October, 1870, he unexpectedly received notice of dismissal from his post of head master. The loss of income and status thus brought about appears to have preyed on his mind. There were no means of recouping his loss, and his means became exhausted. On the evening of Sunday, October 8, whilst the servant was absent, he killed his wife by beating her on the head with a pistol, and concealed the body in her bedroom (they had for three months slept apart), locking the door, and telling the servant on her return that his wife had gone into the country. From a paper written by the murderer, there appears to have been some sudden quarrel between him and his wife, and he spoke of previous provocations. Either these must have been fictitious, or the guilty man must have exercised great command over his temper; for their only servant, who had lived some years with them, had never noticed them to be on any but amicable terms. A Mrs. Tully, who called at the house on the evening of the murder, and saw both the murderer and his victim, spoke, how-

ever, of signs of displeasure in the former towards the latter. Be this as it may, there was no evidence to reduce the act to one of manslaughter; and the plea set up in defence was simply one of insanity, no attempt being made to deny the crime. After its commission he attempted to remove all traces of blood from the library, in which the horrid deed had been committed. He pointed out to the servant a mark on the stair-carpet, saying that some port wine had been spilt. The subsequent actions of Mr. Watson are important, as bearing upon the question of his sanity. We confess we do not see anything in these during the next three days to show that he was not in the full possession of his faculties. The people who saw him observed no marked change in his conduct. The next day he went to a trunkmaker and ordered a huge packing-case—for books, he said, but apparently for the purpose of stowing away the corpse in it. On the Tuesday he evidently abandoned this idea, countermanding the box, and paying for it with some confusion of manner. He appears next to have contemplated suicide, purchasing prussic acid, but warning the servant that he expected to be ill, and choosing a Doctor to attend him. On the Wednesday he took an insufficient quantity of the poison to destroy life. The whole state of affairs then became apparent. Dr. Rugg, on his arrival, found a document of Mr. Watson's, confessing the murder—"I have killed my wife in a fit of rage"—and giving minute directions as to the disposal of his property. In all this we note nothing but the actions of a sane man, and entirely fail to detect any evidence of insanity, *except the apparent utter absence of remorse*. The careful settlement of his affairs was obviously not the action of a lunatic, and such a person would never for a moment think of hinting to another person his intention to take poison. Lunatics carefully conceal their intentions in this respect. It is more probable that the attempted suicide was a mere blind to raise the question of insanity, and that the guilty man of purpose took an insufficient dose of prussic acid to insure death. By-and-bye, when he was sufficiently recovered to bear removal, the frivolity of his manner attracted attention; but this might also be assumed for a purpose. Whilst in gaol awaiting his trial, there have been noticed in him certain peculiarities of conversation which may be supposed to betray incipient senility, but we confess that they are trifling, and are not for a moment to be allowed to outweigh the complete lucidity of reflection and expression observed in the documents he wrote in the interval betwixt the murder and its discovery; and, indeed, it is not to be wondered at, that the guilty man's mind should have become unhinged after the commission of the deed. That he—a man of culture, refinement, character, and position as a clergyman—should in a moment of passion kill in the most brutal manner the object of his youthful affection, the partner of his married life for a quarter of a century in peace and harmony, would surely be a circumstance that would deeply affect his mind, and perhaps eventually result in insanity. Doubtless the evident depression under which he was suffering, consequent upon the loss of fortune and the prospect of beggary, must be taken into account in weighing the question of unsoundness of mind; but, as Mr. Denman observed, if the depression caused by a disappointment were to be received by a jury as a defence for murder, it would greatly increase the risk to human life from violent acts.

We consider that the jury had no option but to return a verdict of guilty, accompanied by a recommendation to mercy. The plea of melancholia set up in defence, and supported by Drs. Maudsley, Blandford, and Rogers, though entitled to every respect, was outweighed by the adverse opinions of Drs. Waterworth, Sheppard, and Begbie. Dr. Maudsley stated that a person suffering from melancholia is subject to bursts of mad violence, and while these outbursts continue his reason is quite in abeyance, and he is unconscious, or nearly so, of what he is doing, and his mind is decidedly deranged. After such an attack, the mind sometimes recovers in a comparatively short

time—perhaps within an hour; and immediately before the attack a patient might appear *comparatively* calm and rational, and his conversation be perfectly coherent. But does Mr. Watson answer to this description? Very slight evidence of melancholia antecedent to the crime was offered, and none subsequently; moreover, there has been no recurrence of the homicidal tendency. Of course, the jury returned a verdict of guilty, and declined to entertain the notion of insanity; equally as a matter of course, Mr. Watson will not be hanged. The circumstances of the deed are so unparalleled that there is nothing to guide us in the way of precedent as to what is to be done with such a criminal. To have adjudged him insane would have been to open the flood-gates to every form of brutal murder; to hang him would revolt the feelings of the community at large. Justice will, we doubt not, be met by a commutation of the sentence to lifelong servitude—surely a punishment more terrible to a man of Mr. Watson's stamp than any other that could be inflicted.

THE BRIGHTON POISONING CASE.

THE Central Criminal Court has during the last two weeks been rich in cases replete with Medico-legal interest; the trials of Mr. Watson for the Stockwell murder and of Miss Edmunds in the Brighton poisoning case being among the most important of modern times. As in the former, so in the latter, the plea of insanity was raised and set aside, and Miss Edmunds now lies under sentence of death.

Last summer the circumstances of the Brighton case (the murder of the boy Barker), and of a supposed attempt to poison the wife of Dr. Beard, together, no doubt, with much wild fiction, were familiar to the public. The convicted person, Miss Edmunds, a maiden lady, 43 years of age, living with her mother in Brighton, was arrested on a charge of attempting to poison Mrs. Beard, the wife of the prisoner's Medical attendant, by means of a present of cake and fruit supposed to have been sent by an anonymous donor. This charge formed, however, no part of the case on which the prisoner was convicted, Dr. and Mrs. Beard's evidence not being received by the Court. On June 12 last a boy named Barker, staying with his parents in Brighton, died twenty minutes after eating a chocolate cream purchased at the shop of a confectioner named Maynard. A quarter of a grain of strychnia was found in the remainder of the creams purchased, and a quarter of a grain of the same poison in the stomach of the deceased. Creams subsequently taken from the same stock contained no strychnia. It was clearly proved that the accused was in the habit of purchasing strychnia in considerable quantities; of sending boys to the shop of Mr. Maynard to purchase creams, which she subsequently returned in exchange for others; and that after these returns persons purchasing creams at the shop suffered from illness, though much doubt exists whether the symptoms from which these persons suffered were caused by strychnia. Further, she was also accustomed to drop packets of creams in shops visited by her, and these sweets produced sickness—indeed, there is no doubt, as was alleged by the prosecution, that a considerable number of poisoned sweetmeats were in these various ways distributed through Brighton, resulting—in one case, at least—in the death of the victim.

Of course attention was attracted to the shop from which the sweetmeats were procured, and this was increased by the fact that, before and at the inquest, the prisoner asserted that she herself had suffered from eating chocolates purchased at the same shop. After the inquest on the boy Barker she also wrote anonymous letters to his father, endeavouring to confirm the suspicions attaching to the sweets sold by Mr. Maynard. In a word, we have the history of a diabolical and systematic attempt, made in the most cunning manner, to poison innocent people, with whom the prisoner had no connexion, and whom

she did not even know. In this respect the case for which Miss Edmunds was tried differs from her alleged attempt to poison Mrs. Beard; for she had shown an improper affection for Dr. Beard, and had a motive in attempting to get rid of his wife. The theory of the prosecution appears to have been that Mrs. Beard, having discovered the attempt to poison herself, and suspicion attaching to the prisoner, the latter, in order to avert suspicion, resorted to these reckless and diabolical proceedings for the purpose of drawing off attention, and fixing it upon other and unknown persons. We confess that no other supposition bears such an air of *vraisemblance* as this, horrible beyond description as it appears.

The only plea set up in defence was that of insanity, if we except the feeble attempt of Serjeant Parry, in his opening speech for the defence, to show that there was no absolute proof that the chocolates which caused the death of the child had passed from the prisoner to Mr. Maynard. Perhaps, in the existing state of the law, no other verdict could have been returned than that of "guilty." Of the insanity of the prisoner, beyond the act itself, no evidence was tendered. The deliberation of purpose, the artful manner in which her design was carried out, the care and skill shown in diverting suspicion and in fixing it upon innocent people, were great. Of hereditary insanity there was a superabundance of evidence. Her father suffered from acute mania, ending in general paralysis; a brother died in Earlswood Asylum, an epileptic idiot; her sister suffered from violent hysteria, and endeavoured to destroy herself; her maternal grandfather had died at 43 (her own age) from general paralysis. Moreover, it is said that she herself had, eighteen years ago, suffered from hysteria and paralysis. A more complete history than this of family insanity cannot be imagined. And yet, beyond the fact of Christiana Edmunds having suffered eighteen years ago from presumably hysterical paralysis, there is nothing else to induce us to suppose that she is insane. Well might her leading counsel declare himself baffled. A more extraordinary case never came before a court of justice.

Of the legal sanity of the unfortunate woman we entertain little doubt; and yet this case adds new force to the outcry proceeding from so many members of the Profession for a revision and modification of the existing legal definition of insanity. Miss Edmunds knew perfectly well that she was violating the law; she knew the difference between right and wrong; and if she entertained any delusion it was that Dr. Beard had returned her affection. Unwisely, as we think, the presiding judge excluded Dr. and Mrs. Beard's evidence, in the interests, as he said, of the prisoner. We may remark, in passing, that Dr. Beard is thus allowed to rest under an imputation which probably has no foundation in fact. It is well known how this sort of woman conceives an affection for her Medical attendant, and imagines it to be returned. But assuming that this idea of hers was a mere delusion, the existence of such a delusion does not exculpate the culprit from the consequences of an act done under the influence of the delusion; it would not justify her in attempting Mrs. Beard's life; still less, in order to place others on a false scent, in distributing poisoned sweetmeats wholesale among a large community. The rule laid down in M'Naughten's case—that, if the individual accused of a crime labours under a partial delusion, and is not in other respects insane (and this appears to be exactly Miss Edmunds' case), he shall be considered in the same situation as to responsibility as if the facts with respect to which the delusion exists were real—afforded no ground for acquittal on the ground of insanity. Baron Martin, in passing sentence, said the real question was *not whether she was a person of weak mind*, but whether her mind was in a state to distinguish right from wrong. He admitted that she had got into a morbid state of mind in consequence of her relations with Dr. and Mrs. Beard, and that had led to all that had occurred. Yet, surely, such a ruling is a bar to the plea of insanity in nearly

all criminal cases. We think it high time that lawyers should reconsider their definition of insanity, though we do not wish to see in every criminal act a deed of insanity.

After sentence was passed, the prisoner pleaded pregnancy in bar of execution. No similar plea for arrest of judgment has been made at the Central Criminal Court since 1847. A jury of matrons, assisted by two Surgeons, pronounced her not to be pregnant. We shall recur to this plea next week.

DR. TODD.

MANY of our readers were not a little surprised and shocked at some expressions of Dr. Forbes Winslow in a letter to the *Times* last week. Speaking of the late Dr. Todd, he said that he had known many persons who cursed the day when he entered their house, because he had recommended alcoholic drinks as remedies, and thus had sanctioned a course of tippling to which the patients became slaves. Dr. Winslow has the reputation of being a kind-hearted man, and hence we wonder at his use of expressions regarding one who, alas! cannot defend himself, which are sure to cause pain to his friends and pupils. It is notorious enough, however, that Dr. Todd has been criticised pretty freely, and, as one instance among many, we may refer to what Dr. Gulia, of Malta, says of him, in the work on diphtheria which is reviewed in another column.

Dr. Gulia, after treating of the abuse of bloodletting, proceeds to speak of the abuse of stimulants. "An outrageously Brownian school," he says, "is endeavouring, with little good sense, to establish a treatment not less fatal than that of the Tommasiniani" (the bleeders), "and despises those who, under due restriction, have recourse to bloodletting in idiopathic croup, acute hydrocephalus, and similar cases; meanwhile, they make their patients gulp down wine and brandy and every sort of diffusible stimulant in a routine fashion, and without any moderation, and, loathing every other medicine, try to convert the chemists' into liquor shops. Lucky dogs! they have found the trick of curing with drink—

"Han trovato il bindolo
Di medicar col ber."

They are, for the most part, followers of Todd, who holds that where strong doses of alcohol are not used it is impossible to overcome a serious attack of fever, and insists that its use is in no way to be given up, even if the febrile symptoms are aggravated, and delirium or coma, twitching of the tendons, with other adynamic and ataxic symptoms, come on; because 'it is better,' he says, 'to err by excess of stimulants than to give too little;' and elsewhere he asserts that it is much more dangerous to diminish or discontinue alcohol than to give large doses. With Todd's school, alcohol is the single nourishment to which recourse should be had to replace the material wasted in fevers and the greater number of acute maladies, and to withstand functional exhaustion." Dr. Gulia goes on to say, that it is clear that Todd's practice was not universally approved in England. "Il Wilks, fra gli altri," scornfully notices that *aqua vita* is with many Practitioners a universal remedy, like revalenta, chlorodyne, Morison's pills, and other mountebank drugs. Wilks adds, "before giving any medicine to the sick in our Hospital, we discuss the benefits likely to be gained from it—such, for instance, as a few drops of ether or a few grains of henbane—and meanwhile we give brandy by the ounce without thinking of its effects."—(*Lancet*, 1867.) "When Todd's practice (*la terapeutica toddiana*) was first made known in France," says Dr. Gulia, "people took him for a stark madman, and in 1869, in a report to the Paris Society of Practical Medicine, it is said that 'the alcoholic treatment has been tried in Hospitals, but there are great difficulties with regard to private families, for these are addicted to routine, and if they were to see a pneumonia treated by *la pozione di Todd*, instead of bleeding and tartar emetic, they would be filled with wonderment, and would lose all confidence in the Physician.' "

This, then, is the indictment against Dr. Todd, as presented by a foreign Physician of candid mind, and free, apparently, from personal bias: that he introduced a reckless method of giving brandy in disease, bad in itself, and bad also because it led to the neglect of therapeutics as a science. There is no doubt in our mind that there is some truth in the accusation. Todd was eminently incautious. The passages which Dr. Gulia cites from his "Lectures on Acute Disease" are very indiscreet, because they were sure to be quoted without the context, and without reference to the particular cases which induced Todd to make so strong a statement; and although Todd's practical sagacity may have led him right, still, strong statements in books usually fall into the hands of persons who misquote and take them in a sense more absolute than their author intended. Let it be granted, then, that Todd was indiscreet, often erroneous, and that reliance on any exclusive treatment (supposing he used one) is, *ipso facto*, vicious. Yet there is something to be said on the other side.

Dr. Gulia, in another page of his work, speaks of Todd with respect, as one of the modern teachers who mitigated the severity of ancient treatment, and quotes Béhier, Gingeot, Pécholier, and others in favour of the discreet use of alcoholic drinks in disease. But, after all, the main fact is, that Todd was an iconoclast, and, like other revolutionists, resorted to something stronger than rose-water. Men who have been thirty years in practice may well overlook his indiscretion on account of the solid work he helped to do. If he ended by promoting a doctrine of imaginary debility and the employment of injurious stimulants, he found a very different state of things at first. A pernicious doctrine, concocted out of Haller's physiology and Hunter's pathology, prevailed, according to which inflammations and fevers were regarded as states of increase of the powers of life, which required lowering, reducing, and weakening remedies. We need not allude to the "vampirism," justified by such men as Marshall Hall and Elliotson, to show that, though we abhor the alcoholic extreme, there was some excuse for a genial and kind-hearted Irishman like Todd, whose zeal led him from one extreme to another.

Moreover, Todd was right, though not original, in his assertion of the calming effects of weak alcoholic drinks, even for young children, in scarlatina and other adynamic fevers. We know the fact; but whether alcohol is "food for the nervous system" or not belongs to a different line of research.

THE WEEK.

TOPICS OF THE DAY.

THE convalescence of the Prince of Wales being, happily, now fairly established, already the question of what honours are to be bestowed on the Physicians who have guided him through his perilous and protracted illness is being discussed, not only in the columns of Medical contemporaries, but in those of the daily press. It has been announced in one morning paper that Sir William Jenner, being already a baronet, is to receive the decoration of a Civil K.C.B., and that Dr. Gull is to have a baronetcy. That these honours will be welcomed by the Profession as marking the debt of gratitude which the whole nation owes to the distinguished Physicians on whom they are to be conferred we do not for one moment doubt; but we would suggest that the present is no ordinary occasion. The heir to the throne of Great Britain has, under Divine Providence, been rescued from death, and restored to the Sovereign his mother, his family, and to the nation, by unremitting Medical skill and care exercised for a long period of weeks. As a reward for these inestimable services, one of the Physicians, who is a baronet already, is to have a civil knighthood such as might be bestowed on an Accountant-General of the Navy or a Governor of Vancouver's Island; the other is to have a *petit titre* which a Minister will give to a popular Lord

Mayor, or to a county Member who can be relied on in a division. We would not be supposed to underrate these honours; they are good and worthy rewards for ordinary services, but they are not worthy the occasion. Never was a more fitting opportunity for commencing that reform of the House of Lords, which Earl Derby himself thinks desirable, by the creation of a few life peerages, and of doing away with that absurd etiquette which has hitherto excluded one only of the three learned professions from the Upper Chamber. Let a life peerage be bestowed on Sir William Jenner, at least, whose past as well as present services to the Sovereign of this Realm and to Medical science render him specially worthy of such an honour. It is not for us to suggest how the distribution of other honours should be graduated; but Dr. Gull's baronetcy might be accompanied by some less usual distinction, and Dr. Lowe and the other Medical men who have contributed to the Prince's recovery should not be left without public recognition. In fact, the occasion of the Prince's recovery might well be made the opportunity for the expression of the public appreciation of the services rendered to society by the Medical Profession. A long gazette of promotions in the army and navy always marks the accession of a Sovereign or a Royal marriage. Surely no event can be more deserving of being celebrated by an unaccustomed shower of honours on Medicine than the rescue of the Heir-apparent of Great Britain from impending death, and the consequent diffusion of joy throughout the greatest empire of the world.

The Council of the Royal College of Surgeons have agreed to the scheme for the partial Conjoint Examining Board, which has also been accepted by the Royal College of Physicians and the Committees of the four Universities. It has now to receive the assent of the Universities themselves, and will then be submitted for the approval of the General Medical Council. The objection to the scheme is clear and patent. Whilst the Act of 1815 remains in force, and the Apothecaries' Society is one of the Examining Bodies mentioned in Schedule A of the Act of 1858; whilst, also, that Society does its duty by insisting on a thorough Medical education of candidates and a sufficient examinational test; whilst, moreover, it offers the attraction of a useful diploma at a moderate fee fixed by Act of Parliament, it is childish nonsense to suppose that it will cease performing its functions as an Examining Body. The scheme, as proposed, would exclude its licentiate from obtaining the diploma of Membership of the Royal College of Surgeons without paying a large fee for the diploma of the Royal College of Physicians; the General Medical Council will therefore be asked to sanction the formation of a new grade of Medical Practitioners with one diploma only. As this would be contrary to the general tenor of all the Council has done since it was called into existence, we think it will pause before it does so. At any rate, we do not believe that any such imperfect combination, entailing the serious consequences at which we have hinted, would be approved by the Legislature of the country.

We are glad to announce that her Majesty has been pleased to confer the honour of knighthood on Dr. John Rose Cormack in acknowledgment of his services to English subjects during the two sieges of Paris. Sir John Rose Cormack has already received from the French Government the decoration of the Legion of Honour, in recognition of the skill and devotion he displayed on various battle-fields, and as Medical Officer to the Ambulance Anglaise. For more than thirty years our Profession has not had a more thorough, hard-working member, nor one who has had a greater vicissitude of experience and fortune, than Sir John Rose Cormack. In 1843 he published an account of the fever which ravaged Edinburgh in that year. He had always had a prominent position in Medical periodical literature, and after the cholera of 1854 wrote a good book on the pathology and treatment of that disease. After practising

for a few years in Edinburgh, where he held the position of Physician to the Royal Infirmary, he removed to Putney, and, after a few years, to Tours, in France. After a few more years, seeing an opening for an English Physician in Paris, he boldly went to that capital, and, not content with a mere licence to practise, entered the Medical schools side by side with his own son, studied the most recent doctrines and modes of research, wrote a thesis in classical French, and passed the very arduous Medical examination of the Paris Faculty. Then, when he was beginning to enjoy an increasing practice, came the first siege, then the second—bringing with them exposure on the battle-field and incessant toils among the wounded, together with something very like starvation, which he and his devoted wife and son endured during that terrible winter. No honour was ever better earned. But we may add our wonder why Drs. Gordon and Wyatt, the only two English officers who remained in Paris during the siege, have not received a like acknowledgment of their services.

We hear that Dr. Priestley has sent in his resignation of the offices of Professor of Obstetric Medicine in King's College and of Physician for the Diseases of Women and Children to King's College Hospital—offices which he has held with great distinction for nearly ten years. We are glad to say that it is no failure of health or energy which thus cuts short a brilliant career as an obstetric teacher, but the increase of private practice which has rendered class-teaching and attendance at the Hospital at stated hours impracticable without serious sacrifice. Much, therefore, as we regret the loss of Dr. Priestley's name from the list of English obstetric teachers, we can only congratulate him upon the large measure of practical success which has thus early and deservedly rewarded his labours.

The testimonial to Sir James Paget is to take the form of a portrait, to be painted by Millais, and presented to St. Bartholomew's. The artist is to have a thousand guineas for the work.

We are sorry to see it stated that Professor Huxley's health has been impaired by over-work, and that he has started on a trip to Italy and Egypt by way of Gibraltar.

PROFESSOR FLOWER'S LECTURE ON FISHES AT THE CRYSTAL PALACE.

ON the evening of the 12th inst. a very pleasant and most instructive *soirée* was held in the new aquarium at the Crystal Palace, when, besides enjoying a quiet promenade among the tanks, the visitors had the opportunity of listening to a highly interesting lecture by Professor Flower, F.R.S., on "The Structure and Habits of Fishes."

The Professor commenced his remarks by expressing the satisfaction he felt at seeing such a large audience before him, and the hopefulness with which he was thus inspired that Nature was daily becoming more studied by the non-scientific, not only on account of the external beauty, but also for the wondrous structure of her parts. He then proceeded to teach his audience something about one of the numerous groups of living animals—the group which of all others is most prominently represented in the aquarium—viz., fishes. How many persons, he asked, are there whose notions of a cod might not be summed up in the definition that it is a large fish, with proportionally large head, staring eyes, and great gashes in its sides—tasting well with oyster-sauce? And this is not to be wondered at, for rarely is a cod presented to metropolitan eyes in any other condition. Now, he could tell them that in this very aquarium they had an opportunity of seeing a cod as it lives and moves in its native element; now they could inspect the various wonderful parts of its body; and, not only that, but see them freely used. And, that they might study the animal more successfully, he wished to demonstrate to them on the diagram on the wall the various parts to which they ought more especially to direct their attention.

Professor Flower then made a rapid but clear and accurate survey of the external anatomy of the body of the cod-fish, describing in succession the head, the mouth with its apparatus, the ever-open and never-weeping eye, the peculiar olfactory organs, the arrangements for hearing, the body with the *lateral line*, the fins, and, lastly, the organs of respiration. On the two parts of the body last mentioned he dwelt especially, entering at some length into the homology of the pectoral and ventral fins, and into the structure of the gills, and the process by which oxygen is brought into contact with the blood in them.

One extreme deviation from the usual piscine shape was, he said, to be seen in the flat-fishes; and this division was well represented in the aquarium. The true nature of the flattening was pointed out; reference being made to the investigations of recent zoologists on the relative position of the eyes in the embryo, and the gradual change in this as development proceeds. The essential distinction was also carefully drawn between the plaices and the skates.

The Professor concluded by giving his audience some idea of the enormous numbers of fish to be found in the sea. He said there are now about 9000 known species, and that it is computed that probably ten times as many more remain to be discovered by future naturalists. And fishes form but a fraction of the inhabitants of the ocean.

The lecture was listened to throughout with the greatest attention, and at its conclusion the learned Professor was warmly applauded.

Filled with a light which, to many of their number, must have been quite new, the audience now adjourned to the aquarium. This is truly a place of enjoyment for those who, for the sake of watching animal life, willingly sacrifice not a little of their leisure time, and patiently submit to frequent disappointments arising out of untoward accidents, unfortunate sanitary arrangements, or the unexpected exhibition of a taste for eating each other on the part of the occupants of an aquarium. Here one may walk along the main saloon, with its eighteen large tanks, and almost believe himself at the bottom of the sea, so large is the amount of water presented to the eye; so natural the rocks; so numerous, so healthy, and so evidently at home the various animals. As we remarked before, fishes perhaps occupy the most space in the aquarium, but the collection of sea anemones is also exceedingly large and fine. But to enumerate all the other animals that abound in the tanks would almost be to give a list of the leading groups of the animal kingdom found in the sea. A beautiful specimen of octopus was prominently exhibited in the centre of one of the rooms, and quite absorbed the attention of many of the visitors.

Professor Flower supplemented his lecture by most kindly passing from tank to tank, drawing attention to many of the anatomical and physiological peculiarities of their occupants, and replying to numerous inquiries addressed to him by the visitors.

Altogether the *soirée* was a most successful one, and we hope it will be followed by others equally so, when the remaining groups of the inhabitants of the sea may be, as regards their structure and habits, as lucidly described as fishes were on the present occasion.

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.

AT a meeting of the Medical Board of this Hospital, held on Saturday, the 6th inst., Lambert Hepenstal Ormsby, L.R.C.S.I., L.K.&Q.C.P.I., etc., Demonstrator in the School of Surgery, Royal College of Surgeons in Ireland, was elected Surgeon to the institution, in the room of Robert St. John Mayne, deceased. Mr. Ormsby was educated at the Meath Hospital, having served his apprenticeship to Mr. Porter, Surgeon-in-Ordinary to the Queen in Ireland; he also studied at the Royal College of Surgeons, where he has been Demonstrator of Anatomy in that school since the year 1869.

BRITISH MEDICAL BENEVOLENT FUND.

THE annual general meeting of this Society was held at 11, New Burlington-street, on Friday, the 12th inst., the President, Dr. Burrows, F.R.S., in the chair. The report showed that during the past year the total receipts in the Donation Department were £1177 6s. 5d. (exclusive of a legacy of £500 from the late Dr. George Cursham, which had been invested for the benefit of the annuitants in accordance with the laws); 113 distressed Medical men or their families had been assisted, the sum of £951 having been paid in grants to the same. In the Annuity Department, dividends from invested money produced £570 13s. 11d., of which £560 had been paid among thirty-three annuitants. The Committee called attention to the fact that they had only been able to elect three fresh annuitants during the year, although there are still twenty-five candidates anxiously awaiting vacancies. Additional donations of £50 from Dr. Gull, F.R.S., and of £52 10s. from Dr. Warburton Begbie, of Edinburgh, were gratefully referred to. Votes of thanks to the Messrs. Churchill for the use of a room for the meetings, to the editors of the Medical journals for their advocacy of the claims of the Fund, to the various officials, and to the Chairman, terminated the proceedings. The following is a list of the officers and committee for the ensuing year:—

President: George Burrows, M.D., F.R.S. *Vice-Presidents*: Edgar Barker, Esq.; Sir H. Holland, Bart., M.D., F.R.S., D.C.L.; H. Bence Jones, M.D., F.R.S.; Henry Sterry, Esq., J.P. *Trustees*: H. W. Acland, M.D., F.R.S.; Geo. Burrows, M.D., F.R.S.; Dr. G. C. Jonson; Sir James Paget, Bart., D.C.L., F.R.S.; Edward H. Sieveking, M.D. *Other members of Committee*: Edward H. Ambler, Esq.; Edmund L. Birkett, M.D.; W. H. Broadbent, M.D.; H. Bullock, Esq.; John Churchill, Esq.; Andrew Clark, M.D.; Nath. H. Clifton, Esq.; George T. Dale, Esq.; Campbell De Morgan, Esq., F.R.S.; J. F. France, Esq.; D. de Berdt Hovell, Esq.; Thos. Jervis, M.D.; John Liddle, Esq.; W. Martin, Esq.; John Morgan, Esq.; J. T. Mould, Esq.; Harvey K. Owen, M.D.; John C. Steele, M.D.; Richard Stocker, Esq.; E. Parker Young, Esq. *Treasurer*: Charles J. Hare, M.D. *Honorary Secretaries*: Stamford Felce, M.R.C.P. Ed. (Cases); Charles S. Webber, Esq., F.R.C.S. (Finances).

THE BEDFORDSHIRE INFIRMARY.

It will be in the recollection of our readers that in the *Medical Times and Gazette* of October 28 we made some severe observations on the conduct of the Committee of the Bedford Infirmary, in their refusal to carry out the recommendations of the principal Surgeon, Mr. Sharpin, with respect to giving more cubic feet to each patient, and the construction of water-closets projecting from the main building, with a cross-draught through them. These recommendations the Committee rejected by a considerable majority at the Michaelmas meeting. We said at the time that the improvements would eventually be carried out, and we are glad to record that our words were not without effect. The Board, at the meeting referred to, passed the following resolution:—"That there is no evidence before us sufficient to enable us to come to a conclusion upon the subject." Things consequently went on as before until the middle of November, when a case of erysipelas occurred after operation, and within a month five other cases, two proving fatal, and a third nearly so. Upon this the Weekly Board of Management were compelled to sanction the reduction of the number of beds in the Surgical wards at the discretion of the Surgeons; and at the Quarterly Board, held on Monday se'nnight, recommended that Mr. Sharpin's proposition respecting the building of more water-closets should be carried out. The Quarterly Board approved the steps taken by the Weekly Committee in reducing the number of beds in the Surgical wards. After much opposition, these salutary reforms are now being carried out, but the Medical wards are still overcrowded with beds, there not being more than 753 cubic feet to each bed. The

reduction, however, of the number of beds in the Surgical wards will soon result in the refusal of admission to urgent cases, and will, no doubt, show the governors the absolute necessity for enlarging their institution so as to enable them to accommodate the same number of beds as hitherto. The statement of the House-Surgeon, who has held the office for nearly twenty years, that the erysipelas began in a female ward in which were nine beds, four being unoccupied, is admitted; but it should also have been stated that the corridors leading from the densely crowded wards communicated directly with this ward, and that the patient attacked lay next the entrance.

ARMY MEDICAL DEPARTMENT.

THE following Administrative Medical Officers sailed on Thursday, the 18th inst., in her Majesty's troopship *Scrapis*, for India:—Deputy Inspectors-General H. K. Innes, C.B.; R. J. O'Flaherty, C.B.; and M. B. Gallwey. We understand that Mr. Innes relieves Deputy Inspector-General H. G. Gordon, M.D., at Meerut; Mr. O'Flaherty takes the place of Deputy Inspector-General L. C. Stewart at Poonah; and Mr. Gallwey relieves Deputy Inspector-General M. W. Murphy at Mhow. We believe that Inspector-General Beatson, C.B., and Deputy Inspectors-General Dr. Massy, C.B., and Dr. Crawford are likely to sail early in February, to take up their appointments in India—Dr. Massy at Bangalore, and Dr. Crawford at Umballah. We have not yet learned who is to succeed Dr. Crawford as head of the Medical Branch in the Director-General's Office.

INCREASE OF SALARY TO DR. TRIPE.

Good sense and a strict regard to justice have, we are pleased to say, influenced a majority of the Hackney District Board of Works with respect to the treatment of their indefatigable and able Officer of Health, Dr. Tripe. It will be remembered that the Board had passed a resolution to increase the salary of Dr. Tripe. The Hackney Vestry attempted to frustrate this really wise intention, and at a late meeting, by a majority, requested the Board of Works to rescind their resolution. At the last meeting of this Board the "false economy" of the Vestry resulted in a resolution to carry out their original proposition by a majority of 23 to 15.

SIR W. BODKIN ON THE HAMPSHIRE SMALL-POX HOSPITAL.

COMPLIMENTS from the Judicial Bench are not so common as to be regarded with indifference. The venerable Assistant-Judge of the Middlesex Sessions, on a late trial for robbery of a servant of the Small-pox Hospital, for which she was convicted, thus addressed Dr. Grieve, a witness in the case:—"I take this opportunity of congratulating you on the result of the recent inquiry into the charges made against the Small-pox Hospital of which you were the Medical Superintendent. The effect of those charges upon the public has been very bad indeed; it has not yet passed. I know that people in my neighbourhood have positively refused to go into the Hospital in consequence of the scandalous lies which have been told about it."

PHYSICIANS *versus* PATIENTS.

"STRIKES" are not confined to what are erroneously called the "working classes." It is certain that no working men work harder than Medical Practitioners, and in many instances none are worse paid. We recorded last week, in our Correspondence, an all but universal strike of the Medical Practitioners of Valparaiso. We have to add to this a similar proceeding on the part of the Medical gentlemen at Bas-Interwald. The *Swiss Times* states that the Physicians of this peaceful Areadia have united and struck work, demanding an increase in their fees. The Landrath, however, refuses to entertain their claims, and advises a strike of the patients as the best answer to the demand of the Doctors. We fear that the "remedy would be worse than the disease."

UROSCOPY.

THE current number of the *British and Foreign Medico-Chirurgical Review* contains an able summary of recent contributions to our knowledge of the urine, from the pen of Dr. Karl Hofmann of Vienna. Dr. Hofmann is the author of an excellent guide to the examination of the urine, and is in every way a most reliable authority on the subject.

The transformations of albumen have long and carefully been studied, but hitherto without success so far as their ultimate transition into urea is concerned. Frequent attempts have been made to form urea in this fashion in the laboratory, but all have failed, including one recently declared successful by a Frenchman, M. Béchamps. Attempts at forming urea by synthesis have, however, been more fortunate, and another process has recently been added to the number by Basaroff. Certain researches by Cyon as to the origin of urea within the system have led him to believe that it is formed to some extent, if not mainly, in the liver. The more difficult question of the connexion of elimination of urea with high bodily temperature is also referred to, but the results are utterly conflicting, and we shall not further allude to them. But, on the other hand, it seems clearly proved by Senator that in tetanus the urea eliminated is not increased, even when the disease is accompanied by high temperature; neither in his cases was the quantity eliminated greatest about the periods when the spasms were most severe; nor did the kreatinine seem to be increased.

Some interesting researches have been made as to the urine in acute liver-atrophy and acute phosphorus-poisoning. In the cases of poisoning it was noted that towards the end urea was replaced by other nitrogenous materials not known, and that the urates appeared in forms resembling tyrosin. Acute atrophy of the liver gives rise to somewhat similar changes in the urine as phosphorus-poisoning does, but the urine contains notable quantities of leucin and tyrosin not present in the latter, or only present in small quantity.

We also find here some account of the urine in leukæmia. Various observers agree in stating that in this condition the quantity of uric acid is notably increased, although the urea is not in all cases, at all events, diminished. In point of fact, all the researches go to show that though the blood corpuscles are diminished in number, the oxidising power of the blood is not essentially diminished.

Reference is made to the detection of albuminuria by carbolic acid. Hofmann does not give us his own experience; but we confess that our own is unfavourable. There are difficulties in the way of precipitating albumen under various conditions which have yet to be explained. No doubt this is due to the fact that albumen is not invariably in the same form. Thus, Hefsen has shown that in thirty-one cases he has found globulin to be present instead of serum-albumen.

The last portion of Dr. Hofmann's article is concerned with the determination of sugar in diabetes. He mentions a new method invented by Knapp, cyanide of mercury being the reagent. The reaction is finished when the mixed fluids no longer give a brown stain when exposed on filter-paper to the vapour of ammonium sulphuret. Another proposal worthy of note is to use glycerine instead of Rochelle salt in Fehling's fluid. It will remain to be seen how the new fluid will keep.

OVERCROWDING AND DRUNKENNESS AT MANCHESTER.

IT is universally admitted, notwithstanding the "Manifesto respecting Drunkenness," that one of the chief causes of the vice is the wretched state of the lower classes with respect to their dwellings. At a conference held in Manchester last week, Professor Leone Levi said that the cause of the increase of drunkenness in that city, during the last ten years, was mainly due to overcrowding, the city in question being the most densely populated of the large towns.

SMALL-POX JOTTINGS.

SMALL-POX still increases in Stourbridge. Four fatal cases have occurred since the outbreak of the disease. In only one of the fatal cases had the sufferer been vaccinated. It may be remarked that most of the cases were unvaccinated persons. Vaccination seems to have been greatly neglected in the town and district for some time past.—Small-pox still prevails at Mold.—In Hackney Union eight deaths had occurred from the disease last week, and thirteen patients had been discharged. A child, aged 1 year and a half, who had been admitted as a patient to the Homerton Small-pox Hospital, died in forty-five minutes after admission. In the past three weeks sixteen deaths from the disease had occurred in the district.—In Northampton, last week, the borough magistrates held a special session, and heard 120 charges of non-compliance with the Compulsory Vaccination Act. Heavy fines were inflicted in many cases.—Small-pox continues on the increase in Ireland. In the South Dublin Union alone there were, last week, 103 cases; of these thirty are serious. Nine deaths occurred during the week. In the Union Small-pox Hospital no fewer than twenty-seven deaths have taken place of persons who had never been vaccinated. In the Postal Telegraph-office eleven clerks are suffering from the disease. Some of the female clerks are also suffering from it. The disease has broken out in the Royal Artillery quartered in the Portobello Barracks in Dublin.—In Yeovil thirty-nine cases of small-pox are reported. At Charminster, near Dorchester, the disease has also appeared.—The Metropolitan Board of Works has granted an extension of twelve months to the Metropolitan Asylums District Board for the use of the Temporary Small-pox Hospital at Hampstead, and of the wooden huts for the use of the convalescents at Hampstead.—At Marylebone, the father of a child which had been vaccinated by the Vaccination Officer, having refused to allow the lymph to be taken from its arm, the Guardians have instructed their officer to prosecute the father.—The Kensington Vaccination Officer reports that upon his accession to office, nine months since, 107 cases were unaccounted for; 2893 persons had since been vaccinated, out of which 1736 certificates had been received of successful vaccination.—At Newington, during the past fortnight, four fatal cases of small-pox had occurred.—At Wakefield, last week, there were eleven cases in the Hospital.—The small-pox is rife in Gotha, the cases among the civil population of the town exceeding 1000. In consequence of the epidemic the Ducal Court will remain at Coburg for the winter, and the united Parliament of the two Duchies has, for the same reason, been further prorogued.—At Mounthooly, Scotland, a building is being rapidly adapted for the purposes of a Small-pox Hospital. The epidemic, it is hoped, is rather declining in severity.—At Sheffield twenty-seven cases of small-pox were reported in the workhouse, against thirty-seven the week before. Forty-two deaths occurred in the town from the disease in the same period, showing a decline of eight on the previous week; of these twelve were returned as unvaccinated, three vaccinated, and twenty-seven "not stated" as to vaccination.—Five deaths from small-pox are reported in the Poplar Union last week, and seventeen fresh cases were brought under notice. During the same period thirty-five persons were vaccinated at the public stations.—Eighteen small-pox patients are under treatment in the North Kent Infirmary.—At Oxford the weekly report shows six fresh cases of small-pox, making thirty-two under treatment.—There were seven deaths during the past fortnight from small-pox at Halifax, and sixty cases under treatment. To check the spread of the disease in the town, the Guardians of the Union will not allow any scholar who has recently suffered from small-pox, or who has formed part of a family who have suffered, to enter the schools without producing a Medical certificate of convalescence, nor allow to be admitted any new scholars without

their being carefully examined to ascertain whether they have been properly vaccinated, and if not, that they should be immediately revaccinated.—Two cases of small-pox were reported last week at Elland.—The correspondent of the *Liverpool Courier*, at Bonny, Africa, writing on November 30, says—"The town of Brass lies about fifteen miles higher up the river. The small-pox has broken out there, and has been raging for a long time, 500 having died in one day. The Brass men have found out rather a novel way of stopping the epidemic, and that is, whenever a poor wretch takes sick, they cure him 'one time,' by cutting his head off, and thereby saving all trouble."—Ninety deaths from small-pox occurred in the metropolis last week.—In the four Small-pox Hospitals at Hampstead, Islington, Homerton, and Stockwell, forty-two fatal cases were registered, against forty-one and twenty-seven in the previous fortnight.—Small-pox is increasing rapidly in Cork; 117 cases were reported on Monday to the Sanitary Board, and it was stated that the existing Hospital accommodation would be quite inadequate.—In a letter to the Dublin papers, Sir Dominic Corrigan has proposed that patients suffering under small-pox should be conveyed through the streets of that city in shallow baskets or cots, six feet long, resting on poles on men's shoulders. The *Irish Times* says, "no suggestion was ever made so well calculated to drive from the city of Dublin everyone who could leave it."—It is reported from Birmingham that there is a great decline of the small-pox epidemic in that town.—Dr. Aldis, Medical Officer of Health, St. George's, Hanover-square, reports four small-pox patients in the out-wards, three of whom were vaccinated; two were sent to the Hospital.—Mr. Fred. J. Burge, in his report just issued of the health of the Fulham district to the Fulham Board of Works, states—"With regard to the mortality of the 234 cases of small-pox, 40 died; out of 168 vaccinated persons, 10 per cent. died; of 34 unvaccinated persons, 50 per cent. died. It will also be seen that, despite the Compulsory Vaccination Act, 36 out of the 234 cases were unvaccinated persons. The total mortality of our district has been—in Hospitals, 26; within the district, 60; total, 86. From these statistics it will appear that 50 per cent. of unvaccinated persons attacked died of the disease; whilst 10 per cent. of the vaccinated shared the same fate. Amongst the persons included in this return of 234 cases, 32 are taken as undefined—that is, I have excluded from the positive every case in which the absolute 'Yea' is not given, but amongst those I have reason to believe nine-tenths might have been ranked with the vaccinated. Had vaccination, therefore, carried with it the proper results of its operation as a prophylactic against small-pox, no such figures as these ought to be produced."

THE MEDICAL PROFESSION IN VALPARAISO.

WE last week published a statement from Dr. Joy, of Valparaiso, as to the position of the Medical Practitioners of that city. We understand, from advices since received, that this has become most unpleasant and unsatisfactory. They have been expected and required by the Government to attend all cases, day or night, with or without payment, whatever the position of the patient might be. This was felt to be a great hardship by the Profession, and a meeting was called of almost all its members in the place, to take steps to remedy the abuse. Certain resolutions were passed in favour of payment by the Government of Medical Practitioners for night and other attendance upon the poor. Nothing could be fairer or more just than this proposition, but it was answered by the insolent and intolerant Manifesto of the Intendant, inserted in our last issue. Upon the issue of this precious document all the Medical Practitioners of the town, with the exception of Drs. Birt and Fischer, resigned, and refused to practise their Profession at all. This was hasty, no doubt, and we believe it would have been better if they had continued to practise under protest against the

infamous Manifesto. This, it is true, Drs. Birt and Fischer did, and performed the duties assigned to them. But we regret that there was not complete union, and that all did not act in concert, and in one direction. Never was there a case in which "Union is strength" would have been more manifest. It is stated, but it is by no means certain, that the fourteen seceders from practice had returned to their duties, under a private promise of the Intendant that the Manifesto should be modified. However this may be, we trust that no Physician or Surgeon will be tempted to "try his fortunes" at Valparaiso—will not, in fact, lend himself to be the upholder of a tyranny and insolence all but unparalleled in our history.

THE ROYAL INSTITUTION.

AT the Royal Institution, on Tuesday, January 16, Dr. Rutherford gave a brief sketch of the nutrition of animals, and devoted the remainder of his lecture to the consideration of blood. He showed how the blood pigment may be separated from the stroma of the blood corpuscles in various ways. He exhibited the effects of oxygen, carbonic acid, water, and a saturated solution of sodium sulphate upon the colour of the blood; and demonstrated, by means of the electric light, the spectra of oxidised and reduced hæmoglobin, acid hæmatin, and the carbonic oxide and nitrous acid hæmoglobin compounds. Crystals of hæmoglobin and various kinds of blood corpuscles were shown, and the function of the blood-colouring matter and the effects of nitrous and carbonic oxide and nitrites were dwelt upon. The most delicate test for blood-stains—the guaiacum test—was also exhibited.

PRESENTATION TO A POLICE-SURGEON.

IT is gratifying to record that on his retirement from the office of Surgeon to the F Division of Police, the duties of which he fulfilled for many years with great efficiency and satisfaction to all, Dr. Alfred Harvey has been presented with a silver salver. The salver bears the following inscription:—"F Division of Police of the Metropolis, Bow-street.—Only a small token of esteem of our officers and men towards their kind friend, Dr. Alfred Harvey, who never spared himself to help and soothe any of them, often at times when a cheering word was so welcome. Our Divisional Surgeon is leaving us, and the loss is ours; may he be happy wherever he goes. *In memoriam*, James J. Thomson, Superintendent, London. Christmas, 1871." We congratulate Dr. Harvey on this well-merited tribute to his skill and worth.

DUBLIN BIOLOGICAL CLUB.

UNDER this title a Society, having for its object the investigation of matters connected with histology in all its bearings, has just been inaugurated. The first meeting was held on the evening of Saturday, the 6th inst., at No. 30, Trinity College, Dublin, and was largely attended by the members. The *réunions* are to take place weekly during eight months of the year, and from the character of those which have already been held we anticipate the complete success of the undertaking.

INCREASE OF SALARY TO DR. J. N. VINEN.

AT a numerous meeting of the St. Olave's District Board of Works, Southwark, held on Tuesday last, an increase of £50 a year in the salary of Dr. J. Northcote Vinen, the Medical Officer of Health, was unanimously voted, in appreciation of the manner in which he has performed the duties of his office for the last sixteen years. This act was rendered the more graceful by its being entirely voluntary on the part of the Board.

HEALTH OF SCARBOROUGH.

IT is understood that a Commission will be issued by Government to inquire into the sanitary condition of this town. The

Local Government Board has been induced to take this step in consequence of a memorial addressed to them, signed by three Medical Practitioners of the town, stating that they considered such a step necessary in consequence of the number of cases of zymotic disease prevailing at the present time.

AN OPENING FOR A MEDICAL CORONER.

It is officially announced that the office of Coroner for the upper division of the county of Gloucester has become vacant by the resignation of Mr. Joseph Lovegrove. Here is an opportunity for the freeholders to elect a Medical coroner. We hope it will not be neglected.

FROM ABROAD.—MEDICAL MARRIAGES IN FRANCE—TREATMENT OF FISTULE OF THE TESTIS—THE NEW HÔTEL-DIEU.

M. AMÉDÉE LATOUR, in one of his amusing *causeries*, declares that nothing can be more quiet and sedate than Medical Paris at the present time.

"For example, it is marrying plenty of its sons and daughters, for never have we witnessed so many nuptial benedictions. A symptom very interesting to analyse is that not one of these alliances has taken place between the son and daughter of a Doctor. What does this mean? Is it for good or for evil? Willingly disposed to look upon the best possible side of matters, I do not see that we should augur anything ill of the Profession from these hybrid marriages. If the sons of our *confrères* are able to contract alliances with good and rich *bourgeoises* families, it shows that the Profession is not of the slight consideration that it has been said to be. If their daughters are sought for by the wealthy *bourgeoisie* merchants and manufacturers, and by the bar, it shows that their fathers must be enabled to insure them tolerably good dowries, as also that the Profession is not so generally profitless. For the *sans dot* is just as cruel a position at the present time as in the days of Molière; and the poor girls who can add nothing palpable and sounding to their virtues, their youth, and their beauty are more than ever condemned à *coiffer et à recoiffer Sainte Catherine*. Poor girls! how many have I known of you who were truly charming, and who would have made the happiness of a brave man! These intermediate social positions are the most terrible of all. The boys always manage to extricate themselves in one mode or another; but the unfortunate girls, with their education, instruction, tastes, and habits contracted in the family, what are we to do with them, and how are we to marry them? Are there many Doctors who would imitate the courageous example of one of my friends, who, having attained a high administrative position, and finding himself with two daughters to whom he could only give small marriage portions, married one to a grocer and the other to a butcher. My friend was no simpleton, for both marriages turned out excellently, providing most comfortable homes; while an alliance with a so-called liberal Profession would only have led to the liberality of privation, and perhaps to something worse. But go and speak such language as this to our fine young ladies!

"I am told that among the young women who have presented themselves for the examinations for the governess's diploma a considerable number are the daughters of Doctors. This is a good sign; for no direction can be imparted to a young girl more useful, more moral, and more respectable than that of teaching. If they are compelled to make it their profession, none can be more honourable; while, if a more happy destiny awaits them, they may become the teachers of their children, and may save them from the dangers of boarding-schools and convents. Dear *confrères*, whether rich or poor, try to give this hint to your daughters; for who can tell what may happen to any of you? The General Association is now aiding the daughter of an illustrious Professor plunged into distress by a reverse of fortune."

At a recent meeting of the Paris Surgical Society, M. Chassaignac introduced the subject of the "Treatment of Fistule of the Testicle and Epididymis," summing up his paper in these words:—

"Whenever, by the long standing of the disease, the exhaustion, suffering, and wasting of the patient, the question of castration for a tumour of the testis comes to be considered, we should always, before resorting to this, employ an exploratory trocar, and, if the instrument exhibit pus, a simple incision

should be practised. If an incision alone prove insufficient, we should have recourse to drainage, as removal of the testis ought never be performed on account of mere suppurations, however complicated these may seem at first."

He cannot understand how an operation has become current which, in his hands, has so often been followed by a fatal result. In good Surgery an important organ should never be removed on account of an abscess. M. Demarquay agreed with these views, so far as fistulæ of the testis attended only with suppuration are concerned; but in cases of tubercle of the testis, with its multiple fistulæ, the number of tubes required cannot be borne by the patient, who at last compels the Surgeon to operate—which, indeed, is the best thing he can do. The operation should, however, be limited to cases in which there is tubercular infiltration of the testis and epididymis, and when the disease is reacting on the entire economy. M. Chassaignac replied that a single drainage-tube will suffice in even multiple fistulæ when it passes out by the most dependant part of the serotum. At all events, the tubes should be tried before resorting to castration. M. Demarquay, however, does not believe that drainage is attended with success in true tubercle of the testis, while castration in ulcerated tubercle is not a dangerous operation. He has never met with a single death from it, while castration for cancer of the testis is a much more serious operation. M. Tillaux, while agreeing with M. Demarquay, believes that castration should be reserved for extreme cases of even tubercular testis, and should be abstained from so long as the patient's strength is good. When, however, an abscess has been opened, and one or more drains have been employed in vain, and the patient's strength fails him, delay of the operation would be a fault. M. Giraldès agreed with M. Chassaignac so far as purulent fistulæ of the testis were concerned; but, in tubercle of the testis, caseous and fatty matters are infiltrated in the substance of the dilated epididymary canals, which, as well as the deposits in the vas deferens, may give rise to multiple purulent centres, formed amidst an altered fibrous tissue, and produce interminable suppuration. In such cases, drainage ceases to suffice; and if the patient has not tubercle of the lungs, we must amputate with the view of preventing the accidents which result from chronic suppurations, inflammations, and the pains which prevent the patients from walking or working. Moreover, castration is not the serious operation it has been represented to be. M. Giraldès has practised it a great number of times, and has never met with a fatal case. M. Léon Le Fort, also, has never known death to occur, in a whole series of castrations performed for tubercular testis. M. Chassaignac, in reply, observed that he had never had occasion to resort to castration in tubercular testis, as drainage, in these cases, had always succeeded in his hands. He does not admit that patients should be allowed to dictate to the Surgeon the performance of an operation, which, indeed, would no longer be demanded if relief by drainage were obtained. A changed condition of the vas deferens in tubercular testis is, in his opinion, a contra-indication to the operation. He also thinks that his opponents should furnish a more complete statistical account of the results of castration.

When the construction of the new Hôtel-Dieu was in contemplation, the Hospital Medical Officers of Paris strenuously exerted themselves in opposition to the monstrous proposition of erecting a vast Hospital capable of containing 800 beds in the midst of the most crowded portion of the capital, the absence of sufficient space preventing its superficial development, and compelling the raising of storey upon storey to an altitude setting all hygienic provisions at defiance. A strong opposition was organised by the Société de Chirurgie and the Société des Hôpitaux, and all the weight of unanimous Professional opinion brought to bear on the authorities, in order to obtain an abandonment or modification of the project. All in vain! Baron Haussmann's view of beautifying the capital

required an imposing building to be erected on this site, and the sentimental ideas of the Emperor hastened on its construction, in order that this palace of the poor might proceed *pari passu* with that sample of extravagance, the New Opera-house. Extravagance, indeed, has prevailed in the construction of both edifices, for it is calculated that the cost of the Hospital will amount at least to forty-two million francs, which, supposing it destined for 800 beds, will bring the annual charge of each bed to the fabulous sum of 2500 francs. There might be some consolation even for this wanton expenditure if a good Hospital might be expected to result from it. But the mere agglomeration of so many patients is fatal to any such expectation, as might indeed have been anticipated from the experience derived from the Lariboisière, where, notwithstanding the space it occupies, and the effective ventilation its mode of construction admits of, the mortality is as high as at the Hôtel-Dieu, now to be destroyed. But, in comparison with the new Hôtel-Dieu, the Lariboisière enjoys many advantages. For 625 beds it has about 52,000 metres superficies, while for 800 the Hôtel-Dieu will have only 21,600 metres. The pavilions of the Lariboisière do not rise above from 20 to 25 metres; while the buildings of the Hôtel-Dieu, four storeys high, reach 35 metres, and are so disposed as to render effective ventilation and illumination impossible.

Encouraged by the recent political changes, the Hospital Surgeons and Physicians have again moved in the matter. It has, indeed, been hoped by some that the authorities may find a new destination for this vast edifice so ill-suited for the sick; but of this there is little probability, and, accordingly, the Paris Hospital Medical Society has appointed a committee to visit the Hospital and report upon its capabilities. This committee comprises the well-known names of MM. Hardy, Broca, Marjolin, Giraldès, Hérard, Lallier, Trélat, Vidal, and Lorrain, and has delivered in its report. This we have not yet seen; but at the meeting held to receive it numerous proposals were suggested. Some proposed to retain the Hospital only for special diseases, such as those of the skin, eyes, etc., excluding fevers and surgical and lying-in cases; others thought that only a portion of the building should be utilised, diminishing the beds by one-half; while the extreme reformers demanded the demolition of a building so unsuited to its objects. However, after these various suggestions had been discussed, the resolution was unanimously carried—"That the Hôtel-Dieu, as it is constructed, does not respond to the conditions required for a Hospital according to the present state of science and hygiene." It remains to be seen whether those in authority have either the power or disposition to listen to the warning voice once more raised.

INSTRUCTIONS TO VACCINATION OFFICERS.

THE following instructions to Vaccination Officers have been issued by the Local Government Board in readiness for the commencement of the operation of the Vaccination Act, 1871:—

1. The duties of a Vaccination Officer, whether already appointed or hereafter appointed by the guardians, will be to act as Registrar of Vaccination for the district to which he is appointed; to see that all children resident therein are duly vaccinated; and, generally, to carry into effect, under direction of the guardians, all such provisions of the Vaccination Acts as are not expressly assigned to the execution of other officers.

2. He will receive from the Registrars of Births and Deaths, and will be responsible for the safe custody of, the "Monthly lists" of births and deaths which will be sent to him under the provisions of the Act of 1871. The first of these lists will be due on February 1, 1872, or within three days thereafter. On the lists of births he will duly enter in columns which are provided for the purpose, as shown in an annexed form, all certificates he may receive of the successful vaccination of the children whose names are entered on the lists, or of their insusceptibility to vaccination, or of their having already had small-pox. All such entries must be made immediately on the receipt of the respective certificates. He will compare each monthly list of deaths with the corresponding and with preceding lists of births, and as regards any children included in the death-return whose names are on the birth-lists, but for whom he had not received one of the certificates above referred to, he will enter the death in the column provided. An alphabetical index to his birth-lists will greatly

facilitate this comparison. And when, on his personal inquiries, or by information from the Vaccination Officer of another district, or on other reliable authority, he shall have ascertained that a child included in the birth-lists for his district has died in some other district, he shall write off the case in like way.

3. He will enter at the end of each quarter, on blank "birth-list" sheets (which will be supplied him for the purpose), certificates which he may have received during the quarter of the successful vaccination, or insusceptibility to vaccination, of children whose births had not been registered at all, or whose district of birth-registration he has been unable to ascertain.

4. The monthly lists of births, together with the supplemental sheets referred to in Section 3, shall in the first instance be kept stitched, or otherwise fastened together, in a stiff cover, so as to preserve them from damage or dirt, and shall from time to time be bound into volumes as the guardians may direct, and shall constitute the "Vaccination Register" of the district.

5. If any list of births or deaths be not received from a Registrar within one week from the time it is due, the Vaccination Officer shall report this to the guardians at the next board meeting, with a view to the Registrar being immediately called upon for an explanation, and, if need be, to communication with the Local Government Board. A Vaccination Officer who shall lose any of these lists shall be bound to obtain another from the Registrar of Births and Deaths at his own cost. The steps that the Vaccination Officer will be required to take in discharge of his duty to see that all children entered on the birth-lists are duly vaccinated will vary, according as the vaccination district in which the parent resides is one in which continuous weekly public vaccination is maintained, or one in which the public performance of vaccination is only periodical—I. As regards districts in which there is continuous weekly public vaccination—(a.) He will keep his birth-lists examined from week to week, and in each case of default which may arise he will, immediately on such default arising, intimate the fact to the parent. For this purpose a notice in a form annexed, or to the like effect, may be used; and such notice may, if he think fit, be sent by post. He should make a mark ✓

in the margin of his Vaccination Register in each case in which this intimation of default has been given. If the intimation be not attended to within a reasonable time—say fifteen days—or, if in the case of a notice sent by post, the person to whom it was addressed has not been found by the post-office, the Vaccinating Officer shall at once proceed to make personal inquiries with a view to obtaining the requisite certificate or taking the necessary proceedings. (b.) If on these personal inquiries the parent be found in default, an exact date should be specified by which he must have complied with the law; and a notice in a form annexed, or to the like effect, should be given. (c.) Failing compliance, the Vaccination Officer (unless he shall have been authorised by any general resolution of the guardians to take legal proceedings without further instructions) will report the case to the guardians at their next board meeting for their instructions thereon. II. As regards districts in which the public vaccination is periodical—(a.) He will previous to each vaccination period, examine his birth-lists, and extract therefrom the name of all parents who would fall into default provided their children were not vaccinated before the termination of the next ensuing attendances, in order that intimation to this effect may be given to such parents a few days before the attendances commence, with warning of the penalties which will result from non-compliance. A form annexed, or to the like effect, may be used for this purpose. He should make a mark ✓ in the margin of his Vaccination Register against each case in which this intimation has been given. (b.) And, failing compliance, he will inquire personally into the circumstances of the case, and (unless he shall have been authorised by any general resolution of the guardians to take legal proceedings without further instructions) report the case to the guardians at their next board meeting for their instructions thereon.

6. He will keep a book to be called "The Vaccination Officer's Report-book," according to a form annexed, in which he will enter the names, with the other particulars required, of parents of whom personal inquiries may have been made, as above, with the dates of such inquiries. He will note in his book any further action taken in any case, and make any remarks which the case calls for. He will take care to make the necessary reference in column V of his "Vaccination Register" to each case thus entered in the Report-book.

7. When on his inquiries the Vaccination Officer finds that a child has been successfully vaccinated, but the vaccination not certified, or that any other certificate due, as of postponement, etc., has not been transmitted, he shall ascertain with whom the default rests, having regard to the requirements of the Vaccination Act, 1867, sections 21, 23, 30, and Vaccination Act, 1871, section 7, and shall forthwith take the necessary steps for obtaining the certificate required.

8. All certificates of postponement shall be entered in the Report-Book, with the date of the certificate, the name of the Practitioner who signed it, and the period for which it was given, with a view to any inquiries which may be necessary at the expiration of that period. He will take care to make the necessary reference in column V of his "Vaccination Register" to each case so entered. When certificates of postponement are delivered to him on the form of "Notice of requirement," he will see that the parent is always supplied with a new form of the notice of requirement, with the particulars of attendance, etc., duly filled in.

9. When the Vaccination Officer shall find that any parent, respecting whose child he has not received a certificate of successful vaccination, has removed from the district, he shall take pains to ascertain the Vaccination Officer's district to which such removal has taken place, and shall give notice to the Vaccination Officer of that district, with a view to the vaccination of the child, and a due return of the certificate to himself. And whenever a certificate respecting a child whose birth was registered in the district of some other Vaccination Officer is sent to him, he shall take pains to ascertain the district in which the birth took place, and forward the certificate accordingly.

10. He shall submit to the guardians, in duplicate, at the end of every quarter or half-year, as they may direct, a summary of his Report-Book, in the form to be prescribed by the Local Government Board, the duplicate to be transmitted to the Local Government Board.

11. The Vaccination Officer will at all times use his best endeavours to ascertain whether children resident in his district, but not having been born in it, or (if so born) not having had their births registered in it, are unvaccinated, and will, in such cases, take the requisite steps for procuring their vaccination.

12. He will, on outbreaks of small-pox, make any house-to-house visitations which the Local Government Board or the guardians may direct in.

reference to vaccination, and will carry out any special instructions they may issue on the subject.

13. As the guardians' officer for the administration of the Vaccination Acts, he will see that the Registrars of Births and Deaths in his district are kept informed of the arrangements for public vaccination as settled by the contracts, and of all alterations legally made in such arrangements, as well as of his own place of abode, in order that the entries required to be made in these respects by the Registrars on the notices of requirement of vaccination delivered by them to parents may be correct. The best course will be for the guardians to have the particulars of the arrangements, and the name and address of the Vaccination Officer, printed in red ink on the notice forms with which each Registrar is supplied.

14. He will also see that public notifications of the arrangements for public vaccination are duly given; and especially in districts in which public vaccination is periodical, will see that such notices are distributed and placarded through the districts a week or ten days before the commencement of each period.

15. He will, as far as possible, attend the public vaccination stations during vaccinating hours, and report to the Guardians any insufficiency of accommodation at these stations, or any failure of parents to bring for inspection the children on whom vaccination has been performed, or any other matter concerning the business of the station on which the guardians may require his report.

16. He will also undertake the distribution of the certificates, books, and other forms issued by the Local Government Board, to the public vaccinators and Medical Practitioners in his district.

17. The Vaccination Officer will further have to inquire into the circumstances of the cases included in the default-lists under the Act of 1867, which will be presented by the Registrars of Births and Deaths in the first week of January, 1872, as well as into any other cases in previous default-lists under that Act, which remain unaccounted for in the "Registers of Successful Vaccination." In districts in which there is continuous weekly public vaccination, he will forthwith make the personal inquiries into these cases, and follow the further course prescribed above in Section 5. In districts in which the public vaccination is periodical, he will (except when the ordinary period of attendances is at hand, or where the defaults are so few as to render this course unnecessary) submit to the guardians to direct special attendances to be at once given for three or four weeks, with the view of clearing off these past defaults; and he will, in either case, give notice to the parents in default, a few days before the attendances for public vaccination commence, requiring the vaccination to be then done, and will, in all cases in which this notice has been neglected, forthwith make personal inquiries, and (unless he shall have been authorised by any general resolution of the guardians to take legal proceedings without further instructions) report the cases to the guardians for their instructions.

18. He will receive from the Registrars of Births and Deaths of his district, early in January, 1872, and will be responsible for the safe custody of the "Registers of Successful Vaccinations" which have been kept by those officers under the Acts of 1853 and 1867. The Registers kept under the Act of 1853 may, if the guardians permit, be deposited in the Union offices; but all Registers which contain entries of births subsequent to December 31, 1867, must be retained by the Vaccination Officer. He will duly and forthwith enter in these Registers the certificates which he may receive or obtain of the successful vaccination of children whose births are therein recorded. He will write the word "dead" against the names of any of the children whose births are entered in these Registers, whom he may ascertain, either by the monthly death-lists or by his own inquiries, to have died without having been vaccinated. And he will write, *in pencil*, against the respective names, any information (as of removal from district, certificate of postponement and its date, etc.) which does not finally dispose of the case.

(Signed) JOHN SIMON, Medical Officer.

Issued by direction of the Local Government Board, this 21st day of December, 1871.

(Signed) JOHN LAMBERT, Secretary.

REVIEWS.

Notizie Cliniche sulla Difteria. Per CAVINO GULIA, Membro della Società di Medicina pratica di Parigi, etc., etc. Malta: Tipografia Anglo-Maltese. 1870.

Clinical Notices of Diphtheria. By CAVINO GULIA, etc., etc. Price 4s. 2d.

THIS short but excellent work on diphtheria comes from the pen of a Maltese Physician, and consists of a reprint of papers which originally appeared in a local journal. It is complete, erudite, and amusing, and shows that the writer is thoroughly well acquainted with the science and practice of Medicine in France and England, as well as in Italy. It is agreeable to see names familiar to us here, equally honoured abroad; and the works of Sir T. Watson, Aitken, Jenner, West, W. Farr, Burdon-Sanderson, Tanner, Greenhow, C. J. B. Williams, W. Squire, Wharton Jones, and the *Medical Times and Gazette*, are constantly referred to by Dr. Gulia.

He begins by defining diphtheria; and as there is some little ambiguity of meaning amongst ourselves on this point, we will quote what he says. By *diphtherite* he understands the pellicular exudation which may be found in various diseases—as, for example, in the course of scarlatina, in croup, in some mercurial sorethroats, and the like. But by *diphtheria* he understands the special "angina cotennosa" properly so called, or exudative inflammation of the throat, which occurs from the poisonous action of a special miasma generated or introduced into the blood. It will thus be seen that *diphtheria* is understood to be a specific disease, of which *diphtherite*, or pellicular exudation, is a symptom; but that pellicular exudation is not confined to diphtheria. We think it a pity that there should have been such confusion in the use of these

similar words, but will not add to it by proposing a new name. He goes on to define it as a malady akin to typhoid—a fever, a constitutional disease, highly contagious, and slightly infectious, characterised by septicæmia, sorethroat with exudation, often fatal by asphyxia, or by typhoid paralytic or embolic accidents.

Dr. Gulia believes the disease to have been known from ancient times to the present. He identifies it with a malady described in the sixth Book of Epidemics of "Il Macstro," with the *Syrian angina* of Aretæus, and with various epidemic *anginae* which ravaged Naples in 1610, and were described by F. Nola; which in the century before ravaged Holland, and was described by Forestus; was intense at Basle in the seventeenth century, in the eighteenth in America, and has had its chief home in the nineteenth century in France. In Malta, it seems to have been excessively fatal in the fifteenth century, and during the last two years has reappeared in an epidemic form. But we have not space to follow him in his *catena* of authorities. He tells us how extremely liable the throat is to suffer whenever the entire system is subjected to debility, derangements, or blood-poisoning. Sorethroat is a symptom in scarlet fever, in small-pox, in other eruptive fevers (amongst which may be reckoned measles and severe lichen), in typhoid and dysentery, in any pyæmic or septicæmic maladies, and in many chronic conditions—as phthisis, scurvy, syphilis, leucocythæmia, intense debility, Bright's disease; also from the influence of poisons—as iodine, mercury, antimony, arsenic, and lead. But no one would argue that similarity of effect in these cases, or even identity of certain symptoms, proves identity of cause; and in throat maladies the whole nature and complexion of each case depends on its cause.

Our author goes on to lament the confusion which has been made of croup with diphtheria by some men of much experience, as Bretonneau, and other men of little or none. He shows that croup is an acute inflammation, diphtheria a blood disease, a primary fever. Croup is a malady of early childhood, rare after the seventh year; it is liable to recur in the same individual; it is not contagious; it is accompanied with dry, harsh, "croupy" cough and hoarseness; usually attended with constipation; is benefited by leeches; is not attended with enlargement of the cervical glands; is caused by cold winds—in all which particulars diphtheria presents the opposite features.

Diphtheria may attack persons of any age; second attacks are not recorded; it is eminently contagious; is attended with loss of voice, or nasal twang, with visible exudation on the tonsils and pharynx; there may be no dyspnoea if it spreads over the velum palati and avoids the larynx; is attended with fetid diarrhoea, and great prostration; depletion and antimony are inadmissible; enlargement of the cervical glands is a frequent and most unfavourable symptom; is complicated by albuminuria; is indifferent to sex, age, and climate; and often comes on at the close of other febrile and septicæmic diseases, as typhoid, scarlatina, and puerperal fever. The spinal paralysis and sudden deaths from embolism which mark a bad epidemic must also be noted.

The diagnosis of the various local and general affections of the throat, and the symptoms and varieties of the disease, are given fully, with constant reference to the writers' names above; but these we pass over to come to the causes. Dr. Gulia discusses the existence of a special morbid poison, in the form of air-wafted sporules, and he is quite familiar with the doctrines of Pasteur and the latest utterances of Tyndall. Anyhow, whilst declaring contagion to be the means of propagation, he believes that sudden check to the action of the skin by cold is the most frequent adjuvant cause. In his experience, the better classes, who live in good houses, are greater victims than the poor. Trousseau, he says, declares that diphtheria has a predilection for low and damp places; but Gulia says that it often passes over such places, and ravages villages that are high, dry, and airy. He thinks that the children of the easy classes are more liable than the poor, because of their more frequent exposure to cold air whilst changing their dress, or because their houses may be over-ventilated and draughty. He declares that there is far more danger from this cause than from privy emanations in ill-ventilated houses, and quotes Greenhow and Gull to show that faecal miasmata have not been proved to have any relation to diphtheria; in fact, he believes that the *colpo d'aria*, or *coup de vent*—or *wind-stroke*, as we may call it—and damp cold are the gravest predisposing causes. Not only so, but he advances doctrines respecting sewer gases which surprise us. The habitude of living in the poisoned atmosphere of poor houses, he says, often renders the children of the poor exempt from zymotic disease, whilst those who live

in a pure atmosphere fall victims most easily. "In Malta," he says, "typhoid fever is more benign in the case of persons who live in unwholesome houses than in those who live in wholesome ones. This year, out of thirty-two cases of *ileo-typhus* treated by me, twenty-six were developed in respectable well-aired houses. . . . In poor houses I have only seen six cases, five of which were *benignissimi*," one disastrous. "This has often struck me," he goes on to say. "In 1867 I lost from typhoid a most distinguished *signora* that lived in the loftiest house of the Collina Santa Margherita, a distinguished personage in the very healthy Bay of Marsascala, and other persons who lived in the best quarters of Cottonera; but not one of the many cases I saw in the houses of the poor." The experience of Dr. Carpenter at Croydon is probably to the same purport; but he takes account of the various unsuspected paths by which subtle sewer-gas may obtain entrance, whilst Dr. Gulia does not. Malta, he goes on to say, is one of the most crowded spots on the face of the globe, containing 1200 persons to each square mile. The population is for the most part commercial, subject to great fluctuations of fortune, and to the nervous and nutritive disorders which accompany extreme wear and tear of mind. The modern houses are tall, with meagre corridors and courtyards, and the apartments small and ill-ventilated. For the walls they often now employ (unlike wiser ancients) a porous sandstone—"tanto aborrita degli architetti Romani." Bedrooms in such houses are cold and damp, and whoever sleeps in them feels cold all night, and has frequent desire to empty the bladder. The water is stored in cisterns, whose cement impregnates it with lime salts, but does not hinder percolation from the neighbouring sewers. The water is coloured, heavy, stinking, and nauseous, and whoever drinks it is liable to bowel disorder and nervous debility. The kitchen adjoins the other apartments—often contains the pump, the sink, and ill-trapped drain, and this horrible hole ("orribile bolgia") serves as dining-room. In the houses of the poor, a family in each room sleeps, eats, deposits its "immondizie et gli escrementi in una chiavica mal chiusa."

Each house in the Tre Città lodges thirty to fifty persons, without reckoning dogs, cats, poultry, some sheep, and not seldom swine. Here are bred, says Dr. Gulia, the zymotic diseases which the poor are proof against, but which decimate the better classes. Villages that seem to be beautiful as the gardens of the Hesperides are, for want of hygiene, filled with the rickety, scrofulous, and blear-eyed. (He mentions Gozo as an island where the population is virtuous, hardworking, and healthy.) The Maltese redouble their cachexies by breeding in and in, owing to the straitness of their boundaries and want of choice of wives. To add to their miseries, the habit of spirit-drinking has spread wonderfully during the last thirty years, and, with the abuse of tobacco and the prevalence of constitutional syphilis, account for much of the nervous debility and scrofula, and an increasing moral and physical degeneration. Hence, even sthenic inflammations require consideration before the lancet is used; gentle antiphlogistics and diffusive stimulants suffice for the cure. The commoner people, of their own accord and experience, not from Medical teaching, are giving up the habit of being bled in May, although some disciples of Sangrado still keep up the ancient vampyrism. Not that Dr. Gulia is a partizan of the debility school; he divides his brethren into three classes: the hæmophobists, who never bleed; the contrastimulant school, who follow the now discredited doctrines of Tommasini, and bleed always; the moderates, who bleed with caution when necessary—and he belongs to the last. But we must hasten on. These observations on the constitution of the Maltese are intended to oppose the views of some Maltese Physicians who seem still to adhere to the contrastimulant school, and who see in diphtheria nought but a vivid local inflammation, to be treated by depletion. The local and general measures proposed by Dr. Gulia are treated of in the most judicious manner, and with constant reference to the best practice recorded in every Medical book or journal of authority. If Dr. Gulia writes another book, we hope to be allowed to review it.

Medals, Clasps, and Crosses, Military and Naval, in the Collection of J. W. FLEMING, F.R.C.S. Ed., Surgeon-Major, late 4th Dragoon Guards. 1870.

ALTHOUGH this work bears in its title-page the words "for private circulation only," we venture to break the seal of secrecy, and give it due honour in our columns for many and good reasons. First of all, it is a most creditable example of

the manner in which many of our brethren, and more especially those who are engaged in the service of the army and navy, despite of their hard routine duties, of the uncertain and fleeting character of their residence, and of the difficulty of carrying about libraries and collections from one military post to another, and of the temptations to frivolous amusements, yet continue to devote their leisure hours to some substantial branch of science, moral or physical. In the next place, although the book is marked "private," the demands of scholars, antiquarians, and historians must ere long compel it to be made public, as the unique authority on the subject it treats of; and, lastly, should anyone desire to get the book at present, we are pretty sure he could not, for it is not in the market, and not likely to be let go out of the hands of private possessors.

It appears, from the text and notes, that the author has succeeded in procuring examples of every kind of medal, cross, and clasp conferred on the military and naval forces. There is an enumeration of all, a description of many; a set of engravings of many of the more remarkable, and a series of annotations referring to little by-passages in military and naval history, which are full of the deepest interest. There is a distinction, by-the-bye, into those medals which are intended for the personal reward and decoration of the actors in various incidents in flood and field, and the medals of a public order, struck in commemoration of the events themselves. Such are the medals beginning with the defeat of the Spanish Armada, 1588. There is also a small appendix of miscellaneous medals. But the main catalogue exhibits the medals, clasps, and crosses granted to individuals or regiments. The army series begins with a gold medal granted by the unfortunate and much-maligned King Charles I. to Sir Robert Welch, an Irish gentleman, for gallantry at the Battle of Edgehill, in 1642. Next comes the first medal struck for the British army, given by Charles I., in 1643, for soldiers engaged in "forlorn hopes." Their names were returned by the commanding officer, and they were then presented with the medal, "which was worn on the breast." Respecting the medal granted for twenty-seven battles, sieges, and other military operations from 1793 to 1814, Dr. Fleming says, "When these medals were authorised, in 1848, *six* survivors of the Peninsular War applied for fifteen clasps each, but only two made good their claims—privates James Talbot, 45th Regiment, and Daniel Lookstadt, of the King's German Legion. The other pensioners received from ten to fourteen clasps each. The cross worn by the Duke of Wellington had nine clasps, being the highest number obtained by any officer in the army." The navy series begins with the gold medal given by Queen Elizabeth to distinguished officers serving in the fleet against the Spanish Armada. We have said enough to show the character of Dr. Fleming's catalogue. We think it a matter most creditable to the Medical Profession that a Medical officer should have undertaken such a work. The real reward of life-risking services is honour. "No man," says Sir Charles Napier, in distributing the medals for the Battle of Meeanee, "can walk with one of these medals on his breast without feeling the conscious pride of an intrepid soldier." Such decorations are amongst the most conspicuous and personal marks of honour. May we add that we hope our Medical brethren in the military service may always earn and have their full share. We are well aware of the difficult, delicate, and perplexing nature of the *status* of Medical officers of the army and navy. They are *in* the army, but not *of* it in the same sense in which the combatant officers are. Although exposed to equal (or greater) risk, both from their share in the general movements of the army and from their own special duties, yet the question arises—Shall they be considered as soldiers with Medical duties, having the peculiar *caste*, discipline, rank, and authority of soldiers, only modified so far as need be by their Medical duties? or shall they rank as civilians attached to an army—as Medical men whose *clientèle* happens to be a movable body of armed men, instead of the stationary population of a town? Of late years an opinion has prevailed that they should fall back on the civilian type; but we have good reasons for knowing that some of the most distinguished military Medical officers, who have been spectators or actors in the late Franco-German war, have had their opinions on this point quite reversed, and now see the necessity of securing a military status with *real* rank and title instead of "relative" rank, which is a metaphysical shadow. We all know how this was felt by brave old Guthrie, and must conclude by wishing the Medical officers of both services a full realisation of Dr. Fleming's motto:

"— In this glorious and well-foughten field
We kept together in our chivalry."

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

January 16.

At the annual meeting of the Liverpool Medical Institution, held on the 9th inst., Dr. John Cameron, Physician to the Southern Hospital, was elected President in room of Mr. Bickersteth, whose term of office had expired. At no previous period of its history has the Institution been so flourishing, both in respect of the number of its members and the character and amount of work done by it. The former amounts to 140; and to give an opportunity for the reception of papers which would otherwise have had to be deferred, the period during which meetings were held was last year extended one month, and now, therefore, embraces the time between October 1 and May 1. The Microscopical Section, established two years since, has become an important feature of the Institution, and is doing a great deal of useful work, a number of specimens being exhibited at each of its meetings illustrative of the minute pathology of cases which have come under the exhibitors' own observation. The Northern Medical Society—a sister institution, established three years ago, more especially for the benefit of gentlemen living in the northern district and suburbs, and having the same aims and objects as the older Society—is also in a vigorous condition.

The results, so far as they are at present published, of the simultaneous collections made on last Sunday for the Medical charities, has more than answered expectations. The entire amount that will be obtained cannot be known for some time, as some of the collections are unavoidably postponed until next Sunday, and as special contributions to the fund by working men will be made on Saturday next through the medium of boxes left at all the large establishments for the employment of labour. The sum advertised to have been collected as yet is over £5300, being nearly £500 in excess of the entire amount obtained last year; so that it is confidently believed that the aggregate returns will be not much less than £7000.

The interest thus manifested in the prosperity of our Medical charities exceeds, it would seem, that of those on whom their government ultimately rests—viz., the trustees; for at the annual meeting of the trustees of the Royal Infirmary, the important alteration in the law relating to term of service, which was noticed in your last issue, was actually made by fifteen voters, with only five dissentients. It thus appears that so little interest is manifested by the subscribers concerning the internal affairs, at least, of this institution, towards the maintenance of which they contribute, that a change of law, practically amounting to the extension of the term of service of two of the present honorary staff by fifteen years, could be, and actually was, made with only twenty trustees present. Considerable dissatisfaction is now being expressed at the change in question; though it really does not appear that those who indulge in it have anyone to blame but themselves, as the motion which resulted in the alteration was brought forward pursuant to notice given in strict accordance with the laws of the Institution, and it would have been easy for any number of dissentients to have been present to oppose it if they had felt so disposed.

Owing, probably, to the exceedingly mild weather, the mortality of the town continues exceptionally low.

GENERAL CORRESPONDENCE.

THE MEDICAL PROFESSION IN VALPARAISO.

LETTER FROM MR. J. W. DUFFY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Being aware that orders have been forwarded to certain parties in England, for them to try and persuade young men of the Medical Profession to come to Chili, you will be conferring a great benefit to those so inclined by putting them on their guard against entering into any engagements binding themselves to serve in any form or capacity which may be proposed to them by agents of the Chili Government.

By this mail I have forwarded a letter to the editor of the daily *Times*, requesting him to publish it. It will give the public a full statement of the condition of the Medical Profession in this country; and although it was in a sufficiently

degraded state before, the Governor of Valparaiso has issued a decree which has placed the members of the Profession in a state of slavery not possible to be borne; the consequence has been, *the Doctors are all on strike*, and have been so for more than ten days. We should have bettered our condition had it not been for two of ourselves, who, seeing what a rich harvest could be made by their practice when all the rest of us should retire, allowed their cupidity to get the better of the feelings of what was due to themselves, to their colleagues, and to their Profession, and resolved to take advantage of the situation.

The shortness of the time before the departure of the mail prevents me from going into particulars, which are explained in my letter to the *Times*. Please beg of your readers to pay attention to it should it appear in that paper, which I trust it will, as my object is to advise most earnestly Medical men not to allow themselves to enter into any engagements with the agents of the Chili Government.

The decree of the Governor of Valparaiso, which has caused the Doctors, with the exception of two, to abandon the practice of their Profession—in other words, *to strike*—among other oppressive articles contains the following:—

The Doctors are obliged to attend *all* the poor of a town containing 80,000 inhabitants *for nothing*. Every Doctor must visit every person, rich or poor, at any hour of the day or night he may be called upon; should he refuse, the person seeking his assistance may call a policeman to compel him; should the Doctor still refuse, he will have to pay a fine of 25 dollars (£4 13s. 9d.); should he repeat his offence, the fine will be 50 dollars, with suspension from practice for six months. Every Doctor must give part of his time to attend every day at a dispensary *for nothing*. He must perform any service (post-mortem, for example) the authorities may require of him *for nothing*. The Doctors must meet twice a year, or at any other time the authorities may order them, to discuss questions, and answer all questions put to them, *for nothing*. The names and residence of the Doctors must be kept registered in a book kept by the Governor. Any Doctor wishing to leave the town for a short period must obtain permission in writing from the Governor. Only fancy a Medical man practising in London being obliged to obtain in writing a permission from the Lord Mayor to accompany for a few days his family into the country!

The Corporation of the town has just voted a large sum of the public money for the purpose of sending to England for Doctors, who are to be bound by agreement for four or five years to obey all the above rules, and to replace the rebellious ones now on strike. I am, &c.,

J. W. DUFFY,
Member of the Royal College of Surgeons, London;
Licentiate of the University of St. Andrews, Scotland.
Valparaiso, December 1, 1871.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 2.

MR. HILTON, F.R.C.S., President, in the Chair.

ANNUAL MEETING.

MR. HULKE read the report of the Council on the condition of the Society, which was considered favourable in every way.

MR. COOPER FORSTER moved, and MR. RENDLE seconded, the adoption of the report. This was carried unanimously.

MR. SIBLEY exhibited, for Dr. Bakewell, of Trinidad, some Photographs of Patients suffering from Leprosy. The chief was one of an old negro, both of whose legs were affected, the right leg and foot being nodose, the left foot ulcerated.

DR. GALTON could hardly accept the theory of causation advanced by Dr. Bakewell—viz., exposure to cold—as the disease occurs frequently in the scrotum, which is ordinarily protected. Bandaging was the best method of cure applicable to the lower extremities. In reply to Mr. Hulke, who asked if the lymphatics were enlarged in the scrotal cases, the speaker stated that the only structural change he noticed was increase in the amount of the areolar tissue.

DR. KELLY showed, for Mr. Bradley, of Manchester, a portion of the Throat of a Man who had suffered from Syphilis. He was a prisoner in the gaol, and complained of difficult deglutition. After death, it was found that the soft palate was com-

pletely adherent to the posterior wall of the pharynx. The curtain consisted of cicatricial tissue. There was no epiglottis.

The PRESIDENT referred to the case of a patient in his charge who came in hardly able to breathe or swallow. A membrane was seen at the back of the mouth, occluding the passage, and apparently without an opening. Tracheotomy was first of all performed, and the patient was for a time fed per rectum. After a time a small opening was found in the curtain, and by frequent small incisions they were ultimately enabled to enlarge it, and the patient has since remained pretty well, but with a tube in the trachea. He considered it of great importance in such cases to open the trachea before doing anything else.

Mr. HULKE exhibited, for Mr. Hickman, a Small Body, said to be a green pea, removed from the Lachrymal Canal. The patient, a young lady, had a swelling in the corner of her eye, near which were two openings yielding pus. There was no interference with the flow of tears. The swelling was opened, and a small body like a green pea escaped. This was supposed to be a pea, which had made its way up the nasal duct, and so into the lachrymal canal. For his own part, Mr. Hulke doubted that the body was a pea. (Referred to Dr. Bristowe.)

Dr. GALTON exhibited a specimen of Bowel Perforated by Typhoid, one of the ulcers being situate in a diverticulum from the ileum. The patient was a boy who had not presented any marked indications of illness. Perforation suddenly occurred, and he died forty-seven hours after. The treatment was mainly expectant.

Dr. ALBUTT remarked that not only might perforation occur with very mild symptoms of fever, but that itself might give rise to no marked indications. In two cases to which he referred, pain, etc., did not occur for two days after the occurrence of perforation. In one, death did not follow at all. There might be extensive peritonitis without very marked symptoms.

Dr. WILKS confirmed what had been said by Dr. Allbutt. He was inclined to think that powerfully marked symptoms were the exception after perforation in typhoid. Spots occurred in about 80 per cent. of the cases. As to duration, the fever constantly lasted more than three weeks, and not unfrequently more than five.

Dr. KELLY exhibited a specimen of Ulcer of the Bronchus. The patient came complaining of slight hæmorrhage from the lung. He was sent up into the wards, where he died suddenly, before he could be fully examined. He had suffered from syphilis. There was an ulcer over his vocal cords, and another in the right bronchus. The latter was very large, and had eaten into a vessel—a branch of the pulmonary—the inner coats of which seemed as if they had cracked and given way. There were nodules in the liver, and the testicles were diseased. The ulcer was probably, therefore, syphilitic.

Dr. CLIFFORD ALBUTT exhibited some Sections of Spinal Cord from a case of Hydrophobia. They presented evidences of congestion and transudation. There was softening of the medulla, perhaps due to serous infiltration. There was a hæmorrhage about the roots of the eighth pair of nerves. The spleen was enlarged. The clinical and pathological facts seemed thus to go together. Dr. Bastian had pointed out something of the same kind. It was a question how far the tetanic movements might not have given rise to these appearances.

Dr. CRISP thought these indications would not be special to hydrophobia.

Mr. HULKE said that in the treatise of Billroth and Pitha dilatation of the vessels was spoken of. In a case under the care of the late Dr. Todd, as far as could be made out, the vessels were dilated. He asked what the condition of the kidneys was in Dr. Allbutt's cases. In that case the urine was like porter, and the kidneys intensely congested. So, also, in another case in Charing-cross Hospital.

In reply, Dr. ALBUTT stated that the kidneys were not examined by himself. The spinal appearances resembled those of tetanus, but were less intense in degree.

Dr. ALBUTT next proceeded to show some specimens of Syphilitic Disease of the Encephalic Arteries. The patient had general syphilis, and died of it. He had made some sections of the brain and its vessels. The vessels seemed thickened, or, rather, their perivascular walls seemed filled with gummy matter. Several were thus united together into a mass. The appearances were something like those in general paresis.

The following office-bearers for the ensuing session were next elected, and a vote of thanks given to the President:—*President*: John Hilton, F.R.S. *Vice-Presidents*: Edwards Crisp, M.D.; *William Howship Dickinson, M.D.; Richard Quain, M.D., F.R.S.; Samuel Wilks, M.D., F.R.S.; John

Cooper Forster; John Gay; *Jonathan Hutchinson; *John Wood, F.R.S. *Treasurer*: Charles Murchison, M.D., F.R.S. *Honorary Secretaries*: *William Cayley, M.D. John Whitaker Hulke, F.R.S. *Council*: William H. Broadbent, M.D.; William Cholmeley, M.D.; William Selby Church, M.D.; *John Langdon H. Down, M.D.; *Alfred Baynard Duffin, M.D.; Charles Hilton Fagge, M.D.; Thomas H. Green, M.D.; *J. Hughlings-Jackson, M.D.; Robert Martin, M.D.; *Charles R. Nicoll, M.D.; *Frederick William Pavy, M.D., F.R.S.; Frederick Robinson, M.D.; *Henry Arnott; Thomas J. Ashton; John Couper; John Croft; *E. Dennis Hacon; *Arthur B. R. Myers; William Potts; William Squire. The gentlemen whose names are marked with an asterisk (*) were not on the Council or did not hold the same office during the preceding year.

Mr. FAIRLIE CLARKE next proposed a vote of thanks to the retiring office-bearers, which Mr. SIBLEY seconded.

Mr. CROFT proposed a special vote of thanks to Dr. Dickinson on retiring from the duties of Medical Secretary.

Mr. ARNOTT seconded the motion, and Mr. HULKE said a few words in acknowledgment, Dr. Dickinson being absent.

This concluded the proceedings, and the Society adjourned.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 12.

Dr. W. W. GULL, F.R.S., President, in the Chair.

ANNUAL MEETING.

THE President having taken the chair, and the minutes of the last meeting read, the report of the Council was brought forward. They were able to report an increase in their members, and an increase in the ordinary attendance at the Society. The finances were also good—a balance of £249 3s. remaining in the hands of the Treasurer. It was recommended that £200 of this sum should be invested in Consols for the behoof of the Society.

The Treasurer's report was then read, whereupon—

Dr. GLOVER moved, and Dr. POLLOCK seconded, the adoption of the Council's report; and

Dr. POWELL moved, and Dr. SYMES THOMPSON seconded, the investment of the £200 as recommended.

Both motions were agreed to.

Mr. BRUDENELL CARTER moved, and Dr. ALTHAUS seconded, a vote of thanks to the retiring members of the Council, which being carried, the ordinary work of the Society was commenced.

Mr. BRUDENELL CARTER brought before the Society a woman who had been cured of Extreme Convergent Strabismus of the Left Eye, due to paralysis of the external rectus, with secondary contraction and shortening of its antagonist by iodide of potassium, tenotomy, and localised faradisation with the primary current. The patient was 33 years of age, apparently in good health, with no history of syphilis or of any disorder of the nervous centres. She applied at St. George's Hospital on May 16, 1870. The left eye was then so much rolled inwards that only the outer third of the cornea was visible, and was almost immovable in this position. The patient had been in the same condition for more than five months, and she ascribed her malady to some rough usage from her husband. She was ordered to take thirty grains of iodide of potassium daily, and this was continued for nine weeks; at first with very slight benefit, which reached its limit at the end of three weeks. On July 19 the tendon of the left internal rectus was divided, and localised faradisation with the primary current of a Stöhrer's battery was afterwards regularly applied to the external rectus twice or three times a week, by a pair of small rheophores designed for the purpose and exhibited to the Society. Under this treatment the muscle gained sufficient strength to roll the eye to the middle of the palpebral opening when the other eye was closed. On November 22, no further progress having been made, both internal recti tendons were divided, with the result of completing the cure. The eyes were movable to the normal extent in all directions, and retained their parallelism in all positions, no trace of any squint remaining. Mr. Carter said that he had been led to devise this method of treatment in consequence of the very imperfect results obtained from operations for shortening or readjustment of the paralysed muscle.

Dr. OGLE remarked on the extreme rarity of finding paralysis of the nerve to the external rectus muscle alone, the other motor nerves of the eye remaining intact. As to the pathology

of Mr. Carter's case, he (Dr. Ogle) suggested that, as the woman had been suckling (as she informed him) when the eye became affected, might it not be owing to nervous exhaustion consequent on this—the abducent nerve becoming specially affected by reason of the greater communication which exists between the sympathetic nerve and this cerebral nerve in the cavernous sinus. He alluded to cases of internal strabismus sometimes noticed in cases of irritation of the digestive organs. To such Sir C. Bell among others has specially alluded. It seemed very clear that the case was not one of lesion of the central nervous system.

Mr. GEORGE EASTES said he had seen Mr. Bader in such cases cut out a bit of the affected muscle.

Mr. HOLTHOUSE asked what would be the good of shortening a paralysed muscle. He thought that in this case the operation might not have been required had strengthening and specific remedies been persevered in.

Mr. GANT thought the appearance of the patient good. What operation was performed?

Mr. GEORGE LAWSON said syphilis was a very common cause of paralysis of the muscles of the orbit, but often the sixth was affected from other causes due to its intimate connexion with the sympathetic.

The PRESIDENT said here the physical diagnosis was exact, but he would like to know the ultimate cause of the squint. If it was due to affection of the sympathetic, the patient might have recovered without operation.

Dr. ALTHAUS said such a paralysis often arose from syphilis, but he thought that sometimes it came from cold alone. He considered Mr. Carter's plan the best for dealing with them. He had tried faradisation himself, and sometimes it did very well, and sometimes not. The application of the current directly to the conjunctiva was objectionable, so he directed it through the eyelids. A change to the constant current might be useful.

Dr. GLOVER asked if hypodermic strychnine would have been of any use.

Mr. CARTER, in reply, said that he had been unable to discover any cause for the paralysis, which had existed for five months when he first saw the patient, and he could find no indications for any special Medical treatment. In his experience paralysis of the external rectus was more often non-syphilitic than paralysis of any other ocular muscle; but he, nevertheless, gave iodide of potassium experimentally, and continued it for a considerable time. The cutting out of the centre of a paralysed muscle had no tendency to cure paralysis, and the operation ascribed to Mr. Bader by one speaker could only produce very imperfect results, with troublesome double vision. In applying the rheophores to the conjunctiva over the paralysed muscle, he was carrying out the general precepts of Duchenne with regard to localised faradisation, and he should fear that the intervention of the eyelids might prevent the current from reaching the part where it was most required. He had no experience of the use of strychnia in such cases; but he could not conceive that any treatment would have been of much avail until after the first tenotomy, by which the weak muscle was relieved from the preponderating force of its antagonist. His operations were subconjunctival, with a fine hook and fine sharp-pointed scissors, so as to divide the tendon with the smallest possible disturbance of neighbouring tissues. He thanked the Society for the manner in which his case had been received.

Dr. JOHN W. OGLE read a paper on the "Temperature in certain Affections of the Nervous System, and especially in Tetanus." Dr. Ogle first alluded to a case of traumatic tetanus which he had described to the Clinical Society the previous session (which had recovered under the use of chloral, belladonna, wine, ice to the spine, etc.), and which had exhibited tolerably regular or periodic daily variations of a remarkable kind in the heat of the body—variations not corresponding by any means with pyrexia, with any rise in the frequency of respiration or of the pulse, and having no apparent relation to the food taken, the degree of sweating, or the amount or force of muscular spasm. He then described other cases of tetanus in which the evening temperature had been found to be remarkably high compared with that of the morning. Of these, one was a case which he had received from Dr. Keen, of Philadelphia, in which, out of fifteen days that the temperature was taken, there were nine in which the evening temperature was much higher than that of the morning, being in several instances more than $1\frac{1}{2}^{\circ}$ and in some cases 2° higher; the pulse being the while often as low as 60 per minute. A second case was one sent to him by Mr. Dixon, of Preston, in which, during six days that the temperature was taken, there was a great evening increase of

temperature over that of the morning, being on one occasion nearly 3° higher. A third case was one recently published by Mr. Poland; and a fourth one published by Mr. Croft in the *Lancet* for November 4 last. Dr. Ogle did not consider that the great nightly exaltation of temperature was attributable to remedial agents used, though he recognised the fact that certain agents notably affected temperature, and quoted numerous instances in which it had been demonstrated experimentally both on man and animals, that temperature could be both increased and diminished, instancing (and giving authorities) the decrease of temperature from chloral, bromide of potassium, quinine, digitalis, alcohol, mercury, lead, etc., and quoting experiments in which nicotine, curare, strychnia, vomica, veratria, quinine, and phosphorus were injected into the veins of animals. Examination of the results of such experiments and trials showed very great diversity and discrepancy, and Dr. Ogle suggested that research into the action of agents (both in health and disease) in modifying temperature might well and fitly be undertaken by the Clinical Society, and would prove a field worthy in every way of their cultivation. He alluded to observations which his friend Dr. Fox, of Clifton, was engaged in on this subject. Referring to the modifications of temperature of tetanus, and to the possibility of the existence of variations in these modifications, according to the character and nature of the tetanic attack, Dr. Ogle remarked that it would be a question whether such variations have any relation to vascular changes in the spinal cord, or to such textural changes in the central nervous system as have been observed in certain fatal cases of this disease by Rokitansky, Wedl, Wagner, Demme, Fleckner, Eisenmann, Oppolzer, Wunderlich, and more recently Clarke and Dickinson. Dr. Ogle said that he thought it was a matter of consideration how far such histological changes were due to vascular congestions or to increased blood-temperature induced in the course of the disease. In connexion with the high temperature of tetanus, he alluded to the views which had lately been promulgated, especially in Germany, as to the condition termed fever—a condition which was supposed to result from an unwonted state of the central nervous system, by Wunderlich, Virchow, and many others. He specially drew attention to the researches of Tscheschichin, who looked on fever as the result of a morbidly increased activity of the spinal centres in consequence of a weakening or paralysis of the moderating portions of the brain, by which a number of chemical processes are increased to an extent which is never attained under normal conditions of the functions of the brain. He observed that, whatever part the central portions of the nervous system may play in the increase of temperature in disease, we must of course allow that the vasa nervosa, as well those which contract the vessels as those which actively dilate them (if such there be), are intimately concerned, and that an arrest of the natural loss of heat by radiation may lead, by causing its accumulation, to an increase of general temperature as much as an actually and positively increased production of heat. Dr. Ogle then alluded to other cases ordinarily looked on as non-pyrexial, in which the evening temperature was very much higher than that of the morning; for example, those of diabetes, published by Dr. Foster, of Birmingham. (The examination of temperature in cases of diabetes by himself had given different results.) It was to be remembered that in many cases of diabetes the central nerve-structures were at fault. He alluded to cases of meningitis in which the exceedingly high temperature was noted; one noticed by Dr. Bradbury, of Cambridge; also to cases of general paralysis of the insane, for which he was indebted to Dr. Mickle, of the Derby Asylum; and finally to a probably exceptional case of chorea which he had lately treated, and in which the temperature for twenty-one days was noted morning and evening, the latter being almost always much higher than the former. Dr. Ogle referred to the great importance which the thermometer, as supplying a measure of expenditure of nerve-force and tissue-waste, was assuming in our clinical wards, thus competing with the stethoscope, microscope, and test-tube. He hoped shortly to have the opportunity of offering to the Society some remarks on the temperature of the body in paralysis.

Mr. CROFT said he had verified the temperature of 106° Fahr.

Mr. BUTT had noticed an evening elevation in leukaemia.

Dr. CHOLMELEY said that in two fatal cases of tetanus in the Great Northern Hospital there had been a slight degree of elevation in the evening—before death both patients suddenly increased in temperature.

Dr. ALTHAUS remarked that in some of Dr. Weber's cases of

injury to the cord there had been an extraordinary increase of temperature.

Dr. BARCLAY asked if there was any relation between spasm and temperature. He thought temperature was being used too hurriedly as a guide to practice.

Dr. WEBER had some years ago carefully studied the temperature in a case of tetanus. The remedies did not seem to affect its rise or fall. Spasm, too, would occur during the night as during the day, and then failed to produce any influence on the temperature; if any, it lowered it.

Mr. GANT thought the general condition of the system after injury was too much overlooked in considering temperatures.

Mr. CROFT said muscle was often to a great extent ruptured in tetanus; might not this have something to do with increase of evening temperature?

Dr. WILTSHIRE thought chloral sometimes reduced temperature a good deal.

Dr. POORE, referring to a case of uræmic convulsions, said that in it the temperature rose during the convulsions and fell afterwards.

Mr. T. SMITH asked if temperature did not as a rule always rise at night.

The PRESIDENT thought so. He, too, agreed with Dr. Barclay that they were too recklessly applying this kind of knowledge to practice.

Dr. OGLE, in replying, observed, in reference to observations made during discussion on the temperature in leucæmia, that he had lately tried it in one case of leucæmia, but failed to find any positive modification. Dr. Goodhart had found a rise of evening temperature in one case. He also, in reference to the influence which late observations had shown to be exercised by the spinal cord on temperature, alluded to the well-known case published by Sir B. Brodie of laceration of the spinal cord and dislocation of cervical vertebrae, in which the temperature rose to 111°, and so remained even after death. (a) The highest temperature Dr. Ogle had registered had been 111°, and that was in a case of rheumatic fever with cerebral complications. Wunderlich had found it in a case of tetanus as high as 112.5°. In reply to the suggestion that the evening temperature in a state of health was always higher than in the morning, Dr. Ogle believed that if the temperature was taken at 9 or 10 a.m. and again at 10 p.m. this would be found not to be the case.

The PRESIDENT referred to a case in Guy's Hospital where the patient had had his neck broken at the fifth cervical. In that case the temperature was over 109° Fahr. on the exposed abdomen.

The following officers for the ensuing year were declared elected:—*President*: William W. Gull, M.D., F.R.S. *Vice-Presidents*: Thomas King Chambers, M.D.; G. Owen Rees, M.D., F.R.S.; J. Burdon-Sanderson, M.D., F.R.S.; *Alexander P. Stewart, M.D.; *Geo. W. Callender, F.R.S.; *J. Cooper Forster; Henry Lee; Campbell De Morgan, F.R.S. *Treasurer*: E. Headlam Greenhow, M.D., F.R.S. *Council*: *James Andrew, M.D.; William H. Broadbent, M.D.; William Cholmeley, M.D.; *Edward Clapton, M.D.; John Langdon H. Down, M.D.; *Alfred B. Duffin, M.D.; *J. Hughlings-Jackson, M.D.; *John C. Langmore, M.B.; Alfred Meadows, M.D.; Sydney Ringer, M.D.; Samuel Wilks, M.D., F.R.S.; *Henry Arnot; *Richard Barwell; *Thomas Bryant; John Croft; Berkeley Hill; Carsten Holthouse; William B. Kesteven; Septimus W. Sibley; *Alfred Willett. *Honorary Secretaries*: Thomas Buzzard, M.D.; George Lawson. *Trustees*: *E. Headlam Greenhow, M.D., F.R.S.; *J. Burdon-Sanderson, M.D., F.R.S.; *George W. Callender, F.R.S. The gentlemen whose names are marked with an asterisk (*) did not hold the same office during the preceding year.

OBITUARY.

JAMES BAKER, M.D.

WITH him the Profession has lost a faithful follower—one of the few remaining pupils of Abernethy. The parish of St. Leonard's, Shoreditch, has lost one of its oldest and most respected inhabitants. Born in the year 1800, after studying at St. Bartholomew's with Messrs. Skey, Wormald, and Mr. Coates, of 201, Euston-road, he qualified in 1826, and settled in his native parish, where he continued to practise upwards of forty-five years. Here he soon acquired a good share of Professional work and public trust. He was many years a

(a) See *Medico-Chirurgical Transactions*, vol. xx., 1836.

deacon of Whitfield's Tabernacle, vestryman of the parish, and two years churchwarden, for which latter services, in 1864, the vicar, the Rev. T. S. Evans, presented him with the Book of Common Prayer, handsomely bound in morocco and gold. The vestrymen at a public meeting unanimously presented him with a vote of thanks engrossed on vellum, framed and glazed; and in the following year his fellow-parishioners and friends, at a dinner at the London Tavern, presented him with a valuable service of plate. But Dr. Baker was best known to the Medical Profession, especially of the past generation, by the active part he took in securing the passing of the Medical Witnesses Act—being, in fact, the sole author of it; for in 1834, being unable to obtain any fee for twice giving evidence, making analysis, and post-mortem, he ventilated the subject of remunerating Medical witnesses, and finding the whole Profession was with him, he got up a petition, known as Mr. James Baker's petition, bearing the signatures of over 800 Medical men, and containing the names of the Presidents of the Royal Colleges of Physicians and Surgeons of England, and all the eminent Physicians and Surgeons of the period. He carried his petition to Westminster, Messrs. Whittle, Harvey, and Wilks having kindly promised to present and support it; but the late Mr. Wakley took charge instead, and presented it the following day, at the same time asking leave to bring in a Bill, which he did. The Bill was passed, and is known as the Medical Witnesses' Remuneration Act. For the trouble taken and expense incurred Dr. Baker received the first fees after the passing of the Act from many Practitioners, and letters of thanks from numbers of others. Dr. Baker died on Christmas-day, 1871, at Tottenham, in the 72nd year of his age, beloved by all who knew him. He has left a faithful, fond wife; not having been blessed with any family of his own, he took care of others'.

MARTINDALE WARD, L.R.C.P.E., F.R.C.S. ENG.

DIED, on the 12th inst., at the residence of his eldest son, Saltburn, Twickenham-common, aged 52. The deceased's residence was in Markham-square, Chelsea. He was Surgeon-Major South Middlesex Volunteers, and for upwards of twenty-one years Assistant-Surgeon Royal Military Asylum, Chelsea, Medical Officer and Public Vaccinator North-west District, Chelsea, and for thirty years actively engaged in parochial matters in the parish of Chelsea. He was much respected.

HENRY CHARLES ROBINSON, M.R.C.S.E., L.S.A.,

Son of Captain Bethel Martin Robinson, was born at Parkhurst Barracks, Newport, Isle of Wight, in 1807. After pursuing his studies at Guy's and St. Bartholomew's, he commenced his career in 1829, and had an extensive private practice, and subsequently devoted thirty years of his life to the care of the poor—sixteen years as District Surgeon and Senior Medical Officer to St. Pancras; and nearly fourteen years as Senior Medical Officer to Mile-end Old Town. He died January 8, and leaves eight children, who deeply mourn his loss.

ROBERT WADE, F.R.C.S.

WE regret to have to announce the death of Mr. R. Wade, which took place on the 16th inst. Mr. Wade was the Senior Surgeon to the Westminster General Dispensary, and practised in Dean-street, Soho. He was the author of works on "Stricture" and on "Conservative Surgery of the Urethra," which went through several editions. He also contributed papers to the *Medico-Chirurgical Transactions*, and to the Medical periodicals. He was elected an Honorary Fellow of the Royal College of Surgeons in 1844.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual monthly examinations, held on January 8, 10, and 11, the following received the Licence to practise Medicine:—

- | | |
|-----------------------|------------------|
| Murphy, William Reid. | Mulvany, Edward. |
| Hamilton, Stewart. | Roche, Anthony. |
| M'Guire, Edward. | |

The successful candidates for the Diploma in Midwifery were:

- | | |
|------------------|-----------------------|
| Marshall, John. | Murphy, William Reid. |
| M'Guire, Edward. | Prendergast, John. |
| Mulvany, Edward. | Roche, Anthony. |

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 16th inst., and, when eligible, will be admitted to the Pass Examination:—

Alford, Frederick S., student of University College.
 Brodribb, C. Aikin, of St. Mary's Hospital.
 Coote, Michael, M.D. Univ. Laval, Quebec, Canada, of St. Thomas's Hospital.
 Cossham, W. Raymond, of the Bristol School.
 Dobson, Joseph, of the Leeds School.
 Drew, Clifford L., of the London Hospital.
 Essex, J. Rowlands, of the Bristol School.
 Hamilton, A. M. S., of the Belfast School.
 Hartley, E. Baron, of St. George's Hospital.
 Herapath, C. K. C., of the Bristol School.
 Hills, T. Hyde, of St. George's Hospital.
 Hynes, A. Mortimer, of the Manchester School.
 Jewesbury, Charles F., of University College.
 Keyworth, George H., of Guy's Hospital.
 Lawrence, George E., of University College.
 Morris, George, of the Manchester School.
 Sargent, George, M.A. Cantab., of St. Bartholomew's Hospital.
 Tyson, William, of the Leeds School.
 Wallace, Thomas, of the Belfast School.
 Ward, L. Breton, of St. George's Hospital.
 Webb, Charles L., of Guy's Hospital.
 Williams, Alfred H., of St. Thomas's Hospital.
 Winkworth, F. Sydney, of University College.

The following gentlemen passed on the 17th inst., viz.:—

Bowen, Edward, student of Guy's Hospital.
 Buck, William E., B.A. Cantab., of St. Bartholomew's Hospital.
 Carey, John Thomas, of Guy's Hospital.
 Collins, Henry A., of Guy's Hospital.
 Dove, Harry, of St. Bartholomew's Hospital.
 French, A. Martin, of Guy's Hospital.
 Gibb, Robert Charles, of Guy's Hospital.
 Lewis, Ivor A., of Guy's Hospital.
 Leonard, John, of Guy's and Charing-cross Hospitals.
 Lloyd, John D., of the Bristol School.
 McMonagle, Joseph, M.D. New York, of St. Thomas's Hospital.
 Owen, William, of St. Bartholomew's Hospital.
 Penny, George T., of St. Bartholomew's Hospital.
 Robey, Ralph P., of the Birmingham School.
 Seward, William J., of University College.
 Strickland, H. G. T., of King's College.
 Talbot, Russell M., of Guy's Hospital.
 Taylor, A. Norton, of Guy's Hospital.
 Tucker, R. Goldsworthy, of St. Bartholomew's Hospital.
 Webb, Edward R., of St. George's Hospital.
 West, Rowland Hill, B.A. Cantab., of St. Thomas's Hospital.
 Wigan, George, of Guy's Hospital.
 Williams, Richard, of St. Bartholomew's Hospital.

The following gentlemen passed on the 18th inst., viz.:—

Black, Robert F., student of St. Bartholomew's Hospital.
 Dry, Robert B., of Guy's Hospital.
 Johnstone, Charles R., of St. Mary's Hospital.
 Morris, Edward J., of St. Bartholomew's Hospital.
 Pletts, J. Menham, of St. Bartholomew's Hospital.
 Sewell, William, of St. George's Hospital.
 Smith, T. W. T., of the London Hospital.
 Spear, John, of St. Bartholomew's Hospital.

Thirty-four candidates out of the eighty-eight examined, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for three months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, January 11:—

Salmon, Alfred Lidger, Truro, Cornwall.
 Sylvester, Kirwan Francis, Trowbridge, Wilts.

As an Assistant in Compounding and Dispensing Medicines:—
 Houghton, Robert William, Waite-street, Old Kent-road, S.E.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BANKART, JAS., M.B.—Surgeon to the West of England Eye Infirmary, Exeter, *vice* P. C. De la Garde, deceased.
 CARTWRIGHT, S. HAMILTON, M.R.C.S.—Lecturer on Dental Surgery and Pathology at the Dental Hospital of London, *vice* Mr. Samuel Cartwright, resigned.
 COLES, GEO. CHAS., M.R.C.S.—Assistant-Surgeon to the Central London Ophthalmic Hospital, Gray's-inn-road, W.C., *vice* H. A. Reeves, M.R.C.S., resigned.
 LIDBETTER, T. G., L.S.A.—Assistant to the Resident Medical Officer of the Holloway and North Islington Dispensary, *vice* Alfred H. Hackney, M.R.C.S.E., L.S.A., resigned.
 MOORE, J. W., M.D., Ch.M. Dub., L.K.Q.C.P. Ire., L.M.—Temporary Physician to the Fever Hospital and House of Recovery, Cork-street, Dublin.
 O'REILLY, RICHARD, L.K. & Q.C.P.I., L.R.C.S.I., L.M.R.C.S.I., M.B., M.A.—Medical Officer, etc., for the Lismore Dispensary District of the Lismore Union, co. Waterford.

PEGUM, THOMAS, L.K.Q.C.P., L.R.C.S.I.—Medical Officer, Public Vaccinator, and Registrar of Births, Deaths, and Marriages for the Craganock Dispensary District of the Kilrush Union, co. Clare.

PHILPOTS, EDWARD PAYNE, M.D. Aber., M.B., etc.—Medical Officer for the Third District of the Poole Union.

ROBERTS, JOHN D., M.R.C.S.E., L.S.A.—Surgeon for the Blackfriars District of the Royal South London Dispensary, *vice* H. J. Thorp, resigned.

ROSE, HARRY, L.D.S.—Dental Surgeon to the National Dental Hospital, 149, Great Portland-street, W., *vice* Mr. C. Lane Clark, resigned.

ROWAN, JOHN F., L.K.Q.C.P., L.M., L.R.C.S.I.—Medical Officer, etc., to the Kilkee Dispensary District of the Kilrush Union, *vice* John Griffin, M.D., L.R.C.S. Edin., resigned.

SAUNDERS, MR. CHARLES EDWARD—Surgical Registrar at St. Thomas's Hospital.

STANLEY, WILLIAM E. S., L.R.C.S., L.R.C.P., and L.M.—Medical Officer for the Eighth District of the Thingoe Union, Bury St. Edmunds.

MILITARY APPOINTMENTS.

3RD FOOT.—Surgeon John Lyster Jameson, having completed twenty years' full-pay service, to be Surgeon-Major, under Article 342 of the Royal Warrant, dated December 27, 1870.

68TH FOOT.—Staff Assistant-Surgeon William Francis Burnett, to be Assistant-Surgeon.

BIRTHS.

BLACKMAN.—On January 8, at 4, York-road, S.E., the wife of Frederick Blackman, Surgeon, of a son.

CLARKE.—On January 6, at 11, Stafford-street, Edinburgh, the wife of J. J. Clarke, M.R.C.S., H.M.'s 3rd Bengal Cavalry, of a daughter.

CROCKER.—On January 4, at Stoke, Devonport, the wife of Staff Surgeon-Major Crocker, of a son.

DALY.—On January 10, at 101, Queen's-road, Dalston, London, the wife of Frederick H. Daly, M.D., of a daughter.

GROSVENOR.—On January 13, at 121, Ladbroke-grove, Kensington-park, W., the wife of George Fox Grosvenor, M.D., of a son.

HAYNE.—On January 8, at 2, Manor-place, Northfleet, the wife of Frederick Greaves Hayne, M.R.C.S.E., of a daughter.

KIRK.—On October 11, at Zanzibar, the wife of John Kirk, M.D., Acting Political Agent, of a daughter.

RICE.—On January 11, at 8, Sloane-terrace, S.W., the wife of M. W. Rice, M.D., of a daughter.

TERRY.—On January 10, at Newport Pagnell, Buckinghamshire, the wife of Charles Terry, Surgeon, of a daughter.

WRIGHT.—On December 11, 1871, at Katmandor, Nepal, the wife of D. Wright, M.D., Residency Surgeon, of a son.

MARRIAGES.

MARTIN—MAYBERRY.—On January 11, at the parish church, Kenmare, William Holt, third son of William Shuebrick Martin, Esq., The Firs, Burton-on-Trent, to Elizabeth Macgillycuddy, eldest daughter of George Mahony Mayberry, M.D., J.P., of Riversdale, Kenmare, co. Kerry, Ireland.

ROGERS—WILLMOTT.—On January 11, at St. John's Church, Weston-super-Mare, the Rev. Hawkesworth Rogers, Vicar of St. John's, Kilkenny, to Frances Valpy, daughter of Alfred Willmott, M.D., of Weston-super-Mare.

TALAMON—JOHNSON.—On January 11, at Stafford, Georges Paul Talamon, of Elbeuf, France, Vice-Consul of St. Salvador, to Edythe Mary, second daughter of James Johnson, M.R.C.S., of Harcourt House, High Offley, Staffordshire.

TRONSON—CHAPMAN.—On January 13, at St. Mary's, Kilburn, Norman Percy Miles, eldest surviving son of the late Colonel Tronson, 13th (Prince Albert's) Light Infantry, to Emily Harriet, widow of Dr. E. Chapman, and third daughter of Drewry Ottley, M.D., of Pau.

WALKER—HAMMONDS.—On January 16, at the parish church, Clifton, James Frederick Walker, L.R.C.S.I., of Bonmahon, county Waterford, and Swallowfield, Berkshire, to Laura Sarah, daughter of William Thomas Hammonds, Esq., of Clifton, Gloucestershire, and Berrow, Somersetshire.

DEATHS.

FRANKS, GEORGE, M.R.C.S.E., at 3, Mayow-road, Forest-hill, on January 15, aged 68.

KENNEDY, CHARLOTTE, the widow of James Kennedy, M.D., of Woodhouse, Leicestershire, on January 11, aged 80.

WADE, ROBERT, F.R.C.S., at 68, Dean-street, Soho, on January 16.

WARD, DR. MARTINDALE, of Markham-square, Chelsea, Surgeon-Major South Middlesex Volunteers, at the residence of his eldest son, Saltburn, Twickenham-common, on January 12, aged 52.

WILLIAMS, ANNE, widow of the late J. Calthrop Williams, M.D., of Nottingham, at the residence of her son, Rhys Williams, M.D., Bethlem Royal Hospital, London, on January 11, in her 70th year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BATH ROYAL UNITED HOSPITAL.—Medical Officer. Must be M.R.C.S., and either L.R.C.P.L. or L.S.A. Applications and testimonials to the Secretary, on or before January 22. Election February 6.

BLACKBURN AND EAST LANCASHIRE INFIRMARY.—House-Surgeon. Must be qualified to practise. Applications to Mr. E. Halliwell, Secretary, on or before January 20.

CALNE UNION.—Medical Officer for the entire Union. Candidates must possess the qualifications prescribed by the General Orders of the Poor-law Board. Applications and testimonials to Mr. H. S. Heath, Clerk, on or before January 30.

CANCER HOSPITAL, LONDON AND BROMPTON.—Resident House-Surgeon. Must be M.R.C.S.E. Applications and testimonials to the Chairman of the Weekly Board, 167, Piccadilly, on or before January 22.

CHARING-CROSS HOSPITAL, WEST STRAND, W.C.—Assistant-Physician and Physician for the Treatment of Diseases of the Skin. Candidates must possess degrees from one of the Universities recognised by the General Medical Council, and be F. or M.R.C.P.L. Applications to the Secretary, on or before January 30.

CHESTER GENERAL INFIRMARY.—Visiting Surgeon. Double qualifications required. Further particulars to be obtained of Mr. T. Jones, Secretary, on or before January 22.

CHRISTCHURCH UNION.—Medical Officer. Candidates must be qualified in accordance with the General Orders of the Local Government Board. Applications and testimonials to the Clerk to the Guardians, on or before January 22. Election the same day.

DORSET COUNTY HOSPITAL, DORCHESTER.—Honorary Physician. Candidates must be Graduates of some University of the United Kingdom, or be Fellows or Licentiates of the College of Physicians. Applications and testimonials to the Chairman of the Committee, on or before February 7. Election on the 22nd.

GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, 16, BRIDGE-STREET, MANCHESTER.—Resident Medical Officer. Candidates must be duly qualified and registered. Applications and testimonials to the Secretary, on or before January 23.

JERSEY GENERAL DISPENSARY.—Medical Officer. Further particulars of the Rev. P. A. Le Feuvre, Oakwalk, Jersey. The election takes place early in January, and the duties will commence on February 1.

KING'S COLLEGE, LONDON.—Chair of Forensic Medicine. Applications to Mr. J. W. Cunningham, on or before January 27.

MARYLEBONE GENERAL DISPENSARY, 77, WELBECK-STREET, CAVENDISH-SQUARE.—Surgeon. Candidates for this appointment are required to be M.R.C.S.E., not engaged in the practice of Midwifery or Pharmacy. Applications and testimonials to the Secretary, on or before February 7.

MIDDLESEX HOSPITAL.—Resident Obstetric Assistant. Must possess one legal qualification. Applications and testimonials to the Secretary, at the Hospital, on or before January 30.

NEWPORT INFIRMARY.—Dispenser. Applications to Mr. Willey, West of England Bank, Newport.

NOTTINGHAM DISPENSARY.—Resident Surgeon and Assistant Resident Surgeon. Double qualifications necessary. Applications to the Secretary, on or before February 12. Election on the 26th.

POCKLINGTON UNION.—Medical Officer for the Second District of this Union. Gentlemen seeking this appointment are required to have the qualifications to practise prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. W. Silburn, Clerk to the Guardians, on or before January 27.

QUEEN'S COLLEGE, CORK.—Professorship of Chemistry. Applications and testimonials to the Under-Secretary, Dublin Castle, on or before January 22.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Must be a Member of the College of Surgeons of London, Dublin, Edinburgh, or Glasgow; or a Licentiate of the Society of Apothecaries. Applications and testimonials to the Treasurer, Mr. R. Tweedy, Truro, on or before January 20.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—Senior House-Surgeon. Medical and Surgical qualifications required. Applications to the Secretary, on or before January 24.

ST. GEORGE, HANOVER-SQUARE, DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE.—Physician-Accoucheur. Must be M.R.C.P.L. Applications and testimonials to the Honorary Secretary, on or before January 30.

SHEFFIELD GENERAL DISPENSARY.—Assistant House-Surgeon. Medical and Surgical qualifications must be possessed by candidates for this appointment. Applications to the Medical Staff, care of the Secretary, on or before February 2.

TUNBRIDGE WELLS DISPENSARY AND INFIRMARY.—Resident House-Surgeon. Double qualifications required. Applications to the Secretary, on or before January 31. Election on February 5.

WEST HAM, STRATFORD, AND SOUTH ESSEX DISPENSARY.—House-Surgeon, who must be duly qualified. Applications and testimonials to Mr. T. G. Tonge, Dispensary House, Romford-road, Stratford, E., on or before January 24.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Christchurch Union.—Mr. J. H. Cartwright has resigned the Eastern District; area 14,311; population 4321; salary £70 per annum.

Manchester Township.—The office of Senior Assistant Medical Officer at the Workhouse Hospital, New Bridge-street, is vacant; salary £170 per annum, and allowances.

Newark Union.—Mr. R. M. Willan has resigned the Clifton District; area 7970; population 878; salary £12 per annum.

Peterborough Union.—Mr. Joseph B. Bodman has resigned the Caston District; area 9550; population 1643; remuneration per case.

Tonbridge Union.—Mr. E. M. C. Hooker has resigned the Fourth District; area 5784; population 2568; salary £60 per annum.

West Ham Union.—The Second District is vacant; salary £80 per annum.

APPOINTMENTS.

Amersham Union.—John F. Churchill, M.R.C.S. Eng., L.R.C.P. Lond., to the First Chesham District. Richard O. Arnold, L.F.P. & S. Glasg., L.S.A. Lond., to the Second Chesham District.

Nuneaton Union.—Andrew Robinson, M.R.C.S. Eng., L.R.C.P. Edin., to the Nuneaton District.

DR. KEMPSTER has been elected Medical Officer of Health for Battersca.

A COUNTY ANALYST has been appointed for Cheshire.

THE second son of Dr. Livingstone, who is studying for the Medical Profession at Glasgow, has become so anxious about the safety of his father, that he has left for London, to offer himself as a volunteer in the expedition to search for his father.

AT a meeting of the contributors of the Edinburgh Royal Infirmary, held on Monday, a report was adopted recommending the managers to devise means for admitting women to Medical instruction in the institution without prejudice to the male students.

MR. MALTHOUSE called the attention of the Newington Vestry, last week, to the fact of a large number of persons in receipt of parochial relief living in dwellings totally unfit for human habitation. The Medical officer undertook to confer with the relieving officer at once, and to report on the subject at their next meeting.

MEASLES, in an epidemic form, has broken out at the Southall Schools, belonging to the parish of Marylebone. The disease is reported to have been very fatal, but a subsidence is, we are glad to say, observable.

AT the Commissioners of Sewers' meeting, on Tuesday, it was stated that no less than nine main sewers, and nineteen smaller ones, in the city of London, still emptied their contents directly into the river.

ACCORDING to the *Edinburgh Courant*, an interdict has been lodged in the Court of Session against the gentlemen nominated as Managers of the Royal Infirmary by the Lord Provost, at a meeting of the contributors on the 1st inst., taking their seat at the Board of Management. An interim interdict has been granted.

A MAN has been appointed by the Chelsea Vestry to look after the dust-carts and see that the contract is properly carried out and all the dust removed. This supervision is very necessary.

CLINICAL SOCIETY.—At the next meeting of this Society an address will be given by Dr. Gull, the President. At its conclusion Mr. Cooper Forster will read a paper upon "Popliteal Aneurism." The subject of "Condurango, the Reported Remedy for Cancer," will then be introduced by Mr. Hulke; and, lastly, Mr. T. Bryant is announced to read a paper upon "Two cases of Recto-vesical Fistula treated by Colotomy."

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—SESSION 1871-72.—The next meeting will be held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Saturday, January 20, at 7.30 p.m., Robert Druitt, M.R.C.P. Lond., F.R.C.S., President. A letter will be read from the Board of Trade, on the "Water Supply of London." Dr. F. Grace Calvert, F.R.S., F.C.S., will deliver an address comprising the following subjects:—1. Production of Protoplasmic Life. 2. Action of Heat on certain Primitive Forms of Life. 3. Action of Concentrated Solutions of various Chemical Substances on certain Primitive Forms of Life. 4. The Comparative Power of some Antiseptics and other Substances to prevent the Development of Protoplasmic and Fungous Life. 5. The action of the same Antiseptics and Substances upon certain Primitive Forms of Life.

WOMEN-DOCTORS IN INDIA.—The Mahomedan Nawab of Rampore has presented to the Bareilly Mission a large building, for the purpose of a Medical school for women. Several women are now going through a scientific course of instruction.

MEDICAL STUDIES AT CAMBRIDGE.—It is announced that Professor Humphry will continue the course of lectures on Practical Anatomy on Mondays, Wednesdays, and Fridays, at 6 p.m. The course of Anatomy and Physiology will be continued on Tuesday, January 30, at 1 p.m., and on Wednesdays, Fridays, and Saturdays. This course is intended for students of natural science as well as for Medical students. The Microscopical Demonstrations will be continued on Tuesday, February 13, at 6 p.m., and on alternate Tuesdays. The course of Practical Histology will be continued on Saturday, February 3, at 11.30, and on each succeeding Saturday. The Professor of Chemistry will begin a course of lectures on Chemistry on Monday, January 29, at 12 p.m., in the chemical lecture-room, and continue them on succeeding Mondays, Wednesdays, and Fridays, at the same hour. Gentlemen requesting certificates of attendance for the degree of B.A. must provide themselves with tickets from the Registrar; the fee for others will be two guineas. Those who propose attending are requested to leave their names at Messrs. Deighton, Bell, and Co.'s, to whom the fees may be paid.

UNUSUAL RECOGNITION OF MEDICAL SERVICES.—“In testimony of his great kindness and Professional services,” a lady who has recently died has left to our good *confrère* Dr. McIntyre, of Odiham, the sum of £4000. She has also appointed him one of her executors, with a legacy of £100. Such recognitions of Professional services are not merely grateful compliments for the skill which no science or art, except Medicine, can supply; they encourage the skill by proving how handsomely it is sometimes appreciated and acknowledged.

ACADÉMIE DES SCIENCES.—The election of Corresponding Member in the Section of Zoology, which excited so much discussion in the Academy last year, and was on account of the troubles of the time postponed, is about again to be brought forward. The contest of last year in the section arose as to whether Bischoff or Darwin's name should head the commendatory list. MM. Milne-Edwards and Quatrefages voted for Darwin, and MM. Blanchard, Robin, and Longet for Bischoff. This year the Darwinites will prevail in the section, as M. Lacaze-Duthias now occupies the post vacated by the decease of M. Longet. M. Coste this year, as last, has been prevented by official duties from participating in the deliberations.

A PROLONGED WORK.—Professor Chevreul read, at the Academy of Sciences, the other day, the first part of a memoir on “Wools and Dyeing.” The work was undertaken in co-operation with a Spanish general who was shot in 1813. We hope M. Chevreul may be able to take the same period of time for the completion of the second part of this interesting memoir.—*Union Méd.*, January 13.

TEMPERATURE OF THE SUBSOIL IN SEVERE FROSTS.—According to the researches of M. Becquerel, under a denuded soil, at five centimetres depth, the thermometer during severe cold will sink to 1.5° C. below zero; but when the soil is covered with turf or with snow it never sinks below zero. At ten centimetres depth the temperature remains invariable.—*Gaz. Méd.*, January 6.

M. ELISE RECLUS.—The following is a copy of the petition signed by many English scholars and men of science forwarded on January 3 to the Commission of Pardons sitting at Versailles in favour of M. Elisé Reclus. Unhappily, the statement that the prayer of the petition has been granted is premature, and a second or supplementary petition is consequently in the course of signature:—

“To the President, Vice-President, and Members of the ‘Commission des Grâces’ appointed by the National Assembly to consider the applications for pardon and commutation of sentence of persons connected with the Commune.

“We, the undersigned (British subjects and others), men of science, entertaining a high opinion of the past services to literature and science of Monsieur Elisé Reclus, a prisoner now under sentence of deportation, beg permission to make an earnest appeal to your clemency in his favour.

“We cannot but believe that his connexion with the insurrectionary body of the Garde Nationale was solely an accident of circumstance, or an unwilling concession to *force majeure*, and not the result of his natural character, his habits and mode of life being those of a lover of peace, and a calm student of the laws of nature, as his works testify.

“We therefore implore your clemency for him, and entreat that, if it should appear to you unadvisable wholly to remit the sentence imposed on M. Reclus, you may be pleased at least to commute it to simple banishment, so that he may retire to some foreign land, and there pursue his valuable studies.

“In the hope that you will excuse and favourably entertain this petition, your memorialists will ever pray, etc.”

This has been signed by the following well-known Medical authorities:—William Benjamin Carpenter, M.D., F.R.S., Registrar of the University of London; Richard Owen, F.R.S., Associé étranger de l'Institut (Académie des Sciences); Henry Lec, F.L.S., F.G.S.; Henry T. Stainton, F.R.S., F.L.S.; James Salt, F.R.S., F.L.S.; Thomas D. Bott, F.G.S.; Owen Rees, F.G.S.; Benjamin W. Richardson, M.A., M.D., F.R.S., F.R.C.P., Honorary Physician of the Royal Literary Fund; T. Burdon-Sanderson, M.D., F.R.S., Professor of Practical Physiology, University College, London; Charles Murchison, M.D., F.R.S.; T. Spencer Cobbold, M.D., F.R.S., “Swiney Lecturer on Geology, British Museum; H. Charlton Bastian, M.D., F.R.S., Professor of Pathological Anatomy in University College; Erasmus Wilson, F.R.S., Professor of Dermatology in the Royal College of Surgeons of England; and many others equally eminent in their several departments.

NOTES, QUERIES, AND REPLIES.

Be that questioned much shall learn much.—Bacon.

Dr. G. A. Abrath.—We shall be glad to receive your manuscripts.

Podophyllum.—Some time in February. Look out for the advertisement.

Chrystal.—Hartnack has no agent in London. Apply to Rue Dauphiné, Paris.

Mr. F. Staples, Puchmurra Dépôt.—Your letter, with enclosure, has come safely to hand.

THE DECLARATION RESPECTING ALCOHOL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your journal of this week it is said—“One of the latest and most striking instances of this unlucky Declaration (the Medical Declaration concerning Alcohol) is that a proposal is afloat, and several thousands of pounds have been collected, for the erection of a new Hospital, where patients in acute disease are to be treated without alcohol.”

You will, I am sure, be willing to give publicity to the correction of the above statement which I am able to supply. The proposal to found a Temperance Hospital has had no connexion whatever with the Medical Declaration, and until the appearance of that document a majority of the members of the Provisional Committee had no knowledge of its tenor, or of the signatures that would be attached to it. The Hospital suggestion could not arise from the draft of the Declaration, for it was prior to it, and the action in relation to each has been absolutely independent from first to last.

I am, &c.,

January 13.

DAWSON BURNS, M.A.,

Metropolitan Superintendent, United Kingdom Alliance.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The now celebrated Declaration having been sent to me for signature, I think it right to say that while I deeply regret that any Practitioner of Medicine should ever have been guilty of inconsiderate prescription of any drug, I cannot sign the document for the reason that I cannot blame myself for having ever done so in the matter of alcohol.

The Declaration reads very like a confession of sin on the part of those who have signed it; and if so, they may be right in thus unburthening their consciences; but it would have been more considerate had the word “some” been placed before “Medical men,” for then the Declaration would have been more limited in its scope, and more definite in its meaning. As it is, the public may be led to believe that the distinguished names attached to it represent the whole of the Profession, or at least that they are the chief sinners.

I am, &c.,

Birmingham, January 13.

LAWSON TAIT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Notwithstanding the array of great names—leaders of our Profession—names justly celebrated, and giving rank and influence to us—this document, many think, makes a great mistake—a mistake for the most part in phraseology, by which, instead of a caution, it becomes a charge of contributing to and encouraging, at the present time, a most debasing and prolific cause of destruction to health, and also crime and poverty. We are certainly not responsible for the low habit of drinking at public-houses and beerhouses, and its consequence, which is the vice of the working-classes. I was sorry to see that Dr. Dalrymple, to whom society owes an obligation, from his exertions to meet this evil, was so ill-received in consequence at Bath. At all events, it shows that, wherein class legislation was so much talked of as belonging to the upper classes, the remark has a different application. I trust, however, that this document, whatever its informalities, may do good, and caution Medical men not to yield too much to requests from the poor to get recommendations for brandy and wine, which they hawk about; and, at the same time, to be cautious of sending them to the relieving officer for similar purposes, when quinine, sal volatile, and camphor may answer as well or better. As an old-experienced Medical man, I may be excused making these remarks.

Nailsworth, January 16.

I am, &c.,

THOMAS STOKES.

Temperance.—Dr. McMurtry's attack on his Professional brethren is really scarcely worthy of even a passing notice in our columns. Wholesale assertions without proof, and universal abuse without deserving, are the usual characteristics of writers on what is foolishly called the “temperance” question.

L.R.C.P., M.R.C.S., and L.A.S., 1836, must by this time have arrived at our opinion with regard to the “Medical Declaration respecting Alcohol.”

It is probable that the attack upon the Profession by a number of their own body will have met with all but universal condemnation.

Dr. Dunderdale (Warrington).—We are glad to perceive that Dr. Dunderdale repudiates the paragraph which appeared in last Saturday's *Warrington Examiner*, entitled “Gratitude to Dr. Dunderdale.” Sheridan says such puffs oblique are often the work of “a d—d good-natured friend.”

(FROM DR. ABRATH, NEWCASTLE.)

We have at present a great many cases of scarlatina, diphtheria, small-pox, fever, etc., in the country, and frozen milk or cream are valuable agents in such cases. I give you the liberty to mention my treatment in a note in your journal, and I will send shortly a contribution on the subject. *How to freeze milk or cream in the absence of ice-machines.*—Take a half-pint tin pot filled with milk or cream (if the milk, etc., has been standing in a warm room, put a piece of ice the size of a walnut into the milk), and place a cover on the pot. Take a second vessel, say a half-gallon pot, put a handful of common table-salt at the bottom, and place the half-pint pot, filled with milk or cream, on the salt. Now, take about two pounds of ice, broken in pieces, but not too small; mix with the ice two or three handfuls of table-salt, and place in the space between the two pots, until such space is well filled; also, add a tablespoonful of water to it, and occasionally move the half-pint pot round in the ice and salt—the milk or cream will soon freeze. If the quantity is not used in a short time, mix some fresh ice and salt, and place the tin pot, with the ice-milk or cream, in it.

CHARING-CROSS HOSPITAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the *Standard* of the 8th inst. there is a paragraph, extracted from your valuable journal, relative to laying down asphalt in the streets which surround this Hospital; and living, as we do, in the immediate neighbourhood, we fully endorse the statements made therein, more especially as regards the great traffic that takes place after the theatres are closed, and the continued noise made by the passage of market carts on their way to Covent Garden in the nights and early mornings preceding market days.

His Grace the Duke of Northumberland, with that liberality and kindly feeling for which he is so justly esteemed, some short time since made a communication to the Vestry of St. Martin-in-the-Fields relative to this matter, proposing, in the interest of the Hospital, that he might be allowed, by subscription or otherwise, to take up the present old granite paving and lay down asphalt; we are not at present informed of the result of that proposition. In addition to this, the inhabitants of King William-street, Strand, presented a memorial to the Vestry on the same subject, which was answered by stating that the levels of the streets were such as to preclude the possibility of laying down asphalt, an opinion which we certainly do not entertain, King William-street, as stated in the answer, being only one in fifty-five gradient.

In conclusion, we would mention the fact that the inhabitants of the Strand had previously memorialised the Vestry to have that important thoroughfare paved with asphalt, and their memorial was answered in the same terms by the above-named Vestry of St. Martin-in-the-fields, the great majority of whose members happen to reside in other parts of the parish, and so, unfortunately, fail to see the importance of the improvement, although the Vestries of St. Clement Danes and St. Mary-le-Strand had already expressed their great desire to have those portions of the Strand situate in their respective districts paved with asphalt.

We are, &c.,
PHYLLIAN and SONS, Wine Importers.
432, West Strand, W.C., January 11.

Vesalius.—In a memorial to Sir James Graham from the Metropolitan Teachers of Anatomy, accompanied by an official return of unclaimed bodies sent annually to the schools from 1832-33 to 1844-45, it appears that in the former session there were 613, and in the latter only 340.

Dr. Davis.—Sir James Paget delivered his lecture on the "Recent Progress of Anatomy and its Influence on Surgery," at an evening meeting on July 2, 1851, at the Royal College of Surgeons. It will be found in the *Medical Times and Gazette*, vol. xxiv., p. 29 *et seq.*

MEDICAL EVIDENCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It must occur to everyone that there is a sad miscarriage of justice in the trial of cases like that of Mr. Watson (involving a knowledge of abnormal functions of the brain) by an ordinary jury. To be competent to judge of a case demanding the most profound information on the most abstruse department of Medical science, would, it occurs to me, require a special jury of men who had made morbid functions of brain their particular study. Had the insanity been more "pronounced," in the ordinary sense, to the non-Professional mind, he would have been acquitted on the ground of non-responsibility. Because he committed no extravagant acts which violated the conventional ideas of society prior to the killing, he is considered by the jury to have been possessed of his reason, and responsible for his acts. Had they known that this particular form of insanity—melancholia—had arisen as a consequence of the very mental condition—that is, the education, age, sudden reverse of fortune, character, and position of Mr. Watson—no doubt they would not have demanded evidences of mania incompatible with that particular form of the abnormal function of brain.

I have often seen, both in America and England, juries empanelled, who were ignorant of the rudimentary principles of science, yet whose province it was to decide a case involving the most complete scientific knowledge. In Mr. Watson's case it is said by the majority of people, "Had he been a man of no position, the plea of insanity would not have been advanced."

It is exactly these prejudices, outside the merits of the case, which so powerfully bias the mind of the uneducated jury. Collateral circumstances, which are repulsive to conventional ideas, will inevitably cause a conviction of the accused, irrespective of the abstract merits as to his guilt or innocence in relation to the cause which instigated the commission of the act for which he is being tried.

I remember, some years since, a trial for murder in New York. The accused, whose character prior to the event was irreproachable, had, after the killing, which was entirely unpremeditated and in self-defence, and for which he would have been acquitted by any jury in England or America had he at once after the act proclaimed the same to the world, unfortunately become panic-stricken, cut up the body, salted it, and packed it in a box, which he shipped for New Orleans. Decomposition having set in prior to the vessel's departure, the cause of the foul emanation was investigated, the box found, also the carman who brought it. These facts soon led to the discovery of the homicide. The man was duly tried for murder, found guilty, and condemned to be hanged. It was, at the time, a notorious conviction that the fact of pickling the body had produced such a violent repugnant antagonism to conventional ideas, that that fact alone caused the jury to find him guilty, though, in an abstract sense, "the pickling" had nothing to do with his guilt or innocence. The above illustration will enable me to state that, in the case of Mr. Watson, the jury who found him guilty seemed to have been doubly prejudiced—1st, because no act of insanity was committed by the accused according to their conventional ideas of what constitutes insanity; 2ndly, they were prejudiced in the reverse sense to the New York case, as they actually recommended him to mercy in consequence of his advanced age and his previous good character. Had they been educated men in the sense of understanding the abnormal function of the brain arising from sudden reverse of fortune, in a man of special characteristics, education, advanced years, etc., they might have been more influenced by the evidence of so able an authority as Dr. Maudsley, who positively pronounced the accused to be labouring under that most insidious of all mental diseases—melancholia.

For two years I was connected with one of the most extensive lunatic asylums in the United States. The melancholic patients were always marked as being obdurate or insusceptible of kindness; everything connected with themselves was viewed through the most dreary and dismal medium; and when aroused to think, for, in most cases, the brain seemed

to be in a most listless, apathetic condition, but if suddenly aroused they would give way to the most violent impulses—that is in true, cases of melancholia, which was invariably accompanied with a suicidal disposition. My object in calling attention to this subject is to record the apparent indifference with which so able an exposition of melancholia by Dr. Maudsley was treated by the jury, who evidently were influenced more by the social position of the accused than by the condition of his brain involving his mental responsibility.

I am, &c.,
199, Brompton-road, S.W., Jan. 13. ROBERT H. COLLYER, M.D.

* * A correspondent (J. F.) writes from South Australia:—

"I read with great interest your account of the Leeds General Infirmary. I commenced as house pupil to the late Samuel Smith, Surgeon to that Infirmary, and was a dresser at the Infirmary for five years—before the Factory Act was passed; the Act reduced the operations fearfully. I was also house-pupil to Mr. Caesar Hawkins—for whom I have the highest regard—and afterwards curator to the Leeds School of Medicine: myself and another man made the great bulk of the anatomical museum which they now possess. My object is to mention that the name of Samuel Smith is not mentioned by Sir Wm. Fergusson in relation to lithotomy. I see there are some lithotomy knives named after Sir William. I am surprised Sir William should allow his name to be attached to them, as he has not the remotest claim whatever. The late Sir Charles Bell was the first that used the common scalpel. A Mr. Barlow added a probe point, with a long steel neck and an octagon wood handle—an awkward instrument. When I was a pupil with Smith, he added the probe point to the scalpel, and had three sizes—large, middle, and a small knife for children—and they are now made by Gay, of Leeds. Smith was the most successful operator for stone that ever lived. I was always his assisting genius, when a pupil, and was with him at twenty to twenty-five operations, and all good recoveries—not one died. I am only aware of two patients dying that he operated on during his whole life, and he was Surgeon to the Infirmary for about forty years. He was equally successful in all his other operations. He could never bear to have anything he did made public."

We are not acquainted with the lithotomy knives said to be named after Sir William Fergusson. That distinguished Surgeon certainly lays no claim to originality in this respect in his published writings. We believe that he follows the method, long and brilliantly practised by Mr. Liston, of employing a sharp-pointed bistoury for the first incision, usually substituting for it a probe-pointed knife in completing the incision of the prostate. The knife used by Sir Benjamin Brodie differed hardly at all from that employed by Mr. Samuel Smith. Both instruments consisted of scalpels with rather wide bellies, the back of the blade being continued for a few lines as a blunt probe. The only essential difference between the old gorget and the probe-pointed bistoury referred to by our correspondent is, that with the gorget the depth of the incision depends mainly upon the breadth of the instrument; while with the bistoury the angle it forms with the staff when pushed through the prostate regulates the size of the incision. The complaint usually lodged against the gorget is a supposed liability to slip; but to this accident the blunt-pointed knife—as has been pointed out by Sir Henry Thompson—is surely quite as liable.

THE USE OF THE SOIL-PIPE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In 1860 I printed "A House for the Suburbs, socially and architecturally sketched," and, in a second edition the next year, stated explicitly that I had found it advantageous in practice to continue the soil-pipe quite up to the gutter, letting it serve also for rainwater, and where that could not be done, to carry a small pipe upwards through the roof—above windows, for instance—in the same or any immediately contiguous edifice. That edition has been long out of print, but the particulars somewhat amplified are repeated in the issue of last year. My sanitary application of the soil-pipe, therefore, dates previously to 1861.

Two very important improvements distinguish the modern sewerage of London—flushing and ventilation. By the first an end has been put to those enormous and stagnant deposits that went on accumulating and putrefying for years, and were at length removed by opening the surface of the roads. The advantage of this system cannot be over-rated, especially if the fouler effluvia and more dangerous consequences are due to secondary decomposition. By ventilating the main sewers at frequent points, the upward pressure of the gas is relieved, and the exhalations are rendered innocuous by being passed through baskets of charcoal. Were the common sewers of the streets (which are under the care of district boards) dealt with as carefully as the main sewers under the Metropolitan Board of Works the quantity of foul air entering the drains of houses would be greatly reduced.

In 1865 I addressed the Metropolitan Board on the applicability of the soil-pipe to the ventilation of sewers and drains generally, and the next year a committee suggested that a competition should be instituted, and a premium paid for the best communication, but the matter appeared to slumber, though not so in effect; for the Parliamentary powers, pointed to in my letter as requisite, will be acquired under the Building Act expected to pass the Legislature next session. District boards will thus, by means of by-laws, be able to cause every soil-pipe to be left open at the top.

Cases are understood to have happened where officials have connected the public drains with external pipes of private houses, but legal proceedings having been threatened, the nuisance so caused had to be abated. Common rain-pipes are unfit for the purpose, because their loosely fitting socket joints would allow the gas to escape near the ground, but the soil-pipe is continuous, and all the joints rendered perfectly air-tight by solder. Every inlet is trapped, and it should be distinctly understood that I advocate every possible precaution of the kind, and add another which leaves no pent-up body of foul air under pressure ready to force its way through them.

It has been objected that if the soil-pipe is to become a ventilator it should not be used as a rain-pipe, on the assumption that where rain-water is passing down the sewer gas would be unable to ascend; but this is a mistaken view. The object of opening the head of the pipe is not primarily to induce a rush of foul air from the sewers, but to give free vent to such as it happens to contain. If, therefore, the volume of rain-water were so great as to form a sort of moving plug, forcing all other bodies downwards before it, and no foul air could consequently ascend, the chief object would be gained. But the probability is that there would always be a

sufficient void to allow an ample upward current of air. It would be better, if necessary, to increase the capacity of the pipe, since the pure water could hardly fail to act as a washing and purifying agent on the gases rising through it.

I conceive that from the extreme lightness of hydrogen, which is the carrying medium of the gaseous impurities of sewers, they would rise to a considerable elevation before the equality of gravity would take place, and the diffusion must be so extensive as under the natural movement of the atmosphere to meet every sanitary requirement. Whether by largely diluting sewage with water and increasing the quantity of air in contact with it the amount carried off as vapour may be to some extent augmented, is a question for chemists; but it is certain that whatever quantity finds its way into house-drains should be passed freely through the building, and for that purpose no other means has equal facilities with the soil-pipe.

I am, &c., THOS. MORRIS, Architect, M.I.B.A.
Carlton-chambers, 12, Regent-street, Dec. 21, 1871.

P.S.—With some attention to their manufacture and methods of fixing, stoneware pipes would prove admirable substitutes for lead. I have so applied them.

APPOINTMENTS FOR THE WEEK.

January 20. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. A Letter will be read from the Board of Trade, "On the Water-Supply of London."

An Address by Dr. F. Crace Calvert, F.R.S., F.C.S. GRESHAM COLLEGE, 7 p.m. Dr. E. Symes Thompson, "On the Pulse." ROYAL INSTITUTION, 3 p.m. Mr. Wm. B. Donne, "On the Theatre in Shakspeare's Time."

22. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Second Lettsomian Lecture, by Dr. Habershon, "The Liver and its Bloodvessels."

23. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL MEDICAL AND SURGICAL SOCIETY, 8½ p.m. Dr. Rutherford, "On the Excitability of different Parts of the Trunk of a Spinal Nerve." Dr. C. A. Gordon, "On Forms of Surgical Returns and Reports to be used in War."

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

24. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

SOCIETY OF ARTS, 8 p.m. Meeting.

25. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

26. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Meeting.

ROYAL INSTITUTION, 9 p.m. The Most Rev. the Archbishop of Westminster, "On the Demon of Socrates."

VITAL STATISTICS OF LONDON.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.61 in. The highest was 30.01 in. on Friday at noon, and the lowest 29.11 in. on Monday morning.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

† Through an error which was discovered on the revision of the enumerated numbers at the Census Office, the correct population of Manchester at the middle of 1871 was 351,171, and not 356,099, as published in recent Weekly Returns. The number for the middle of 1872 (352,759) shows, therefore, an increase of 1271 upon the corrected number for 1871.

ORIGINAL LECTURES.

LECTURES ON THE
PRINCIPLES OF THE TREATMENT OF
FEVER.

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College
Hospital.

LECTURE II.

(Continued from page 32.)

STATE OF THE BLOOD PRIOR TO AN ATTACK OF FEVER.

THAT the blood is not in a healthy state prior to an attack of fever is proved by many facts, though analyses of the blood during the period of incubation of fever poisons are wanting. The bioplasm is probably in larger proportion than in the healthy state. The minute particles of living matter which I have shown to exist in the blood in vast numbers, and to pass through the walls of the capillaries in certain cases, (a) probably increase in every feverish condition. But, besides this, the white blood-corpuscles and the masses of bioplasm in the walls of the vessels and in the tissues become larger, as was described in my Cattle Plague Report, published in 1866. The increase of the bioplasm in the blood, in the vessels, and in the tissues is preceded by the formation in the blood of pabulum adapted for its nutrition. This soluble nutritive matter would have been converted into excrementitious substances in the normal state, and its accumulation in the blood would have been thus prevented; for, as is well known, in health, excess of food introduced into the stomach does no harm, because the amount over and above that required for the system is soon converted into excrementitious matters, which are excreted and removed altogether from the body. As an indication that the blood is changed, I need only advert to the fact that it has been noticed over and over again that slight wounds or abrasions of the skin do not heal when fever poison is circulating in the blood. The bioplasm of the wound grows very fast, and time is not allowed for cicatrization. Perhaps very minute particles of the bioplasm which multiply in the blood are continually escaping, suspended in the serum through the walls of the capillaries. Unquestionably the capillary circulation is less free than in health, and sometimes this is so marked as to cause a peculiar and characteristic dusky appearance of the skin, which often attracts the attention of friends.

In many instances evidence of derangement of the blood is afforded by the fact of the existence of considerable disturbance in the healthy functions. The appetite is bad, there is giddiness, and perhaps headache, besides which the nervous and muscular systems are so disturbed as to cause a feeling of fatigue and general languor and discomfort. Muscular movements are accompanied by pain and uneasiness, and the patient is disinclined to move about. Very little exercise gives rise to great fatigue, and every movement of inspiration becomes an actual effort. Oftentimes, however, these derangements are not sufficient to attract attention; and when the fever breaks out the patient appears both to himself and to his friends to have passed almost suddenly from a condition of health into what may become a very serious and perhaps dangerous fever. Sometimes during the time when the poison is growing and multiplying in the blood, the person is over-fatigued, and only able to perform his usual amount of work by dint of making a great effort; or by an unfortunate coincidence he may have been compelled to work unusually hard, while at the same time, in consequence of his appetite being bad, he has been able to take little sustenance. The severity of the subsequent fever, as well as the danger to life, are much increased by such circumstances and by want of care during the period of incubation. But the feverish symptoms may come on so gradually that the patient himself is hardly aware he is really unwell, although his temperature may be four or five degrees above the normal standard. Some persons have so much courage that they refuse to yield until they are no longer able to move about, and the state of fever is thoroughly established. If, however, the patient rests much during the ante-febrile period, takes beef-tea and a little wine, and makes no effort to conquer the feelings of lassitude he experiences, he will be more likely to

pass through the illness favourably, and, if he have a severe attack, battle successfully against it, than if his strength be exhausted before or during the first few days of the feverish state.

There is, however, reason to think that changes have been going on long prior to the development of the fever, and that the body of the victim of fever poison has been prepared for the growth and multiplication of disease germs by a long course of preliminary change. I think that the condition favourable to the contraction of fever slowly results from long exposure to circumstances adverse to health. And although an attack of typhoid, for example, may be a direct consequence of exposure to the emanations from filth, it is quite certain that the body and the blood of the person attacked have been seriously deranged by previous exposure to noxious influences, or to circumstances likely to exhaust the energy and depress the health. In some instances we may obtain evidence that for many weeks or months the organism has been unconsciously, but most surely, prepared for the reception of the poison. It is the development of this state of derangement that we so much desire to interfere with. Could we succeed in preventing the preliminary changes in the blood, or restore that fluid to its healthy condition when it is only slightly deranged, thousands of lives would be saved annually.

SUDORIFIC REMEDIES, DIURETICS, AND PURGATIVES.

Under this head I propose to refer very briefly to some of the remedies which I have myself been in the habit of most frequently prescribing. The number of sudorific, diuretic, and purgative drugs is very large, and many of them act in the same manner. Whether, for example, we employ a citrate or a tartrate probably matters, in the majority of cases, very little; but the tendency to diarrhoea or to constipation might, in certain instances, influence our choice of one or other of these salts. Of all the saline sudorifics usually prescribed during the feverish state, I believe *liquor ammonia acetatis* to be one of the most useful. Some consider it, as well as other alkaline acetates and citrates, to be of little or no value; but, from experiments tried upon myself, I feel convinced that the solution of acetate of ammonia does good in the feverish condition of body. Many years ago I used to suffer greatly from quinsy, and I found that, when I took plenty of acetate of ammonia, the swollen tonsil soon became less. My experience of its use in others is equally satisfactory. I think that we usually give it in too small doses. Half an ounce every four hours for an adult is not too much, and it may be continued for several days. I think it really acts upon the liver as well as the secreting organs of the skin and on the kidneys; but, besides this, I believe it does good by promoting the removal of saline and other constituents from the tissues, and favouring their elimination. The feeling of tension and general discomfort which is experienced at the commencement of an ordinary catarrhal attack is often relieved after two or three doses of liq. ammon. acet. have been taken.

A glass of hot spirits or wine and water, a dose of sulphuric ether and sweet spirits of nitre or a little ipecacuanha, a small dose of Dover's powder or of antimonial (James's) powder have been found to work wonders. Even a tumbler of hot water, or a basin of hot gruel or arrowroot, will relieve the feverish symptoms for a time, by promoting perspiration. Diuretic medicines also enjoy a high reputation for curing feverish attacks; bicarbonate of potash, bitartrate of potash, acetate and citrate of potash, and a number of others are in common use. Nitre (nitrate of potash) dissolved in plenty of water, or added to linseed tea or some herb tea, is a very old as well as a very useful remedy. If the kidneys are perfectly healthy their free action should be encouraged, as diuresis affords the greatest relief. There are some persons whose sweat-glands act very slightly, and upon whom neither sudorific remedies nor the hot bath exert much influence, but whose kidneys, on the other hand, are easily excited to act most freely, and respond almost immediately to the simplest diuretics—even a glass of water.

Purgatives.—As already mentioned, the opinion that an attack of impending illness has been averted by free diarrhoea is very generally entertained, and is probably correct. It seems possible that in this way substances capable of producing a deleterious effect upon the economy may be removed, and it seems not impossible that in some cases even disease germs may be carried out of the system before the time has arrived for them to produce their characteristic effects; and it is, at any rate, certain that morbid materials which may have been for some time accumulating in the blood may be in this way directly removed; and at least, in this respect, the body will be in a more

(a) *Transactions of the Microscopical Society*, December 9, 1863, "On the Germinal Matter of the Blood," etc.

favourable condition to bear an attack of acute disease than would have been the case had such noxious materials still remained in the circulation. Moreover, many of us, after having been exposed to the influence of noxious gases and other deleterious agents, have been seized with symptoms similar to those which often precede a specific feverish malady, but have been completely relieved by a sharp and sudden attack of diarrhoea. These and many other circumstances which I will not stop to recount have been considered by many to justify the old-fashioned practice of giving purgatives at the commencement of an attack of acute illness, or on the occurrence of symptoms which seem to portend an attack. Like other routine practice, this has been rightly condemned; but nevertheless, I believe it to be thoroughly sound practice in many instances, and I think that of late years patients have been allowed to suffer from great inconvenience and discomfort for many days, when a simple purge might have produced immediate relief. To purge freely just as an attack of enteric fever is coming on would unquestionably be very wrong; but, on the other hand, what relief is sometimes afforded by the administration of a sharp purge in many a case in which we have reason to think pneumonia, or bronchitis, or pleurisy, or acute rheumatism is about to supervene!

I have more than once seen acute surgical fever, in which the temperature was 104°, following an operation, suddenly cut short by a dose of calomel; and even in cases in which the symptoms were such as to justify the inference that inflammation of the membranes of the brain was commencing, two or three good doses of calomel have apparently been the means of effecting a cure. Nor can I believe that the practice of giving sharp purgatives, so frequently adopted by the late Dr. Chambers, rested upon an altogether erroneous view, and was entirely superfluous and useless. I doubt if the old woman's detestable dose of warm salts and senna, administered with never-failing regularity once a month to each unfortunate little schoolboy of former days, was by any means an unwise or even an unscientific proceeding. I am not at all sure that many an organism which becomes the victim of disease-germs would not have been able to resist the contagion had the excreting organs been judiciously excited to moderate action at the proper intervals of time. It is probable that the occasional free action of the bowels, skin, and kidneys greatly diminishes the chance of contracting disease. Salts, senna, jalap, scammony, and cream of tartar are remedies very often used, in one form or another, by people who are their own Medical advisers, and who work hard; and many of those who waste enormous quantities of meat and beer, upon the false notion that these are required to give them the necessary strength, discover, as they get older, that a good purge every now and then affords the greatest relief, and they not infrequently communicate to others their own experience.

The various purgative saline waters—Carlsbad, Freiderichs-hall, Pullna, etc.—and purgative salts, such as Seidlitz powders, salts of magnesia, soda, etc.—are largely taken by the classes who are not dependent for their livelihood upon muscular exertion, and who take far more nutriment than their system requires. It seems to me quite in accordance with reason to conclude that, where the excreting organs of the alimentary canal habitually act imperfectly, not only will great benefit result from the judicious use of certain purgative remedies, but that the blood may be preserved in such a state as to render the changes which occur in fever improbable, if not impossible.

Upon careful inquiry of those who are the subjects of feverish attacks, it will not infrequently be found that the health has been slightly deranged for some time previously; and that, among the many slight or trivial symptoms experienced, there is almost always evidence of imperfect and irregular action of the alimentary canal, and of the many important excreting glands connected therewith.

Who can suppose that the very imperfect action of the large bowel so frequently experienced by those who live in cities can conduce to the healthy condition of the tissues? Excrementitious materials which should be entirely removed get reabsorbed into the circulation, and, though no doubt changed and perhaps excreted from other surfaces in a different state, cannot fail to derange, at least to some extent, the delicate action of the nervous and muscular tissues. The detestable odour of the breath so disagreeable both to the patient himself and his friends, and more rarely the strong-smelling matters secreted by the sebaceous glands of the skin, are due to this cause in some instances; indeed, the experience of every Practitioner must afford many convincing proofs of the correctness of this reasoning: the patients themselves are well aware of the great benefit which results from an occasional free action of

the bowels, and, indeed, not a few have discovered by experiment that in order to keep themselves in health it is necessary to take at certain intervals a dose of purgative medicine. Of all purgatives, mercurial preparations are of the greatest use in these cases. Purgative treatment is by no means necessary for all persons, but it is unquestionably advantageous to many. Not a few working men have not only discovered that an occasional purge is necessary to keep themselves in a state fit for work, but they have found out by experiment the particular kind of purgative which produces the best effect. Those who have of late years been loud in their condemnation of the use of mercury are perhaps not aware that the much-maligned calomel enters into the composition of most of the purgatives which enjoy the highest repute amongst labourers and artisans, as well as the powders which the mothers of families in every part of England have found to be most beneficial in the treatment of many of the ailments from which their children from time to time suffer. Podophyllin is also a valuable purgative, but somewhat uncertain in its effects. It should be given in doses of not more than one-third of a grain with colocynth, rhubarb, or some other purgative. It should be distinctly borne in mind that the object of giving a purgative is not merely to unload the large bowel, for purgatives are often eminently useful in cases in which there is certainly no faecal accumulation. As has been already intimated, by purgation fluid is rapidly removed from the blood, and with the fluid so passing away many other things the presence of which is deleterious escape.

The different classes of remedies, the action of which has been referred to, effect a change in the composition of the blood. Diuretics, sudorifics, and purgatives promote the removal from the circulating fluid of substances which accumulate in it, and which are calculated to disturb healthy action if they are not got rid of. No doubt, in perfect health, the exercise taken, the fluid drunk, and certain materials taken in the food promote the action of these excretories sufficiently; but the artificial conditions, especially as regards insufficient air and exercise, under which most of us have to live, necessitate attention to these points. By all the remedies above referred to the removal from the blood of fluid holding in solution various substances is insured. Neither perspiration, nor diuresis, nor purgation can occur without the escape of much watery fluid. By the removal of this fluid, thirst is excited, and a demand for the introduction of more fluid—which, in its turn, is got rid of—soon follows. In this way various soluble and some imperfectly soluble substances which had accumulated in the blood in undue proportion are gradually removed, and the feverish condition may cease. In other words, the healthy state may be restored by the use of appropriate remedies in efficient doses. The illness consists of the non-removal of these substances and their gradual accumulation, until the normal action of many tissues, and particularly that of muscles and nerves, is disturbed. In slight cases a similar result is obtained by rest and by withholding food for four-and-twenty hours, and the cure (!) of the feverish condition is brought about as effectually as by the administration of remedies, though perhaps less pleasantly, and oftentimes more slowly.

(To be continued.)

DEATH FROM AN EXTEMPORISED VAPOUR-BATH.—On Wednesday, Dr. Lankester held an inquest at the Middlesex Hospital, Charles-street, on the body of John Thrussell, aged 8½ years. Mrs. Thrussell, of 38, Newman-street, mother, said: A fortnight ago last Sunday she got the water ready the same as usual for a vapour bath. She placed him on a chair, put a blanket round him, and fastened it to keep in the steam. She put a pail of boiling water under the chair, and into the water she put a red-hot iron-heater. He had been ill from scarlet fever and inflammation of the kidneys. He was under Medical treatment. A minute scarcely elapsed till he screamed, "Oh! mother, take me up!" The pail, which was half full of water, was six inches from the bottom of the chair. It was the fourth vapour bath he had had. A juryman remarked there was a great difference between the red and white heat of iron. The Coroner remarked that the body was more sensitive to a damp than to a dry heat. Dr. J. A. Lycett, House-Surgeon, said he was brought to the Hospital on December 31, and died on the 13th inst. from extensive scalding of the cuticle over the thighs, and the destruction of the true skin on the back. The jury returned a verdict of "Death from accidental causes." [* * * A similar case was published in the *Medical Times and Gazette* ten years ago.]

ON THE
VARIETIES OF FEVER WHICH FOLLOW
SURGICAL OPERATIONS.(a)

By T. SPENCER WELLS, F.R.C.S.,

Surgeon to the Queen's Household and to the Samaritan Hospital.

LECTURE I.

GENTLEMEN.—As we walk through the wards here to-day you may see five patients all recovering after the operation of ovariectomy. The rise in temperature after the operation in two of them only pointed out a very moderate amount of fever. In one woman, from whom a very large tumour was removed—forty-one pounds fluid and ten pounds solid—the temperature only rose from 98·8°, which it was before operation, to 101·0°. In another, where the tumour was twenty-seven pounds liquid and eight pounds solid, the temperature being 99·4° before operation, the highest point was 101·8° on the second day, and on the fourth day defervescence was complete. Both women go home to Lancashire on Saturday, within a month after ovariectomy. In the young girl at the top of the house, the curious fact was observed of the subsidence of fever immediately after the removal of the tumour. The explanation is that the cyst was suppurating. The fever was due to the suppuration, and as soon as the cause was removed the effect passed away. The girl is 21, but looks a mere child. She came in here on December 4, suffering extremely from distension of the abdomen, and I tapped her to give some temporary relief. She had been tapped three times before her admission here, and after one of the tapplings had suffered from high fever, with double pneumonia. After a pailful of fluid had been removed from one large cyst, I found some semi-solid masses adherent high up under the right false ribs; the dulness on percussion over the cyst being continuous with the liver-dulness. But the uterus and pelvis were free, and it was arranged that I should perform ovariectomy in a few days. For three days she felt much better. On the fourth day she complained of headache and giddiness; and on the morning of the fifth day after the tapping, I found the temperature had risen to 103·2°; at night it was 103·6°. This temperature was maintained on the next day. The respirations rose to 40 in the minute, and the pulse became intermitting every tenth or twelfth beat. I had no doubt whatever that inflammation of the cyst had followed the tapping, and that the only means of saving the girl's life was to remove the cyst. But the operation was a formidable one in so fragile a girl, debilitated by previous pneumonia, and actually in a state of high fever, the temperature ranging day after day from about 102° in the morning to between 104° and 105° at night. I hardly know a more painful position in which a Surgeon can be placed. He sees a patient being killed by a tumour which he knows he can remove, and yet he fears that the removal can only hasten death, unless some change which can hardly be expected in the general condition of the patient place her in a more favourable state for undergoing a great shock, and repairing the damage done by the incision and the separation of extensive adhesions. If he operate too soon, or if he wait too long, the patient is lost.

I was prepared in this case to operate on very slight encouragement from improvement in the symptoms, but they continued to be very unsatisfactory. On the eighth and ninth days after the tapping the girl was frequently sick. She had bad headache. The skin was hot and dry; the tongue dry and hard; and there was constant short dry cough, with difficult expectoration of viscid mucus. The temperature ranged from 103° to 104°; the pulse 120 to 136; the respirations 36 to 40; and wherever the respiratory murmur could be heard in both lungs, it was accompanied by crepitation. The skin failed in its cooling function, and the bronchial effusion was, I suppose, an attempt to supplement the defective cutaneous exhalation. Reading Dr. Wilson Fox's admirable essay on "Hyperpyrexia," but not daring to try immersion of the body in cold water, I began a system of sponging the whole body with cold water every two hours, and placing the head on an indiarubber cushion filled with iced water. When we began, the temperature was 104°. It was twelve hours before it fell to 103·6°. In four hours more it was 102·8°; and in twenty-four hours after beginning the sponging and cold pillow it was 102°, or 2° lower. It took twenty-four hours more before it fell to 101°; but on the third day it was down to 100·4°. Then we gave up sponging, as the

bowels acted three times; but at night the temperature rose again to 102·8°, and the pulse to 132, and respiration to 40. Then the sponging was resumed. In four hours the temperature fell to 102°, and in four hours more to 101·6°. The next day we gained another degree, the temperature at night being 100·6°; but the pulse was 130, and the respiration 44. The day after, the temperature ranged from 101° to 100·4°, and the pulse was 120. Next day we had a decided gain; the pulse was 108, and the temperature 100°, so we decided to remove the cyst without more delay—not without fear, however, that the patient might not live through the operation. I operated at nine in the morning of the seventeenth day after the tapping. The temperature was 99·6°. Expecting a good deal of pus to be in the cyst, I opened it where there were adhesions, and pressed out thirteen pints of purulent fluid before I separated any adhesions or opened the peritoneal cavity. Then some extensive adhesions were easily separated, and a large cyst removed. The pedicle was long, and was fixed by a clamp outside the abdomen. In an hour the thermometer only marked 98·6°; in two hours 98·4°—a fall of 1·2° within three hours after the operation. Then some reaction set in, and we had a rise to 99·8° in the afternoon, and 100·4° at night. During the next three days we had only a range of 1°—99·4° to 100·4°—the pulse falling to 108 and the respiration to 30. On the seventh day after operation the pulse was down to 100, and the temperature to 99·4°. On the eighth day the normal temperature was attained, and the next day, after some return of sickness, it was as low as 97·2°. Since then we have had a recurrence of the catamenia, a normal temperature, and a gradual recovery in appetite and strength. You see how bright and cheerful she looks now. I doubt whether anybody who saw her three weeks ago would recognise her.

I have seen other cases where high fever, due to the presence of purulent or fetid fluid or gas in an ovarian cyst after tapping, has immediately subsided after the removal of the cyst. About a year ago I saw a lady, 58 years of age, with Dr. Webb, of Woburn-place, who, between October, 1869, and January, 1871, had been tapped eight times. After the last tapping, a fortnight before I saw her, she suffered from severe abdominal pain and tenderness, followed by incessant vomiting and rapid increase in size. Here are some of Dr. Webb's notes:—"January 24: Morning temperature, 99·4°; evening, 101·2°. Pulse 120. Stomach rejects everything. Urine loaded with lithates. No albumen. January 25: Morning temperature, 99·2°; evening, 102·2°. No sleep. Constant sickness. January 26: Morning temperature, 99·2°; evening, 101·4°." On the 27th I removed the tumour. It contained thirteen pints of excessively fetid purulent fluid, and the solid portion weighed five pounds and a half. I had plenty of Condy's fluid ready in the vessel which was to receive the fluid, and every sponge was burnt as it was used. Unusually firm and extensive adhesions had to be separated. Yet, in six hours after this operation the pulse was down to 100, and the temperature to the normal standard of 98·4°. Next day it was 98·2°, and the pulse 96, and I have seldom seen a more uninterrupted recovery. There never was anything like fever-heat even once after the cyst was removed.

So with a patient on whom I operated at Oxford, in 1869, with Dr. Jackson and Mr. Briseoe. A lady, aged 47, had suffered for several years from an ovarian tumour. When the abdomen was excessively distended she had an attack of severe pain, and I tapped her in London for the first time on December 17, 1868, removing twenty-seven pints of fluid. Six days after the tapping she returned to Oxford, suffered during the journey, and, after a few days, was confined to her bed with all the symptoms of cyst-suppurating. I found her, on January 30, 1869, much emaciated, with a cadaverous aspect, high temperature, and pulse of 140. I tapped her again, and removed about ten pints of sero-purulent fluid. Some little relief followed this tapping, but after a few days the state became almost hopeless, and death was expected day after day. At length, after anxious consultations, we decided to give the patient the very poor chance of removing the suppurating cyst which was the cause of the fever, and I operated at Oxford on February 10, 1869. I so arranged that the fetid fluid in the cyst should flow at once into a vessel containing carbolic acid, and it did so but imperfectly, as the contents were too thick to pass through a tube, consisting chiefly of large flakes of purulent lymph-like clots—muco-colloid. These flakes and the fluid were excessively fetid, and weighed eleven pounds. Adhesions were separated, two vessels tied, a long pedicle secured in a clamp, and a semi-solid mass which weighed ten pounds was removed. In two hours after the operation the patient was much stronger than before it. The

(a) Delivered Wednesday, January 10, 1872.

pulse had been very feeble at 140. It became stronger, and fell to 120. The kidneys and skin began to act freely, and, although three opiates were required in succession to relieve pain, Dr. Jackson wrote the next evening, saying "there has hardly been a bad symptom; pulse 112, and of fair volume." Of course a state causing much anxiety continued for several days; but, thanks to the judicious treatment and constant care of Dr. Jackson and Mr. Briscoe, recovery was complete, and the patient has regained the most perfect health. I don't think I ever operated before or since under circumstances apparently so hopeless, and I never saw a more striking example of the subsidence of fever immediately following the removal of its cause.

In all these cases it appears undeniable that the general fever was due to the inflammation and suppuration of the cyst, or to the decomposition of the fluid contained in it. Peritonitis, even if present, had very little to do with the fever. The blood must have been altered in some way by the absorption, or the passage into some open vessel, of the contents of the cyst. But this question is one which we will examine some other day.

ORIGINAL COMMUNICATIONS.

ON PARTIAL CONVULSIVE SEIZURES, WITH PLUGGING OF CEREBRAL VEINS.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P.,

Physician to the London Hospital, and to the Hospital for the Epileptic and Paralysed.

(Continued from page 5.) (a)

Sequence of Spasm in Convulsive Seizures.

WHEN a patient has an epileptic fit of great severity, it is impossible to write down a precise account of what takes place. There is little difficulty in describing its suddenness, severity, and continuance; but to observe the order in which parts are reached by the spasm is very difficult, because the spasm quickly becomes universal, and the parts affected are affected nearly contemporaneously. In cases of partial convulsions we manage better. In the preceding case many points were observed, but it will be seen that in no one fit was it possible to note the whole of the phenomena. In such cases there are three things to do. We shall illustrate by this case, putting in order the things observed in several seizures. (1) We have to note the range of the spasm—the area involved. In this case it affected the left side of the face, turned the two eyes to the left, fixed the respiratory muscles, and there was faint movement of the left arm. (2) We have to note the order in which parts are seized. In this case the order of involvement was that the mouth (all round) was first in action, then the mouth was drawn to the left, then both eyes to the left, the head to the left, then the eyelids of both sides (the left the more) closed; the thorax was affected early and the arm late. But the sequence in partial convulsions is not simple; the spasm of the part first attacked does not cease when the next part is attacked. There is a Compound Sequence. (3) The third thing to observe is the kind of spasm, whether tonic or clonic. It was scarcely practicable in this case to do more than note that it was chiefly clonic; no doubt there was a transient stage of tonic spasm.

It will be observed that in describing the spread of the spasm the muscles in action are not named. The fit is a discharge of a centre which does not represent muscles directly, but which represents them indirectly as movements. There is, however, from the distribution of nerves to muscles by anatomically recognisable nerve-trunks to the centre, a gradually increasing complexity—an increasing harmony. Hilton's observations show that even in the ultimates of the body there is incipient co-ordination—incipient harmony. No doubt the very muscles represent in the most general form the method of co-ordination of the highest centres. But in noting what takes place in a fit, it is better not to speak of the muscles, but to put down what movements take place. When this is done we can afterwards consider the play of the several muscles we suppose to have been directly concerned.

Just as there is an increasing harmony of movement from the muscles to the highest nerve-centres, so, no doubt, there is an increasing melody. Harmony of movements is space

co-ordination—the co-ordination of simultaneous movements; melody of movements is time co-ordination—the co-ordination of movements in succession. The latter is scarcely traceable, however; but we are warranted in assuming that from the (nearly) equal and simple intervals of respiratory movements to the most unequal and intricate intervals of movements represented in the highest centres, there is a gradually increasing melody. The two kinds of co-ordination are inseparable in health, and in disease we have to note abnormal conditions of both; we have to observe not only the region affected by convulsive movements, but the intervals betwixt movements. As we observe that increase in range is from the voluntary to the automatic, it seems probable that, at the same time, the intervals of the movements developed become shorter. It is very difficult to note the latter in cases of convulsion ordinarily so called. But, using the word "convulsion" in an unusually extended sense, we observe that the convulsions from disease of the cerebral hemisphere are chiefly clonic; and that the convulsions of tetanus, which affects more automatic movements (those represented in the cerebellum?), are chiefly tonic. In tonic spasm the intervals are so short that the very "idea" of succession is lost; the intervals are indeed bridged over, and there is, in a sense, no apparent movement—as the humming-top, when in excessively rapid rotation, seems still.

In this case the lesion was not sufficiently local to enable one to conclude that fits beginning in the face show damage to any particular convolutional region. For instance, the fits may have been owing either to discharge of the grey matter of the convolutions of the temporo-sphenoidal lobe, or of the island of Reil. In most cases of convulsion beginning unilaterally the cerebral lesion is very extensive. I shall shortly, however, report a case of convulsion beginning in the left thumb, in which there was a tubercular tumour, the size of a hazel-nut, in the hinder part of one convolution—the third right frontal convolution. By numerous observations of this kind we may confidently expect to arrive at clearer notions on localisation of movements.

FOOT AND MOUTH DISEASE.

By J. C. GOODING, M.D.

IN the autumn of 1869, when Mrs. — was suckling an infant eight months old, and was herself drinking about one pint and a half of milk daily, she complained of soreness of the gums and of the roof of the mouth. Shortly after, the infant exhibited disinclination for the breast, crying when pressed to take it. On examining the mouth, the gums of the upper incisors were found to be swollen, red, and tender. About this time, the husband of Mrs. — experienced soreness of the gums and palate, preventing the use of the brush; he, too, had been taking about a pint of milk daily. Tenderness of the feet on walking, but without any visible change in the appearance of the feet, being now complained of by the lady, "foot and mouth" disease suggested itself as an explanation of the phenomena I could not account for; and on inquiring of the milkman as to what he did with the milk of the diseased cows—some of which he admitted having ill with foot and mouth disease—he said, after a little equivocation, that he mixed it with that given by the healthy animals. On obtaining a supply of pure milk, and without any special treatment, the symptoms in a few days disappeared. A second child, an invalid, three years old, had no symptoms of the disease, although subsisting chiefly on milk; but this was kindly supplied by the clergyman of the parish, from his own cows.

On November 21, 1871, I was called to see an infant twelve months old; he had four upper incisors, and two lower; the upper were embedded in very swollen, red, and hot gums, and the roof of the mouth was also deeply congested. The child was somewhat feverish, but pallid and fretful. The lower gums were of natural appearance. The close resemblance of this to the other cases led at once to the diagnosis of foot and mouth disease. I directed the mother to feed the infant with Nestle's bread and milk flour alone, and to make inquiries as to the health of her milkman's cattle. On the morrow, the pint of milk which had been ordered for the infant was given to three older children. Within two hours the youngest, aged three years, was taken ill with vomiting and diarrhoea, which required Medical treatment; the second, aged seven years, with vomiting only; the eldest, aged nine, did not apparently suffer. These children were quite well

(a) In the first line of the paragraph, page 5, containing an account of the autopsy, for "left side," read "right side."

before taking the milk. The baby, in three days, had quite recovered from the mouth affection, without any treatment beyond change of food, but was irritable and restless, and required a few doses of bromide of potassium. Inquiry discovered that foot and mouth disease was prevalent among the cattle of the milkman.

In all these cases the gums of the upper incisors, and the palate immediately behind, were the first to show signs—swelling, redness, and heat—of the disease. The gums were not spongy, as in scurvy, but firm, yet bleeding slightly on brushing or when roughly touched; the roof of the mouth was corrugated and red, having the appearance produced by, and giving the sensation (as described by the gentleman) experienced on eating rank cheese. In the lady's case, the gums of the back teeth and of the lower jaw became affected subsequently, and in a slighter degree than those of the upper incisors. In neither of these cases did I observe vesicles or ulceration. The health was not appreciably affected in the adults, but the two infants—the one receiving its nourishment entirely from his mother, the other partly from his mother and partly from the cow—were fretful, pinched, and pallid, and slightly feverish.

It is obvious that an affection which is so fatal to beasts, and is conveyed by their milk to human adults, and to infants directly or through their mothers' milk, must considerably deteriorate the health. This deterioration has been very striking in two of the four cases I have seen, but has been quickly recovered from; yet one can easily imagine how fatal would be the continuance of a milk diet—so essential for infants, and so likely to be persisted in, on account of the very soreness of the mouth, which would probably soon become ulcerated—if the milk were derived from unhealthy cattle. That milkmen do mix the scanty supplies of the diseased animals with the milk given by the healthy I know; some do it, perhaps, in ignorance, but, I am sure, many knowingly and fraudulently.

I have penned my scanty experience, in response to your invitation of a few weeks ago, hoping that it may assist your recent correspondent in directing attention to the important article of infantile sustenance, the impurity of which, I believe, so often saps at the foundation the life of man.

Cheltenham.

DESCRIPTION OF
A DOUBLE TOURNIQUET,
WITH SHIFTING PRESSURE, FOR THE
TREATMENT OF POPLITEAL ANEURISM
BY COMPRESSION.

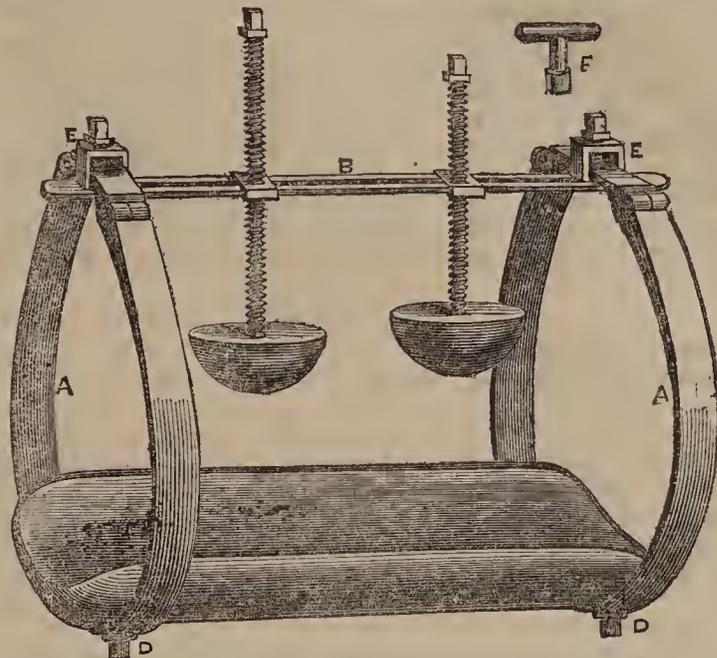

By FRANCIS A. BULLEY, F.R.C.S.,
Consulting Surgeon to the Royal Berkshire Hospital, Reading.

HAVING on several occasions noticed the difficulty of accurately regulating the pressure upon the femoral artery in the treatment of popliteal aneurism by compression, I was induced to direct my attention to the action of the instruments commonly in use for the purpose, with a view of securing a more exact application of the required pressure, and at the same time insuring as much as possible the comfort of the patient during the occasionally protracted progress of the cure.

It may have been observed, during the treatment by this method, that the single tourniquets usually employed, with the exception, perhaps, of the ingenious invention of Dr. Carte, cannot be made to maintain a fixed and immovable position upon the thigh, without screwing down the compressing pad upon the artery so tightly as completely to obliterate its tube, and in some cases to produce agonising pain in the subjacent nerves, with great venous congestion and swelling of the limb below the point of pressure, thus frequently necessitating the removal of the instrument from the limb. I believe it is now generally admitted that the complete obstruction of the arterial stream is not only not required in the treatment of aneurism by pressure, but, on the contrary, is calculated to defeat the object for which it is designed. If, thus, no blood were allowed to pass through the sac, there could be no deposition and lamination of fibrine in its cavity; and it is only by the production of a languid, retarded stream through the conducting artery that the necessary deposit can be certainly secured. The instrument of which I have given a drawing is capable of producing a regular retardation of the arterial current, with comfort to the patient; and I may further observe that it is in

accordance with Dr. Bellingham's recommendation upon the subject.(a)

The instrument is composed of two hinged steel hoops, A, united at the bottom by a padded iron plate, and above by a slotted bar, B, made movable at each end upon the horizontal portion of the hoop, to allow of its adaptation to either limb of the patient. The compressing pads are made to slide easily

along the slot in the bar by means of screw-nuts. The rings can be opened for use or removal by means of a nut and screw at D, where, also, they may be made larger or smaller, as the size of the limb may require. The whole of the nuts and screws are regulated by a key, as at F. The instrument from which the drawing was taken was made by Messrs. Weiss and Co., of the Strand.

TREATMENT OF CHOLERA
BY SUBCUTANEOUS INJECTION OF
MORPHINE.

By JOHN PATTERSON, M.D., L.R.C.S.,
Surgeon-Superintendent of the British Seamen's Hospital, Constantinople.

In an article in this journal on the cholera in Cairo in 1865, I expressed regret at not having tried the subcutaneous injection of medicines, having special reference to quinine. A recent severe epidemic in parts of this city and at Hasskieu, a village on the Golden Horn, the residence of a large English colony, has given me an opportunity of trying the effect of the subcutaneous injection of morphine on a sufficiently large scale to judge of its value. The first cases were treated by the usual remedies; everything rational was tried, and with the usual want of success. Completely disheartened at the inutility of treatment, I went prepared with the instruments and morphine, and, after consultation with my colleague, Dr. Werry, determined to give it a trial. A most unpromising case was selected. The man had been previously suffering from inflammation of the liver, was in deep collapse, pulseless, with rice-water purging, severe vomiting, and cramps. I injected a quarter of a grain of acetate of morphine. The result was beyond our expectations. In a quarter of an hour the cramps and vomiting ceased, the patient fell asleep, the skin gradually became warm and moist, the pulse returned. In two hours he awoke, and said he felt much better. The injection was repeated; he again slept for three hours. The reaction was perfect. He lived three weeks, and sank from typhoid exhaustion, as much produced by his old liver complaint as from the reactionary fever. The same good results followed in almost every case in which it was tried. In ordinary cases one or two injections of from one-quarter to one-half of a grain sufficed. In a few cases three injections were given, and only twice have I had occasion to give four. It was given even to very young children in doses proportioned to their age and condition. I speak more of well-

(a) "Compression by two or more instruments, one of which is alternately relaxed, is much more effectual than any single instrument, and in many cases the pressure can be maintained by the patient himself."—(Dr. Bellingham on the "Treatment of Aneurism," Corollary 5.)

marked cases. In the milder form, where the purging, vomiting, and cramps were severe, and collapse just commencing, we never wasted time on other treatment. An injection of a quarter of a grain was given, perfect quite enjoined, and bottles of hot water placed in the bed. The patient fell asleep and, as a rule, awoke nearly well. Many cases were thus nipped in the bud. I do not, of course, maintain that this treatment is a specific against cholera; I only claim for it that its action is more decided than any other treatment I have seen or practised, and that in the race against death we gain time for further treatment when it is necessary. It is long since I lost hope of the ordinary treatment influencing much the course of the disease, and, after treating more than a thousand cases at various times of epidemic, I am glad to report that this has really been of great service. My colleague, Dr. Werry, speaks equally favourably of the results obtained in his practice. I regret that want of time prevents me at present from giving the cases in detail; but the subjoined table gives at a glance the main results:—

	Number of Cases.	Recovered.	Dead.
Treated in the usual manner . . .	10	1	9
Treated by morphine injections . . .	42	22	20
Total . . .	52	23	29

But of the cases treated by injection, 8 were perfectly helpless from the first, being *in articulo mortis*, 1 had severe liver complaint, and 1 was far advanced in consumption; so that, in reality, we had 32 cases where the treatment had a fair chance, reducing the mortality to 10 in 32; and of these 10, 1 was 60 years of age, 1 within a few days of her confinement, and 3 hard drinkers.

In reference to the subject of cholera, I may here state that I am engaged in a series of experiments on animals, the result of which I hope soon to communicate. So far I have subjected dogs to the action of cholera-matter from the human subject. Injections under the skin, into the rectum, and feeding them with food sprinkled freely with cholera dejections have given negative results.

Constantinople.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

GUY'S HOSPITAL.

COMPOUND DISLOCATION OF HIP-JOINT, THE BONE THRUST THROUGH THE SKIN.

(Post-mortem Report, by Dr. MOXON.)

A RAILWAY porter was closing a door, and was knocked down by the train violently. Further particulars of the accident could not be certainly traced, as the accounts differed. One said that he got between the train and the platform. Another denied this, and said that he was doubled up in some indescribable way. It could not be learned how much blood he had lost; it was said a great deal. He was brought to Guy's Hospital, and died very quickly after admission. It was observed that he was bleeding from a wound in the back of the perineum, and that his left hip was dislocated. At the post-mortem examination by Dr. Moxon, a very singular injury was found. The left lower extremity was much swollen and discoloured throughout its whole extent. The position of the limb was that of dislocation of femur on dorsum ilii. When the body was on its face no wound was seen until the left great gluteal fold was forcibly lifted to expose the anal region. Then a large irregular rent in the skin appeared, its position corresponding to the junction of the left sacro-sciatic ligament with the tuber ischii. On passing three or four fingers into this hole a way was found through a pulp of torn muscles and blood-clot, till the fingers rested on the naked head of the thigh-bone; further dissection showed the gluteal muscles much torn up and infiltrated with blood. The head of the thigh-bone lay half an inch outside the great sciatic nerve, free under the remains of the glutei. It had escaped through the muscles immediately around the joint by passing between the quadratus femoris and the obturator internus. A portion of the head of the bone remained in the hip-joint, attached by the round ligament, so that fracture as well as dislocation had occurred. Evidently,

on the displacement of the head of the bone, some violent force, taking advantage of the leverage the limb afforded, had forced the head of the femur to plough its way among muscles, the thigh being flexed at the same moment that the bone was carried backward, and whilst it pivoted on the side of the pelvis; none but very enormous violence could effect such a terrible injury. Besides a scalp wound there was nothing else wrong discoverable. Death was attributed to hæmorrhage and shock.

ST. MARY'S HOSPITAL.

VERY LARGE MASSES OF WARTY GROWTHS ON LABIA MAJORA—REMOVAL BY KNIFE.

(Under the care of Mr. GASCOYEN.)

At the operations at this Hospital, on a recent occasion, we had the opportunity of seeing the largest warty growths on the external genitals of a young woman we have ever witnessed. The verrucæ presented the appearance of two large pendulous cauliflower- or cock's-comb-like tumours on each side of the vaginal aperture, in the position of the labia majora. Each lateral portion was as large as two closed fists, and the whole hung down between the thighs in one bunch much bigger than a foetal head. The surface of each was red and coated with scanty offensive secretion and a thin layer of cuticle. Besides the two large masses, there were several small condylomatous growths upon the skin surrounding.

The patient being under chloroform, and assistants at hand to press upon the neighbouring parts to prevent hæmorrhage, Mr. Gascoyen, having put the right lateral mass on stretch by seizing it with his left hand, excised the whole with an amputating knife. The course of the knife being well followed by the fingers of his assistants, very little blood was lost, though several large vessels required ligaturing. The edges of the wound were brought together by means of five or six wire sutures. Mr. Gascoyen then proceeded to remove the mass on the left side, and thinking the *écraseur* would cause less bleeding than had followed the use of the knife, he attempted first with a strong twisted wire, and afterwards with a chain *écraseur*; but the resistance offered by the base of the huge mass required such force to overcome it, that the attempts were unsuccessful, through the noose of each instrument breaking. The amputating knife, therefore, had again to be resorted to, and exactly the same course was taken on this as on the right side. Afterwards the small condylomata were snipped off with the scissors, a pad of cotton-wool laid over the perineum, and the thighs kept together by a few turns of a bandage.

In his remarks upon the case, Mr. Gascoyen stated that the patient had been for several months suffering from a discharge from the vagina, and that this, being of an acrid acid character, had so irritated the parts over which it passed that the papillæ had been stimulated to hypertrophy to the remarkable extent witnessed. He warned the students not to be deterred from the removal of similar growths from the labia for fear of the mutilation caused, as the reparative power of the parts was so considerable that he would undertake to say that in a short time his patient would soon present but little trace of the operation under which she had gone, even though the parts removed were so large.

CUTANEO-SUBCUTANEOUS NÆVUS IN MASTOID REGION OF AN INFANT—OPERATION BY LIGATION.

(Under the care of Mr. HAYNES WALTON.)

This was a circular, somewhat prominent nævus in the right mastoid region, which not only involved the skin, but extended deeply into the subcutaneous tissue, and was supplied by branches of the occipital and posterior auricular arteries. Mr. Walton remarked that the best mode of treating such nævi was by the ligature, and the best form of ligature was, he thought, that adopted by him in this case. Having passed a nævus needle, threaded, across the base of the tumour, he withdrew the needle from the double ligature, which he then divided. He next threaded the needle with one of the divided ends, and passed it beneath the base of the nævus, in an axis at right angles to the direction first taken; he then withdrew this end from the eye, and passed the other divided end of the ligature through it before withdrawing the needle; finally, these ends were firmly tied, with the ends hanging from the spot first punctured. In this way, as Mr. Walton afterwards illustrated upon a towel, a double cross is formed beneath the nævus, and on tying the free extremities together the parts are pulled up

and constricted in a most thorough manner. Mr. Walton advises that each of the ligatures be divided about the third day, and that they be not left to slough out, as so much of the tissues would thus be destroyed, owing to the contraction brought to bear upon them by this form of ligature. He has adopted this plan in a large number of cases, and with such success that he has no hesitation in strongly recommending it.

OPERATION FOR DROPPED EYELID.

Mr. Walton also operated upon the eyelid of a young girl to remedy dropped lid. He removed an elongated, oval-shaped piece of skin from the eyelid, near the margin of the orbit, and away from the free margin of the lid, and then brought the cut edges together by fine sutures. In this way the skin over the lower part of the lid would be brought under the influence of the orbicularis muscle, and the deformity got rid of. Mr. Walton strongly advises that in these operations the skin should be dissected off with the scalpel, and not cut away with the scissors. By careful dissection with the knife, one can make quite sure of not injuring the orbicularis muscle—a matter of all importance. Another advantage is that no scar follows the use of the knife, though sometimes an irregular mark is left after using the scissors. Suppuration is of the rarest occurrence, the wounds nearly always healing by first intention. In many cases an arched condition of eyebrow, owing to attempts made to raise the lid, accompanies this deformity, but in this patient the dropped state of the lid had not been of sufficiently long duration to give rise to this.

Mr. Haynes Walton also showed a patient upon whom he had performed Iridectomy for a conical condition of cornea. Previous to the operation the man was nearly blind (having cataract on the other side), but since the artificial pupil had been made a fair amount of vision has been permitted him. He can now see his way about, and count the number of fingers held before him.

ST. PETER'S HOSPITAL.

STONE IN THE BLADDER—LITHOTRITY—RECOVERY.

(Under the care of Mr. TEEVAN.)

J. B., AGED 17, by trade a baker, was admitted into the Hospital on June 3, 1870. The lad is stout and well made, but of pale complexion, probably owing to his occupation. Patient stated that as long as he can remember he had suffered from pain at the end of the penis during micturition, lasting for a few minutes. For a long time his urine has been thick, and he has passed blood on three different occasions. Is unable to ride in any vehicle, on account of the pain caused by the jolting; does not experience much annoyance from increased frequency of micturition. Patient's paternal grandfather suffered from stone. Mr. Teevan sounded the patient, and detected a small calculus, which gave a very clear click when struck.

On June 4 Mr. Teevan crushed the stone, which was of oxalate of lime, and about the size of a small hazel-nut. The patient passed some *débris* the same evening, and on the following day he left the Hospital, as he was quite free from pain.

12th.—The patient came to the Hospital to-day, saying he had remained free from pain, and that his urine was quite clear. Passed no fragments of stone since the day after the operation.

20th.—Remains perfectly well. Has been at work ever since he left the Hospital.

Mr. Teevan remarked that this was the youngest patient on whom he had performed lithotritry, which was clearly indicated in this instance, as the stone was small, and the boy's urethra very capacious.

STONE IN THE BLADDER—LITHOTRITY—SUDDEN DEATH FROM HEART DISEASE.

(Under the care of Mr. TEEVAN.)

W. S., aged 70, coach trimmer, was admitted into the Hospital on December 30, 1868. Patient is of spare form, very nervous, and of very dark complexion. Two years ago first began to pass small quantities of "red gravel," and shortly afterwards, on one occasion only, a little blood. During all the period suffered much pain during and after the act of micturition. At the present time he is much troubled with frequent calls to urinate during the day, but at night has only to rise twice. Urine only occasionally thick. Mr. Teevan

examined the patient with a very short-beaked sound, and detected several small calculi lying behind an enlarged prostate. Patient was put on a mixture of chlorate of potash and henbane.

January 4, 1869.—To-day, at 3 p.m., Mr. Teevan performed lithotritry. The lithotrite was filled with uric acid *débris*.

6th.—A few pieces of stone have come away. Patient's health is good.

11th.—Crushed again to-day; much *débris* came away. The following day a little blood passed, but no stone.

19th.—Another crushing; very little stone came away.

25th.—Crushed to-day; much *débris* came away.

26th.—A great deal of stone has passed since yesterday. Health good.

29th.—Suffers a good deal from straining to expel fragments. Ordered quarter of a grain of morphia.

February 2.—To-day, at 3 p.m., whilst patient was kneeling on bed and urinating with effort, he suddenly became faint, and died a few minutes afterwards.

3rd.—*Post-mortem Examination.*—The mitral valve was found so diseased with calcareous deposit that the auriculo-ventricular orifice would only admit a quill pen. The coronary arteries were similarly affected. The right kidney was little more than a large sac containing several ounces of urine, and the right ureter was greatly dilated. The left kidney was apparently healthy. The bladder was much thickened, but the lining mucous membrane was perfectly free from the slightest ulceration or denudation. The fragments of stone found in the bladder showed that there had been three lithic acid calculi, each apparently about as large as an almond.

Mr. Teevan remarked that death in this case clearly arose from failure of the heart's action during an effort to expel the *débris* from the bladder during the act of micturition. The patient's health had continued good after the various operations, and there was no reason whatever to prognosticate otherwise than favourably. Lithotritry possessed many advantages over lithotomy; but the accident that occurred in this particular instance could not have happened after lithotomy.

LEEDS GENERAL INFIRMARY.

CASE OF ATHETOSIS (?).

(Under the care of Dr. CLIFFORD ALLBUTT.)

IN consequence of some remarks which we made in this Journal for December 16th, on an affection described by Dr. Hammond, of New York, and called by him "athetosis," a short account has been sent to us from the Leeds Infirmary of a case which may be of the same kind, though differing somewhat in detail. The patient, Mrs. D., was only a short time under notice, and, unfortunately, no notes of her state were taken; as she had been, however, in more than one of the London Hospitals, it is hoped that her case has been accurately recorded elsewhere. She was a respectable, temperate woman, of about 55 years of age, sallow in complexion, and a good deal wasted; for some time she had been subject to spasmodic restlessness of the extremities. These movements were best marked in the hands, as was seen in Dr. Hammond's cases; like his cases, also, so in Mrs. D., the feet were rather in a state of tonic flexion, the toes being so spasmodically pointed that she was unable to walk. For this reason she was made an in-patient under Dr. Clifford Allbutt, who took great interest in her. He pointed out that the case differed much from chorea and paralysis agitans, both in the character of the movements and in their limitation to the hands and feet. Unlike Dr. Hammond's patients, however, Mrs. D.'s spasmodic movements ceased, or almost ceased, during sleep. The toes, as aforesaid, were rather in a state of tonic spasm, and forcibly pointed downwards; there were, however, frequent slight alternate movements of flexion and extension. In the hands the movements consisted chiefly of a curious alternation between abduction and adduction, the fingers being quickly agitated in a lateral plane. The district of the ulnar nerve was agitated for the most part in alternation with the rest of the hand, so that many of the movements were of a spreading and closing character. There was, however, much irregularity in all this, and semi-flexions and extensions often occurred among the other agitations. The will had but a slight and transient effect in commanding the hands, and the patient could never succeed in setting them at rest even for a second. The urine was normal, and the bodily functions in fair order. During her short stay the continuous galvanic current was used, but with little or no benefit.

Other countries are far ahead of us in this matter. In the State of New York a jury of six Physicians is called upon to try the question of pregnancy in capital cases. In France the bare proof of pregnancy, as determined by Medical opinion, is all that is required to stay execution. An excellent opportunity is now offered for new legislation on this subject. It is rare that a jury of matrons is called upon to decide the question of pregnancy. We do not wish to see another instance of it.

ARMY MEDICAL OFFICERS AND SICK LEAVE.

WE have on more than one occasion given public expression to the dissatisfaction and sense of injustice which prevail among the Medical officers of the army at the inequality of their lot when suffering from ill-health, as contrasted with that of officers of the purely military branches of the service. A Medical officer, according to the present regulations of the service, must, in the event of ill-health, either be fit for service at home or abroad at the expiration of six months' leave on Medical certificate, or be relegated to the limbo of half-pay until such time as he may succeed in convincing himself or—still more difficult—a Medical Board that he has become fit again to face the malarious influences of Peshawur, the West Indies, or the Gold Coast. His military comrade, who, having gone through a similar ordeal of sunstroke, dysentery, or hepatitis, may have come home with the unfortunate Doctor in the same ship, and appeared before the same Medical Board in Whitehall, obtains off-hand, as the first instalment of the period of leave necessary to restore him to health and the discharge of his duty, the six months' leave which is grudgingly dealt out to the Medical sufferer as the ultimatum between him and half-pay. On the expiration of his first six months, the military officer again appears before the Medical Board, and obtains an extension, and may do so once or twice more until he has quite recovered his health, or until it has become evident that a residence of eighteen months or two years at home having failed to establish his health, he must be put on half-pay, and replaced by an efficient officer.

Now, we maintain that such inequality of treatment is not only unjust, but cruel, to the Medical officer. As a rule, he is exposed more directly and continuously, in the discharge of his Professional duties, to the injurious effects of climate than is the military officer. During an epidemic, or more than usually unhealthy season, he has to endure anxieties and undergo an increase of work, from which the military officer is comparatively, if not absolutely, free. We know of nothing in the constitution of a Medical officer different from that of another man, to render it more elastic and resilient in its recovery from disease; on the contrary, as we have shown, the peculiar nature of his duties renders him liable to depressing influences over and above those of the ordinary effects of trying climates. We repeat, therefore, that the position of Medical officers of the army as regards sick leave is anomalous and unjust when compared with that of officers of the military branch.

The regulation to which we object was introduced, we believe, during the *régime* of a now deceased Director-General, whose administration of his department we criticised so frequently during his lifetime that we need not now resume the subject further than to say that by the establishment and continued existence of the rule referred to, an unfair blow was, and is still, inflicted on many deserving Medical officers, and that the Medical Department of the Army generally has suffered from it very seriously in the estimation of its members, who, of course, have many opportunities of influencing favourably or otherwise the feelings of intending candidates.

The Indian Government makes no such invidious distinction between military and Medical officers in its own employ. An Indian Medical officer in bad health has as good a chance of recovering his efficiency by a residence at home—of eighteen months or two years—as is afforded to the military officer.

Wise in its generation, however, the Indian Government of course adopts towards Medical officers of the British service, who may have lost their health in India, the same rule as is applied to them by the home authorities. A regimental or staff Medical officer who is reported by a Medical Board in India as unlikely to be fit to return to duty in that country at the expiration of six months from the date of his leaving India on Medical certificate, must be replaced by an efficient officer from home. This rule bears with special hardship upon regimental Medical officers, who, under such circumstances, lose their regimental appointments after having incurred the expense of uniform and other charges inseparable from duty with a regiment. Granting that the fixed establishment of Medical officers of the British service must be maintained in India, why should not a staff Medical officer be appointed temporarily to a regiment until the Surgeon or Assistant-Surgeon sent home in bad health be fit to resume his duty in India, or have had an amount of sick leave sufficient to establish the fact that he is permanently unfit for service or not likely to become fit within any reasonable time? So long as the regimental Medical staff system continues to exist, regimental Medical officers serving in India are liable to this hardship.

It is not only to the executive officers of the British Medical service that the Indian Government applies this rule. By a recent order, we understand it has been extended to the administrative ranks, so that an Inspector or Deputy Inspector-General of Hospitals of the British Medical Service, returning from India in bad health, on the recommendation of a Medical Board, must either be fit to return to that country at the expiration of six months from the date of embarkation in India—this, be it observed, giving a residence of exactly four months at home for the recovery of health—or he must be replaced by another officer of the same rank from home. Now this, it appears to us, is unfair both to the sick officer and to the senior Medical officers of lower grade remaining in India. It is well known that a Surgeon-Major, temporarily performing in India the duties of a Deputy Inspector-General, is entitled to a considerable increase of pay and allowances. Why should not one be allowed to officiate in the higher rank during the absence at home of the original occupant of the post for the recovery of his health? It can hardly be maintained that a Surgeon-Major is unfit to perform temporarily the duties of an office to which, in the ordinary course of events, there is some likelihood of his being promoted. The opportunity of doing so would be a qualification for promotion to the higher grade; he would also derive pecuniary benefit, and the officer whose place he had filled might, on the recovery of his health, complete his term of Indian service, and the modest amount of savings to which he may, through a long career, have been looking forward as the means of support and education for his family.

We hope yet to see all such galling and injurious anomalies removed from the position of Medical officers of the army. The person who succeeds in abolishing them will deserve well of the Profession and the public. The authorities of the War and India Offices, in their administration of Medical affairs, should bear in mind that efficiency and content are inseparable elements in the constitution of public departments; and that in all questions in which health and pocket are concerned, notwithstanding all efforts to establish an artificial and unjust distinction, Medical officers are in all respects as other men are.

THE WEEK.

TOPICS OF THE DAY.

TUESDAY'S *Gazette* announced that the Queen has been graciously pleased to give orders for the appointment of Sir William Jenner, Bart., M.D., one of the Physicians-in-Ordinary to her Majesty, to be an Ordinary Member of the Civil Division

of the Second Class, or Knights Commanders of the Most Honourable Order of the Bath. And that the Queen has been pleased to direct Letters Patent to be passed under the Great Seal granting the dignity of a Baronet of the United Kingdom of Great Britain and Ireland unto William Withey Gull, of Brook-street, in the parish of St. George, Hanover-square, in the county of Middlesex, M.D., and the heirs male of his body lawfully begotten. We heartily congratulate Sir William Jenner and Sir William Gull upon the complete success which has rewarded the exercise of their skill in the management of the Prince's illness, and upon the great service they have thereby rendered to the Queen and nation. Last week we expressed our opinion that the honours now announced were in no degree an adequate reward for those services, and we know that this opinion is shared by a very large and influential part of the Medical Profession.

The commutation of Mr. Watson's sentence to penal servitude for life, and the respite of Christiana Edmunds on account of unsoundness of mind, were, we think, the only possible settlements of their respective cases. The recommendation of the jury in Mr. Watson's case could not have been neglected had there not been strong reasons in the history and circumstances of the case for the exercise of the prerogative of mercy. In Miss Edmunds's case, it is announced that in consequence of an opinion expressed by Baron Martin, who tried her, that her mental condition should be examined by competent Medical men, Sir William Gull and Dr. Orange (the Superintendent of the Broadmoor Criminal Lunatic Asylum) have visited her, and, after an interview of four hours' duration, have certified to Mr. Bruce that she is of unsound mind. On this she has been respited, and will be confined as a criminal lunatic in Broadmoor Asylum. We have said that this was the only possible settlement of her case, and we think so for the following reasons:—First, because, although she was not insane according to legal definition, she was proved to have been the subject of marked hysteria, to have inherited a strong family predisposition to insanity; and the very character of her criminal career—its hideous recklessness—was at once sufficient to suggest that it was not that of a sane person. Yet, although of unsound mind, she was not legally insane, for there cannot be a doubt that she knew, in a certain sense, right from wrong. Under these circumstances the Profession and the public will acquiesce in the result. But at the same time it is in another sense a very unsatisfactory one. The law is set aside, a solemn legal process is annulled, because a Medical opinion has been given by two Physicians in exact accordance with that which, when advanced by other Physicians, was sneered at by the counsel for the prosecution, and pooh-poohed by the judge who tried the criminal. The fact is, that the legal definition of insanity is not the true one, and, however lawyers may uphold it in theory, it is one which in the present day they cannot conscientiously put into practice. Persons indubitably mad in every asylum in England know the difference between right and wrong, and will abstain from doing the latter when under supervision, or from fear of punishment. The only way in which scandals of this kind can be avoided—unless, indeed, some new legal definition of insanity can be arrived at which will provide for such cases (and of this there is little hope)—is by the appointment of Medical assessors in our courts of justice, who may be called in by the judge in doubtful cases to examine and report on them, who, being of high scientific standing, and being free from all possible bias, may claim and receive the confidence of the Government and the public.

The controversy on Londesborough Lodge continues. Professor Corfield, an undoubted authority on all that relates to sewers and sewerage, has examined the house, and has written a long statement as to its sanitary condition, which

appeared in the *Times* of Monday last. Our space will not permit us to analyse it at length, but we may state that his observations certainly do not agree with the reports furnished by special correspondents and commissions who obtained their information from "the plumber's man." Whilst he admits that there are certain defects in the sewerage arrangements of Londesborough Lodge, he thinks that the ideas afloat on the subject are many of them incorrect and exaggerated. In another column we publish a letter from Mr. Dale, of Scarborough, on the same subject, which has reference to some statements that appeared in a Medical contemporary. Although the convalescence of the Prince of Wales has turned the thoughts of the general public into other channels, the condition of Londesborough Lodge, and the origin of the fever which attacked so many of its inmates, is still a matter of vital interest on scientific and social grounds. It may be that we must look, not to the sewerage of the house, but to some accidental water-contamination for the cause of the recent national calamity.

A grave charge has been brought against the Metropolitan Board of Works. The Streets Committee of the City has reported that, notwithstanding the enormous sums spent on the main drainage scheme and purification of the Thames, no less than 562 sewers directly or indirectly communicate with the river within the limits of the City alone.

Dr. Paget, the President of the General Medical Council, has been appointed by Government to the Regius Professorship of Physic in the University of Cambridge. Dr. Paget is the sixteenth Professor. The chair was founded by Henry VIII.

PROCEEDINGS OF THE ROYAL COLLEGE OF SURGEONS.

The following is an abstract of the unconfirmed minutes of the last meeting of the Council:—The Library Committee was requested to report on the state of the College collection of engravings and other portraits, and to offer any recommendations as to its exhibition to visitors to the library. The opinion, dated 28th ult., of Council in favour of the draft scheme for an Examining Board for England was read, and the suggestion of the Joint Committee of the Colleges of Physicians and Surgeons, that such opinion did not necessitate any modifications in the scheme, was adopted by the Council; and the Committee was authorised to take the necessary steps to carry out the scheme, and the President and Vice-Presidents were empowered to communicate to the General Medical Council the concurrence of the Council in the scheme. The President stated that the nomination of an examiner, in the vacancy occasioned by Mr. Cock's expiration of office, would take place in February, and that an examiner would be elected at a special meeting of the Council in March, and that the vacancy created in the Dental Board, by the same gentleman ceasing to be a member of the Court of Examiners, would be filled up at the next ordinary meeting of the Council. A letter of the 20th ult., from the Bishop of Toronto, for the recognition of the Medical Department (lately re-established) of the University of Trinity College, Toronto, was read, and the Council resolved to recognise the same. Mr. Erichsen, in pursuance of his notice of the 14th ult., moved—"That on the occurrence of a vacancy in any Professorship or Lectureship in this College, with the exception of that of Hunterian Orator, due notice be given of such vacancy by advertisement in such journals and at such times as the President shall decide; and that candidates be invited to apply for the vacancy." And the motion having been seconded by Mr. Spencer Smith, and the votes of the Council having been taken thereon, a majority was in favour thereof. Sir James Paget, in pursuance of his notice on the 14th ult., moved—"That it is desirable that, before proceeding to any nomination of Members for election to the Fellowship under the 5th clause of the Charter of 1852, the Council should determine the conditions under which the

election should take place." And the motion having been seconded by Sir William Fergusson, and the votes of the Council taken thereon, the same was carried *nem. con.* Moved by Sir James Paget, Bart., and seconded by Sir William Fergusson, Bart.—"That the exercise of the power granted to the Council by Clause 5 of the Charter of 1852 be limited to the election of Members of not less than twenty years' standing, distinguished in science or literature, and not engaged in the practice of the Surgical Profession, and of members of not less than twenty years' standing distinguished in the practice of their Profession, and presenting satisfactory evidence that, through circumstances which they could not control, they were unable to complete the course of study requisite for admission to examination for the Fellowship. Moved, as an amendment, by Mr. Hawkins, seconded by Mr. Spencer Smith—"That all the words in the foregoing motion, after the words 'Charter of 1852,' be omitted, and that the following words be inserted in lieu thereof—viz., 'be not put in force this year, in order that a Committee may be appointed to report to the Council on the conditions upon which members should be elected under the said clause.'" And the votes of the Council having been taken on the amendment, a majority was in favour thereof; there was not, therefore, any nomination of members under the 5th clause of the Charter of 1852. Mr. Simon then gave notice of the following motion at the next meeting of the Council—viz., "That, on the occurrence of a vacancy in any examinership in this College, due notice be given of such vacancy by advertisement in such journals and at such times as the President shall decide; and that candidates be invited to apply for the vacancy."

DR. ODLING'S DISCOURSE ON INDIUM AT THE ROYAL INSTITUTION.

On Friday evening, January 19, Dr. Odling gave a discourse at the Royal Institution on "Indium." It was not till the time of Lavoisier, he said, that the fact was established that the earth's crust is resolvable into a number of independent elements perfectly distinct from each other in their natures, and not capable of being changed into each other or transmuted in any way. Before the discovery of hydrogen, twenty-four of these elements were known to chemists, and since that discovery, thirty-four new substances have been added to the list at varying intervals. In the last fifty years there has been on the average one new element discovered in every four years; but the intervals are very irregular. The last discovered was indium, which was found by Messrs. Reich and Richter in the year 1863, and it is therefore time that some new element should appear. The list of elementary substances is, in all probability, capable of indefinite extension; but it is not likely that any new substance of frequent occurrence will come to our knowledge. All those substances which have been discovered within late years are of extreme rarity, and, being of little commercial value, are considered more as chemical curiosities than anything else. But though rare, it does not follow that these bodies are not widely distributed. As in the case of iodine, so in that of many others, their presence may be detected in very many bodies, but in quantities so minute that their rarity is not affected.

The last four elements which have been added to the list—viz., cesium, rubidium, thallium, and indium—are remarkable for having been detected for the first time by means of the spectroscopie. It is well known that different bodies, when heated in the colourless flame of the Bunsen burner to vaporisation, give off rays of different-coloured light. Lithium gives a red ray, barium a green, and strontium a crimson one; and when only single elements are present it is tolerably easy to decide what the element is by the appearance of the flame to the naked eye; but when there is a combination of elements it becomes necessary to use further means. A coloured screen may be used to cut off some of the rays and allow only others to

pass. But the most perfect means available is the use of a prism, by which the rays are not partly absorbed and cut off as by a screen, but are sorted out, and laid in order before the observer according to their different degrees of refrangibility. It was by the means of the prism that Bunsen discovered cesium and rubidium, in the year 1859, while examining the mineral waters of Dürkheim. Having noticed some bright lines in the spectrum of the flame given off by the salts of these waters, he reduced an enormous quantity of the water, and succeeded in separating these two new alkaline substances. It is now found that they are widely distributed in exceedingly minute quantities, but cesium has not yet been found in the ashes of any vegetable matter. They stand in almost exactly the same relation to potassium as strontium and barium do to calcium.

Thallium was the next element to be discovered. This body was first noticed by Mr. Crookes in the year 1861, while examining an impure deposit of selenium from the Harz Mountains. It is remarkable for the very beautiful green line in the spectrum of its flame. Its true position is still a matter of controversy, since it resembles silver, gold, lead, potassium, and other metals in some characteristics, but differs again from them all by other marked properties.

The last new metal is indium; this was discovered by Messrs. Reich and Richter, of Freiberg, in the year 1863, in some zinc blend or black-jack from the Harz Mountains. Its spectrum contains two lines only, of a bright indigo colour, one situated in the blue and the other in the indigo portion of the spectrum. As to colour, this metal is very white in appearance, with a tinge of bismuth colour in it. On exposure to air it tarnishes rapidly and presents an exact resemblance to tarnished lead, but differs from the lead in that the film can very easily be rubbed off with a cloth, whereas that of lead cannot. Like lead, indium is very compact, and very soft indeed, as was shown by a piece being pressed out into wire in a very short time. In weight it resembles tin. The specific gravity of tin is 7.3, indium 7.4, lead 11.9. Its fusibility is very remarkable; it may be melted in hot spermaceti at a temperature of 176° Cent.; tin can be melted at 228° Cent., and cadmium at 278° Cent. The combining ratio of indium is 38, and its atomic weight is 71.84.

The discourse was illustrated by some fine specimens of some of the rarer metals, such as tellurium, zirconium, yttrium, beryllium, lithium, selenium, and vanadic acid, etc. The spectrum of sodium was shown, and the light itself was displayed with its usual effect upon the audience. The spectra of thallium and indium were also shown by the aid of the electric light.

EXTRACTS OF MEAT FROM A PHYSIOLOGICAL POINT OF VIEW.

P. MULLER (*Moniteur Scientifique*, 1871, p. 611) contributes an important memoir on this subject—important not only from the valuable *résumé* given of all that is known relative to the chemical composition of meat extracts, soups, etc., but as adding to our knowledge of the physiological effects of such extracts. The paper is divided into three chapters, the first of which treats of the fluid of muscles, soups, and extracts, stating the relative proportions of the several ingredients entering into these, and detailing the researches of Liebig and others in this field. Extracts of meat are shown to be destitute, or nearly so, of true alimentary substances (albuminoids), and to be rich in such nitrogenous substances as are incapable of acting as food. The second chapter deals with certain principles of organic origin, such as creatine, found in meat extracts; and these principles are stated from the accordant experiments of the author and Kimmerich (*Wien. Med. Wochenschrift*, 1869) not to be dynaphorics, like tea, coffee, etc. Further, the ash of extracts of meat is shown to exert a poisonous action upon animals. The concluding chapter treats of the action of potash salts upon the animal economy. Neutral phosphate of potash decomposes chloride of sodium, producing phosphate of soda and chloride of potassium; and

phosphate of soda is one of the most important salts found in blood. Carbonic acid is very much more soluble in solutions of phosphate of soda than in water or in solutions of phosphate of potash; hence, this latter cannot replace the former salt in the vital processes and in the manufacture of blood. The experiments of Bernard (Virchow's *Archiv*, xxxii.) have long since shown that so small a quantity of a potash salt as seven or eight grains, injected into the blood, exerts a toxic action on an animal, whilst many times that amount of a soda salt may be administered in the same manner with impunity. We cannot do better than translate the conclusions of M. Muller for the benefit of our readers:—

"1. Meat extracts are neither direct aliments, for they contain no albuminous matters, nor indirect aliments, for their azotised principles do not arrest disassimilation.

"2. In small quantities they may be useful, from the stimulant action of the potash salts which they contain, as these salts aid digestion and circulation.

"3. In larger doses, instead of being useful, they may have an injurious effect. Administered in the course of prolonged illnesses, when the powers are enfeebled by long abstinence, the salts of potash may exert an injurious action, more manifest in proportion to the quantity of chloride of sodium lost by the organism. Far from favouring nutrition, they may impede it—(1) by the direct action of potash salts upon the blood-globules, causing a diminished absorption of oxygen; (2) by the predominance of salts in the serum, which exert no special solvent action on carbonic acid, and do not permit the exhalation of the normal quantity of this gas, and, consequently, the introduction of oxygen.

"4. The Physician should always remember that to give these extracts alone is to keep the patient in a state of inanition."

But we must add, notwithstanding all this, they are good stimulants, and useful to bring up the flavour of poor soup.

SMALL-POX JOTTINGS.

AT Carmarthen small-pox has been carrying off a victim every other week for months, and now the authorities are thinking of erecting a Hospital.—The disease still continues at Mold.—At Limehouse during the past fortnight seventeen fresh cases are reported and five deaths.—Six deaths from small-pox during the four weeks ending the 6th inst. were reported to the Kennington Vestry last week.—Dr. Lankester stated to the St. James's (Westminster) Vestry on Thursday week that "a kind of outburst of small-pox had taken place, twenty-one fresh cases having been reported, most of which had been sent to the Hampstead Hospital. One death from the disease was reported on the previous day, making in all 253 cases and thirty-six deaths which had occurred in the parish since the outbreak of the epidemic. One case occurred in a child who had been vaccinated, three cases in persons who had not been vaccinated. It frequently happened that the Medical Officer knew nothing of the cases until the deaths were registered and many persons had taken the disease."—At Mile-end Old Town two deaths were registered last week from small-pox.—The Small-pox Hospital at Mounthlory, for patients in the district of the local authority, has just been opened. Though small-pox is still pretty prevalent, the worst it is hoped is past. The cases reported from the Infirmary for the week ending last Saturday were more numerous than on the previous week, thirty patients being under Hospital treatment; but the proportion of cases in private practice has been greatly reduced. The number of persons presenting themselves for vaccination and revaccination at the Dispensary has been large.—Eighty-nine cases of small-pox were admitted into the Cork Workhouse Hospital during the last week, and eighteen are under treatment in the City Fever Hospital. In consequence of the Workhouse Hospital and the Fever Hospital being full, the Guardians are about to erect a shed for the reception of fifty small-pox cases. In the South Dublin Small-pox Hospital there were remaining in the Hospital at the last weekly return 103, admitted 34, discharged 31, died 9, now remaining 97.

Seven out of the nine fatal cases had no vaccine marks; twenty serious cases are at present under treatment.—Small-pox is prevalent in Sowerby-bridge and the immediate district.—At Halifax, from the 3rd to the 20th inst., sixty-five cases of small-pox have been reported. The mortality from the disease is at a comparatively low figure, only four deaths having occurred.—Small-pox is on the increase in Lurgan; a number of very bad cases have been admitted into the Workhouse.—In the metropolis, last week, ninety-three deaths were registered from small-pox.—Of five fatal cases in Woolwich Arsenal sub-district, no less than four were unvaccinated children, aged from 2 to 6 years.—Three fresh cases of small-pox were reported last week to the Holborn District Board of Works.—Dr. Aldis, St. George's, Hanover-square, reports two cases—one a woman, aged 27, vaccinated, in the in-wards, removed to the Hospital; the other, a girl of 16 years, vaccinated, in the out-wards.—Small-pox has broken out in several parishes within the district of the Glandford Brigg Union, and stringent measures have been adopted to prevent the disease from spreading.—Small-pox having appeared at Lincoln, the Sanitary Committee of the Local Board adopted the following resolution at their last meeting:—"That, as this Committee has been unable to obtain either of the buildings they had in view for the purpose of providing a small-pox Hospital, it be hereby referred to the Local Board and the Corporation to decide on the expediency of erecting a Hospital on one of the commons, and that the Clerk do bring the subject before the next meeting of the Council."

TREATMENT OF HABITUAL DRUNKARDS.

No problem is more difficult of solution than the proper treatment of habitual drunkards. The liberty of the subject is held so sacred that any infringement of it, even though it be for the benefit of the person coerced, is regarded with much jealousy, and even with abhorrence, by the public. If the plan suggested by Dr. D. Dalrymple at a meeting of his constituents at Bath could be carried out, it would be a great social and public benefit. We fear, however, that difficulties attend it that cannot be easily, if at all, overcome. He suggests that the habitual drunkard should be sent to a reformatory, where he might learn that he could live without getting drunk, and where he could earn money enough to pay his cost whilst there, so that he might not be a burden to society. He has visited the inebriate asylums in the United States and Canada, and he found in many of those institutions over one-third, and in some one-half, of the inmates had been benefited. Whilst on the other side of the Atlantic, he heard that the Permissive Bill would not work; that in districts where it was enforced, with few exceptions, it was found not to prevent drunkenness, whilst the surreptitious and clandestine use and sale of liquors went on to a formidable extent.

MEDICAL MISSION IN INDIA.

PRACTITIONERS of Medicine, from the time of Clive, have had great influence on the native population of India, and have effected immense good, both with respect to our government of the country and the progress of civilisation. At a meeting last week, Lord Lawrence gave it as the result of his large experience that there was no mode of so easily getting at the hearts of the people of India as by Medical missions. There the very name of Medical Practitioner was a kind of talisman, and they almost looked upon him as deriving inspiration from Divinity.

VACANCY FOR A CORONER.

MR. ROBERT WESTON, solicitor, of Brackley, and Coroner for the Western District of Northamptonshire, died last week. It is believed that if an influential Medical candidate were to contend the election he would succeed.

DAMAGES FOR SMALL-POX.

A CASE of much interest was decided in the Liverpool County Court on the 18th inst., arising out of illness caught by the plaintiff through being allowed to become a tenant of a house in which two cases of small-pox had just previously occurred without any steps whatever having been taken to disinfect. Hitherto in such cases proceedings have been taken against the landlord before the magistrate, and a penalty imposed under the Public Health Act. In the present instance, however, the person who had caught the small-pox, a Mr. Pritchard, brought an action against the owner, Mr. Huntington, to recover damages for the breach of duty whereby he had suffered injury; and not only was a verdict given for the full amount claimed, with costs, but the judge, Mr. Sergeant Wheeler, thought that the plaintiff had understated the damages to which he was entitled, by limiting himself to the loss of wages during the time that he was laid up, and not including other expenses necessarily incident to such an illness, the payment of which might properly have been demanded.

DR. CRACE CALVERT ON ANTISEPTICS.

WE are sorry that we are compelled, by inexorable space, to leave out this week our report of Dr. Calvert's discourse on the Effect of various Substances in Preventing the Development of Low Organisms in Infusions of Organic Matter, and in Destroying such Organisms when formed. The reputed effects of sulphate of quinine in preventing the development of fungi were curious; so were those of the well-known "bleaching-powder," or chloride of lime, in promoting decomposition after a certain stage. The general purpose of the experiments showed that it is, on the whole, easier to prevent the development of low organisms than to destroy them when development has begun—in other words, that prevention is easier than cure.

MANCHESTER MEDICAL SOCIETY.

AT the annual meeting of the Manchester Medical Society held on January 10, the following were elected office-bearers for 1872:—*President*: John Galt, Esq. *Vice-Presidents*: M. A. E. Wilkinson, M.D.; T. Windsor, Esq.; D. Lloyd Roberts, M.D.; J. Thorburn, M.D. *Treasurer*: E. Lund, Esq. *Honorary Secretary*: C. Currie Ritchie, M.D. *Honorary Librarians*: C. J. Cullingworth, Esq.; C. E. Glascott, M.D. *Committee*: L. Borchardt, M.D.; J. Buckley, Esq.; J. O. Fletcher, M.D.; J. Haddon, M.D.; W. Heath, Esq.; D. Little, M.D.; T. Mellor, Esq.; J. E. Morgan, M.D.; J. Roberts, M.D.; W. Roberts, M.D.; A. Wahltuch, M.D.; W. Whitehead, Esq.

THE PROFESSION IN FRANCE.

A PARTY of Medical gentlemen forming a portion of the National Assembly of France, about thirty in number, have formed an extra-Parliamentary Committee. Dr. Bouisson, Professor at the Faculty of Montpellier, and Deputy for Hérault, has been chosen President, and M. De Maby secretary. Amongst the numerous questions which this body will have to consider are—public assistance in the rural districts; organisation of military Surgical assistance; public hygiene and legal Medicine; the establishment of regulations for the better security of alleged lunatics; reorganisation of Medical institutions; and examination of the physical conditions of a good soldier. If properly carried out, these inquiries cannot fail to be attended with the most beneficial results.

THE SANITARY STATE OF BELGIUM,

AT the close of last year, was most favourable. Catarrhs and rheumatism predominated. Scarletina, which had been reported in some districts, had abated. Typhoid fevers were very rare. Bronchitis and pneumonia, which had made some victims, had diminished since the severe frost gave way to the

comparatively mild temperature lately experienced. The work recently executed in Brussels leads to the hope that the city will shortly become one of the healthiest capitals in Europe. Not a single case of cholera is reported in the kingdom.

ARMY MEDICAL DEPARTMENT.

DEPUTY Inspector-General of Hospitals H. H. Massy, M.D., C.B., sailed in H.M.'s troopship *Malabar* on the 25th inst. for India. Dr. Massy proceeds to Bangalore, where he will relieve Deputy Inspector-General Barclay. He will be succeeded as head of the Sanitary Branch in the office of the Director-General, Army Medical Department, by Inspector-General of Hospitals W. Muir, M.D., C.B., now principal Medical officer of British troops in India, who will shortly be relieved by Dr. Beatson, C.B.

PUBLIC ANALYST FOR LIVERPOOL.

IT appears, from a report of the Liverpool Health Committee, that some difficulty exists in appointing a public analyst for that town. The Act of Parliament is deficient in this respect. The subject, however, is deemed of so much importance, that it is proposed, as a tentative measure, that an arrangement should be made with a person qualified to make analyses, and to give evidence in respect of articles sent to him by the Medical Officer of Health and the Inspector of Nuisances.

FROM ABROAD.—DEPRESSION OF TEMPERATURE IN GUNSHOT WOUNDS
—M. LASÈGUE'S CLINICAL EXERCISES.

AS the result of his investigations, carried on in numerous cases during the late war, M. Paul Redard contributes to the current number of the *Archives Générales de Médecine* an interesting memoir on "The Depression of Temperature which takes place in Severe Injuries from Gunshot Wounds." The following are the conclusions which he arrives at:—

1. In severe injuries from gunshot wounds, a depression of temperature is of constant occurrence.
2. Various elements are brought into play in the production of this depression. Among the principal may be noted the nervous shock, the excitement of the combat, with the consecutive stupor, hæmorrhage, and alcoholism.
3. Any patient brought into an ambulance with a severe wound calling for operation, having a temperature below 35.5° (95.9° Fahr.), will die, and, consequently, performance of an operation in his case would be useless.
4. Any wounded person, in whom a salutary reaction does not take place by the end of four hours, and in whom the reaction is not in direct ratio to the depression, should be considered in a state of very great danger.
5. Burns give rise to exceptional depressions of temperature.
6. It is the same with penetrating wounds of the abdomen, the depression being more marked in proportion to the propinquity of the stomach.
7. The diagnosis of penetrating wounds is rendered easy by reason of the characteristic thermometrical phenomena which they give rise to.
8. The state of drunkenness in which the wounded are sometimes found singularly favours the production of the depression.
9. Wounds produced by shell, *cæteris paribus*, give rise to a more marked depression of temperature than wounds caused by ball.

The *Gazette des Hôpitaux* of the 20th inst. contains an account from a reporter who attended what are termed the "Clinical Exercises" instituted at La Pitié by Professor Lasègue, and we do not doubt that our readers will feel interested in the narration. The wards were first visited, where, as is the custom generally adopted by the Clinical Professors at Paris, certain of the students were requested to interrogate and examine patients under the eye of the Professor. All then repaired to the theatre, where M. Lasègue, seating himself among the auditors, desired one of the students who had taken part in the examination in the wards to occupy the Pro-

fessorial chair, and furnish a *vis à voce* exposition of the history of one of the patients. His narration having been completed by aid of short rectifications and additions on the part of the Professor, the student was next required to pronounce his diagnosis and to state his opinion concerning the most remarkable circumstances of the case. When he hesitated or went astray, the Professor encouraged him by a few words, having for object to confirm his opinion, or to point out how he might recover the track again. If he stopped short, another student, or even a second or third, was appealed to, so that presently there became established between the Professor, his *chef de clinique* (who naturally took an active part in these exercises), and these students a veritable consultation, the result of which, summed up and formularised by the Professor, must have been not less profitable to the patient who formed the object of it than to the students who took part in it, or those of them who were only listeners. After the consultation had thus been brought into proper shape, the patient, when his condition and the nature of his disease admitted of it, was brought into the theatre, and again placed under the eyes of the students, who were thus enabled immediately to verify, confirm, or correct in their minds, by examination or interrogation, the doubtful points that had been the object of controversy. Two or three cases, according to their importance, are thus treated by as many students at the same *séance*. These exercises, which, as will be seen, constitute a kind of mutual instruction, take place on Tuesdays, the Professor delivering his clinical lectures on Thursdays and Saturdays.

After describing one of the cases examined at these exercises, the reporter goes on to say:—

“I return to the mode of clinical exercise adopted by M. Lasègue, or rather annexed by him to the other modes of teaching followed by his colleagues. Without having the pretension to form by this means a nursery of apprentice-professors, which in any case would only apply to a small number of the students, M. Lasègue, by thus making an appeal to the good disposition and intelligence on the part of his pupils, appears to us to have introduced a powerful element of emulation among them, and, further, an excellent mental exercise. Nevertheless, while recognising all that this mode has good in itself, and applauding M. Lasègue for having put it into execution, we are quite certain that he has never pretended to have invented it. The Germans, so methodical in everything, have been loudly praised in all the official and officious reports that have been made of late years on their mode of teaching, for the luxury of their laboratories, the special importance attached to autopsies, and for their organisations for clinical exercises, wherein the pupils are allowed to actively employ both their hands and their brains, under the name of *pratiquants*. It is therefore, in certain respects, an imitation of what is done in Germany that M. Lasègue has sought to introduce into his Hospital services, but with the modifications required by the *esprit français*—that is, with less elaboration and formality, with more *bonhomie* on the part of the Professor, and with more liberty and spontaneousness left to the students.”

MEDICAL HONOURS.

(From a Correspondent.)

WE have at length, in the *Gazette*, and in formal public announcements, a measure of the value attached by the nation to the life of the Heir-Apparent, as shown by its gratitude to those by whom that life was—if such a term can be applied to any human efforts—preserved.

Sunday after Sunday we have offered up prayers for the preservation of this life supposed to be so dear to the nation. Day by day we have read the frequent bulletins signed by those who were entrusted with one of the most anxious and responsible tasks that ever fell to the lot of man to endure—and endured without remission, and at the sacrifice of all private interest for weeks together, with a loyalty which few but those who know what it is to bear such a continuous strain can estimate; but—well, we hope that, though the end of

the proverb is fulfilled, the other half may escape verification—“God is forgotten, and the Doctor slighted.”

Of the two who might thus be supposed to have earned the nation's gratitude, one—Sir W. Jenner—has already gained the highest honour hitherto bestowed in this country on the Medical Profession, for services by which he had only too well earned the reward of a country squire who votes steadily enough for his party, or of a lord mayor who, by good luck, may once have the honour of presenting an address in person to the sovereign! And what is his further reward? A K.C.B.—the honour of a respectable mediocrity in the Civil Service, or the gift of avoiding any egregious blunder in the walks of diplomacy.

Dr. Gull, again, is to have a baronetcy; and this is the country's measure of the value of the life of the Prince of Wales! We can bestow honours and rewards thick and fast on the negotiators of a treaty which has left us more than ever open to the insolent demands made upon this country by the statesmen of America. We can reward with a peerage and grant of the nation's money an able general who could defeat a poor barbarous king of savages whose sole possession was one big gun. For those, however, who have fought a long month's battle with death, and have rescued the life of the Heir-Apparent, and who did this by a deeper knowledge than even that of the great soldier—a knowledge gained, in the case of Sir W. Jenner at least, at the risk of his own life from the very disease whose nature he was the first to unravel and discover: a task which he did so well, that nothing has since been added to the work he did thirty years ago—for these we have a baronetcy and a second-class K.C.B.!

We are going to have a national thanksgiving; let us hope that this, at any rate, may be real. But the Medical Profession can only feel that for its highest members their virtue is its own reward; and with this we trust they will be content, for they do not seem likely to get any other from a grateful people.

DYTE v. ST. PANCRAS.

(From a Correspondent.)

DR. DYTE's appeal to the judges *in banco* in the case of Dyte v. the Guardians of St. Pancras has been dismissed, of course with costs, which are by no means light. Our readers will remember that that enlightened and liberal body refused to compensate Dr. Dyte for his sudden and injurious removal from the office of Superintendent of the Highgate Infirmary, which had been the outcome solely of one of those outbursts of party spirit which have rendered this parish so notorious. It was admitted that Dr. Dyte's management of the Infirmary was more than usually efficient—a judgment of his merits which was amply confirmed by numerous Hospital Physicians and Surgeons, and other competent judges, official and others. But to gratify party spirit, and perhaps to effect a miserable economy, they justified the dismissal and refused to allow compensation, on the ground that Dr. Dyte's appointment had never been sealed with their common seal! We need not inform our readers that there is scarcely a Poor-law Medical Officer in the country (not to mention other public officers) whose appointment is thus formally and officially confirmed. This mean conduct of the St. Pancras Board of Guardians appears, however, to be *legally* right. It is not difficult to foresee the complications likely to arise out of such a decision. Men who have grown grey in the public service, or who have given up lucrative private practice for infirmary or asylum employments, may find themselves abruptly dismissed, without legal remedy, unless (as hardly ever occurs) they have secured the massive seal of the corporation or vestry. Nor does this apply to Medical men alone. Forewarned is forearmed; and, unpleasant as the news may be to many of us, of the uncertain tenure on which we hold our offices, we have all of us reason to be thankful to Dr. Dyte for his timely warning, and indirectly even to St. Pancras! But, meanwhile, Dr. Dyte is a sort of scapegoat for his Medical brethren. The fund raised for his appeal has hardly reached a third of the expenses which he has necessarily incurred. Under these circumstances, we beg all our readers

to contribute, according to their power, to the "Dyte v. St. Pancras Guardians" appeal fund, subscriptions for which will be received with thanks by Dr. Bathurst Woodman, of No. 6, Christopher-street, Finsbury-square.

REVIEWS.

A Practical Treatise on Fractures and Dislocations. By FRANK HASTINGS HAMILTON, A.M., M.D., LL.D., Professor of the Practice of Surgery, with Operations, in Bellevue Hospital Medical College; Surgeon to the Bellevue Hospital, New York; Consulting Surgeon to Hospital for Ruptured and Crippled; Author of a Treatise on Military Surgery and Hygiene. Fourth Edition, revised and improved; illustrated. London: Trübner & Co., 60, Paternoster-row. Philadelphia: Henry C. Lea. 1871.

So frequently do fractures and dislocations occur in practice; so important is the correct diagnosis and treatment of them, not only to the patient, but for the success and reputation of the Medical attendant; so obscure, in many cases, is the exact nature of the injury, and so numerous the complications which may arise—that the study of them is of the utmost moment.

As levers of indispensable use in locomotion, and in weight lifting and carrying, as necessary for the minutest manipulations, and as parts of the walls of cavities for the protection of important organs, the services performed by bones are of such significance that their fractures are at once productive of the greatest disqualifications. It can never, therefore, be otherwise than a most responsible department of Surgery to unfold the principles by which their cure should be conducted with propriety and success—to restore, that is, the functions, and to preserve the form of the parts injured.

It is not the study of each individual fracture and dislocation that is alone important; the general characters of these injuries, especially of fractures, demand the attention of the Surgeon who would fully understand the nature of special cases. For this reason the etiology, semeiology, course, and terminations (which constitute the science), as well as the diagnosis, prognosis, and treatment (which are the art of our subject) must be taken into consideration.

We find, therefore, that it has long been an object with writers on this branch of Surgery, to state general principles as well as to describe particular forms; and whether we refer to the excellent "Practical Treatise on Fractures," by E. F. Lonsdale, published in 1838, to the small work of John Aitken, on "Fractures and Luxations," of the year 1790, or to the "Syllabus of Surgical Lectures on the Nature and Treatment of Fractures," by Amesbury, in 1827, we see that, in all of them *general* observations precede the description of the details of each kind of accident.

Still, until quite a recent period, the Surgery of fractures and dislocations had been treated either piecemeal or insufficiently. The writings of two of the authors above alluded to relate only to fractures, and the work of Aitken is altogether inadequate for these later times. From the time of the appearance of the works of Wiseman, in 1734, and Pott, in 1768 and 1772, up to the date of Astley Cooper's and Robert W. Smith's writings at the latter end of the first half of this century, there were many good tracts and treatises produced in our language on Fractures, Compound Fractures, and Dislocations, including those of Weldon (1794), Earle (1807), Beaumont (1831), and Guthrie (1838), but none of these presumes to be complete.

The well-known work of Sir Astley Cooper, now before us, is, as its title announces, "A Treatise on Dislocations and Fractures of the Joints," and this alone; it was, however, the most perfect English monograph on the subject until Dr. Frank Hamilton's volume appeared in 1859.

Some twelve years before this date a grand and comprehensive work had been published in the French language by Malgaigne, who, while lamenting that his country was behind England and Germany in this branch of their literature, more than compensated for the deficiency of his countrymen, and, in his "Treatise on Fractures and Dislocations," gave to the Profession a book which, whether we regard it from a historical or dogmatic point of view, and supplemented and enriched as it is by a voluminous atlas, must be esteemed one of the most complete works extant. More recently still, Gurlt has issued, in the German language, an exhaustive treatise on the subject.

To Dr. Hamilton, however, belongs the credit of producing

the first and only complete treatise in the English language; and the volume which has suggested to us the present remarks is far too perfect to permit either of adverse criticism or of praise which could be deemed undeserved. Were this not the case it would be unnecessary for us to describe and review at any length a book which has already more than once passed under the reviewer's notice, and is so well known. It is sufficient to say that the present is the fourth edition; the first three were called for in seven years, and the last is now published four years after the third. This in itself shows clearly the approval with which the results of the author's work have been received.

The volume consists of two unequal parts. The larger portion, on Fractures, includes a general division, an account of their origin, signs, and diagnosis, of the repair and delayed and non-union of broken bones, and of the general treatment, and some peculiarities of fractures. Then follows a detailed account of the special fractures of each region, commencing with the bones of the face, of the hyoid bone and cartilages of the larynx, then going on to the vertebræ, sternum, and ribs, and finally to the upper and lower extremities. Gunshot fractures are considered more or less in detail under the several headings whenever it seemed to the author necessary to allude to them specially; but in the last chapter of Part I. he has given a *résumé* of his own observations and conclusions, and added some general statistical statements upon them drawn from the results of the American war.

Dr. Hamilton has not apparently thought it desirable to act upon the suggestion of some critics of former editions, to add a chapter on Fractures of the Skull, and we quite coincide in this decision. Fractures of the skull are not of the same nature as fractures of other bones (some fractures of the spine excepted); they do not require treatment for themselves, as a rule, but only on account of the effects produced upon the parts within, and they therefore give rise to a totally different class of considerations to those provoked by other fractures.

In the chapter on Fractures of the Femur, the question as to the kind of union which takes place in fractures within the capsule of the joint, is, as formerly, treated of at great length, and many allusions are made to the opinion of other authors; but we notice the omission of some discussions "relating to the value of certain specimens claiming to represent bony union after intracapsular fractures of the neck of the femur." The reflections upon John Bishop, and those who listened to his Lettsomian Lectures at the Royal College of Surgeons in 1855, in which he stated that Sir Astley Cooper believed that the fractures were "incapable of being repaired by osseous matter," find no place; and Sir Astley's views on this subject are, as heretofore, fairly laid before the reader.

The information contained in the chapter on the General Treatment of Fractures is invaluable, and should be known to every Practitioner. Almost every possible form of apparatus is here discussed, and then commended or condemned. The student, too, will find warning of the necessity of refinement and sensibility, *even*—as they may think—in the manipulation of fractured limbs; and he will see that those who cultivate not these qualities are consigned to the limbo of "some more suitable employment than the practice of a humane art."

Part II., though shorter, deals very fully with Dislocations. General considerations precede the *seriatim* descriptions, though these are necessarily more brief than those on fractures. The last two chapters—on Compound Dislocations of the Long Bones, and on Congenital Dislocations—are full of interest and instruction. Finally, 322 figures illustrate and simplify the text.

In fine, the book is full of useful detail, is simple in its arrangement, explicit in description, and pleasantly and lucidly written. Its comprehensiveness and trustworthiness, and the facility with which reference can be made to any portion of its contents, make it a safe and valuable work to recommend as well to every practical man as to every earnest student.

We cannot too thoroughly recognise the merits of the author, who has done so much to justify the fair name obtained by American Surgeons.

A VENERABLE SURGEON AND A TOUGH PATIENT.—A short time ago Dr. Joseph Stevens, now in his 82nd year, amputated the thigh of a patient, 66 years old, for obstinate and extensive ulceration of the foot and leg of forty years' duration! On the second day the patient sat up in bed, and shaved himself, and before the end of a week was able to get out of bed, without assistance, each morning, to have his bed arranged.—*Boston Journal*, November 2.

SCOTLAND.

EDINBURGH, January 24.

EDUCATION OF WOMEN AT EDINBURGH.

(From an old Correspondent.)

I SHALL not trouble you with the reasons of my long silence, but will plunge at once in *medias res*—and thick and slab they are here—about the “woman question.” So far as the University is involved, the business is at an end; the Senatus and Court have both found out that the Medical education of women is both impracticable and illegal. The aggressive party threaten litigation to compel the Professors to teach and the Senatus to graduate women in Medicine; but the head of the law courts (the Lord Justice-General) is Chancellor of the University. As the Tory Lord Advocate Inglis he carried the reform of the Scottish Universities through Parliament, and knows that both law and custom are as dead against these claims as if they were a speculative dream of an estate.

Still the fight rages, and just now around the Infirmary. The women's friends proposed that, as mixed classes for clinical teaching were objected to, there should be thirty or forty beds set apart, in the nature of a distinct Hospital, for the exclusive use of the “ladies.” It was reasonably argued by the Infirmary managers, that a clinical Hospital must have no fewer than eighty beds, and that, consequently, such a scheme would be a fraudulent evasion of a regulation of the examining boards made obviously in the interests of the public; so they declined to adopt it. Professor Bennett, Dr. Balfour (editor of the *Edinburgh Medical Journal*), and Dr. Watson (the author of a shilling pamphlet on syphilis) were its godfathers.

At the annual meeting on January 1 (current), an attempt was made to turn out some of those managers who had opposed this impracticable scheme for a more accommodating set, and hence a contest, involving several hundreds of men of business. Ladies went about canvassing for votes, and the Profession generally took the side of the managers, as in honour bound to do. As only seven “Doctors” voted with the ladies, the whole body, Medical Faculty and all, are denounced by the *Scotsman* as “trades-unionists,” and as actuated by the meanest motives. Threats are not spared that if the ladies do not have their own way the funds of the Infirmary shall suffer by withdrawal of subscriptions. The sick poor (God help them!) are the last to be thought of. The bickering is, however, adjourned to the Court of Session for the present, where a law-plea has commenced in the form of an interdict.

The misery this agitation is inflicting on the society of Edinburgh is inconceivable. Unfortunately, the Lord Provost (an *ex officio* member of various bodies) seems not strong in mind and judgment, and by his conduct only adds fuel to the flame of discord which is running through the University, the Professors, and families, and separating old friends. One lady got into such a state of excitement in publicly supporting “the ladies” (when they occupied the platform and waved their handkerchiefs at the last meeting about the Infirmary managers) that she is said to have died on her doorstep on her return home! It is believed one or two more will find their way to an asylum.

The course that the agitation has taken has raised some curious questions. Why has a portion of the press taken it up so generally on the women's side? And, still more, why is there such a uniformity of tone therein? “The extraordinary history of the vicissitudes endured by the lady-students,” says the *Scotsman* of the day, and *passim*. Further, this paper has an extract from the *Glasgow Herald*, beginning—“The sufferings of Miss Jex Blake and her colleagues,” etc.; another, from the *Lancet*, accusing the Edinburgh school of “want of common courtesy,” and affirming that it “stands convicted of having acted unfairly to seven ladies.” Nor must I omit that the *British Medical Journal* figures amongst the indignants as the representative of the British Medical Association, in company with the *Daily News*, *Examiner*, and other papers, the organs of the general public. I need hardly say that all these numerous accusations are false, whether of individuals, the students generally, or public bodies; but the rule apparently is for the ladies to act the part of peaceful, persecuted, humble suppliants, and for the writers to abuse without scruple as to facts every body or thing that opposes their schemes. The *Scotsman* has been the chief offender in this respect, and an amusing reason why oozed out not long since. The editor proved to be a lonely widower;

a sweet and widowed Medical undergraduate had fascinated the old gentleman; and he finally had to “ring his own (k)nell,” as he facetiously but truly observed, at the altar. Mr. Masson, the Professor of Rhetoric, it is believed, does some of the scolding in the press, assisted by Miss Jex Blake, who also is said to write for the *Scotsman*. He hinted in his speech to the University Court that he “would wear his eyelids off” in the work; but he looks as if he had done that already. This fussiness of the *litterateurs* is the more amusing because it is understood Masson is also under domestic influence. The same applies to Henry Kingsley, eminently one of the *genus irritabile*, late editor of a daily paper the organ of the Free Church—the same gentleman who acted as a Don Quixote in the row the mixed anatomical class excited, and grossly exaggerated it. In consequence of his and Miss Blake's statements, it is quite understood that the whole Medicals of the University “fouly” abused the seven poor ladies; whereas, out of more than 600 there were not forty present, and some of these sympathised with and protected them against the street gamins, the chief offenders. He also defended Dr. Eliz. Blackwell's political economy, as expounded in her wise rule for poor married people “not to burden the household with more children than it can bear.” The tone of all these writers is singularly ultra-feminine, both in its scolding and its unreasonableness. The ladies cajoled some of the Professors into weak concessions; now, when they cannot do more, they are charged with the academical seduction of the ladies—with bringing them to Edinburgh, and then leaving them in the lurch. It is in vain to reiterate that the ladies in the first instance pressed their attentions upon their victims; they are not the less a hard-hearted, selfish, jealous lot—vituperatively, *ad infinitum*.

Some still more curious questions arise as to the reason why the Faculty of Arts has taken such a warm interest in favour of the Medical women, and make no sign as to mixed classes in their own department. Masson's speech, just referred to, opened people's eyes a good deal. The Senatus had resolved to abandon the regulations they had so hastily adopted, but five Professors protested, and appealed against the decision to the Court, and a whip was made to bring up the absentees of the party, who had stayed away for reasons best known to themselves. So, analysing the votes in the different Faculties, Masson showed that, of the fourteen Professors in the Arts-Faculty, ten were in favour of the regulations, two undeclared, and only two against them; but of the twelve Medical Professors ten were against and only two for. That body had, however, he said, “fluctuated on the subject.” Professor Turner showed how this happened. When the matter came first before the Medical Faculty three chairs were vacant, so that instead of twelve there were only nine, and the senior Professor (Christison) was absent in London; of the remaining eight only six were at the meeting, and only four were in favour of the resolution upon which the regulations were founded. I have ascertained that the four were Bennett and Balfour (who declared their readiness to give a special course to the women), and Spence and Maclagan (who would not, but were willing to allow those to do so who would); the six were made up by Laycock and Turner, who declined to vote—Laycock declaring the Faculty had no power by law, charter, or custom of the University to educate women Professionally. The two who judiciously stayed away were Simpson and Allman; neither were supporters in the Faculty, although the name of the former is frequently quoted as having been so. Professor Bennett in his address to the Court (in conjunction with Masson) frankly declared he had the fees in view: he had pocketed this session £160, he said, and in fact he charged the women ten guineas each for their first course, while the male students pay only four guineas. The hard work has cost him dear, for his health broke down under it immediately after the meeting, and he has gone to Mentone, leaving both male and female students to be taught by his assistant. Balfour, more “canny,” says nothing about the “siller.”

Now there is in Edinburgh an association for promoting the higher education of women. It is officered by ladies. Masson at first looked rather shy at it, but being pressed, he gave a course of forty lectures on English literature, and pocketed something very handsome. He now became quite enthusiastic about “the ladies.” This feminine class, with forty lectures, and paying two guineas, was at the end of the course as accomplished in English literature, in his opinion, as his masculine class with one hundred lectures. In truth, in his enthusiasm, he rather over-egged the pudding, for it was thought his male students would have been all the better, too, for only forty of his lectures. His ambition had grown by what it fed on, so that,

in conjunction with his colleagues, he invented a grand scheme for establishing a *female Faculty of Arts*, with a very attractive feature to the Professors in Arts. These have a monopoly of teaching, for no one can graduate in Arts unless they have taken all, or nearly all, their academic diet from these gentlemen. They resist being put on the same footing as the Medical Faculty, on the plea that they would starve. This monopoly they proposed to extend to the new female Faculty of Arts, but the University heads did not quite clearly see their way to adopt the wild scheme; so Masson, in his speech to the Court, attacked the University for neglecting even the general culture of the ladies. "There were between 200 and 300 ladies," he said, "attending separate classes, taught by University Professors, but these ladies were put to all sorts of disadvantages because the University would not pay any attention to them, and would not even give them certificates." The point that was uppermost in Masson's thoughts is conclusively shown by his answer to Mr. Alexander Grant, the Principal, who immediately corrected him as to these assertions. He said, "If the University looked out for stability before it recognised any institution, if it looked out for ready-made sources of income for the Professors, that was not the notion of itself which it ought to adopt."

It is this short-sighted, interested policy, and these crude schemes which provoke the temper. The results of all this folly have yet to come.

COLONIAL CORRESPONDENCE.

AUSTRALIA.

MELBOURNE, VICTORIA, November 6, 1871.

THE subject of cholera is beginning to occupy public attention in these colonies. Hitherto we have enjoyed a complete immunity from its ravages; now and then there have been rumours of its appearance, but the cases which have given rise to the rumour have always turned out to be instances of exaggerated diarrhoea, terminating fatally in consequence of previous exhaustion from other causes. It is felt, however, that, though our freedom from its presence has, so far, been complete, the mere fact of our remoteness from European and Asiatic foci gives us no sufficient grounds for presuming upon a permanent immunity. The conditions favourable to the propagation of the poison, moreover, exist in abundance in all our larger centres of population; in Melbourne, especially, they are in rank excess. Though the largest, richest, and in all other social particulars the most important city of the Australian group, we have not yet been able to settle as to the best mode of getting rid of our night-soil and sewage. For a long time the former of these was deposited in a heap just outside the city, where it underwent some sort of preparation, and was then carted away into the country; but it proved such an insufferable nuisance that the "manure depôt" was at last abolished. Up to that time the rule of cesspits was universal. Having no sewers, water-closets were impossible; and although about half a dozen persons adopted a system of filtration, and allowed the filtered fluid to pass into the street-gutters, this was forbidden by the Corporation. It came to pass, therefore, that the subsoil of the whole city was fast becoming a subterranean bog, and the general health in low-lying situations was observed to be seriously affected in consequence, when the leading journal (the *Argus*) commenced the advocacy of the earth-closet system, and the recommendation was at once largely adopted. The local Board of Health, represented by the City Council, warmly counselled the use of earth-closets, and an endeavour was made to secure a provision in the Amended Health Act compelling the adoption of the earth-closet. This, however, the Legislature did not agree to; but the practice has, nevertheless, become very general. So far as the disposal of our night-soil is concerned, therefore, we are much better off than we were. Many hundreds of cesspits have been filled up, and the City Council have undertaken the duty of emptying the closet-pans. There is now, therefore, no excuse for anyone to neglect the regular removal of night-soil. Coincidentally, a host of disinfectants have sprung up, the most prominent of these being a chloralum prepared from Kaolin clay, which is found in large quantities a few miles from the city. It is manufactured by Mr. John Sullivan, under the superintendence of Mr. Cosmo Newbery, the analytical chemist to the Technological Museum, and it is found to answer the purpose of

deodorisation very well. In this better management of the closet arrangements of our houses, therefore, we may be said to have made some progress, but our sewerage is yet to be decided upon. We have nothing but street-gutters, down which all our liquid refuse runs into the river, which is becoming little better than an open sewer. Some years ago the Yarra was the principal source of our water supply, and it was sufficiently pure for this purpose. It has, ever since the foundation of the city, been the receptacle for our sewage; but since the Yan Yeorn water supply has rendered us independent of river water, the population of Melbourne, especially in the suburbs, has extraordinarily increased, so that now the Yarra, which was once a limpid stream, is pretty much what the Thames was twenty years ago—a very large and nasty gutter. A certain section of our legislators, desiring to make bad worse, and having in view the conciliation of their manufacturing constituents, continually endeavour to promote the establishment upon its banks of factories, which add, of course, their contribution to the vast sum of filth poured into the stream. The noxious Trades Commission have, however, recommended the appropriation of a portion of ground situated about four miles to the south-west of the city, where every manufacture of an offensive kind is to be located; and it is understood that the Legislature will offer no opposition to the proposition to adopt this scheme. Meantime, by way of making a beginning in underground drainage, the Government have ordered a complete survey to be made of the whole metropolitan district, preparatory to the consideration of the sewerage question; so that it must be confessed, although nothing has been done in the way of getting properly rid of our sewage, a good deal of discussion is kept up concerning it. For all this, as will be perceived, our actual condition is anything but satisfactory. It must be admitted, however, that so far as the enforcement of the Health Act, such as it is, can render us hygienically better off, as much is done by the Central Board of Health as well can be. Dr. M'Crea, the Chief Medical Officer, and chairman of this body, is a very model of official activity, and although his vigilance and conscientiousness make him unpopular among those whose habits are lax and whose notions of cleanliness are obscure, he is deservedly held in high esteem by all rightly thinking persons. Whatever he can do, both individually and as a public officer, exercising an important trust in insuring general conditions of health, will not fail to be done. We are fortunate, as may be known to you, in being subject, during the summer months, to fiercely desiccating hot winds, which cause the rapid evaporation of all surface-fluids. To this disagreeable, but nevertheless most salutary wind, we owe our preservation from many zymotic diseases, and it is possible that the poison-germs of cholera might find their propagating conditions limited by this means. This, however, is at best but speculation, and we look, therefore, with no little anxiety to the active condition of the disease in the other hemisphere.

Of news there is not much. Dr. Hunt, an unknown man, has been appointed Physician to the Melbourne Benevolent Asylum, and Dr. Wigg has been elected Pathologist to the Hospital. Mr. Mingaye Syder, an L.S.A. of fifty-one years' standing, has died; and Mr. D. B. Reid, Resident Surgeon to the Geelong Hospital, has proved victorious in the action for slander he brought against a member of the Committee. The defendant's expenses, however, have all been paid by a public subscription. Dr. Jamieson, of Warrnambool, has published an excellent little book, with the title of "How to Feed Infants"; and the Homeopathic Dispensary has been subsidised by Government to the extent of £150.

FOREIGN CORRESPONDENCE.

AUSTRIA.

VIENNA, January 15.

ON THE DIAGNOSIS OF SYPHILIS BY THE MICROSCOPE.

At the last meeting of the Vienna Medical Society, Dr. Losterfer read a paper containing the results of investigations into the nature of the microscopic appearance of the blood of syphilitic patients. The researches have been continued several months in Professor Stricker's laboratory, and, as will be seen, confirmed by no less an authority than that of Hebra, and if further confirmed they will, beyond any doubt, be one of the most important discoveries for practical Medicine.

During the last few years several attempts have been made

at explaining different diseases, and particularly infectious ones, by the presence of fungous growths in the blood, secretions, and excretions, as well as in the tissues of the human and animal body. In syphilis it was particularly the patients' blood which has been searched for organisms of a lower range. The results of these investigations, however, have been negative, with the single exception of Hallier, who describes a fungus, found in different infectious diseases, of that nature which has been called "micrococcus" by the same author. The micrococcus *per se* is not characteristic of any disease, but becomes so—according to Hallier's opinion—in the species produced by artificial cultivation. One of the greatest micrologists (De Bary) has objected in a most emphatic manner to Hallier's method of cultivation—so that it has been abandoned by almost all workers in that direction.

Dr. Losterfer thinks that the negative results of blood investigation have been due to two causes, namely—1. Hitherto nearly all researches have been made with too low powers; he is convinced that such investigations cannot be made with a less magnifying power than with Hartnack's eyepiece No. 3, and the immersion-lens No. 10. 2. All researches have been made with fresh blood, and the objects soon spoiled by an unfavourable method of preservation. The opinion has, unfortunately, always been prevalent, that what is to be seen in blood must be seen best in fresh blood, but it has been overlooked that things may be so minute as not to be viewed at first, but that they may grow to a visible size.

Under these considerations, Dr. Losterfer commenced his researches in August, 1871, in Professor Zeissl's wards for syphilis. The method observed was excessively simple. A small drop of blood, taken from a syphilitic patient, was put as quickly as possible on a clean object-glass, covered, the whole object conveyed to an exsiccatorium, arranged in a kind of Recklinghausen's moist camera, and daily carefully examined with the magnifying powers mentioned above. The result of the first four objects was already positive, and remained so afterwards in large numbers of objects, the blood having been taken from different patients suffering from various, yet unmistakable, forms of syphilis.

During the first two days of investigation nothing could be seen except vibriones, bacteria, and commencing forms of sarcina. In the third or fourth day, however, and, in exceptional cases, after the lapse of twenty-four hours, minute bright corpuscles became visible, some of which remained immovable, whilst others continued in a state of undulation. Some of these bodies exhibited a projection. On the fourth day (exceptionally on the third, fifth, or sixth day) the corpuscles were enlarged in bulk and in numbers. Of those enlarged, the majority had the projections just named, which were undoubtedly a kind of sprouts, which in some cases were larger in size than the corpuscle itself. In the following days the growing continued, so that some of these bodies became as big as, and even bigger than, red blood-corpuscles. Besides these, there were numbers of smaller corpuscles visible, growing and sprouting, some exhibiting one projection, others three or more projections; the latter were sessile, or had a minute pedicle. The corpuscles were by no means all globular, but of different irregular shapes. After eight or ten days a vacuola was formed in the larger corpuscles, which extended over the whole corpuscle, and terminated the further development of the growth. Different fluids, as sugar, Pasteur's liquid, common salt, acetic acid, etc., were not able to arrest the shrivelling of the bodies and further retrograde development.

Concerning the number of corpuscles, it varies greatly in different cases. Whether this be dependent upon the different stage of the disease, cannot yet be said, and must be reserved for further investigation. Dr. Losterfer has treated in a similar manner the blood of patients labouring under gonorrhoea, diphtheria, eczema, typhus, elephantiasis, and lupus, but never found anything to be compared with the appearance of syphilitic blood. Dr. Losterfer is cautious enough not to give any opinion as to the relation of the "syphilis-corpuscles," as he calls them, to the disease; whether they be the cause or the result of the latter he pretends not to know, but contents himself to state the facts he has found. After having alluded to a number of patients (and their histories) from whom he had procured blood for examination, he winds up with the statement that he is able in any case to form the diagnosis of syphilis by examining the blood microscopically.

After the paper was read, and received with great applause and encomiums by Skoda and Hebra, Professor Stricker confirmed, in addition, that the author of the paper had been tried seven times—viz., five times by Stricker, and twice by Hebra—in the following manner:—In the first trial, twelve objects;

numbered and registered, were given to Dr. Losterfer; two (Nos. 8 and 9) were taken from healthy persons, the other ten from three patients suffering from different forms of syphilis. After a few days, Dr. Losterfer responded:—"Nos. 8 and 9 healthy, two objects spoiled, the rest syphilitic." Second trial, made with seven objects—"Nos. 1 and 3 syphilitic, the rest healthy." Third trial, with nine objects—"Nos. 3, 5, and 8 syphilitic, the rest healthy." In both trials, after four days the healthy objects were picked out from the syphilitic ones, with the exception of the two objects which were spoiled. Fourth trial, with twelve objects—four syphilitic, and eight healthy. (The objects by some accident having been exposed to a temperature of 12·15° C., previous to their deliverance to Dr. Losterfer, the latter replied that "Nothing abnormal could be detected.") Fifth trial, with four healthy and three syphilitic objects. The reply was corresponding to the registration made by Professor Hebra and kept by himself secretly. In the sixth trial, one syphilitic object was given, and five healthy; in the seventh, two syphilitic and four healthy; and in both cases recognised accordingly.

AMERICA.

PHILADELPHIA, December 30, 1871.

THE Board of Health of New York has lately been investigating the general hygienic condition of that city, and, among other points of interest, has visited with its sanitary attention some of those homes of misery known as tenement-houses. It must not be inferred, from the oft-repeated allusions to these teeming dens of poverty, that New York offends the eye of the visitor by accumulated masses of unsightly pauper edifices. On the contrary, a stranger in its miles of busiest streets and avenues, might never be brought in contact with them unless by accident he should wander into localities in which they are numerically strongest. Some of these buildings hold out cordial invitations for sickness and death to enter, and, doubtless, under an epidemic infliction, these invitations would be as cordially accepted by those grim visitors. Is it not rather a wonder that the whole population of these frail tenements is not swept away *en masse*, when we read, as we do, in a very recent report from this Sanitary Board, that in two of the houses the roofs were broken through in several places, so that the rain poured in; the floors of the rooms in which the people lived were covered with filth; the cellars were literally gorged with the most offensive nuisances, and were consequently extremely dangerous to the health of the people in the locality; and the gutters ran over with liquid filth? One house was described as a three-storey frame, supported only by the adjoining tenement and a few beams in the corner; and as one moved about in the rooms the whole structure seemed to vibrate; one side was considerably lower than the other, and it was with great difficulty a stranger could safely walk about in them. Sixteen families, making a population of about one hundred persons, lived in these two dens, and the amount of mortality among them, from the condition of the surroundings, may be easily imagined. In two other houses the rooms were so low that a small man could not stand upright in them. The cellar beneath is used as a junk shop; it is very deep, and is made the receptacle for all kinds of rubbish and dirt. In these places there were fourteen families, all of whom were ordered to find new homes. These are Augean stables, but some modern Herculean power will some day sweep them clean, it is to be hoped for ever.

It is desirable that every practicable hygienic and sanitary precaution should be taken throughout the whole country in view of the prevalence of epidemic small-pox. It was at first supposed that the disease had probably passed its crisis in Philadelphia early in December, but since that time the number of cases and deaths has decreased but slightly, and it will be some time, I fear, before we shall be able to speed the parting guest who has so seriously disturbed our equanimity. A fine of fifty dollars is imposed in this city on every Physician who is derelict in reporting all the cases of contagious disease under his care, measles alone excepted, although practically this exception is extended to scarlet fever, hooping-cough, and other diseases of childhood. This law is probably pretty generally respected, although in one case within our knowledge such report, through ignorance, was not made. A patient called upon an eclectic Physician of this city with all the prodromic varioloid symptoms fully developed, and was treated for neuralgia of the head and back; but returning a day or two afterwards with those parts well covered with the characteristic exanthem, he was told that this eruption of

eczema (!) was the very best thing that could have happened to him, as now his neuralgia would be completely relieved; which last soon proved too true, for death before the end of the week relieved him of pain and every other symptom of a most malignant attack of small-pox. The number of cases reported to the Board of Health in Philadelphia during the year 1871—that is, from January 1 to December 30 inclusive—has been very large, and quite sufficient to create general alarm, being probably over 7000, while the mortality has averaged about 20 per cent. One per cent. of the population has been attacked with the disease during the year, a proportion which seems less remarkable when thus barely stated than when reduced to actual figures, and brought home—to yourselves in London, for instance. This percentage would represent with you an alarming total of about 40,000 cases, and about 8000 victims. I find in glancing over the columns of the *Medical Times and Gazette* for last spring, that they are full of appeals and warnings in behalf of protective measures against the small-pox at times when there were scarcely 100 deaths from it weekly in all London. Can you wonder that the public mind here has been materially agitated, when, with a population hardly one-fifth of that of your great city, the mortality from this one disease alone has risen from a minimum of 1 for the week ending September 9, 1871, through successive increments, until at last, with a total of 502 deaths in November, we have for December the following unusual summing up:—

Week ending December 2	.	233 deaths.
" " " 9	.	199 "
" " " 16	.	211 "
" " " 23	.	228 "
" " " 30	.	223 "

Total for December . . . 1094 deaths.

A very singular coincidence in the mortality-rate of small-pox in Philadelphia, through a long series of years, is given in the *Medical Times* of this city. In a table embracing every year from 1860 to 1870 inclusive, taken from the records of the Board of Health, there was an average of one death to 6.6 cases reported, or 15 per cent., in every year except 1868, and the exception here is so insignificant that it does not vary the general average for the whole eleven years from 15 per cent.

Years.	Deaths.	Cases.	Average.
1860 .	57	380	1 death in 6.6 cases.
1861 .	758	5,053	" 6.6 "
1862 .	264	1,760	" 6.6 "
1863 .	171	1,140	" 6.6 "
1864 .	260	1,733	" 6.6 "
1865 .	524	3,493	" 6.6 "
1866 .	144	960	" 6.6 "
1867 .	48	326	" 6.6 "
1868 .	1	7	" 7.0 "
1869 .	6	40	" 6.6 "
1870 .	9	60	" 6.6 "

Total . 2,242 14,952, 1 death in 6.6 cases, or 15 p.c.

It will be noticed, from our previous remarks, that the epidemic of 1871 has been much more fatal. The statement is made, in connexion with this table, that this average mortality "evidently refers to the unvaccinated as well as the vaccinated; for, apart from the fact that no such distinction is made in the reports, it is much less than the ordinary death-rate for the former, and much more than the average mortality among the latter. At the London Small-pox Hospital, during a period of fifteen years, the average mortality among unvaccinated persons of all ages was 37 per cent., while among the vaccinated the average mortality was 6.56 per cent. It is evident, therefore, that in our community, although a large measure of protection is derived from vaccination, a still larger one—one twice as great, indeed—would be secured by universal and thorough vaccination."

Cases of accidental poisoning are exceedingly rare among us, but whenever they do occur a great popular outcry is raised and reverberated through the land—that druggists are insufficiently educated; that they are not properly restricted; that it is a relic of barbarism for Physicians to write prescriptions in musty Latin, etc. These, and a score of other ill-natured reflections are then indulged in at the expense of pharmacists and Medical men. It is too true that hitherto there has been but little, if any, legislation in some of the States to prevent untutored youth in apothecary shops (or drug-stores, as we usually style them) from compounding prescriptions. It is a universal rule, probably without exceptions in the larger towns for Medical men to prescribe

only, the patient taking the prescription to the nearest apothecary, or to any he may prefer, be he good, bad, or indifferent, to have it put up. There has not been any law, beyond the druggist's good sense and regard for his own interests and reputation, to interfere with his delegating this duty to the merest tyro behind his counter. The best-regulated establishments of this kind are, of course, more particular, and one or two confidential clerks attend to all the compounding; but a law has long been needed to compel less conscientious employers to exercise greater care and caution. In the country towns, the Physician is obliged, by the force of circumstances, to be Medical attendant, apothecary, and midwife—"three single gentlemen rolled into one." New York city is endeavouring to correct some of these hitherto existing evils by subjecting all dispensers of drugs to a rigid examination, and seems to be pretty thoroughly sifting the wheat from the chaff. Sooner or later Philadelphia, Boston, and Baltimore must follow in the same path, and set an example to the rest of the country. These examinations in our sister city have been going on uninterruptedly for several months past, and according to the provisions of the law, any druggist pursuing his calling after last Thursday (December 21) without the authorisation of the Board of Examiners, will be deemed guilty of a misdemeanour, and be subjected to fine and imprisonment. One great difficulty hitherto has been that the drug business has not been restricted to the graduates of colleges of pharmacy, of which there are several in the United States; but anyone who had sufficient capital, and often sufficient assurance as well, to open a drug store, could do so, though he had never attended a pharmaceutical lecture, manipulated a pill-machine, or stirred a pestle in a mortar. If it should occur to any charlatan who had devised a panacea for all human ills, that by throwing the cloak of respectability around him, and assuming the virtue of Professional regularity when he had it not, he could put money into his purse under the disguise of an apothecary, there was no law to intervene between him and the public safety.

As a general rule, drug stores in all our populous cities aim at ornament quite as much as usefulness. They are almost always situated at the intersection of streets, their brilliant globular show-bottles visible for half a mile, perhaps, in their many hues of red, violet, green, and yellow. Medicines in fancy phials on polished shelves form the substratum on which they are founded; but with the expensive plate-glass windows, tiled floors, frescoed ceilings, elaborate white marble and silver-plated soda-water apparatus, marble counters, show-cases stocked with fancy soaps, perfumery, scented sachets, eau de Cologne, cigars—rarely chewing-tobacco, however—tooth-brushes, and a hundred other valuable adjuncts to personal adornment, all of which address the eye conspicuously in the shop of our modern apothecary, one is almost induced to wonder sometimes whether Shakespeare's picture of the laboratory of the attenuated culler of simples of the days of the Capulets has any counterpart in the existing condition of things on this side of the Atlantic. The druggists are far from satisfied with the new order of things. Many of them approve of the purposes of the law, and hope for an exact adherence to its provisions and penalties; but it is exceedingly probable that the Legislature of New York will be obliged to make some slight changes in it to render it more effective. It is said, for instance, that it punishes those who compound Physicians' prescriptions, but does not prevent an apothecary from compounding and selling a remedy, or himself prescribing, and making up his own prescriptions; nor does it suggest any penalty for the adulteration of medicines. The amount of medicine prescribed in a large city is prodigious, the estimate being that in New York alone at least a million and a half prescriptions are compounded annually, and this, too, with scarcely a fatal error. How much of this is wasted on imaginary ills no statistics will ever inform us.

A law to repress quackery and abortion is to be brought before the New York Legislature during its coming session. The spirit of reform seems to be earnestly at work in Medical politics as it is amid the greater bustle and turmoil of more-impure political atmospheres. Committees are actively engaged in various Medical societies, both in New York and Philadelphia, devising plans for the purification of the Profession, and for the punishment of every form of criminal tampering with human life by men or women pretending to a knowledge or skill which they have acquired neither by education, experience, nor refinement. It is probable that all the Medical associations in New York city will unite in one solid front to present to the Legislature a statement of their grievances, and thus give them an insight into the amount of injury to health and life daily inflicted upon the public in every

form of quackery. Many of the members of that body are, however, as loose in their notions of propriety on these subjects as the veriest quacks themselves. The effect of politics on most of those who meddle with them in this country is to warp them from an exact adherence to moral principle, and when this proposed Bill comes up for discussion, we may expect to find decided opposition to it from men who are themselves even below the level of the empirics they would protect. The Medical Profession in New York is fortunate in having a strong legal ally in whom they can confide, in the person of Judge Gunning S. Bedford, of the Court of Common Pleas, who honours the memory of his father and namesake, the late Professor of Obstetrics in the University of New York, by his careful regard for its interests. The Medico-Legal Society, which embraces some of the best Medical and legal talent of New York, recently appointed a Committee, on which this gentleman was associated with several prominent Physicians and Surgeons, to frame a Bill especially to correct defects in existing laws on abortion. It is suggested that this crime shall not in future be punished as manslaughter in the second degree, but as a felony, without limit as to the maximum amount of punishment. The following is the title and most important section of the proposed law:—

“An Act for the better prevention of the procurement of abortions and other like offences, and to amend the laws relative thereto.

“The people of the State of New York, represented in the Senate and Assembly, do enact as follows:—

“Section 1.—The first section of an Act entitled ‘An Act relating to the procurement of abortions and other like offences,’ passed May 6, 1869, is hereby annexed, and shall read as follows:—

“Section 1.—Any person who shall administer to any woman with child, or prescribe for any such woman, or advise or procure her to take, any medicine, drug, substance, or thing whatsoever, or shall use or employ, or advise or procure her to submit to the use or employment of any instrument or other means whatever with intent thereby to produce the miscarriage of any such woman, unless the same shall have been necessary to preserve her life or that of such child, shall, in case the death of such child or of such woman be thereby produced, be deemed guilty of a felony, and upon conviction shall be punished by imprisonment in a State prison for a term not less than four years.”

One of our own judges has within a few days past called attention to the violations of law respecting advertisements of medicines for the cure of secret diseases, or for the cure of diseases peculiarly appertaining to females. By the Act of the Pennsylvanian Legislature, of March 16, 1870, “It shall not be lawful to print or publish advertisements of medicines, drugs, nostrums, or apparatus for the cure of secret or venereal diseases, or for the cure of those diseases peculiarly appertaining to females; . . . and every such person so offending shall be guilty of a misdemeanour, and shall, upon conviction thereof, be fined in any sum not exceeding \$1000, or undergo an imprisonment not exceeding six months, or both or either, at the discretion of the Court. A second section of the Act prohibits the advertisement and sale of any secret nostrum or drug purporting to be for the use of females, for the purpose of preventing conception, or of procuring abortion or miscarriage, under the penalty of being deemed guilty of a misdemeanour; and, upon conviction thereof, to be fined in any sum not exceeding \$1000, or be imprisoned in the county gaol not exceeding six months, or both, at the discretion of the Court.”

Dr. Robert P. Harris, President of the Philadelphia Obstetrical Society, has recently published, in the *American Journal of Obstetrics*, a record of the cases of Caesarian section, or gastro-hysterotomy, which have been performed in the United States alone. He has collected, in all, the statistics of seventy operations, only two of which were performed in New York, and three in Philadelphia. Of the Southern cases, there was a larger proportion among the blacks than among the whites of the whole country; and in some of the cotton-growing and sugar-producing States nearly every subject of the operation was a negress. Deformed pelvis in this country are, as a rule, dependent on rickets, which, at one time, was regarded as far more prevalent among the foreign than the native portion of the population. The worst cases of deformed pelvis have certainly been hitherto found almost always in foreigners, dwarfs, and negroes. Of over 400 operations of gastro-hysterotomy performed since the beginning of this century (statistics of which, collected from all countries, have been published), 53 per cent have recovered. Of the seventy American cases given by Dr. Harris, 56 per cent. recovered.

GENERAL CORRESPONDENCE.

DR. TODD.

LETTER FROM DR. FORBES WINSLOW.

[To the Editor of the Medical Times and Gazette.]

SIR,—I hope you will do me the favour of correcting an error into which you have inadvertently fallen in your last number relative to an observation I made in my letter to the *Times* on “Alcohol as a Medicine.” I did not say, as you represent, that “I had known many persons who cursed the day when he (Dr. Todd) entered their house, because he had recommended alcoholic drinks as remedies, and thus had sanctioned a course of tipping,” etc. What I said was, that I once heard a distinguished member of the Profession make this remark to a number of Medical men; not that I said it. I regretted after my letter was published that I had quoted this statement, for I should be greatly grieved if by so doing I had given unnecessary and unintentional pain to any of Dr. Todd’s friends or connexions.

I always had a great respect for Dr. Todd’s teaching and practice, setting aside altogether the question as to his excessive stimulation in acute diseases. I believe he introduced into the practice of Medicine a *conservative* element which was productive of much good, and no doubt saved many lives. I refer particularly to his views as to the necessity of supporting the *vis vite* by the administration of generous nutriment, and that, too, in cases where formerly a lowering (antiphlogistic) treatment was usually adopted. I am, &c.

23, Cavendish-square, Jan. 23. FORBES WINSLOW, M.D.

UROSCOPY.

LETTER FROM DR. THOMAS STEVENSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last number, under the head “Uroscopy,” it is stated that “the current number of the *British and Foreign Medico-Chirurgical Review* contains an able summary of recent contributions to our knowledge of the urine from the pen of Dr. Karl Hofmann, of Vienna. Dr. Hofmann is the author of an excellent guide to the examination of the urine, and is in every way a most reliable authority on the subject.”

Without any wish to impugn the claims of Dr. Hofmann as an experimenter and a teacher, I venture to demur to this tribute of approbation to his paper, at all events in its English dress. The memoir in question is so full of misprints, errors of statement as regards facts, and wrong references, as to render it useless to anyone who either wishes to gain a knowledge of recent uroscopy from the memoir itself, or to use it for reference to the original papers. Either Dr. Hofmann has put forth a careless *résumé* of his subject, or, as I suspect, the translation of the paper has been entrusted to someone quite unacquainted with physiological chemistry.

In the sixteen pages to which the paper extends, I have discovered between thirty and forty errors. Passing by the errors in chemical formulæ and nomenclature, and mistakes in the figures relating to the quantities of various substances excreted, I find the utmost confusion between grains and grammes. Here is an instance (page 203)—“The quantity of the urine was much diminished (in the first case 500—600 c.c., in the second 485—870 c.c.); likewise the urea (on an average 1 grain to 3 grains, and 21·8 grains).” If this is at all intelligible, it scarcely represents with sufficient accuracy the statement in the original paper of Senator, of which Dr. Hofmann is giving an abstract, where it is stated that the total quantity of urine was 500—600 c.c., etc., and that the urea averaged 19·3 and 21·8 grammes daily. At page 205, again, there is an obscure and erroneous statement relative to the amounts of uræa and uric acid respectively excreted in leucocythæmia. In this disease it is further stated that “lactic, formic, and acetic acid, as well as oxalic acid, were found, [he is speaking of urine] whereas Salkowski, from whose paper he is quoting, expressly states that he did not test the urine for oxalic acid.

I might multiply instances, but I have said enough, perhaps, to justify me in taking a different view of Hofmann’s paper to that taken by your critic; and your readers will have been sufficiently cautioned against accepting the statements put forth in the article on “Uroscopy” in the *British and Foreign Medico-Chirurgical Review*. I am, &c., THOS. STEVENSON.

Laboratory, Guy’s Hospital, January 23, 1872.

that may be considered as ophthisis, joined with much mental disturbance. The cases were as follows:—Two sisters (seamstresses) lived together in lodgings, where their bedroom was only about eight feet square by six feet high, and situated in a very low, hot part of the town, and in the vicinity of cattle-yards. One of these girls was engaged to be married, and everything was prepared for the wedding, when it was suddenly broken off, and stories very defamatory to her character were falsely circulated. This affected her so much that she was seized with all the symptoms of typhus fever, well-developed maculæ appearing on the fifth day, with high delirium and much hysterical complication. She died on the tenth day from the commencement of the attack. On the day following her death, her sister, who attended her during her illness, and was very much affected at her death, was also taken by the same form of fever, and died on the ninth day, with similar hysterical complication and similar well-developed maculæ. These are the only cases I have seen, since I came to the colony, that I could possibly class as cases of typhus fever.

Sporadic cases of typhoid fever sometimes occur—enteric fever—with rose-coloured maculæ appearing about the tenth or twelfth day of the disease, with crepitus on pressure in the caecal region, and accompanied with diarrhoea. I have generally been able, in those cases that I have met with, to trace their origin to the use of water contaminated with faecal matter.

In the last two years, during which time water has been supplied to the town by an aqueduct leading the water from a river three miles above the town, and distributing it in iron pipes, I have met with much fewer cases of this disease. Before the present waterworks were in operation the cases of typhoid fever were more numerous; thus, in 1867 there were in my practice thirty cases, with three deaths; in 1868 eleven cases, with one death; in 1869 five cases, with two deaths; in 1870 five cases, with no death; and in 1871 three cases, and one death. From this it will be seen that the new supply of water has much improved the health of the town in regard to this particular form of disease, and I believe that this fever could be altogether kept out of the community by ordinary precautions—precautions which are very difficult to take in long-established towns at home; but in a new settlement like this it could and ought to be followed out; but, unfortunately, it is as difficult here as it is at home to instil the common principles of hygiene into corporations or other public bodies.

During the year 1862 fifteen of the cases of typhoid fever occurred in the one part of the town, within a period of three months, and among the poorer class of the population; and the water used by them was taken from a part of the river contaminated by sewage, slaughter-houses, and clothes-washing. (All the washing of clothes is done here by natives at the river.) Of these cases seven were attacked with cerebro-spinal arachnitis during the course of the fever, and this complication appeared to me to be caused by exposure to the heat of the sun, amongst children going out without covering to the head while incubating the disease.

Typhoid fever in this country presents no difference in character from what it does at home. It follows the same course in every respect, and can nearly always be traced to the same cause—viz., contamination of water with faecal matter.

The treatment I have found most useful for ordinary cases of the fever is two grains of quinine, twenty minims of dilute sulphuric acid, and ten drops of laudanum every four hours, complications being treated as they may arise. I find that the sulphuric acid is generally sufficient to control any diarrhoea that may occur, but in some cases I have used a mixture of acetate of lead and acetic acid with morphia.

A great deal of this fever is now prevalent at the diamond-fields, and it is a thing that must be expected there. Dr. Atherstone, of Grahamstown, who has paid much attention to geology, and visited the diamond-fields especially to examine the geological formation of the country, wrote a letter, on his return, to one of the local papers, pointing out that typhoid must arise there, if proper sanitary arrangements were not instituted; because the chief place—"De Toits Pan"—where diggings were being carried on, and where a population of over 15,000 persons were congregated, was geologically formed as a basin (or Pan), of primitive rock, filled with drift and alluvial deposits. This pan is oval, about 1000 yards in one diameter, and 500 in the other. It is in this deposit and on the hills surrounding it that the diamonds are found, and the only water for drinking or other purposes is obtained from wells sunk through it. This water is only derived from the rainfall of the Pan or basin, and in soaking through the alluvial deposit must wash along with it all the faecal matter

and slaughter-house refuse of 15,000 people accumulated on the surface of and around the "Pan"; and I agree with Dr. Atherstone in thinking that the percolation of the rainfall through the alluvial deposit cannot remove the contamination derived from the immense quantity of faecal and other matter strewn over the surface.

De Beer's and New Rush are geologically formed much the same as "Du Toits Pan," and are becoming equally unhealthy. The forewarnings of Dr. Atherstone are now becoming facts, and typhoid fever is very prevalent and fatal at these two parts of the fields; and I fear that, before the summer is over, many persons will fall victims to the want of sanitary arrangements. I have seen some cases in persons returning from the fields—and they were pure cases of typhoid fever—and there did not appear to be anything of a malarious nature in them.

The filthy state of the camp has been described to me by persons returning from the fields, and they report that human ordure is scattered everywhere over the surface (no arrangements having been made for its removal); and along with this are the carcasses of oxen dead of lung sickness (pleuro-pneumonia), and the refuse of beasts slaughtered for food.

I enclose the following extracts from the local papers to give some idea of the utter want of sanitary arrangements, and the present state of health at the camps:—

"*Sanitary.*—The sanitary condition of the various camps in the neighbourhood requires the immediate attention of the Government. Any delay just now might result in a serious calamity. As a preparatory step a sanitary inspector has been appointed, but as yet nothing whatever appears to have been done with a view to the removal of these impurities, which so injuriously affect the health of the diggers. In some parts of the camps the effect of effluvia of putrid matter must necessarily give rise to various forms of fever, unless active steps are adopted by the Government to check the evil. Sanitary regulations should be framed and rigidly enforced at once."

"*Let the Dead Bury the Dead.*—We suppose this to be the motto of the sanitary authorities—if there be any such authorities—at De Beer's and New Rush, for on Wednesday last, at high noonday, rotten in the blazing sun, there lay in the middle of the camp there, stiff and stark, with clenched fingers, lips drawn up so as to reveal the ivory-whiteness of the teeth, and with flies clustering about his eyes, mouth, and nostrils, the body of a coloured man who had died, or was said to have died, early in the night. His 'mother' was at work close by, taking no more notice than if it had been the carcase of a dog, and all that passers-by did was to say, 'it was a shame—somebody ought to put the corpse out of the way,' but no one seemed to care to stir a step to remove the ghastly object from the public gaze."

"*One Hundred Persons Dead in a Day.*—From the diamond-fields the most lamentable accounts are being received of the increase of the fever and the terrible mortality among the diggers. On one day it is said that no less than a hundred persons had died at the fields. The average number of deaths is computed to be about twenty-five daily. From one claim we are told in the last week five corpses were conveyed at one time in a Scotch cart. Many of the diggers, it is said, are leaving the fields to return to their home till the winter sets in."—*Burghersdorp Gazette.*

Besides typhoid fever, a great deal of dysentery and diarrhoea are also present, and the absolute want of all kinds of vegetable diet must also lay the foundation of much disease. As typhoid fever is a disease that can be prevented by proper sanitary arrangements, the present unhealthy state of the fields would not have arisen if ordinary precautions had been taken; but there being no proper government when the place was first occupied, and everyone who went there being altogether taken up with digging and seeking for diamonds, all such things as sanitary arrangements were totally neglected, and now they are suffering from that neglect.

Fevers of malarious origin are unknown here as a disease arising in the colony, and the only cases of the kind that I have seen were in persons who had contracted the disease in other countries.

Almost every year, either in spring or autumn, influenza is very prevalent here—coming on quite suddenly, with intense headache, pains in back and limbs, general prostration, and fever, accompanied sometimes with coryza or bronchitis. At present there is a severe epidemic of this disease here—much more severe in adults than in children. I usually administer large doses of carbonate of ammonia (ten grains), spirits of chloroform, and camphor mixture, which I find to be very successful—not shortening the duration of the disease, but relieving the headache and muscular pains. The disease

usually lasts four or five days, and leaves the patient very prostrate and weak for some time after. In some cases, which have commenced as pure influenza, a sudden change has taken place, and severe diarrhoea has set in, relieving altogether the acute headache, but leaving the patient even weaker than if the disease had followed its usual course. In such cases I have found the most useful treatment to be a mixture of dilute sulphuric acid and tincture of opium. I have remarked that in those years in which influenza is most prevalent, there is an unusual amount of disease amongst horses (known here as "horse sickness"). This disease, in my opinion, is a form of suffocative catarrh, or congestive bronchitis. It is rapidly fatal, horses dying in from one to ten hours from the first appearance of the disease. I have known cases of horses being attacked with the disease while in harness, and dying within an hour.

The breathing of the animal during the attack is very short and difficult, with much discharge of mucus from the nostrils, but without much cough (indeed, I think cough is usually absent), and the animal appears to die suffocated. In every case that I have seen opened after death, there has always been present much congestion of the trachea and bronchial tubes, and always, invariably, great effusion into the pericardium. No treatment that has been tried has been of any use in this distemper. It is most prevalent in grass-fed horses, seldom attacking those in a stable, unless they have been taken out for night-work. But when a stable has been full of horses (say over four), and some of these are out at work, and one left alone at night in a stable which is usually full, that animal in such seasons is very apt to be found dead in the morning.

In those seasons in which this distemper is so virulent among horses, a large number of cases of disease of the throat and respiratory organs occur—such as croup, cynanche pharyngea, and tonsillitis—and these are very fatal amongst children.

I am, &c.,

CHARLES J. EGAN, A.B., MR. C.S.E.

December 10, 1871.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 9.

MR. CURLING, F.R.S., President, in the Chair.

DR. WILLIAM OGLE read a paper on a "Case of Complete Recovery after Removal of the Body of a Cervical Vertebra." In this paper a case was narrated, of which the following were the chief points:—A man, after suffering for some months from sorethroat, became out-patient at St. George's Hospital. It was found on examination that some bone was exposed at the back of the pharynx, but the patient suffered so little inconvenience from this that he could not be persuaded to become in-patient. The man's attention having been directed to the exposed bone, he got into the habit of fidgeting it about with his fingers, and at last loosened and removed it himself. On maceration, the piece thus removed was found to consist of the antrum of one of the cervical vertebrae and a small portion of the antrum of a second one. After remaining for some months out-patient, the man was persuaded to enter the Hospital. He was placed on his back, and his head fixed; and remained in this position six months. During this time he expectorated numerous spicules of bone, and what appeared to be portions of fibro-cartilage. The lesion eventually healed completely; and the man at the present time—two years since the lesion—is able to occupy himself with the heaviest farm-labour, and to amuse himself with field-sports. There is no visible deformity of the neck, nor any other sign of what has occurred except a slight stiffness in rotating the head. The piece of bone was exhibited.

MR. HENRY LEE thought it would be highly important to know more of the early history of the case; and believed that the explanation of its successful issue was to be found in its syphilitic character. In syphilitic cases, in which the periosteum was primarily and for a long time affected, it was not unusual to see a great development of new bone in the thickened membrane, and he conceived that in this case such thickening and eventual ossification might have extended to the bodies of the adjacent vertebrae, and might have afforded support to the

interrupted column. If the disease of bone had been of a strumous character, no ordinary powers of repair could have brought about recovery.

MR. BRODHURST thought Mr. Lee's explanation insufficient. He passed his finger into the space from which the dead bone had been cast out, and he felt no trace of any new formation.

THE PRESIDENT asked whether Mr. Lee meant to say that he thought there had been syphilitic disease of bone, leading to repair of bone.

MR. HENRY LEE explained that he thought there had been syphilitic lateral periostitis leading to ossific deposit in the thickened periosteum.

MR. SAVORY thought it was not necessary to determine between scrofula and syphilis. Mr. Lee's observations had struck him with much surprise; for if there was any dyscrasia, which especially hindered the reproduction of bone it was syphilis.

Several of the Fellows addressed questions to Mr. Lee intended to shake his position, to which he nevertheless adhered; and much amusement was produced by the brisk sort of cross-examination to which he was subjected.

DR. JOHN W. OGLE and MR. HENRY LEE communicated a case of Tracheotomy in which the Tube, having become detached from its Shield, escaped into the Trachea, and was Removed by a Second Operation fourteen months afterwards. The patient, a man aged 32, had been the subject of typhus fever in 1865. He recovered, but never afterwards felt thoroughly well, and about a year subsequently had an attack of laryngitis and bronchitis. Tracheotomy was performed, and the patient continued to wear the tracheotomy tube for three years, when the shield became detached. It was improperly reunited to the canula, and in another year's time it was again detached, and on this occasion the canula slipped into the trachea. A few weeks after this the patient was placed under Dr. Ogle's care in St. George's Hospital, suffering from great dyspnoea, and having the sensation as if the tube were situated on a level with the upper part of the sternum. Auscultation failed to help in deciding the position of the tube, and the patient refused to have chloroform administered with the view of search being made for it. He then left the Hospital (September, 1870), and continued to go about, suffering from dyspnoea and irritation about the windpipe, until his symptoms became more urgent, and he was obliged to come to the Hospital again on November 5 last. He said "he had coughed the tube up into the throat, and could feel it there." No time was lost. The patient was at once placed under the influence of chloroform, and as he lay upon his back tracheotomy was a second time performed, and two eroded portions of metal were taken by means of curved forceps from the trachea. The pieces were almost the length of a tracheotomy tube, and gave origin to the idea that the original tube had been bivalved. This, however, upon inquiry turned out not to have been the case. The pieces of metal had been eroded into their present shape while in the trachea. The pieces were shown to the Society.

A second case, which some years ago had occurred under the observation of Mr. Lee, was related. In this instance a boy had swallowed a fourpenny-piece. This was expelled without operation through the glottis during a fit of vomiting. In the observations made attention was drawn to the different modes of treatment likely to be required in cases of smooth or round bodies in the trachea, as in the last-mentioned case, and cases in which pointed or rough bodies had to be removed, as in the instance first recorded.

THE PRESIDENT thought the rule of Surgery was clear—that a foreign body in the trachea should be extracted by operation.

MR. POWER said that smooth bodies, even of considerable size, might pass out by the natural passages. He described the case of an Irishman who had a pebble in his larynx. By putting the man on his face on a table, with his head low, and giving him a slap on the back, the pebble was immediately ejected.

MR. COUPER mentioned a child who was brought to the London Hospital with a foreign body in the trachea. The Surgeon who saw the case deferred operation, on account of the absence of urgent symptoms; but a paroxysm of dyspnoea came on in his absence, and he (Mr. Couper) opened the trachea at the request of the House-Surgeon at a time when death seemed impending. The foreign body was a bean, and it passed up and down behind the tracheal opening during the respiratory efforts, but with some difficulty was seized and extracted. The patient died of pneumonia.

MR. HOLTHOUSE mentioned having once permitted a pill to slip into his own larynx, and having ejected it at once

and without any trouble. He also showed the pieces of a tracheotomy tube which he had himself extracted, under circumstances similar to those detailed in the paper under discussion.

Mr. THOMAS SMITH pointed out that children sometimes got acidulated drops into the trachea, and that these might safely be left to dissolve. Among other foreign substances that he had known to lie in the air-passages was a common dress-hook, the loops of which were directed downwards, while its bent extremity was hung upon one of the vocal cords.

Other cases were also mentioned by Dr. O'CONNOR, Mr. HENRY LEE, and the PRESIDENT.

Mr. BRUDENELL CARTER thought that cases of the detachment of a tracheotomy tube from its shield were to be prevented by using a well-made instrument. Instead of the tube and shield being imperfectly soldered at their junction, they should, when intended to be worn permanently, be made out of a single piece, and even electro-gilded at the angles, to protect the metal against chemical corrosion.

OBITUARY.

ROBERT WADE, F.R.C.S., ETC.,

DIED at his house in Dean-street, Soho-square, on Thursday, January 16, at the advanced age of 84. His father was a brewer at Woodbridge, in Suffolk, near which place Robert was born on November 23, 1788. He received his early education at a neighbouring school, and having been duly apprenticed, came to London when almost 20 years of age. He had expected that he would at once enter to lectures and Hospital practice, but his father having become involved in difficulties, young Wade was thrown upon his own resources. Of a robust frame, strong will, and of a hopeful disposition, he looked to the future with confidence. Like many other members of our Profession who have risen to distinction, his earlier years were those of self-denial, hard work, and scanty income. He became assistant to one of the "top apothecaries" at the West-end, and for some years was a veritable drudge. He made up all the medicines, attended most of the night cases, and all the lower class of midwifery. At this time the unqualified Medical assistant was regarded more in the light of a domestic servant than a gentleman. Wade's lot in this respect was of the "common." At length, after eight years of incessant labour and great thrift, he had saved sufficient to pursue his studies, and entered in 1817, we believe, to St. George's Hospital. He passed the College of Surgeons in 1819, and the Apothecaries' Society about the same time. He again became an assistant, but under very different circumstances. The office of Apothecary to the Westminster General Dispensary becoming vacant, Wade became a candidate for it, and was elected by a small majority. He fulfilled the duties of his appointment with great credit to himself and benefit to the institution for some years. About 1828 he commenced practice on his own account at the house in which he resided till his death, 68, Dean-street. For some time he eked out a somewhat scanty income by taking pupils. The Medical students of that day were less orderly and correct than those of the present time. I have heard Wade relate many of the annoyances to which he was subjected by his young friends; but some of his pupils have reached to high and deserved distinction. I can bear testimony to the regard which some of his old pupils had for the good old man even to the last; and they always spoke of him with affectionate respect. Wade, on his retirement from the office of Apothecary to the Dispensary, was unanimously elected Surgeon to the institution, and this office he held to the day of his death, performing his duties to the last with a fidelity and punctuality which contrast favourably with the attendance of many Surgeons to Hospitals and Dispensaries in the metropolis. Some years since he was presented by the governors with a handsome piece of plate, in recognition of his services. The name of "specialist," when he took the office of Surgeon to the Dispensary, was all but unknown, but circumstances drove him, as it were, to choose a particular line of practice. Amongst the crowd of patients which attended on his "days," numbers were affected with stricture of the urethra in all its forms. He soon found that some of those cases of the most intractable kind could not be successfully treated by simple dilatation, and he directed his mind to discover some means by which they could be treated with safety. Shortly before the system of treatment carried on most extensively by Sir Everard Home had fallen into discredit, in consequence of the disas-

trous results ensuing from it. Home had recourse to the nitrate of silver, and, no doubt, was very successful in many cases; but he carried his practice to a degree of heroism which eventuated in its downfall. Mr. Whateley, after the failure of the lunar caustic, practised and advocated the use of the potassa fusa in cases of stricture of the more intractable kinds. Whateley had but a limited success, and, at his death, no one seemed desirous to become his successor. Then a new system of treatment was practised by some Surgeons of more or less eminence, Guthrie and Stafford being foremost amongst them. This consisted in what was termed internal incision: a bougie, armed with a knife, was inserted into the urethra, and when the seat of obstruction was fairly reached, the knife, being worked by a spring at the handle of the instrument, was protruded, and the stricture freely divided. For a time all went well, but cases of severe hæmorrhage were common, and fatal results occasional, so internal incision lost ground, and died, I believe, with Mr. Stafford, who, notwithstanding all its dangers and drawbacks, contended to the last that it was, on the whole, the most efficient and the safest that could be employed. Wade had opportunities of trying these plans of treatment, and, after a long and anxious trial, came to the conclusion that Whateley's was the best remedy. But he was soon convinced that the caustic potash had been used too freely by Whateley, just as the lunar caustic had been too freely employed by Home. He accordingly, in the most obstinate cases of stricture, commenced his use of the caustic potash in very minute quantities, and gradually increased them. He soon found that all the benefits of this agent could be obtained without resorting to the more powerful, and sometimes dangerous, "doses" employed by Whateley. Always cautious and painstaking, he hesitated long before he gave his views to the Profession. But at length, fortified by an experience of several hundred cases in public and private practice, he ventured to stand forth as the advocate of the use of that remedy in cases of irritable and intractable stricture. And here, in justice to the memory of my old friend, I must attempt to remove a misconception which prevailed, that he invariably resorted to this remedy. As I had the pleasure and privilege of seeing every work he published through the press, I am bound to say that no Surgeon ever rode his "hobby horse" more tenderly and with more skill. Often has he said to me, "The potassa fusa is not the main power which I rely upon in my battle with cases of stricture. Far from it; most cases of the disease can be successfully treated by careful and persistent dilatation; but I have found such extraordinary results from the employment of small quantities of the caustic potash in cases of irritable and intractable obstruction, that I should fail in my duty if I did not use it." I must confess that I believe the conclusion he arrived at was sound and practical, and that, by his consistent and persevering advocacy of this remedy, he has snatched a valuable agent from oblivion, and added a page to the history of conservative Surgery. And here I may diverge for a moment in this narrative, to say that I consider Wade had inestimable advantages over the so-called "specialists" of the present day, and these were his early training, his vast experience as a Surgeon in general practice, and his good knowledge of pathology and therapeutics. He did not, as the tanner in the fable, think that there was "nothing like leather," but he resorted to "leather" when other means of "defence" had failed. His courage and consistency never deserted him. With his usual energy he denounced in unmeasured terms the "perineal section" of Syme. Can it be said that he was wrong in that opposition? But he was not a bigoted antagonist. When he found that he was wrong, no man was more ready to acknowledge his error. One instance will suffice. Mr. Thomas Wakley, it is well known, proposed and practised a most ingenious plan of treating stricture by gradually enlarged tubes. In one edition of his work Mr. Wade strenuously opposed this plan, believing that it would cause laceration and danger; but he felt bound to satisfy himself on this point, and after some trial of the plan, he was convinced that in certain cases it might be employed with safety and advantage. What did he do? In the very next edition of his work on stricture, he not only acknowledged his error, but actually gave a lithographic illustration of Mr. Wakley's instruments, and spoke of them with qualified approbation. This is to his honour; for the journal which represented the interests of Mr. Wakley had attacked him with a rancour which was neither just nor justifiable. I say this from a knowledge of the facts. Fortunately in these days, when the "balance of power" is more righteously adjusted, no such system of persecution could be successfully maintained. I became acquainted with Robert Wade in consequence of attending a course of lectures on

pathology delivered by him at the Little Windmill-street School in 1834. I was on intimate terms with him, and for many years spent my Sunday evenings at his house. In his "happier hour" the man came out enthusiastically an admirer of Shakespeare and Byron; it was a delight to discuss with him the merits and beauties of these great masters of English literature. No man had a greater appreciation of them than Robert Wade. He took few holidays—"work to him was leisure;" but he annually rented a house at Hampstead for a "little change." I was his frequent visitor on these occasions, and amid the quiet lanes, the fertile fields, the wooded heights of that suburban "paradise," I have walked and talked with him and his family. The pleasure of those "outings" I shall not easily forget. I know your tourists on the Rhine and the Moselle, your Alpine climbers, and your yachters may smile at the "Coekneyism" of such scenes; but they must not, or ought not, to forget that those scenes were dear to men like Coleridge and Leigh Hunt, and have been immortalised by the pictures of some of the greatest landscape painters of the present and a past age. A great appreciator of everything beautiful in nature, and a lover of the arts, he was anxious to obtain some works of the late William Hunt, that marvellous portrayer of fruits and flowers. It was not, however, until 1851 that his means allowed him to indulge in what he then regarded as an expensive outlay. This was done with much caution and misgiving. The drawings by this distinguished artist at the period named were but one-tenth of the value which they now realise at public auction. In an interview with Mr. William Vokins, who at this time had the majority of Hunt's works from the easel, and while contemplating a drawing of a "Bird's Nest," the price of which was but twenty-two guineas, Wade expressed his great desire to purchase, but added—"I am but a poor Surgeon, and though I should like it much, I hardly feel justified in doing so; but tell me honestly, should it so occur that I am unable to retain it, is it likely I may get my money again?" Being perfectly assured on this point, it was bought, and was the nucleus of a collection of drawings of fruit, flowers, etc., entirely by this master—not large, but admitted to be unique in quality by everyone acquainted with the matter who has seen them, either on his walls or at the loan exhibitions, to which he was at all times a willing contributor. The possession of these drawings led to his acquaintance with the artist, and he became his Medical adviser, attending him in his last illness. It would be a misfortune, I think, if this splendid collection should be lost to the nation. Its proper place would be at the South Kensington Museum, amongst the productions of those who have shed a lustre on British art. His contributions to Medical literature were:—"Stricture of the Urethra: its Complication and Effects; a Practical Treatise on the Nature and Treatment of those Affections;" "Conservative Surgery of the Urethra—on the Treatment of Stricture;" "Exfoliation of Anterior Arch of Atlas," *Med.-Chir. Trans.*, 1849. "Remarks on Strangulated Hernia, reduced *en masse*, with a case in which an Operation was Successfully Performed," *Lancet*, 1845; "Treatment of Permanent Stricture of the Urethra," *Medical Times and Gazette*, 1851; with other contributions to Medical journals.

In all the relations of life, as husband, father, friend, or Medical adviser, Robert Wade was most exemplary. He literally "died in harness." He rose on Tuesday morning in his usual health, saw patients until one o'clock, was seized with apoplexy at two, and breathed his last at four.

J. F. C.

CHARLES FERNELEY, M.R.C.S. ENG., L.S.A.,
L.R.C.P. EDIN.

WE have to record the death of Dr. Ferneley, which took place at his residence, Grantham, on Saturday, December 23, 1871, in the 61st year of his age. He was a student of St. George's Hospital, and in 1832 commenced practice at Denton, near Grantham, which village he left on the Royal South Lincoln Militia, of which he was Surgeon, being sent into garrison duty at Chichester, and subsequently at Portsmouth and Cork, during the Crimean war. On the regiment being disembodied, he settled at Grantham, retaining the office of Surgeon until his death. He held the post of Medical Officer for the Denton and afterwards the Grantham districts of the union for a period of thirty-two years; he was also Surgeon to the borough gaol.

Dr. Ferneley was an ardent Freemason, and rose to a very high rank among his brethren. He was a diligent student of masonic lore, and published some remarks on "The Origin of Speculative Freemasonry." He devoted considerable time to

the study of the theory of Medical science, and to the pursuit of science generally. He also published some lectures on "The Nutrition of Plants," and contributed various papers to the *Medical Gazette* and other journals.

His death is deeply regretted by his fellow-townsmen and regiment, the officers of which recently presented him with a handsome piece of plate in recognition of his valued services.

SURGEON V. M. McMASTER, M.D.V.C., 78TH REGT.

THIS distinguished and highly esteemed military Surgeon died in his quarters at Belfast on the 22nd inst., rather suddenly, from valvular disease of the heart, from which he had long been a sufferer. Surgeon McMaster entered the service on March 27, 1855, as Assistant-Surgeon of the 78th Regiment, with which he served in the Persian war in 1857 (medal and clasp). He afterwards went with his regiment to India on the outbreak of the mutiny. He served with Havelock's column at the capture of Cawnpore, and during the advance into Oude. He was present at the relief of the Residency of Lucknow, and was wounded during that exciting episode. He also accompanied Outram's force during the final capture of Lucknow, the expedition into Rohilcund, and capture of Bareilly. For his services during the Indian mutiny campaign he obtained a medal with two clasps and the Victoria Cross. The latter distinction was voted to him by the universal acclamation of the men and officers of the regiment, by whom he was esteemed with a fervour almost amounting to devotion. On promotion in March, 1868, he was for a short time removed from the regiment in which he had gained so many friends. The separation was not for long, and he has now terminated his brilliant and useful career among those who knew and loved him most, and who now, with many a tear, will have the sad pleasure of placing his honoured remains, with regimental honours, in a soldier's grave.

NEW INVENTIONS.

ROBUR.

(Arthur, Monroe, and Co.—Office, 1c, Brecknock-street, N.W.)

UNDER this emphatic title we have a spirit, which comes to us with the private recommendation of a Belgravian Practitioner who is well qualified as a judge in such matters. This spirit consists, of course, of strong alcohol; but it is prepared and compounded in a way which is intended to bring it into competition with brandy, whisky, and the other spirits in popular use. It contains the active principles of tea and of fruit, the nature of which has been communicated to us, and is quite harmless. It is claimed for it, not that it shall be used instead of wine or beer, but instead of the *schnaps* or *petit verre*, or hot grog, or "cold without" of those who are already in the habit of using spirits. The combination of tea and fruit gives a softness to the taste, and it is suggested that they act in a complementary manner to the spirit, and tend to refresh the nervous system. Many people, when fatigued or exhausted, like to "laec" (this is the technical expression) their cup of tea with a teaspoonful of spirits; therefore, they may like spirits flavoured with tea, or may feel it convenient to have their tea and brandy in one bottle. Anyhow, the spirit seems wholesome, and is cheap, and may fairly compete with other articles of its class.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 23rd inst., viz.: Bower, Augustus Edward, L.S.A., Nantwich, Cheshire, student of King's College. Brittin, Frederic George Morris, L.S.A., Thornhaugh Wansford, Northamptonshire, of the London Hospital. Chambers, Eber, Ryde, Isle of Wight, of St. Bartholomew's Hospital. Deeping, George Davidson, L.R.C.P. Lond., Newark-on-Trent, of Guy's Hospital. Dempsey, Meldon Joseph, L.S.A., Charterhouse-square, of St. Bartholomew's Hospital. Dobie, Stanley Locker, Irthington, near Carlisle, of St. Mary's Hospital. Dunstan, Robert, L.S.A., Liskeard, Cornwall, of Guy's Hospital. Ferris, John Edward Charnock, L.S.A., Cornwall-road, Bayswater, of St. George's Hospital. Garrett, John, Salisbury, of the London Hospital. Godfrey, Amiraux, Jersey, of St. Bartholomew's Hospital. Johnstone, John Lawson, Liverpool, of the Liverpool School.

Kelly, Michael James, Talbotstown, Baltinglass, co. Wicklow, of the Dublin School.
 Langdale, Henry Marmaduke, L.S.A., East Hathley, Sussex, of Guy's Hospital.
 Llewellyn, George Joseph, L.S.A., Haverfordwest, of Guy's Hospital.
 Moseley, William Arthur, L.R.C.P. Edin. and L.S.A., Nassau, Bahamas, of St. Bartholomew's Hospital.
 Pigeon, Henry, L.R.C.P. Edin., Redland, of the Bristol School.
 Pike, William Royston, L.S.A., Leicester, of St. Thomas's Hospital.
 Salmon, Alfred Lidgley, L.S.A., Truro, Cornwall, of St. Bartholomew's Hospital.
 Sarjant, Josiah John, L.S.A., West Ferry-road, Isle of Dogs, of the London Hospital.
 Shearman, William Millar, Gateshead, of the Manchester School.
 Steele, Russell, L.R.C.P. Edin., Reigate, Surrey, of University College.
 Sylvester, Kirwan Francis, L.R.C.P. Edin. and L.S.A., Trowbridge, Wilts, of St. Bartholomew's Hospital.
 Taylor, Herbert, Kennington-park-road, of St. Bartholomew's Hospital.
 Underhill, Charles Edward, B.A. and M.B. Cantab., Tipton, Staffordshire, of the Edinburgh School.
 Wallis, Edward Darby, L.S.A., Bodmin, Cornwall, of University College.
 Woodward, George, Bicester, Oxon., of St. George's Hospital.

The following gentlemen passed on the 24th inst., viz. :—

Barton, James Edward, Redcliffe-street, Brompton, student of the Westminster Hospital.
 Buchanan, Arthur, The Spa, Gloucester, of Guy's Hospital.
 Corie, Alfred Thomas, L.S.A., Plymouth, of St. Bartholomew's Hospital.
 Edwards, John Ellis, L.S.A., Aberdare, Glamorganshire, of Guy's Hospital.
 Hues, James John, Handsworth, Staffordshire, of the Birmingham School.
 Jackson, James Elwes Corrie, North Reston, Lincolnshire, of the Charing-cross Hospital.
 Jones, Lewis Herbert, Ruthin, Denbighshire, of the Birmingham School.
 Marsh, Walter Alfred, L.S.A., Dante-road, Newington, of Guy's Hospital.
 Procter, Thomas, Wigan, of St. Mary's Hospital.
 Pugh, Edgar Joseph, L.S.A., Waltham Abbey, of University College.
 Rae, William, King's Lynn, Norfolk, of King's College.
 Rix, Benjamin, L.S.A., East Meon, Hants, of Guy's Hospital.
 Rosten, William Martin, Rushall, Walsall, of the Birmingham School.
 Thornton, Philip, L.S.A., Norwood, of the London Hospital.
 Tudge, James McDougall, L.S.A., Hereford, of Guy's Hospital.

Five candidates were referred in Surgery, five in Medicine, and eleven were altogether referred to their Professional studies for six months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, January 18 :—

Dempsey, Melden Joseph, Charterhouse-square.
 Ferris, John Edward Charnock, St. George's Hospital.
 Hammond, William, University College.
 Marshall, Lewis Walter, Southville, Bristol.
 Morris, Malcolm Alex., Tavistock-road, Westbourne-park.
 Odell, William, Newport Pagnel, Bucks.

As Assistants in Compounding and Dispensing Medicines :—

Brewster, William, Kimbolton Hunts.
 Shone, John, Union-square, Islington.

The following gentlemen also on the same day passed their first Professional examination :—

Clague, John, Guy's Hospital.
 Kingcombe, Alfred Partridge, Guy's Hospital.
 Welch, William John Joseph, Queen's College, Birmingham.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ATKINS, T. L. J., late Dispenser to the Ebbw-vale Steel, Iron, and Coal Co.—Dispenser at the Newport Infirmary.
 BALL, J. B., M.B. Lond.—House-Surgeon to the Evelina Hospital for Sick Children, *vice* Michael Harris, resigned.
 HARRISON, J. W., M.R.C.S. and L.S.A.—Public Vaccinator for the 1st District of the Eccleshall Bierlow Union, Yorkshire.
 HAYNES, STANLEY, M.D., M.R.C.S.—Surgeon-Accoucheur to the Malvern Lying-in and Samaritan Charity.
 TAYLOR, ALGERNON, M.R.C.S., L.S.A., A.K.C.—Medical Officer for District No. 2 of the Eccleshall Bierlow Union, Yorkshire.
 WILLIS, JULIAN, M.R.C.S.E., L.M., L.R.C.P. Edin., L.M. Edin.—Medical Officer for the Mitcheldever District of the New Winchester Union.
 WOOD, WILLIAM, M.R.C.S.E., L.S.A.—Medical Officer and Public Vaccinator of the Middleton District of the Driffield Union, Yorkshire.

NAVAL APPOINTMENTS.

The undermentioned Assistant-Surgeons have this day been promoted to the rank of Surgeon in Her Majesty's Fleet :—Henry A. Close, Joshua P. Courtenay, George A. Campbell, and Daniel R. Alcock.

BIRTHS.

COOKE.—On January 18, at 30, Gower-street, Bedford-square, the wife of Thomas Cooke, F.R.C.S., M.D. (Paris), of a son.
 FEGAN.—On January 20, at 1, Charlton-park-terrace, Old Charlton, S.E., the wife of Richard Fegan, M.D., L.R.C.P., etc., of a son.
 FENNINGS.—On January 13, at 26, Clarendon-road, the wife of Dr. Fennings, of a son.
 HARVEY.—On January 18, at 26, Rue Wissocq, Boulogne-sur-Mer, the wife of Dr. J. T. S. Harvey, prematurely, of a son.

RADCLIFFE.—On January 22, at Sandfield-park, West Derby, the wife of Dr. Radcliffe, of Ballarat, Australia, of a son.

TONGE.—On January 20, at The Cottage, Harrow-on-the-Hill, the wife of Morris Tonge, M.D., of a daughter.

MARRIAGES.

DANBY—SMITH.—On January 20, at St. George's, Hanover-square, Thomas William Danby, M.A., F.G.S., Fellow of Downing College, Cambridge, and one of her Majesty's Inspectors of Schools, to Gertrude, only daughter of William Tyler Smith, M.D., of 21, Upper Grosvenor-street.
 DENNISS—GORDON.—On January 16, at St. Peter's, Dublin, Alfred Digby Denniss, Captain Royal (Bengal) Artillery, son of the late Colonel G. G. Denniss, C.B., Bengal Artillery, to Edith (E. S.), eldest daughter of Samuel Gordon, M.B., Dublin.
 HULL—OOLE.—On December 4, 1871, at St. George's Cathedral, Cape Town, by the Very Rev. the Dean T. F. Lightfoot, George Askew Hull, House-Surgeon, Provincial Hospital, Port Elizabeth, eldest son of Dr. George Hull, of Kensington, to Isabel Henriette, fourth daughter of J. Connell Ogle, Esq., of Kensington.
 NIVEN—HALSON.—On January 17, at All Saints' Church, Upper Norwood, William Niven, M.D., H.M. Indian Army, to Margaret Minnie, daughter of the late John Halson, and niece of Alex. Croll, Esq., of Mavis Bank, Grange-road, Upper Norwood, Surrey.
 WEBB—WATERS.—On the 23rd inst., at St. Paul's, Newton Abbot, G. Fortescue Webb, F.R.C.S.E., of Exeter, to Georgina Marion, daughter of George Waters, F.R.A.S., late of the Madras Civil Service.
 WOOLLEY—ELLIS.—On January 16, at Willingham, Cambridgeshire, J. Woolley, Esq., son of the late Dr. J. Woolley, of the Bengal Army, to Sarah Maria, second daughter of R. S. Ellis, Surgeon, Willingham, Cambridgeshire.

DEATHS.

CLAYTON, M. H., Surgeon, eldest son of the late Rev. John Clayton, vicar of Stratford-on-Avon, at Calthorpe-road, Edgbaston, after a short illness, on January 23, aged 46.
 GOOCH, MARTHA, the beloved wife of William Henry Gooch, M.D., M.R.C.P. Lond., at Ventnor, Isle of Wight, on January 16.
 HILL, JOHN, M.R.C.S., at his residence, Wentcliffe House, Ferrybridge, on January 17, aged 56.
 HOLT, CATHERINE, the wife of J. R. Holt, M.D., at Uckington, Gloucestershire, on January 22, in her 76th year.
 MOORE, J. H., M.R.C.S., Sherburn, East Riding, York, on January 15, aged 31.
 WELCH, JOHN GOODWIN, M.D., late of Maidstone, Kent, and of Uplands, near Bridgwater, on January 17, aged 70.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
CALNE UNION.—Medical Officer for the entire Union. Candidates must possess the qualifications prescribed by the General Orders of the Poor-law Board. Applications and testimonials to Mr. H. S. Heath, Clerk, on or before January 30.
CHARINO-CROSS HOSPITAL, WEST STRAND, W.C.—Assistaut-Physician and Physician for the Treatment of Diseases of the Skin. Candidates must possess degrees from one of the Universities recognised by the General Medical Council, and be F. or M.R.C.P.L. Applications to the Secretary, on or before January 30.
DORSET COUNTY HOSPITAL, DORCHESTER.—Honorary Physician. Candidates must be Graduates of some University of the United Kingdom, or be Fellows or Licentiates of the College of Physicians. Applications and testimonials to the Chairman of the Committee, on or before February 7. Election on the 22nd.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—House-Physician. A recognised Medical or Surgical qualification required. Applications to the Medical Committee on or before February 3. Further particulars of the Secretary.
KING'S COLLEGE, LONDON.—Chair of Forensic Medicine. Applications to Mr. J. W. Cunningham, on or before January 27.
MARYLEBONE GENERAL DISPENSARY, 77, WELBECK-STREET, CAVENDISH-SQUARE.—Surgeon. Candidates for this appointment are required to be M.R.C.S.E., not engaged in the practice of Midwifery or Pharmacy. Applications and testimonials to the Secretary, on or before February 7.
MIDDLESEX HOSPITAL.—Resident Obstetric Assistant. Must possess one legal qualification. Applications and testimonials to the Secretary, at the Hospital, on or before January 30.
MIDDLESEX HOSPITAL, W.—Physician. Full particulars may be obtained upon application to Mr. H. M. Evans, Secretary-Superintendent, on or before February 20.
NOTTINGHAM DISPENSARY.—Resident Surgeon and Assistaut Resident Surgeon. Double qualifications necessary. Applications to the Secretary, on or before February 12. Election on the 26th.
POCKLINGTON UNION.—Medical Officer for the Second District of this Union. Gentlemen seeking this appointment are required to have the qualifications to practise prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. W. Silburn, Clerk to the Guardians, on or before January 27.
ST. GEORGE, HANOVER-SQUARE, DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE.—Physician-Accoucheur. Must be M.R.C.P.L. Applications and testimonials to the Honorary Secretary, on or before January 30.
SHEFFIELD GENERAL DISPENSARY.—Assistant House-Surgeon. Medical and Surgical qualifications must be possessed by candidates for this appointment. Applications to the Medical Staff, care of the Secretary, on or before February 2.
TUNBRIDGE WELLS DISPENSARY AND INFIRMARY.—Resident House-Surgeon. Double qualifications required. Applications to the Secretary, on or before January 31. Election on February 5.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Calne Union.—Mr. Campbell has resigned the Union and the Workhouse; area 27,689; population 8879; salary £200 per annum.
Chelsea Parish.—The North-West District is vacant; salary £80 per annum.
East Stonehouse Parish.—Mr. H. Perry has resigned the Parish and the Workhouse; population 14,292; salary £55 per annum.
Eccleshall Bierlow Union.—Dr. J. W. Beaumont has resigned the Second District; area 545; population 16,193; salary £55 10s. per annum.
Scarborough Union.—The Sherburn District is vacant; area 10,606; population 1564; salary £30 per annum.

APPOINTMENTS.

Cardigan Union.—David Havard, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., to the Newport District.
Hailsham Union.—Henry C. Holman, M.R.C.S. Eng., L.S.A., to the Second District.
Pocklington Union.—Alfred Jackson, L.R.C.P. Edin., L.R.C.S. Edin., to the Second Market Weighton District.
St. Marylebone Parish.—Alfred J. Bell, M.R.C.S.E., L.S.A., to the St. John's District. Richard L. Shone, M.R.C.S.E., L.S.A., to the St. Mary's District.
Sudbury Union.—William E. S. Stanley, L.R.C.S. and L.R.C.P. Edin., to the First District.
Whitechapel Union.—Hardwick H. Braye, M.R.C.S.E., L.S.A., to the Fourth District.

DR. PURCELL has been appointed District Medical Officer for No. 7 District, St. Pancras, in the place of Mr. Wickham Barnes, resigned.

THE Bradford Fever Hospital was opened last week. IT is proposed to present a testimonial to Dr. Pierce, ex-Mayor of Denbigh.

THE UNIVERSITY OF BONN.—The matriculated students this year include 175 in the Faculty of Medicine, 10 being foreigners; 201 in that of Philosophy, 46 being foreigners.

WE learn by the Cape mail that sickness prevailed to a large extent at the South African diamond-fields, and the deaths were numerous.

DR. BUTTER, who (now blind himself) has for forty-five years rendered valuable and gratuitous services to the Plymouth Eye Infirmary, has resigned.

CHOLERA is reported to be at Konfudah, on the eastern shore of the Red Sea below Jiddah, where, by the same accounts, the deaths were twenty a day.

DR. FALCK has been appointed Minister of Ecclesiastical Instruction and of Medical Officers at Berlin.

THE COLLEGE LECTURES.—Professor Erasmus Wilson, F.R.S., will commence his course of six lectures on "Dermatology" in the theatre of the Royal College of Surgeons on February 2, and will be succeeded by Professor Flower, F.R.S., who will deliver eighteen lectures on "The Comparative Anatomy of the Organs of Digestion in the Vertebrata." Professor Holmes and Dr. Humphry will complete the course for the present year, the former by a course of six lectures on "The Surgical Treatment of Aneurism in its various forms," and the latter by three lectures on "Human Myology."

AT the Clerkenwell Vestry, last week, Mr. Brooke called attention to Dr. Lankester's recent observations on the neglected and unwholesome condition of the houses in several of the courts and alleys of Clerkenwell, and proposed that a report upon the subject from the Medical Officer of Health should be laid before them. Vestries and Local Boards have power to remedy this crying evil under the provisions of the Artizans' and Labourers' Dwellings Act, and by neglect of the duties imposed upon them are incurring a very heavy responsibility.

DR. CORFIELD'S Report on the Sanitary Condition of St. Mary, Islington, for December, 1871, states that for the five weeks ending December 30, 1871, a number of deaths occurred (690) far exceeding the largest ever recorded during the corresponding five weeks, which was 460 in December, 1867. Diseases of the respiratory organs were remarkably inactive in October, causing only 33 deaths in the four weeks, but attained their usual severity in November, when they caused 81 deaths in the four weeks, and during the five weeks under review were fatal to the amazing number of 236 persons, while in December, 1867, there were only 167 deaths from these diseases. Of these fatal cases 132 were children under 4 years old, and 84 of persons between the ages of 40 and 80. As usual, it is bronchitis that is pre-eminent among these diseases, 157 (or about two-thirds) of the deaths being due to it; except in December, 1867 half this number has never been recorded in any December. Pneumonia of course, with 64 deaths, comes next to bronchitis. The causes which influence these diseases are chiefly meteorological, and prevail all over London, as the Registrar-General's returns show; it is worthy of note

that the mean temperature of the week ending December 9, was no less than 12° Fahr. lower than the average temperature of the same week during fifty years. Measles caused 98 deaths in five weeks, as against 22 in four weeks last month, and hooping-cough 42 as against 15. Dr. Corfield, in conclusion points out that the death-rate, during the past five weeks, of nearly 33½ per 1000 per annum, on the population calculated to the middle of 1871, although very high for healthy Islington, is not such as need alarm us, "especially when we know that it is chiefly brought about by causes over which we have but little control"! The last clause bears marks of haste.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The Directors of the above Society held their usual quarterly Court on January 10, the President, Dr. Burrows, being in the Chair. Fresh applications for grants were made by three widows and four children. The case of one widow was postponed for further information respecting her income. The sum of £1249 was distributed amongst the fifty-five widows and forty-three children now recipients of assistance from the funds of the Society. The death of one widow was announced, and the grant to another was no longer required. Several children had become ineligible for grants during the last half year, two having been elected scholars at the Medical Benevolent College, Epsom, and the grants to others ceasing on account of age. Six candidates for membership were proposed to be elected at the next Court.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN THE YEAR 1871.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	19.56	0.102	0.128	0.003	14.8	3.8
West Middlesex	18.71	0.040	0.124	0.001	14.4	3.3
Southwark & Vauxhall	19.44	0.089	0.125	0.003	14.8	3.8
Chelsea	19.48	0.093	0.136	0.003	14.9	3.8
Lambeth	19.79	0.082	0.123	0.003	15.0	3.8
<i>Other Companies.</i>						
Kent	27.60	0.010	0.215	0.000	20.7	5.7
New River	19.19	0.032	0.132	0.001	14.8	3.5
East London	20.39	0.060	0.143	0.001	15.0	4.0

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

It appears, therefore, that the average amount of saline matter dissolved in the water supplied to London during the year has ranged, in the case of the Thames supply, from 18.71 grains per gallon (West Middlesex Company) to 19.79 grains (Lambeth Company); in the New River water it has averaged 19.19 grains; in the River Lea water (East London Company) 20.39 grains; and in the water from the deep chalk wells of the Kent Company it has amounted to 27.6 grains per gallon. The fluctuations of these proportions have not been considerable during the year, although in all cases the water has contained more saline matter in winter, during wet weather, than in summer—the maximum being in January and February, and the minimum in September. The hardness of the general supply has been from 14.8 to 15 degrees of Clark's scale, and this has been reduced by boiling for a quarter of an hour to about 4 degrees. In the case of the chalk well water it has been 20.7 degrees, and the permanent hardness 5.7 degrees. As to the proportion of organic matter in the water, it has been very small, for the quantity of oxygen required to act in every description of oxidisable matter has ranged from only 0.010 of a grain per gallon in the chalk water of the Kent Company to 0.102 of a grain in the Thames water of the Grand Junction Company; and the proportions of ammonia and of organic nitrogen have not exceeded the one-hundredth part of a grain per gallon of water. As regards turbidity, the water of the Chelsea and of the Grand Junction Companies has, in each case, been more or less turbid on eight occasions, while that of the Lambeth Company has been turbid on five occasions, and that of the Southwark and Vauxhall Company on one occasion. The quantity of water supplied to the metropolis has averaged 106,929,244 gallons daily, and of this 55,695,796 gallons have been derived from the Thames, 44,161,791 from the New River and the River Lea, and 7,071,657 from the chalk wells of the Kent Company. The maximum daily

supply (116,799,067 gallons) was in August, and the minimum 100,782,216 gallons) in February. These quantities were supplied to 487,230 houses, and it therefore amounts to an average daily supply of 32.7 gallons per head of the population, or nearly 220 gallons per house. It is very probable that from 80 to 82 per cent. of this supply was used for domestic purposes; and, considering that in many well-regulated towns, where the supply is constant, it does not exceed twenty gallons per head of the population, it is manifest that at present there is a considerable waste of water in London, from the neglect of domestic fittings. This will no doubt be remedied when the Metropolis Water Act, 1871, comes into operation (as it will do on February 21 next), and a constant service is supplied; for it will then be the duty of the water companies to see to the proper condition of the fittings of every house, and to enforce the provisions which will be sanctioned by the Secretary of State. How far the public, who have clamoured for such a supply, will like the interference and expense which it necessarily entails is very doubtful; for the fittings in use in this metropolis are generally so imperfect, and are situated in such out-of-the-way and inconvenient places that, for the purposes of preventing waste and misuse of water (as the Act of Parliament directs), they must be, to a large extent, repaired and renovated. The penalties for defective fittings are sharp and decisive; for not only is the defaulter liable to a fine of £5, but the companies have power to cut off the supply of water, and to report him to the nuisance authorities. In the 32nd section of the Act it is declared that, if the provisions of the Act are not complied with, as regards fittings, misuse of water, and undue consumption of it, the company supplying the water may, without prejudice to any remedy against the defaulter, cut off the service, and cease to supply the water so long as the injury remains or is not remedied; and in every case of so cutting off or ceasing to supply, the company shall, within twenty-four hours thereafter, give to the nuisance authority, as defined by the Sanitary Act (1866), notice thereof; and if the fittings are not repaired within the prescribed time, the house shall be a nuisance within Section 11, and Sections 12 to 19 inclusive, of the Nuisances Removal Act (1855), and shall be considered as unfit for human habitation. These summary powers are absolutely necessary, not only for the prevention of such waste as might occasion public calamity, but also to guard against destruction of property by overflowing cisterns and the giving way of defective pipes. When, however, all this is brought into proper and harmonious working, as no doubt it will be by due caution and forbearance, the results will be most advantageous, especially to the poorer classes of the community.—*Hy. LETHEBY, M.B., etc.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

"The Sketches of Success and Failure in Medicine," by Dr. C. J. B. Williams, will be continued next week, and in alternate numbers of this journal.

A Student.—The lectures in question have not been published.

R. E., Parkstone, Poole.—A well-made water-bed should not leak. Use a waterproof sheet under the blankets.

Scarborough.—We are glad to perceive that Dr. Rooke continues the publication of his able letters on the "Health of Scarborough" in the *Express*.

LITHOTOMY KNIVES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your publication of to-day I am surprised to see the letter from your correspondent J. F., in which he attempts to disprove a claim which Sir William Fergusson, I am sure, never made. What authority he has for such information I am at a loss to know, as, in common with you, I am quite unable to find any publication in which a knife used in lithotomy is claimed by Sir William as his invention, or, indeed, where any of the authors who so justly quote his practice with regard to this operation attach his name to such an instrument as originated by him.

The injustice of the observations, as well as their inaccuracy, will be the more apparent if in connexion with the following facts it be borne in mind that Mr. Smith, of Leeds, in performing the operation used two knives; one for the primary incision, and another having a beak-point for carrying the incision upon the groove of the staff into the bladder. Sir William Fergusson, in his description of the operation as performed by himself, uses the same knife throughout, and that a sharp-pointed one. Having been present on a considerable number of occasions when he has cut for stone, I have observed that the sharp-pointed knife used in the first part of the incision has never been laid aside for a probe-pointed one. The same knife was invariably used in carrying the incision into the bladder.

It is evident, therefore, from the facts of the case, that the probe- or beak-pointed knife, as regards Sir William Fergusson's practice, remains not only unclaimed but unused. I am, &c., E. B. ROCHE.

King's College Hospital, January 20.

Warrington.—We have this week to record the case of a board of guardians energetically defending one of its Medical officers. The facts briefly are, that the Local Government Board having seen reason to find fault with Mr. Spinks, of Warrington, for the manner in which he has performed his duties as Public Vaccinator, has called on him to resign his post as Vaccinator, and also as Medical Officer to the workhouse. The Guardians, in discussing this summary dismissal, defend their officer, and think they might have been asked if they were satisfied, and this all the more because they are satisfied that they possess, and have long possessed, in Mr. Spinks, a zealous and faithful public servant. We may add, on our knowledge, that having once visited the workhouse at Warrington since it has been under Mr. Spinks's Medical superintendence, we were struck with the singularly able and excellent management of the Medical department, as well as with the devoted interest and the practical skill shown by Mr. Spinks in his work. Experienced in observing the arrangements of sick wards, we were struck by one or two improvements suggested by Mr. Spinks, which to us were new in workhouse infirmaries, and which indicated how truly he had the interests of his patients at heart. We shall hope the Local Board will reconsider the decision it has taken.

PROXY-VOTING AGAIN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Recent vacancies in the Medical staff of one of our local Medical charities—the Brighton Dispensary—afford another example of the unfairness of proxy-voting. Several weeks ago—I believe prior to these vacancies being advertised, certainly before they were generally known, and before I myself knew a word about them—one of the candidates called on me to solicit my vote, when he informed me there was also another similar vacancy, which some gentleman (a total stranger to me) had already secured for himself, or it had been secured for him, by means of the proxies (ladies' votes) then in hand—obtained from these ladies, be it remembered, actually before the vacancies were made known to the general body of governors.

Although I believe that both of the gentlemen elected are exceedingly well qualified for the duties they have undertaken, yet, to my mind, the system by which one, at least, of the appointments was obtained is so derogatory and altogether objectionable, that the sooner another mode of filling vacancies, in our Medical charities be everywhere introduced, the better for the public and for the Medical Profession.

Brighton, January 24.

I am, &c.,

A GOVERNOR.

Sanitary State of Londesborough Lodge and Scarborough.—Mr. George P. Dale, F.R.C.S., writes to the *Lancet* as follows, in reply to the Editor's remarks on his letter to him of the 15th inst. :—

"In the summary of your 'Report' on the sanitary state of Londesborough Lodge, you base your condemnation upon the following facts:—The dead rat—the head of the sewer—the absence of sewer ventilation—the defective water-closet—the suction-action of the rarefied air of the house upon the traps—and lastly, the 'damning fact' of the late Earl of Chesterfield having occupied the same bedroom as the Prince of Wales in the succeeding week.

"As the apocryphal rat has been dropped like a hot coal, there we will leave it. The real facts then show that the 'Lodge' is not placed upon the end of the main sewer, but upon a branch of a branch; that it possesses ventilating shafts amply sufficient to relieve any pressure to which the drain-sewer might be subjected, and to supply an abundance of fresh air to establish inside currents; that the defective water-closet was found, for all practical purposes, as safe as if no hole existed in the pipe of the D trap; that the rarefied air of the house did not, and could not, exert any influence upon the traps; and lastly, that the late Earl of Chesterfield did not occupy the same bedroom as the Prince of Wales. I am prepared to substantiate these facts, either by unimpeachable testimony or by experimental proof.

"I did not there affirm that I had attended *nine hundred* cases of diarrhoea among visitors, during the past ten years; nor did I lead you to suppose the diarrhoea cases were caused by local conditions, in any other sense than *might* happen in any house filled with guests and servants. In reality they had no significance, and no further bearing upon the question at issue, than had the two cases of diarrhoea which followed the dinner at the London Club.

"You remind me that I had forgotten to mention the two cases of typhoid fever which happened a few years ago at Grove Villa. It was only from fear of trespassing upon your valuable space that I refrained from alluding to them. Your own commissioner is indebted to me for his knowledge of them; and, moreover, they are 'typical illustrations' for establishing my conclusions. This outbreak of enteric fever took place some seventeen years ago. Search was made to discover its local origin, as the disease was unknown in the neighbourhood. On raising the hearth-stone, the crescent main sewer was found underneath, and the surrounding earth soddened with sewage filth. There, in that blackened, festering mass, was the veritable 'plague-spot'—the birthplace of typhoid fever—the signs, real, tangible, and conclusive. The sewer was diverted, and no case has occurred since. In similar isolated outbreaks, we have traced the disease as unerringly to its source. Here let me correct some other mis-statements. 'The pure and rapid sewer of Londesborough Lodge' (as you are pleased euphoniouly to call it) does not pass under Grove Villa; nor is this house included in the twenty-four villas and houses to which I called attention, for the obvious reason that it is quite apart and distinct from them. It is situated at the bottom of the hill, whilst the others are at the top, and stand together."

INSANITY.—THE WATSON AND EDMUNDS CASES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the Watson case your review evidently does not agree with the letter of an intelligent correspondent in the same number; but although not practically acquainted, like him, with the treatment of insanity, I can fully endorse your observations as agreeing with the legal decisions in these cases.

I do not myself see that our learned Physicians at the head of asylums, and who claim on that account an amount of psychological analysis above other men, possess often the discernment in detecting moral or legal

responsibility more than non-Professional men of good common sense and a knowledge of mankind. The fact of so much division of opinion often amongst those gentlemen, on public trials affecting the question of insanity, substantiates my remark, and hence the public would say, does say, "Defend us in such trials from a jury of Doctors!" If we ask, "What is insanity?" the question comprehends a large sphere of inquiry. We are all insane, inasmuch as our opinions do not bear the test of truth—"Nemo mortalium omnibus horis sapit." But when the law is called in to decide for the advantage of an individual, or against him for punishment, or aught else, the circumstances differ. Society is capable of judging for itself as to the fitness or unfitness of its members to be at large or under restraint or punishment; and this is an opinion of lawyers of eminence and many others, and, I presume, would have been the opinion held by such men as Locke and Shakespeare, who were clearly as capable of drawing the line of demarcation between a sound or unsound mind as Dr. A or Dr. B for delusions. Taints and lucid intervals are open to common observation; and, let me ask, What are our pretensions to an exclusive knowledge of mind from our knowledge of the brain and its functions? Can we explain definitively and progressively the processes and parts concerned in the exhibition of mind? We know mind differs in estimation and value, like clocks or watches; but we understand the mechanism of the one, and what it can do. Are we acquainted so with the other? I am, &c.,

Nailsworth, January 22.

THOS. STOKES.

Lincoln.—It would certainly have been more consistent, and in accordance with the usual practice, if the names of Dr. Lowe and his son had not been connected with the inquiry. Though there can be no doubt as to the *bona fides* of the whole proceeding, it is well not to give the semblance of a "family party" in any judicial matter.

Dr. C. J. B. Aldis, in his special report, dated November last, to St. George's Vestry, Hanover-square, makes the following suggestions for preventing the spread of infectious diseases:—

"1. I would suggest that the Medical Department of the Local Government Board be asked to empower the Vestry to refer to a committee, the authority to carry out such sections of the Metropolis Local Management Acts as relate to the abatement and removal of nuisances, in the same way as they are empowered to refer the carrying out of the Nuisances Removal Acts by the 5th Section of the 18th and 19th Vic., cap. 121.

"2. That with a view to steps being taken to prevent the spreading of infectious diseases, every Medical Practitioner should immediately report such cases, occurring in private or public practice, to the Medical Officer of Health of his district.

"3. The 23rd Section of the Sanitary Act stipulates that the nuisance authority in each district may provide a proper place, with means of disinfection. The word 'shall' should be used for 'may' when necessary, adding also a power to destroy infected articles where necessary.

"4. The 25th Section of the same Act provides a penalty on a person suffering from any infectious disorder entering a public conveyance without notifying to the driver that he is so suffering. This clause should be so modified as to impose the duty and penalty on the person in charge of the sick, when the latter is of tender years, or is incapacitated by bodily or mental disease.

"5. That the board of guardians of every parish or union be compelled to provide suitable carriages for the removal of patients suffering from infectious diseases, and to give public notice where such carriages can be obtained.

"6. The 27th and 28th Sections should be made compulsory for the provision of mortuaries and reception-houses.

"7. In the 38th Section the words 'public place' should receive some addition, so as to prevent persons who have just recovered from infectious diseases from selling goods in their shops before they have been certified to be free from the risk of infection.

"8. Persons should incur a penalty who wilfully conceal the existence of scarlet fever or small-pox."

"AFTER MESS."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Wishing "Medicus," "An Old Subscriber," "Chirurgus," "Anti-Humbug," "A Hater of Injustice," and "Studeus"—the wily flatterer, who, alluding to the "world-wide circulation, enroaches on your valuable space"—in short, the communicative correspondents, as well as the brilliant staff of the *Medical Times and Gazette*, a happy new year, I venture to commence a series of letters strictly Professional. After the fashion of the Greek chorus, a little preliminary explanation appears necessary. Well, sir, middle-aged bachelors find that mess life, however nutritious, luxurious, and independent, after a few years becomes terribly tedious; it is only human nature to sigh for an anchor and to long for a home. Whereas Brown, F.R.C.P., angling for F.E.S., is spoken of as "that eminent Physician,"—Jones, J.P., happy in his family and country practice, receives claret-jugs, tea-pots, and silver salvers; and fat Robinson's communications, such as a "Successful Case of Vaccination," "The Temperature in Scabies," etc., etc., are never contemptuously torn and tossed into the waste-paper baskets of cynical editors. Some contemporaries are dead, a few gone wrong, but, on the average, the majority have not done badly. It is too late to enter into competition with these. No; quoting an able writer, "you cannot teach an old dog new tricks." Resembling Mrs. Wilkins Micawber, our motto is never to desert the department. In spite of debts, drawbacks, and disappointment, every man is sorry to leave the army. *J'aime les militaires*, and to-night, when, regardless of gout, the Queen's health was drank in heady port, and the band played "God bless the Prince of Wales," one thought of eventual farewell, when Othello's occupation will be gone; when, according to ancient custom, on half-pay, we shall haunt railway-stations, auction-rooms, and the Medical club; or else, affecting money in the funds, be the oracle amongst tabbies at Continental boarding-houses. In terrible fear of nipping, marrying beneath one, or forming a disreputable connexion (contingencies peculiar to despondency), the *caecithes scribendi* suggests a prophylactic. It is significant of age to find at balls young girls, unless very plain, refusing to take the floor, pretending to be engaged. It is a bore to escort fat old ladies down to supper, who, instead of poetry, pictures, and pantomimes, will talk shop, chiefly endeavouring to worm out their neighbours' ailments. Excepting as a choke-off, dinner parties are not so numerous as of yore; entertainers very properly consider inviting stupid ineligible old bachelors as throwing good money after bad. So there are many solitary evenings

when bitter thoughts of the insuperable poverty that cruelly cancelled a long engagement will intrude themselves, and in fantastic faces in the fire we are sadly apt to meet those "eyes that shone now dimmed and gone."

Let me apologise for not entering into any cases to-night; the list as to quality has been very fatiguing, including a Medical man and two fidgetty old maids, recalling to the mind Professor Haughton's calculation that the exhaustion of one day's fever corresponded to the exertion of a fifty-mile walk. Occasionally religious people are very trying, and when texts such as "I would rather be a doorkeeper," or "Better is a dinner of herbs than a stall at the opera," are too lavishly scattered about a house, not unfrequently look out for hard suspicious individuals who, instead of assisting diagnosis, delight in setting traps to confuse and confound the puzzled Practitioner.

Many patients are very nice, and, as long as things go straight, most men find their pleasure at the sick bed, especially if the cases are not in miserable, loathsome, horrible habitations. He jests at scars that never felt a wound; but there are Medical men who, after the excitement of the day, do acutely feel the reaction of extreme depression, and in dreary solitude sometimes agree with Artemus Ward that it would have been money in their pockets if they had never been born.

A sledge-hammer knock is heard at the door. "Please, sir, you are wanted in the guard-room—a drunken recruit, a plumber's man, wishes to see the Doctor." As Charles Lamb would say, I don't know this future Wellington, but heartily and emphatically, at a venture, HANG HIM.

DE MULTIS.

By RICHARD GUMBLETON DAUNT, M.D. Edin., Brazilian Citizen.

THIS sheet of memoranda is a transition. I have just closed two letters, one urging the reasons for the creation of two life baronies, and the other respecting the granting of a bank charter. Previous to entering on the Medical topics I wish to speak on, allow me to refer to the speech of Sir William Stirling Maxwell at the Scott Centenary celebration in Edinburgh, in which he, speaking of the Scott school of novelists in foreign lands, omits all mention of Portugal and the two most distinguished imitators of Walter Scott—Alexander Herculanus and the Viscount Garrett. This ignorance of Portuguese and Brazilian literature in English-speaking lands is prejudicial to the progress of learning, and exercises a bad influence on Medicine—reciprocally—and so may justly be noticed here.

I introduce Medical matters by the offering of the formula employed by a skilful Saxon apothecary of this city for the administration of phosphorus in a pillular form. It is this—*R. Phosphorus gr. j., oil of sweet almonds ʒss., Japan wax gr. xij.* Place these several ingredients in a phial, and submit them to a gentle heat until the phosphorus is dissolved. Let the mass become cold, and then divide it into fifty pills. Of such pills I give usually two in the *nyctemera* or period of twenty-four hours, and sometimes I give three. I use this medicine not only in the ataxic forms of fever, but principally in conditions of defective nerve nutrition; and I have observed that in obscure chronic diseases, where there is sleeplessness and an internal sensation of cold, it is of great service. The fault of good formulæ for the administration of phosphorus is one of the many *lacune* of the British Pharmacopœia. The Japan wax is met with in commerce, and is attributed to the *Ceroxylon anticola*.

What is the therapeutic value of *pulsatilla* as an emmenagogue? Is the oxide of antimony which the British Pharmacopœia orders to be employed in the formation of the official imitation of James' powder the same oxide as that known and so much employed in European Continental Medicine as *antimonium diaphoreticum*, or white oxide of antimony? If it be so, then James' powder of the Pharmacopœia is useless in the doses usually given, as this white oxide is administered in doses of from one to two drachms in the twenty-four hours to adults suffering from pneumonia of an inflammatory form, and to young children in doses (in the twenty-four hours) of twenty-four to thirty-six grains, in which latter dose I give it to children of two to three years of age. This preparation of antimony has the great advantage of being tolerated even when there is intestinal irritation and diarrhoea, when I associate it with *oculi cancorum* and cherry-laurel water. If I am rightly informed, British wisdom excludes both these articles from the Pharmacopœia, in which, I think, it errs—as in many other things. Here we have the true so-called crabs'-eyes imported from Russia, where on the shores of remote seas the crabs agglomerate in incredible quantities. I do not think the prepared chalk and the hydrocyanic acid therapeutic equivalents of the two above-mentioned drugs.

Is there recognised in European pathology a form of paralysis produced by the solar rays, reflected from a mirror, from any shining metallic surface, or from water? That such a form of paralysis exists here is an undoubted fact. The face is the part attacked. The medium must certainly be the optic nerve. I am told on credible authority that if some dishes of water are placed in a room or any enclosed space so that the surface of the water can reflect the rays of the sun, and if partridges are introduced into the same room or enclosure they quickly become paralytic or convulsed. On this account the itinerant Neapolitan vendors of objects made of tin or pewter, who infest this country, are obliged by the laws of many municipalities to cover their wares with an ample blue cover, in order that in going through the streets they may not cause attacks of paralysis, and I have seen them more than once in prison for disobedience to such by-laws or police regulations. This form of paralysis is accompanied by much general suffering and disorder of health.

It is a fact well-known here that persons once struck by lightning, but apparently recovered with more or less local lesion, undergo a modification in their nervous organisation, which causes them to suffer more or less acutely previous to and during thunderstorms, and this in a way not to be explained by apprehension, fear, or any moral cause.

A question to Pharmacæutists. What is the theory of the gelatiniform change presented in saline saccharated liquids after a few hours of preparation, and before ascendent fermentation? This change is very frequent here in hot weather. I saw it the other day in a decoction of althea with syrup and bicarbonate of soda. In a saccharated solution of citrate of magnesia it is quickly formed, also in one of salt of seignette, and of the borated or boracic cream of tartar, an elegant cooling laxative ignored by the English Pharmacopœia. Another article ignored by English pharmacy is the tea of St. Germain, an intelligent scoundrel who was broken on the wheel in the reign of Louis XIV. or XV. The chief ingredient is senna from which the resinous and gripe-producing principle has been extracted by maceration in alcohol. The broth made from the flesh of the cascade or Brazilian rattlesnake is a popular remedy here for cancerous ulcers, and for syphilitic secondary ulcers in cachectic persons. The snake being killed, is disembowelled, and then about two inches of the head and caudal extremities are cut off and thrown away; the rest of the

animal is *moquéada*—that is, dried in the sun—and is then fit for use. About three inches of the body are boiled in three or four cupfuls of water until a strong broth is obtained, which is taken *duabus vicibus* during the day, the patient eating, or not, *ad libitum*, the flesh. A Physician of good standing affirmed to me that he had personal knowledge of the cure of two cases of epithelioma so obtained.

There lately occurred a case of a small bird like the European sparrow (the tico-tico) killing a cascavel. The cascavel was kept in a cage, and one day the owner, a Doctor in Civil Law, of Selborne-White proclivities, introduced into the cage a tico-tico for the snake's breakfast. It happened, however, that the snake was indolent, and began to protrude its tongue, which the tico-tico mistook for a worm and wounded with its beak. The snake continued (now irritated) to protrude the tongue and the tico-tico to wound it, until after a short space the snake died. Where was the mysterious attraction which, as a rule, the snake exercises on little birds, until, trembling, they walk into the open mouth of the reptile and are swallowed?

Campinas, October 24, 1871.

COMMUNICATIONS have been received from—

MAHOMED; Dr. FRANCIS R. HOGG; Dr. RUSSELL REYNOLDS; Mr. F. CHURCHILL; Dr. J. H. SCRIVENER; Dr. B. W. RICHARDSON; A GOVERNOR; Mr. J. B. BLACKETT.

BOOKS RECEIVED—

Morgan on Contagious Diseases—Niemeyer on the Symptomatic Treatment of Cholera—Deakin on the Contagious Diseases Acts—Aitken's Science and Practice of Medicine, 6th Edition—Dalton's Treatise on Human Physiology—Wickham Legge's Treatise on Hæmophilia—Sir J. Y. Simpson on the Diseases of Women, edited by Dr. Alex. R. Simpson—Dr. Hayes' Case of Ovarian Tumour—Jacobi's Inaugural Address, including a Paper on Infant Asylums—Grimshaw's Remarks on the Prevalence and Distribution of Fever in Dublin.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Pharmaceutical Journal—Scarborough Express—The Salopian—O Correio Medico—Lincoln Gazette—Camden and Kentish Towns Gazette—Bath Express—Dublin Journal of Medical Science, January—Michigan University Medical Journal.

APPOINTMENTS FOR THE WEEK.

January 27. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Mr. Wm. B. Donne, "On the Theatre in Shakespeare's Time."

29. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Henry Lee, "On some Cautions necessary to be Observed in the Use of Calomel-vapour Baths." Dr. Richardson, "On the Science and Art of Healing Wounds."

30. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

31. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

SOCIETY OF ARTS, 8 p.m. Meeting.

February 1. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

2. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 9 p.m. Prof. Tyndall, LL.D., F.R.S., M.R.I., "Remarks on the Identity of Light and Radiant Heat."

VITAL STATISTICS OF LONDON.

Week ending Saturday, January 20, 1872.

BIRTHS.

Births of Boys, 1309; Girls, 1156; Total, 2465.
Average of 10 corresponding weeks, 1862-71, 2163·9.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	779	849	1628
Average of the ten years 1862-71	816·4	842·4	1658·8
Average corrected to increased population	1825
Deaths of people aged 90 and upwards.

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Popula- tion, 1871.	Small-pox.	Measles.	Scarlet Fever.	Diphtheria.	Whooping-cough.	Typhus.	Enteric (or Typhoid) Fever.	Simple continued Fever.	Diarrhoea.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·47 in. The highest was 29·90 in. on Sunday evening, and the lowest 28·80 in. on Thursday morning.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

† Through an error which was discovered on the revision of the enumerated numbers at the Census Office, the correct population of Manchester at the middle of 1871 was 351,171, and not 356,093, as published in recent Weekly Returns. The number for the middle of 1872 (352,759) shows, therefore, an increase of 1271 upon the corrected number for 1871.

PART III.

*Minor Successes. Examples of Success and Failure in Practice.
Pneumonia—Essential Seat and Relation to the Blood—Not a
mere Local Inflammation—Pathology and Varieties.*

IF, from these great successes in Medicine—great in the completeness of the cures by remedial means, or great in the number of lives saved by preventive measures (the successes marked A in our table)(a)—we turn to the minor successes (marked B), we find them specified under the heads, Mitigation and Retardation of Disease, Prolongation and Utilisation of Life, and Alleviation of Suffering. These smaller successes may seem very subordinate to the first in their value and importance, yet, in actual experience, we often do not find them to be so lightly esteemed by the patients themselves. I think that we meet with more gratitude for these minor successes than we do for the most perfect cures. Life is more precious when there is a near prospect of losing it, and relief from pain is more prized than constant ease. No doubt patients often flatter themselves as well as their Doctors, and sometimes give us more credit than we can honestly appropriate. They call themselves cured when we consider them only relieved. They desire to be delivered from present pain, weakness, and danger. If we can effect this, prospective evils trouble them little; and it becomes no easy matter to convince them of their reality. This great preponderance of the present over the future is a remarkable trait in human character, which Practitioners have to bear in mind in the disclosure of their opinions to their patients. Present and imminent dangers are exaggerated and become objects of overwhelming terror, while far-distant prospective evils are hardly realised.

A patient is incautiously told by one Doctor that he has organic disease of the heart, which can never be cured, and that some day he may drop down and die suddenly! The terrified patient consults another Practitioner, who, although he admits the presence of organic malady, holds out a more hopeful prospect, and assures him that such terrible events are extremely rare in comparison with the number of cases of structural disease that occur. He can therefore honestly encourage the affrighted mortal in the belief that there is no present danger to life, and that with care and proper management he may live for years in safety and comfort. This last adviser seems like a saviour to the patient; and, if his predictions are fulfilled, his minor success will be valued as much as if he had made a perfect cure.

Another common case, in which both patients and Practitioners are apt to take an exaggerated view of present danger, is that of hæmoptysis. When a person sees for the first time that he is spitting blood, he commonly thinks that his fate is sealed, and that he is going to die. Examples of sudden fatal hæmoptysis certainly do sometimes occur, but they are comparatively very rare. In looking back in a cursory manner on my own experience on this point, I think that, on an average, I meet with an instance of fatal hæmoptysis once in six months, yet hardly a day passes in which I do not see several cases of hæmoptysis; and I know of many instances of persons who, after bringing up appalling quantities of blood, have yet regained health and strength, and have lived in safety and comfort for many years.

Another circumstance, tending to multiply the number and enhance the value of minor successes, is the fact that the subjects of them are much more amenable to the Physician's influence than those who are habitually healthy, and who are prone to carelessness and delay; and it may fairly be said that a person with a small amount of organic disease, who, being aware of his state, lives by rule and within prudent limits, has a good chance of surviving his healthy contemporary, who continu-

ally transgresses the bounds of moderation, and sets all sanitary rules at defiance.

After these preliminary expositions and examples of Success and Failure in Medicine in general, I proceed to illustrate our subject by sketches derived from my own experience; and in order to render my illustrations representative, as well as moderate in numbers, I propose to select samples of cases which have occurred within a limited period. My notes of cases extend over upwards of a quarter of a century, and considerably exceed twenty thousand in number, which are more than I can at present profitably deal with; but taking those of seven years as a sample—from 1849 to 1855 inclusive—I find 7840 cases noted, and out of these I have selected about 300, the histories of which are sufficiently complete to serve for illustration of our subject.

As a large proportion of the patients who seek my advice are suffering from diseases of the chest, I therefore take my clinical illustrations from them; but I wish, on this and all occasions, to repudiate the imputation of being a *specialist*. People often come to me, saying—"I understand you devote your attention exclusively to diseases of the chest." I always reply—"You are quite mistaken; I should be very unsuccessful in treating diseases of the chest if I did not attend to other diseases as well." In fact, I believe that the best security that a Physician's views are comprehensive and not one-sided would be, that he should, for a number of years, as in my case, have had charge of patients in a general Hospital, and have given several courses of lectures on general pathology and the practice of Medicine.

In pursuance, then, of our subject of Successes and Failures in Medicine, I propose to draw from my own experience examples of certain diseases, with brief pathological considerations on their essential nature as well as on their successful treatment.

PNEUMONIA.

This disease is to be regarded, not simply as a local inflammation, but as one involving more or less of the great vascular plexus of the lesser circulation, conveying the whole blood of the body in the process of aëration. It stands, therefore, among inflammations pre-eminent, in the character of a blood disease, mutually affecting the composition of that fluid, and being induced by agencies operating on it. Thus, persons dying from the bite of the rattlesnake and other venomous serpents are found to have inflammation of the lungs. The same thing occurs in those poisoned by arsenic, even when the poison is applied to a wound; and also in animals in which phosphorus dissolved in oil has been injected into the veins. In certain epidemics, pneumonia is a common result of the operation of the blood poison of fevers. Various asphyxiating influences, if long in operation, tend likewise to produce pneumonia. And of more common causes, those which simultaneously affect to a great degree both respiration and circulation—such as prolonged violent exertion or over-fatigue, either alone or combined with cold—are among the most usual antecedents of inflammation of the lungs. With regard to cold, it is not the transient application of cold, however intense, that commonly excites this inflammation; it is rather prolonged and deep-reaching cold that has this effect. Thus, if a person gets thoroughly wet, and remains long in wet clothes, or lies out on damp ground; or a sentinel standing, or only slowly pacing, for hours in a cold wind; in such cases, the chill goes to the heart, as it were, and paralyses the deep circulation, and pneumonia is likely to be the result. Observe, further, in reference to the nature of pneumonia as a blood disease, how much more than other inflammations it affects the depurative secretions, especially the urine, which is not only scanty and high-coloured, and sometimes albuminous, but is wanting in its ordinary saline matter. The chlorides are no longer thrown off in it, but are actually retained in the inflamed lung,(b) and, so soon as this is resolved, they reappear in the urine. If time permitted, I could give you many other proofs, in the history and varieties of pneumonia, of its title to be ranked as a blood disease as well as a local inflammation; and we shall find this view aid us in considering the treatment.

Note added in 1872.—This view of the systemic nature of pneumonia (sketched in the "Cyclopædia of Practical Medicine" in 1833) has been generally overlooked, even by the most recent authors. Thus, Dr. Wilson Fox, in his elaborate article in "Reynolds's System of Medicine," whilst largely diverging into multifarious distinctions and divisions, which involve much reiteration, in great measure misses the fundamental question as to the true seat and essential nature of

(a) See second table, page 1 of *Medical Times and Gazette*, January 6.

(b) Dr. Lionel Beale.

pneumonia, the answer to which supplies the best clue to its pathology and varieties.

Being distinctively the inflammation of the great capillary plexus conveying the systemic mass of blood from the pulmonary arteries to the pulmonary veins, its process and products are more substantially sanguineous than those of inflamed mucous membranes or other less vascular textures. Therefore, the lung is deep red and blood-filled in the first stage, and consolidating with abundant fibrinous and other blood-products in the stage of hepatisation. Its inflammatory exudation-matter is rich in corpuscles and fibrils fresh from the blood; to which may be added, incidentally but not necessarily, epithelium and connective-tissue cells, if the inflammation extend to the mucous membranes and connective tissues adjoining the great vascular plexus. And herein we have a clue to those varieties in the necroscopic appearances of pneumonia which have caused so much confusion and discussion. In the simplest forms of pneumonia the inflammation is limited to the pulmonary plexus, and the resulting hepatisation is uniformly red, and not granular, as in the pneumonia of the aged (Hourmann and Dechambre) and in the carnefied lung of pleuro-pneumonia. But in ordinary acute pneumonia the inflammation extends to the alveoli and interstitial connective tissue, and the hepatisation is granular, from the alveoli being filled by multiplication of cells or corpuscles of these parts. A further participation of the bronchial membranes in the inflammation, as in broncho-pneumonia, adds their products in the form of viscid mucus, pus, or croupous exudation, according to the stage, in the air-tubes; a section of which presents rounded spots in the hepatised lung, which a hasty inspection might mistake for tubercles.

Further varieties in pathological tendencies and necroscopic appearances arise from differences in the nature and aptitudes of the exudation-matter, whether more *corpuseular*, and tending to softening, suppuration, or caseation; or more *fibrous*, and tending to indurate and contract; or of a mixed *fibro-corpuseular* nature, tending variously in either way. In these varieties may be traced the origin and history, not only of the results of inflammation, but also of contractile and consumptive lesions of the lung, which, under the term *phthinoplasms*, I have considered in another work.^(c) I would refer especially to the fourth, seventh, and eighth chapters, where the pathology of pneumonia is brought under discussion.

(To be continued.)

ORIGINAL COMMUNICATIONS.

ON THE

MODE OF PROGRESS OF THE SCIENCE OF NATURAL PARTURITION.

AN ADDRESS TO THE ROYAL MEDICAL SOCIETY ON JANUARY 19.

By J. MATTHEWS DUNCAN, M.D.

In this discourse I mean to direct attention, not to any original observations or new discovery in midwifery, but to the mode in which increasing knowledge of the function of natural parturition has been ripened into a science of this department of Medical study. The history of midwifery records the appearance of each new item of obstetrical knowledge, one after another, and attaches to it the honoured name of its discoverer or expounder. But the time has arrived when we may classify these discoveries and observations, and show how all this knowledge or mass of details can be arranged in logically connected order, so as to form a science of natural parturition. Doing this, we find their characters and order of succession to be full of suggestions, which are valuable in the sense of hastening future progress. If we, for the occasion, suppose, as we may justly do, that all this acquisition of knowledge and formation of a science has been effected by one great perennial obstetrical mind, it will facilitate our apprehension of the point of view I wish to occupy—namely, that of an observer watching and describing the method of philosophising which has been pursued by this supposed perennial obstetrical genius, and which has at length guided him in selecting from the heaps

of detached pieces of obstetrical knowledge, accumulated for ages or only recently acquired, those shapely portions which were wanted to enable him, all within the last two centuries, to lay the foundation, and continue slowly rearing, the little court of the science of natural parturition in the great temple of modern science. It is the mode in which this genius has so successfully worked that I wish to describe.

There are many departments of midwifery, and of them the chief, in every sense of the word, is what is called Natural Parturition. To it alone do I now confine my remarks. It has advanced in scientific rank far before any other department. In proportion as natural parturition is more common than morbid labour, so is this department of science more important than that of unnatural parturition. Indeed, the science of morbid labour must always lag far behind that of natural parturition, and owe much of its progress to light reflected from that greater and higher neighbour.

Modern philosophers cannot, like the great majority of their predecessors, be reproached with disdaining utility. On the contrary, the expectation of direct practical results, or of what is in Medicine called practical bearings, is a powerful stimulant of their efforts after truth, and the attainment of improvements in practice is a chief source of their justifiable pride. But if they are wise, they do not work with a direct aim to practical results. They do not set about the search for gold by digging in the nearest field, but by the study of geology. They seek new items of knowledge with a view to the advancement of science, sure that practical good will, sooner or later, appear as the ultimate fruit of their labours; and that their discoveries and reasonings are essential preliminaries to the ripening of the full crop of beautiful practical fruit.

Cheered by such reflections, obstetricians cannot be too ardent in the pursuit of the science of midwifery. The labours of all the great, and in their times famous, Practitioners—but *mere* Practitioners—who have flourished since the world began, have done very little progressive work for the benefit of the race. That has to be slowly elaborated by an humbler sort, the men of science. Much, indeed, of what is esteemed by the Practitioners of one age is forgotten or rejected by those of the next, and the circumstance shows its real character. To-day, we bleed like Sangrado; to-morrow, we don't bleed, but pour in alcohol. Both practices have, to the philosophical mind, an equally ridiculous character. The skill and wisdom of the Practitioner, so far as it really is such, is mainly of an esoteric character. It can neither be described nor handed down. It is the individual's property. Others may attain to equal or greater skill; they cannot inherit his.

On the other hand, Science, the grandest result of the efforts of the human intelligence, stands contrasted. Its achievements are certain, secure, beneficent. They may be diffused over the world without being thereby diluted. They are capable of being expressed in written language, and handed down to every coming age. They are as necessary to every coming age as to the age which saw their appearance. They are the best pabulum of that intelligence which is the most useful armament of the Practitioner; and they are the most prolific source of those more glaring and more directly, though less widely useful, practical discoveries which alone attract the vulgar gaze. They enable the informed Physician to distinguish the real gems from those flashy pieces of therapeutical paste which dazzle, I grieve to say, not only the public, but also a very large part of the Medical Profession.

Now we see partially the rich fruitfulness for mankind of Harvey's discovery. Without it, how very ignorant should we be as to the diseases of the heart and lungs. No doubt the Practitioner, were this knowledge wanting, would look very sagacious, shake his head *secundum artem*, and write a prescription, just as he does now; but what value could be attached to the advice or prescriptions of one so ignorant of the primary elements of a sound judgment? The practical men of Harvey's day did not recognise the practical value of his discovery; and I am not sure that I belie even the Practitioners of the present day, when I say that were Harvey's discovery—a set of dry mechanical details—hard reading—published for the first time now, when as yet practical results were only dimly foreseen by a few, they would turn from them without compunction, to regale themselves with the confident boasting of some vain discoverer of a new medicine or a new treatment, whose future history, unlike the ever-widening beneficence of Harvey's discovery, may be a mere drowning in the waters of Lethe, or nailing to the wall (as of some foul, injurious bird), but which may very probably deserve

(c) "Pulmonary Consumption, etc." By C. J. B. Williams, M.D., F.R.S.; and C. T. Williams, M.D., 1871.

the praise of being as useful as any of the other and older modes of treating the same malady.

The world had to wait very long before progress or even commencement in the science of parturition was possible. Knowledge of obstetrics was, from the earliest times, gradually increasing, and heaps of it were to be found among Practitioners and in books; but a science was impossible, because the essential knowledge was wanting. Obstetricians proceeded without sufficient data—they tried the deductive method; they vainly struggled to discover and to reason aright. They did not as yet fully see the first step of scientific progress. In evidence of this, I refer to the great work of Deventer, published in the first year of the eighteenth century. The knowledge collected in this book is very valuable, and especially noteworthy in the light of this discourse, for it preceded the dawn of obstetrical science, and its appearance and character might justly excite hope for the future.

There could be no beginning of scientific progress till at least the locality of the operations to be studied was known—till the common anatomy of pregnancy was described—till the rude outlines of the machine whose action was the subject of study were mapped out. Mundinus, Vesalius, Ruysch, Noortwyk, Smellie, and others had already flourished since the revival of learning, and had all made some contributions to the rough anatomy of pregnancy—and it was only the rough anatomy that was as yet desiderated. But for the science of parturition they all together did not enough; it was reserved for William Hunter to complete this satisfactorily. His great work was published in 1774, and this grand foundation-stone of obstetrical science still remains securely fixed, unsurpassed in perfection of elaboration, and more admired than when it left his hands. The most superficial observer must easily see that this first step—this foundation—was essential to future progress in the science. It was the first in time as well as in logical order; there were no other stones ready to be placed as soon as this was laid. Others were already in process of preparation, and they were soon required and used—being those which should properly come next.

Midwifery was now fairly started in a course of scientific progress. To advance it, obstetricians must follow William Hunter. If they do not, they go astray, and lose the fruit of their labour. Deventer's motto was, "Manet post funera verum." It was scarcely appropriate to the kind of work he did; but it fits William Hunter perfectly. He completed that body of truth which was the first requirement of the scientific obstetrician, and which was truly so designated by Deventer, who says, (a) "Primo. Requiritur generalis aliqua cognitio muliebrum, quæ generationi inserviunt, partium, quales eæ, ubi vel quo loco sitæ sunt: generalis, inquam, cognitio."

Already was this general knowledge of parts—the *generatis cognitio* of Deventer—insufficient in some points. On these it was necessary to get information of a precise kind, and one of these was the important subject of measurements. A body had to be propelled through a passage, and it was necessary to have a good idea of their comparative dimensions. But it was long before a correct view was got, because, before it could be obtained, it was necessary to find out the adaptation of parts in the body and in the passage, and their mutual relations.

As early as the middle of the eighteenth century Ould and Levret indicated in their writings some feeling of the want of knowledge of measurements, which has now grown to so large a department of descriptive obstetrics. They advanced farther than a mere vague feeling of this want, for they indicated the child's head and the pelvis as the chief parts correlated in the function of parturition whose dimensions should be studied.

The notions of Ould and Levret were far from being accurate or precise. This we may almost argue from Levret's comparing the circumference of the brim of the pelvis with the height of the individual. But though this great author did only a little for the subject of measurements, he distinctly pressed on the minds of students the great and fertile principle which has been the guiding star of all future explorers. Eminent men, even of his own country, have expressed their difference of opinion from Levret; but every day shows more and more that Levret was right, and that his assertion that parturition is a "natural operation, truly mechanical, susceptible of geometrical demonstration," (b) will soon be nearly realised by the labours of philosophical accoucheurs. All progress in the science of natural parturition has been, and continues to be, made in the line indicated by Levret.

As we have already said, Ould and Levret did not do for

measurements what William Hunter did for anatomy, and I know no individual name that deserves the place of honour in connexion with them. We have to come far on in the decades, past the time of Denman, to find them fully stated and their relations and importance understood. Even in some text-books of our own day there is great deficiency and evident want of intelligence in the authors—want of such just appreciation as is to be observed in the writings of Smellie, or such fulness and completeness as are found in the manual of Paul Dubois, published in 1849. (c)

The study of anatomy, and especially of measurements, necessarily leads to observation of shapes and directions. So, from the first, there have been attempts made to determine shapes, planes, and axes. Obstetricians are familiar with the learned writings on these points by Roederer, Stein, Bakker, Carus, Nægele, and others. But the writings of these authors could scarcely be expected to be complete enough for us. They could not, in their day, foresee the direction in which midwifery, as a science, would advance, and could not meet wants which were not felt. The subject of axes, especially, is found to be so connected with that of the exercise of force, that, even in our own day, determinations which were long considered quite accurate are subjected to reinvestigation.

Topography, measurements, shapes, axes—these were now all achieved pieces of obstetrical knowledge. None of these departments has as yet received the highest development which the inquiring mind of man can give it. But already, about the beginning of this century, not only was the want of knowledge of them felt, but the want was in a rough, yet satisfactory manner, supplied. The first stage of the progress of the science of natural parturition was completed. The passage to be traversed, and the body to be pushed through, are carefully measured and described.

Students, and even those of them who are at the same time successful pioneers of science, are very apt, when taking a retrospective view of the road over which they have travelled and of the difficulties which have been overcome, to underestimate the amount and value of the thought expended in finding the road, as well as the labour and ingenuity expended in overcoming the difficulties met with by the way. The student is like the woman who, as soon as she is delivered of the child, remembereth no more the anguish, for joy that a man is born into the world.

So, again, when the first stage of progress is finished and recognised, and the second pretty well elaborated, it is easy for our supposed perennial genius of obstetrics to see what should be the next; and, curiously enough, what is naturally expected to be the next stage is really so. The second stage of scientific progress has been far more difficult to effect than the first; and we may venture to predict that each succeeding stage will be more and more difficult than its predecessors. But though more difficult to effect, it is not more difficult to comprehend after it is effected—perhaps even the contrary; while it is, and will be, certainly more glorious to its promoters and more useful to mankind. It is only in a rough way that the second stage can be said to succeed the first in point of time, as it certainly does in logical order; but the student who enters into the details can, I believe, satisfy himself that, taking, as he must with this purpose, a wide view of the matter, the second has really followed the first in order of time.

The second great stage in the advancement of scientific midwifery is the discovery of the manner in which the foetus traverses the maternal passages, and the alterations in form thereby produced.

The passage being known, and the body that has to be pushed through it being known, and it being known that the latter is large when compared with the former, and cannot easily or at all permeate it unless it is aptly placed and pushed, and that it generally requires strenuous exertion on the mother's part to force it on, it is evident that the next point to be studied is—How does it pass?

The answer to this great question involves a mass of details which have been, for the most part, well made out; yet many remain for investigation or for reinvestigation and confirmation, or the reverse. It had, for example, to be observed how the foetus lies before it starts on its course, or, when it starts, how it is adapted to, or lies in, the passages at every stage of its course; how it emerges from the passages into the world; what changes in attitude it has in its course undergone, and

(c) The succession, in order of time, of cranial measurements to pelvic is well illustrated by the circumstance that while for a long time pelvimeters have been invented, and especially internal pelvimeters, internal craniometers have as yet never, so far as I know, been proposed, as they certainly ought to be.

(a) "Ars Obstetricandi." 1733. Cap. ii.

(b) "Art des Accouch.," p. 83.

when they took place; what changes in form it has undergone; how the placenta is separated, how it is expelled. When William Hunter's work was published none of these points was generally known; most of them were entirely undecided; some are not yet decided.

The second stage is peculiarly interesting to the obstetrical historian; for he observes that it was only after it had made decided progress that obstetricians generally began to see that the subject of their studies was not a mere heap of blocks and chips of knowledge, but that there was a true science of natural parturition. To speak figuratively, it may be said for the world, and especially for Great Britain, that it was only when Naegele's paper on the "Mechanism of Birth" appeared that the little plant of obstetrical science showed itself above ground. A new enthusiasm entered the Medical mind, and it has not died out, and will not, for it has living substantial roots. Every step in advance increases the growth, and stimulates the cultivators. The epoch of this new and generous enthusiasm can be easily fixed by historical marks; but it is also easy now to make manifest its weak juvenility. This is aptly illustrated by the very name of the memoir by Naegele—the "Mechanism of Birth," or rather the "mechanism of labour"; by which latter title the subject of it has been, and unfortunately is still, designated among the English-speaking nations. Naegele and his contemporaries and followers were fired with enthusiasm by the discovery of a new science. Their *eureka* was designated mechanism. They saw now, as a Profession, for the first time, the grand idea of Levret, and they gave this name to the limited branch of investigation which they had cherished. The whole plant was mechanical; they erroneously designated as "mechanism" one early leaf of it. Had William Hunter seen as far as Naegele, he might with equal justice, and perhaps he would, have named his volume of plates "the mechanism of labour." The mechanism of labour is a grand idea, for whose just application as the title of a book or of a chapter in a book we have still long to wait. We are still only working out the elementary parts of this mechanism. The second stage of the progress of the science of parturition has no more, perhaps less, claim than any other to this special name; and it is desirable that it should be at once denuded of an honour of which it is not worthy. To say that the course described by a train as it passes along the rails is the mechanism of railway travelling, is utterly absurd. But Naegele may well be pardoned this fault, seeing that he was the means of a great revival of the obstetric genius, and christened his work by a name which, though erroneously applied, expressed the grand basic idea of the whole modern progress of obstetrics.

There are many names worthily connected with the second stage of our science's progress. Among these may be placed Ould, Smellie, Roederer, Solayres, Saxtorph, Naegele. All these, and many others, have contributed to its progress. But if one name is to be singled out for the place of honour, it is that of Solayres of Reuhac, who flourished at Montpellier, was the teacher of Baudelocque, and in 1771 published his dissertation "De Partu Viribus Maternis Absoluto."

Every point in the whole of this progress of the foetus and placenta has been the scene of contests most interesting to watch. But this is not the place for historical sketches of them; and, besides, this piece of historical work has already been very thoroughly done. Truths have been attacked, errors introduced, errors corrected, errors revived, truths triumphant; and, after all, knowledge has increased, and has, with general acceptance, come to be regarded as positive. Now the great outlines of the subject are agreed upon, and for me, at least, well settled. But the obstetrical student of the present day knows that much is still wanting in this department, and much confirmation of what is generally regarded as secure knowledge. The works of Küneke and of Schatz, full as they are of observation, hypothesis, and clever reasoning, are too recent, and have too much shaken the obstetrical mind of the world to allow us to regard the second stage in the progress of scientific obstetrics with complacency as a work quite done and finished. We are justly proud that it is a work whose great features are easily seen, and whose place is well known and universally recognised.

In recent years an interesting feature has been added to this department of obstetrics, in the description of changes of form undergone by the propelled foetus. It had been long known that the head was changed in form during labour, but the change that was chiefly dwelt upon was produced by alteration of the condition of the soft parts. The new investigations refer to changes undergone by the plastic cranium of the foetus, and are an important addition to our knowledge, for

which we are indebted to Dohrn, Barnes, Olshausen, Ahlfeld, and others.

If the second great stage of progress of the science of natural parturition is not nearly completed, if its maturity is not as that of the first stage, still it is old and highly developed compared with the third stage. It may be truly said, that as yet the Profession does not desiderate the increments of knowledge destined to be produced by the promoters of the third stage. The second stage has come nearly to completion during the first half of the nineteenth century. The third stage has only made a small beginning in the second half of the same century; but as the number, the zeal, and the attainments of the modern students of midwifery have increased above those of past times, we may expect a rapid increase of our knowledge and new eras for our cherished and beneficent science.

The first department of the science of natural parturition is occupied by the description of the passage and of the body to be passed. The second department is occupied with the description of the mode in which the foetus passes, and the physical changes it undergoes during its passage. The third department of scientific midwifery is engaged with the forces employed to do the work. The sequence of the three stages is natural and logical, and also historical. The first two stages or departments are comparatively simple—they are mainly descriptive; but the third involves problems of much higher complexity than the first two. It taxes other faculties than that of observation; and its results both in theory and in practical usefulness will be much more conspicuous. It is destined to comprehend the knowledge of the amount of the efficient powers of parturition; their direction and application to the passages, to the bag of membranes, and to the foetus at every part of its course. When the physicist considers the nature of the passages, their curvature, and their development during the process of labour, as well as the other factors in this function, he may be excused if he almost despairs of making progress. Many students are, however, already diligently occupied with work in this field, measuring forces, ascertaining angles, observing levers, studying the influence of curves. As might be expected in the present day, these students are chiefly to be found in the German schools; but there are cultivators of this department among the French and among ourselves. The Germans are, however, pre-eminent, and among them we may name Hecker, Poppel, Kehrer, Schroeder, Schulze, Winkler, and Schatz.

These three great stages appear to me to comprehend all that can be well called a constructed science in Midwifery—an ambitious title which I use and apply as it is used in describing the advanced parts of physics and of chemistry. Many departments of Medicine are regarded justly as in some sense scientific, while there is as yet no constructed science of them, nothing so advanced as in the part of obstetric science, which I have been describing. Among these departments I may cite as examples the great subjects of therapeutics and of lunacy. These are replete with valuable knowledge of a scientific kind, but they get no farther. They lean upon various neighbouring scientific departments of knowledge; but they are themselves destitute of scientific structure as departments of Medicine. There is in these subjects as yet only blind and often frantic groping for scientific order: there is no good foundation of a science of either of them laid.

These remarks I make partly in order to explain how it comes to pass that my sketch of the constructed science of natural parturition appears to be, and really is, so limited. In truth it goes no farther; and obstetricians may, perhaps, be proud that it goes so far as it does. But in addition to this science of natural parturition there is a very great accumulation of valuable pieces of obstetrical knowledge, all destined (I hope at an early day) to take their place in the constructed science, but as yet too chaotic for that ultimate destination.

There are two collections of obstetric knowledge in two great fields of obstetric labour, which deserve mention in this place. They are included in the physiology of parturition, but are engaged with matters which are not exclusively or purely obstetrical. I allude to the histology of the uterus and the functions of the various kinds of nerves supplying it. Although much has been done, and continues to be done, in these departments, yet ignorance may be said to prevail. We know nothing certain of the cause of labour, of the intermissions of pains, of the part of the nervous system presiding over the function of birth, of the connexion of the nerves with the muscular fibres, their nuclei, or their nucleoli; and we know the history of the decidua vera and of the serotina very imperfectly.

Besides these two great masses of knowledge in the science of

natural parturition, who will say how many more there are? Who will tell us how great is our ignorance? Each department was an unknown and probably unimagined territory to the most advanced obstetricians of earlier days; and there can be no doubt that new territories for exploration will be discovered, of which, as yet, the obstetric mind has formed not the slightest conception. Each stage of advance involves increased difficulty of progress, and demands increased education in its promoters. The obstetricians of the future must be more talented and as laborious as their predecessors; they are certain to be better informed.

All honest work contributes to progress; for if the result is not a new piece of knowledge for all obstetricians, it is probably new for some, and the time expended on it is not lost, for it has at least contributed to increase the intelligence of one obstetrician, and has added to the common stock of intelligence in the community of obstetricians.

The work most likely to be successful is that done in a spirit of utmost humility by a man well informed as to the limit of present knowledge. If I may presume to criticise the ingenuous labours of my contemporaries, I should say that the prevalent error is an overweening ambition. They try to go farther than it is as yet possible to go—faster than is consistent with safety—to establish a theory or a treatment without sufficient grounds. They should learn to do a small thing well before they try high tasks. They should study the history of midwifery, and, observing how small and easily made the greatest discoveries now appear to us, though they cost great labour to their authors, they may justly reflect that when the next great discoveries are made they will have the same appearance to our successors, but cannot at present offer such an aspect to ourselves. It may be thought that there was little ingenuity or merit in measuring the pelvis or the foetal head, or in telling what part of the head first emerged from the mother's body; yet the world waited for more than a thousand years before these simple things were done, and one of them is even now the subject of respectable controversy!

After all my discourse is finished, I think I hear sounding around me, and finding an echo even within my own microcosm, the question—Can it be that our great and proud Medical discoveries, brought to the birth after such painful and tedious labours, are so simple that a child may comprehend them? Can it be that our highest Medical science of the nineteenth century is so elementary, so mechanical? Yet the more the question is forced home the more clearly does the affirmative answer come back; and it is amply confirmed by a wide circumspective view, as indicated by the answers to other like questions. Of what consist the greatest discoveries of man, if not in the discovery and application of the simplest mechanism? Regard the steam-engine and its applications, telegraphy, photography. Regard the ophthalmoscope, the laryngoscope, the stethoscope—a simple bit of wood, whittled into convenient shape—or any sound-conductor, to convey as much as possible of sound to the ear; yet a grand invention of recent times. In what consists the greatest modern scientific progress? Regard the already extensive and prospectively total reabsorption of chemistry by physics as an outlying or surrounding province. Regard the advancing researches in the nervous system, ever bringing the human frame nearer and nearer to the conditions of an as yet inconceivably fine automatic electro-magnetic machine. Regard the securest and best knowledge of the Physician in the departments of dropsies, of hæmorrhages, of embolisms, of unnatural labours. Before their exploration all these were inaccessible alps, utterly hidden or only dimly seen through thick clouds of ignorance; now they are green pastures by still waters, where a child may be safely led, and where a man may humbly step with courage, striving to subdue the next obstacle to his progress.

PROFESSOR JAEGER.—This distinguished Professor, a Foreign Associate of the Paris Society of Surgery, died on December 26, 1871, in his 88th year, having been born in 1784. Studying at Würzburg, Landshut, and Vienna, he established himself at this last city in 1812, confining himself to the practice and teaching of ophthalmology. His lectures were greatly resorted to, and among other distinguished Practitioners was Sichel, who afterwards introduced ophthalmology as a specialty in Paris. Very skilful as an operator, he continued until an advanced age the most delicate operations with surprising precision and firmness of hand. Dr. Preyss has published a long account concerning him in the *Österreich. Zeits für prakt. Heilkunde*, xvii., No. 53.—*Gazette des Hôpitaux*, January 27.

THE PATHOLOGY AND TREATMENT OF CHOLERA.(a)

By GEORGE JOHNSON, M.D., F.R.C.P.,

Physician to King's College Hospital, Professor of Medicine in King's College, London.

(Concluded from page 37.)

THE abrupt stoppage of the blood-stream by arterial contraction explains those cases of rapidly fatal collapse in which the discharges have been either absent or extremely scanty. So long as the circulation is unimpeded, the amount of discharges, resulting from the dose or the virulence of the poison, is an index of the severity of the disease; but from the time that an impeded flow of blood through the lungs begins to check excretion from the alimentary canal, there ceases to be a direct relation between discharges and the degree of collapse. In the worst cases the relation is inverse: the more extreme the collapse, the more scanty are the discharges; in other words, the impeded circulation, which is the immediate cause of collapse, arrests or very much lessens excretion from the stomach and bowels. Feebleness of the muscular walls of the heart does not explain the arrest of the circulation in cholera. There is no poison which has the effect of weakening exclusively the right side of the heart; and weakness of the right side of the heart would not explain the fact that, while the blood has been abruptly stopped just before reaching the capillaries, the trunk of the pulmonary artery is so distended that when its walls are punctured soon after death the blood spurts out with considerable force, showing that, while the right ventricle had continued to contract, some obstacle in front had prevented the onward movement of the blood. In addition to the debilitating effect of copious discharges there probably is some weakening of the heart's walls during collapse, in consequence of the scanty circulation of blood through the coronary as through all the systemic arteries. This weakening of the heart's walls affects equally both sides of the heart, and is a consequence and not the cause of the impeded pulmonary circulation.

The dark and viscid condition of the blood is a result of its defective aëration and movement. The same condition of blood occurs in all forms of apnoea. Slowly moving, imperfectly oxygenised blood becomes dark, thick, and treacly, and in extreme cases coagulates within the vessels. On the other hand, so long as the circulation and respiration are unimpeded, mere loss of water does not thicken the blood, for the reason that water is rapidly absorbed from the soft tissues throughout the body to supply the place of that which is lost by vomiting and purging. By a like process the action of a hydragogue purgative promotes the absorption and then the expulsion of a dropsical accumulation. So rapid is the absorption of water from the tissues when the contents of the vessels are escaping, that the blood which flows from a vein at the end of the operation of venesection is more watery and of lower specific gravity than that which escapes when the vein is first opened. After the choleraic discharges have ceased, the borrowed water has to be restored to the now partially dehydrated tissues, and the urine remains suppressed or scanty until the tissues have regained their normal proportion of water.

The greatly diminished, almost suspended, secretion of bile and urinary solids, and the lessened exhalation of carbonic acid, during collapse are explained by the defective circulation of the oxygen-bearing blood to the tissues. Bile, urine, and carbonic acid are joint products of oxidation. In contrast with these excreta it is found that, when a nursing mother is passing through the stage of choleraic collapse, the mammary secretion continues and the breasts become distended; the reason being that the milk-constituents—casein, sugar, oil, and water—are not oxidised products.

It has been suggested that the continuance of the mammary secretion during collapse is the result of a supposed antagonism between the nutritive and the reproductive functions, it being assumed that the reproductive functions are unaffected by cholera. This fanciful notion is at once disposed of by the fact that the foetus in utero is, in a large proportion of cases, killed by cholera affecting primarily the mother. M. Briquet, referring to a tabular statement by MM. Bouchut and Millet, shows that, out of 120 pregnant women who had cholera, abortion occurred in fifty-four. He says there is reason to believe that the death of the foetus often occurs before its expulsion, and adds, in confirmation of this, that the infant

(a) A paper read at a meeting of the West Kent Medico-Chirurgical Society at Greenwich, January 5, 1872.

was born alive in only six out of sixteen cases of abortion occurring during the progress of cholera. (b) Since "the life is more than meat," the death of the fœtus proclaims, notwithstanding the continuance of the mammary secretion, that the reproductive functions, as such, are not untouched by cholera.

The marvellous temporary relief which follows the injection of a warm saline solution into the veins during collapse, is due partly to the morbid blood being diluted, and thereby rendered less irritating to the resisting pulmonary arterioles, just as diluents taken into the stomach, and there absorbed and passing off by the kidneys, relieve the pain and spasm of strangury. But the immediate effect of the saline injection is mainly due to the relaxation of the arterial spasm in the lungs by the high temperature of the injected fluid, and with this the removal of the impediment to the free circulation of blood. It has been found by those who have had most experience of this method of treatment that hot injections are more efficacious than those of lower temperature. It has also been found that the application of warmth to the surface of the body, and the injection of hot liquid into the bowel, have often had the effect of greatly improving the circulation, and so mitigating the symptoms of collapse.

While the immediate and most striking results of the injection into the veins are due to the relaxation of the resisting arteriales, it is probable that the injection may indirectly assist recovery by increasing the liquid medium for conveying the poisonous products out of the vessels, just as a copious imbibition of water helps to clear and cleanse the bowel.

To sum up, then, the main points relating to the pathology of cholera. The exact nature of the cholera poison—as of every other morbid poison—is unknown. We know nothing of the nature of morbid poisons beyond what we learn of their influence upon the fluids and tissues and functions of the living body. The cholera poison is probably as specific in its nature as that of small-pox, but it certainly has a very close affinity with filth. We inhale the gaseous products of decomposing organic matter, or, as a result of our defective sanitary arrangements, we drink diluted sewage, with which it may be that the poisonous choleraic discharges have been mingled. If the dose of the poison be moderate, the loathsome stuff is soon expelled by vomiting and purging. If, however, the fœul leaven be more abundant or more virulent, or if its exit from the body be hindered by opiates and astringents—so that, the natural expulsive efforts being thwarted, the morbid material has time to multiply and accumulate—it may by its irritant action so excite the contraction of the arterial stopcocks as to bar the passage of blood through the lungs. Thus collapse occurs, and the danger is incalculably increased. During the period of collapse the blood undergoes great changes—partly through the multiplication of the cholera poison, partly through the defective oxidation of the blood and the tissues; hence, when reaction comes on, there is excessive oxidation of accumulated combustible products, and often a dangerous and destructive consecutive fever.

In the *treatment* of cholera and choleraic diarrhœa (which is, in fact, cholera in a mild form), the main principle to bear in mind is, that the discharges are as essentially curative as is the cutaneous eruption of small-pox. The practice of arresting or attempting to arrest the discharges by opium was based upon an erroneous theory of cholera; and experience, apart from all theory, has proved that the practice is unsuccessful and injurious. No theory or pathological reasoning is required to demonstrate that the choleraic discharges have usually a peculiar and offensive odour, and that their retention within the bowel is a frequent source of distress and danger to the patient. The effect of opiates in the diarrhœa stage is various. In a large proportion of cases the absorption of the opium is prevented by the rapid flux of liquid from the blood into the bowel; and so, being expelled together with the morbid secretions, it is powerless to arrest or even to check the discharges. In a considerable proportion of cases the opium causes sufficient torpor of the bowels to prevent their prompt and complete evacuation; the result is that the diarrhœa is prolonged, or, being arrested for a time, it again and again returns. A more decided arrest of the diarrhœa by opium is often followed by painful distension of the bowels and abdomen, the tongue becomes coated, and fever is excited. Again, in other instances, as in the case referred to at the commencement of this paper, a prompt arrest of the diarrhœa by opiates is quickly followed by collapse of an alarming and fatal character.

That plan of treatment for diarrhœa is obviously the best

which most speedily and completely puts a stop to the disease without subsequent ill-effects. The most rational and the most successful method of treatment is the cathartic system, using that term in its wide and literal sense of cleansing or purifying. A cathartic is not of necessity a bowel purgative. There is one simple "cathartic" remedy which is almost universally applicable in all forms and stages of the disease, and that is a plentiful supply of cold water to flush the intestines and to wash out the poisonous discharges. A copious imbibition of pure cold water will suffice for the cure of most curable cases of cholera. This will appear too simple a remedy for many patients and many Practitioners, who will have more faith in the liquid draughts if they hold in solution some acid or alkali, or some aromatic and carminative drug, supposed to have a curative influence. There are many cases in which something more than diluents is needed. Palpation and percussion of the abdomen often reveal the fact that the bowels are more or less distended by morbid secretions, which are frequently poured out with great rapidity. This distension of the bowels, if not promptly relieved, may even go to the extent of causing paralysis of the muscular coats of the intestine, and so an insuperable obstruction; more especially is this likely to happen when the sensibility of the bowel has been deadened by narcotics, but I have seen it occur under the expectant treatment by coloured water. The choleraic secretions appear often to have but little stimulant action upon the bowel, which consequently becomes over full, while little or no expulsive effort is made. The plan to prevent and to remove this painful and paralyzing distension is to give some quickly acting yet unirritating evacuant dose. For this purpose castor oil is, on the whole, better suited than any other remedy. If it be thought desirable to disguise the taste of the oil, this can be effectually done by mucilage and cinnamon-water. The objection sometimes raised, that all medicines must be useless because none are absorbed, does not apply to such a remedy as castor oil, which, by its merely local action upon the mucous surface, stimulates the bowel to expel its contents. The intention and, I believe, the effect of the oil is not to increase the amount of secretion from the blood into the bowel, but to facilitate and quicken the expulsion of the morbid secretions.

Castor oil has no special curative influence, and other evacuants may be substituted for it, if, on account of its taste, or the difficulty of retaining it on the stomach, or for any other reason, the oil be objected to. Rhubarb (either in the form of tincture or powder), Gregory's powder, or a few grains of calomel (either alone or combined with rhubarb or colocynth), may be substituted for the oil.

If the diarrhœa have continued for some hours, the stools having been copious and liquid; if there be no griping pain in the bowels, no signs of distension of the intestines, the abdomen being flaccid and the tongue clean, we may conclude that the poison has escaped: there will, therefore, be no need for an evacuant dose, and we may safely soothe the bowels by an opiate. While there are some cases in which an evacuant is not required even at the commencement of the attack, there are others in which the opiate is unnecessary in the later stage.

The opiate should be withheld so long as there is reason to believe that the blood is poisoned or the bowel distended by morbid secretions. The cause of the diarrhœa should be carefully sought for. It has often happened that diarrhœa which has continued from day to day has been excited and perpetuated by the breathing of impure air or the drinking of contaminated water. In such cases the only safe course is to discover and avoid the exciting cause of the symptoms.

If the diarrhœa be associated with vomiting this should be assisted by copious draughts of cold or tepid water. If there be nausea, without vomiting, and more especially if the stomach be supposed to contain undigested or unwholesome food, or morbid secretions, an emetic may be given—either a teaspoonful of powdered mustard, or a tablespoonful of common salt, or twenty grains of powdered ipecacuanha in warm water.

When vomiting is excessive in violence or in frequency, it may sometimes be checked by small draughts of iced water at short intervals. Another plan is to place three grains of calomel on the tongue, and wash it down with cold water. The calomel probably operates by reversing the action of the stomach and bowels, and thus causing evacuation downwards. When given as a powder it is less likely to be rejected by the act of vomiting than when it is made into a pill. While the diarrhœa continues the diet should be liquid and scanty; milk, rice, or arrowroot with or without a small quantity of brandy, gruel, or beef-tea may be given.

(b) "Mémoires de l'Académie Impériale de Médecine," tome 28, p. 238.

In all cases of severe diarrhoea the patient should remain in bed.

As to the treatment during the stage of collapse, it should be distinctly understood that in the worst forms of cholera, as the disease often presents itself at the commencement of an epidemic, and in most cases of pulseless collapse, the disease is so deadly that no treatment can be of any avail; and a sure way to bring discredit upon any method of treatment is to apply it in this desperate class of cases. It is obvious that castor oil is as powerless to overcome an extreme impediment of the pulmonary circulation as croton oil to remove a large blood-clot from the brain. In cases of extreme collapse it is much easier to do harm than good. The injurious influence of opium and alcohol in the collapse stage is now almost universally admitted. Their noxious effects are intelligible if we bear in mind that during collapse, in consequence of the impeded circulation, the oxidation of the blood and tissues is greatly diminished, and that both opium and alcohol still further impede oxidation, while opium also retards the escape of the poison.

The collapsed patient should be strictly kept in the recumbent posture—he should not be raised even to go to stool; he should be abundantly supplied with fresh air, and allowed to drink pure water freely. The water may usually be taken cold—that is, of the temperature of the room—but it should not be iced, except occasionally to check excessive vomiting. Large quantities of iced water may do harm by chilling the patient and checking the process of cure by elimination. Some care is required not to over-distend the stomach by liquid. Unless vomiting occur from time to time, the drinking of large quantities of liquid may so distend the stomach as to impede the breathing, and thus cause much distress.

The muscular cramps of cholera are probably excited by the action of the poisoned blood upon the nerves and muscles. As a rule, cramps are more frequent and severe during the diarrhoea stage than during collapse. Whenever they occur, they may be relieved by rubbing the affected parts with the warm hand alone, or with the addition of a stimulating or anodyne embrocation. Cramps in the legs are often most effectually relieved by hot flannel fomentations covered by macintosh. Hot baths, whether of water or of air, certainly relieve the cramps, and effect a temporary improvement of the circulation; but, on the whole, it is a question whether they are not more distressing and exhausting than beneficial. The temporary improvement of the circulation by hot baths is one fact amongst a number pointing to an essential difference between the collapse of cholera and ordinary exhaustion. An exhausted patient usually becomes more feeble and faint when placed in a hot bath.

Five grains of sesquicarbonate of ammonia may be given in an ounce of camphor mixture every two or three hours as a diffusible stimulant.

If we carefully observe the condition of a patient in collapse, we shall often find that the intestines are more or less distended with liquid, while perhaps there is general torpor and little or no effort at expulsion, the vomiting and purging having ceased. Again, it has often been found that, although there has been much watery purging during life, the small intestines contain after death a large amount of a peculiar, viscid, dirty-white material, having a very offensive odour. An occasional dose of castor oil may be useful in removing both these conditions—namely, over-distension of the bowel by liquid, and retention of offensive viscid secretion. I have no doubt that by this treatment, watchfully and carefully carried out, I have rescued patients who would have died if they had been left to the unaided efforts of nature.

It may be confidently maintained that since the choleraic discharges are the result of specific blood changes, induced by a morbid poison, no ordinary purgative can increase those discharges, although it may facilitate and quicken their expulsion.

It is worse than useless to attempt to feed a patient during collapse. The secretions of the stomach are utterly deranged, and the power of digestion is suspended. The blandest nourishment given at this time often adds to the feeling of oppression and general distress, from which the act of vomiting sometimes gives immediate relief. After reaction has occurred, and when the normal secretions are restored, the mildest nourishment should be given frequently, but in small quantities—such as milk, gruel, or rice, or arrowroot with a small quantity of brandy, soup, or beef-tea, or chicken broth. Until the secretion of bile and urine has been restored, neither alcohol nor opium should be given.

Hot saline injections into the veins have unquestionably saved life in some apparently desperate cases of collapse. I have

already given what I believe to be the true explanation of their operation.

Consecutive fever is more common when, during the earlier stages of the disease, opium and alcohol have been freely given; but it may occur after severe and prolonged collapse, when no such means have been employed. The best treatment consists in a liquid diet without alcohol; copious diluent drinks, with saline effervescing draughts; an occasional aperient, such as castor oil or a Seidlitz powder; hot fomentations, or dry cupping over the lungs and kidneys, and sometimes local bleeding to relieve congestion of those organs.

When the urine is suppressed or scanty, one of the safest and most efficacious diuretics is the "imperial drink" (cream of tartar and lemon), from one to three pints of which may be taken cold in the course of the twenty-four hours.

Before I conclude, I wish to comment briefly upon two statements which have often been made by the opponents of the evacuant or cleansing treatment of cholera.

The first is, that if the diarrhoea can be stopped before the onset of collapse, the patient is saved. I have before said that the best treatment for diarrhoea is that which most speedily arrests it without subsequent ill-effects; but it is certain that the sudden arrest of the diarrhoea by opium has often been the immediate precursor and cause of collapse.

The second statement is, that the action of an aperient has sometimes been followed by fatal collapse. This is probable enough. In like manner, the application of a mustard poultice for a sorethroat has often been followed by fatal scarlet fever. While I would deprecate the needless or careless employment of aperients at all times, but more especially during a cholera season, it appears to me about as reasonable to suppose that scarlet fever may be caused by a mustard poultice, or typhoid fever by a purgative, as to attribute an attack of cholera to the operation of a dose of rhubarb. When cholera has followed such a dose, the reasonable inference is that the disease was latent in the system before the drug was taken. I was once accused of having "brought out the small-pox" in a child by a saline mixture which I had prescribed for a feverish attack. It is obvious that that which thus comes out has before been latent within, and its outcoming may be the saving of the patient.

CHEMICAL EXAMINATION OF THE URINE.

By J. ALFRED WANKLYN,

Corresponding Member of the Royal Bavarian Academy of Sciences.

SOME experiments made during the past year have led me to believe that Medical men would do well if they were to supplement, or even to replace, the determination of specific gravity of urine, to which they almost invariably resort, by determinations of the solids left on evaporation and of the ash left on incineration. That the determinations of specific gravity actually made in the course of practice are often faulty through inattention to the temperature, whilst a slight alteration in specific gravity corresponds to a great alteration in solid contents, will be at once admitted. Moreover, whatever value a specific gravity determination of urine may possess depends on its being in some sort an index, more or less accurate, to the solid contents of the urine. I believe that an exaggerated idea of the trouble involved in taking solid residues, and a notion that the amount of residue is inconstant, depending upon the custom of operating upon an inconveniently large quantity of liquid, accounts for the disuse of so obvious a procedure as the direct determinations of the solids and ash in urine.

The following experiments show that there is no difficulty in obtaining these data, and that they are very constant:—

A very accurate 5 cubic centimetre pipette (not 0.05 cubic centimetres in error, as was ascertained by weighing the water discharged by it) was employed. With this pipette 5 centimetres of urine was measured out into a small platinum dish, the weight of which had been ascertained. The dish with its contents was then placed in the water-bath and heated for one hour, and then cooled, and with its solid contents weighed. It was then heated again for half an hour, and reweighed. Finally, it was heated a third time for another hour, and reweighed. This experiment was made three times on urine

belonging to the same sample. The following are the results:—

(Quantity of urine taken, five cubic centimetres.)

	After drying at 212° Fahr. for		
	1 hour.	1½ hour.	2½ hours.
<i>Experiment I.:</i> —			
Weight of dish and residue	12·692	12·687	12·687
„ empty dish	12·484	12·484	12·484
Therefore, residue	·208	·203	·203
<i>Experiment II.:</i> —			
Weight of dish and residue	12·743	12·737	12·737
„ empty dish	12·534	12·534	12·534
Therefore, residue	·209	·203	·203
<i>Experiment III.:</i> —			
Weight of dish and residue	12·223	12·216	12·216
„ empty dish	12·017	12·017	12·017
Therefore, residue	·206	·199	·199

Calculated in percentages, we have, therefore, 100 cubic centimetres of urine, yielding respectively:—

	1 hour.	1½ hour.	2½ hours.	
Experiment I.	4·16	4·06	4·06	grammes of residue.
„ II.	4·18	4·06	4·06	„ „
„ III.	4·12	3·98	3·98	„ „

This shows that a urine residue is very constant in weight, and that a period of one hour and a half is sufficient for its complete desiccation.

In order to determine the amount of mineral matter in the urine residue, all that is necessary is to ignite it for a short period, when it will leave a grey residue. It is not desirable to prolong the ignition until the residue becomes quite white, and the addition of nitric acid (which is sometimes advised) is to be absolutely condemned. Either of these procedures, and especially the latter, will cause an appreciable loss. The trace of carbon, on the other hand, which makes the difference between a white and a grey ash, is comparatively a trifling matter.

In the specimens of urine which furnish the above results, it was found that five cubic centimetres left 0·075 gramme of ash, therefore 100 cubic centimetres yielded 1·50 gramme of ash.

The success of these determinations, and certainly their facility, depends to a great extent on the employment of an appropriate quantity of urine—on not working on too large a scale. The 5 cubic centimetres of urine equal about 77 grains, and those persons who prefer to use grain weights would do well to take a 100-grain pipette, and, if they had operated on the above sample of urine, would have arrived at the result that 100 fluid grains of urine contained 4·06 grains of solids, of which 1·50 grain was mineral matter.

Besides the sample of urine just mentioned, I have examined a good many others on different occasions. The following will serve as examples:—

Specific gravity of the sample at 60° F.	Weight, in grammes, yielded by 100 cubic centimetres.		
	Total solids.	Mineral matter.	Organic matter.
A . . 1·020	4·52	1·56	2·96
B . . 1·0176	3·86	1·46	2·40
C . . 1·0057	1·40	0·60	0·80
D . . 1·0167	3·86	1·48	2·38
E . . 1·0101	2·66	0·63	2·03
F . . 1·0185	4·03	1·50	2·53

Sample C had been passed by a man immediately after taking some beer. Sample E was from a patient suffering from some disease of the kidneys. F is the urine the analysis of which has been given in detail, the mean of the three determinations being taken.

On inspecting these numbers, it is interesting to note that the pathological specimen—viz., E—exhibits an extraordinary ratio between the organic matter and the mineral matter (mineral matter 0·63, organic matter 2·03), there being three times as much organic matter as mineral matter. Not one of the other samples (which are from healthy persons) exhibits so high a ratio as twice as much organic matter as mineral matter. In order, however, to derive as much benefit as possible from examinations of urine, the total quantity of urine passed by a patient in a given period, extending possibly over several days, should be saved, measured, mixed together, and analysed. In this way, using the above method, it would be easy to arrive at a fairly accurate estimate of the amounts of organic and mineral matter excreted by the kidneys in a given time. The

mineral matter admits, also, of further analysis in several obvious ways—thus, the chlorine may be determined, and also the phosphates, by well-known volumetric processes.

Liebig's method of estimating urea, by means of standard solution of nitrate of mercury, is acknowledged to have rendered excellent service, and to have furnished a very good approximation to the nitrogenous excretion by the kidneys. I have made a special adaptation and modification of the ammonia process, which Chapman, Smith, and myself applied to water-analysis some few years ago. This modification is designed to meet the case of urine, and to furnish a substitute for the Liebig's urea-determination, and, in laboratories where the water process is already worked, will be found easier of execution than the Liebig's urea-titration.

My process is carried out as follows:—

Five cubic centimetres of urine are placed in a 500 cubic centimetre measure, which is filled up to the 500 cubic centimetre mark with water. Thus there results a dilute solution of urine, of which each cubic centimetre contains $\frac{1}{100}$ cubic centimetre of urine. Of this dilute urine either 5 or 10 cubic centimetres is the proper quantity to be taken for an experiment. A strong solution of potash is prepared (17 to 20 per cent. solution). This is boiled, and carefully tested for ammonia and for nitrogenous organic matters. These being absent, the potash solution may be used. About 10 cubic centimetres of it with 5 or 10 cubic centimetres of the above-described dilute urine is evaporated to dryness in a small retort, placed in the oil-bath, and heated to about 160° Cent. The ammoniacal distillate is condensed with a small Liebig's condenser, and properly diluted with water and *nesslerized*; and so the amount of ammonia furnished by the action of potash on the urine may be measured. A few little precautions have to be taken; thus, a little fresh water must be put into the retort, and the heating to 160° Cent. repeated until no more ammonia distils over. After the action of the potash is complete, solution of permanganate may be introduced, and so the "albuminoid ammonia" determined.

The working of this process has proved to be very easy and satisfactory. The sample of urine yielding 1·50 gramme of mineral matter and 2·53 grammes of organic matter in 100 cubic centimetres of urine, furnished quite constant results in two experiments—viz., 0·92 gramme of ammonia from 100 cubic centimetres of urine. In a single trial I also obtained 0·06 grammes of "albuminoid ammonia" from 100 cubic centimetres of this urine. This result requires verification. Probably the small quantity of "albuminoid ammonia" is from Thudichum's kryptophanic acid and allied substances; and any way, in the action, first of potash and then of permanganate of potash, we have a very promising method of attacking urine. Obviously a urine containing albumen would disclose that fact when the treatment with permanganate came to be applied.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,

Student of Guy's Hospital.

No. II.

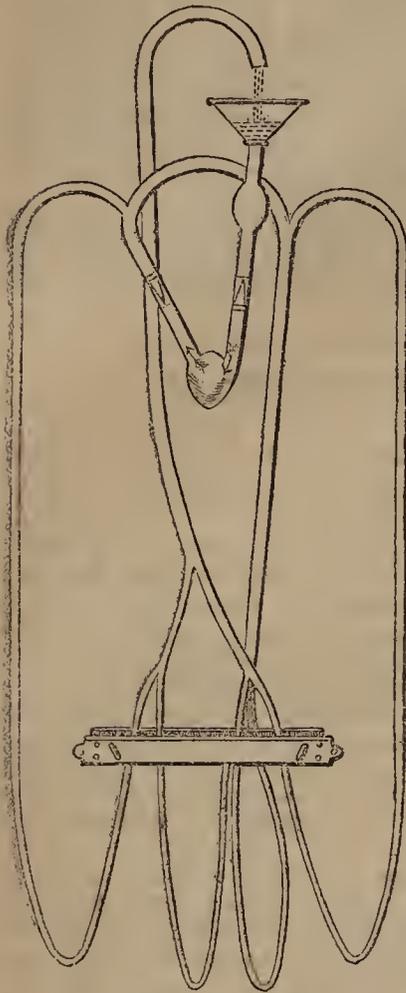

Description of a Schema—The Normal Pulse—The Percussion and Tidal Waves.

In order to study the pulse in disease, it will first be necessary to understand it perfectly in health, and to appreciate, as far as possible, which of the various phenomena of the circulation combine to produce the various details of a pulse-tracing. Much has been written of late years on this subject; in our own country, Dr. Sanderson especially has thrown great light on the arterial movements. Many points may therefore be accepted as well-ascertained; but, besides much truth, numerous errors and a vast variety of theories have been formed. I propose in this and the following paper first to assign the meaning I have been led to attach to each portion of a pulse-tracing by my own observation and experimental investigations, and afterwards to give such proof as lies in my power of the truth of my statements.

In order to facilitate the study of the pulse, and to apply to each theory the crucial test of experiment, by the kind permission of Dr. Pavy, I have constructed, in his laboratory at Guy's, a schema of the circulation somewhat resembling Marey's, in which the mechanical conditions of the pulse can

to a certain extent be imitated. The accompanying diagram shows the construction of the schema that has been employed

FIG. 3.

in the experiments to be described. The left ventricle of the heart is represented by an indiarubber bag having two necks, into which are introduced two short pieces of large glass tubing, containing valves representing the mitral and aortic valves of the heart; each valve consists of a hollow cone, made of caoutchouc, and attached to the glass by wire passing through two fine holes bored in the tubing. One part of the base of the cone is therefore retained in apposition with the interior of the tube, the remaining circumference being unattached. A column of water, flowing in the direction indicated by the arrows in the diagram, compresses the cone against the side of the tubing, and has free passage, while a flow in the opposite direction distends the cone, and keeps its circumference in close apposition with the wall of the tube. To the tube containing the aortic valve a system of vulcanised indiarubber tubing is attached, representing the aorta giving off from its arch the two subclavians, and terminating by dividing into two branches to represent the external iliacs. The subclavians and iliacs are continued by tubing gradually diminishing in size; the four smallest-sized tubes are then conducted between two pieces of wood fixed to the board, on which the whole is suspended, having four shallow grooves, capable of being screwed close together, so as to completely constrict the tubes passing between them, and of being unscrewed to allow of dilatation of these tubes to their ordinary dimensions. By this means the capillary obstruction can be imitated and regulated. Having passed this representation of capillaries, the tubes now represent veins; they join by means of Y-shaped junctions, first to form two and afterwards one tube, representing the inferior vena cava, which empties itself into a funnel connected to the glass tube containing the mitral valve by a piece of wide vulcanised tubing, in the course of which is introduced a thin, distensible indiarubber bag to represent the auricle. This is always full, and insures a constant supply of fluid to the ventricle during its dilatation or diastole. The contraction of the ventricle is produced by the hand. The hand has been said to be an inefficient way of representing the contraction of the heart; but by practice it may be made to do so in the most perfect manner, as the tracings obtained will show. Every variation in the heart's action may be thus imitated, and the force employed regulated at will. Tracings may be obtained from any part of this system of tubing. It will be convenient to speak of the large-size tubing in the arterial part as the aorta, the medium size as the brachials and femorals, and the smallest size as the radials and posterior tibials.

FIG. 4.

It will, however, be necessary to obtain some idea of the form of the normal pulse, and of the terms used to describe it, before its imitation be attempted or the theories of its production discussed. Fig. 4 represents a pulse-tracing, in which all the undulations usually met with are visible; it may be taken as a typical pulse for analysis. The first question which suggests itself is, To what is the almost vertical upstroke (marked A) due? It appears that the first and main upstroke

in a pulse-tracing is almost invariably due to percussion, and might with advantage be called the *percussion-stroke*. This term will be employed to denominate it in these papers. It is produced usually by the shock received by the blood-column on the sudden bursting open of the aortic valves, which is transmitted almost instantaneously throughout the whole arterial system, the column of blood transmitting it as a solid body, and imparting it to the arterial walls. It is to be entirely separated from the true pulse-wave, except under certain conditions to be mentioned below, when it is identical with it. It indicates the suddenness and force of the heart's contraction, and forms an important pathological element of the tracings obtained in acute and other diseases; but it does not by any means afford a guide to the amount of blood impelled into the aorta at each systole. The truth of this statement it will be my endeavour to prove hereafter.

After the percussion-stroke, a sudden fall of the lever—i.e., collapse of the artery—is seen. This, however, is cut short at B by a slight elevation of the lever—i.e., distension of the artery—or, as in this instance, only by an arrest of its downfall; this is the true *tidal wave*. The whole of the tracing anterior to this may be called the *percussion-wave*; this term will therefore include the percussion-stroke. The interval between the percussion-stroke and the next elevation of the lever almost corresponds to the interval between the contraction of the heart and the transmission of the pulse-wave to the radial artery; it strictly corresponds to the interval between the transmission of the percussion-stroke and the tidal wave. The height of this second elevation above a line drawn horizontally through the bases of the percussion-strokes indicates the amount of blood forced into the arterial system at each ventricular systole; it need not bear any proportion to the height of the percussion-stroke; the pressure required to extinguish it indicates the real amount of propulsive power of the cardiac contraction. The pressure employed to obtain a perfect tracing giving the full height to the percussion-wave does not necessarily bear any relation to the power of the heart; for though only a light pressure may be required to cut short the percussion-wave, a much heavier one may be necessary before the tidal wave is diminished.

The succeeding portion of the tracing, as far as the next sudden elevation of the lever, corresponds to the passage of the true pulse-wave or tidal wave through the artery, the force of which is diminishing, and the elastic walls of the artery steadily contracting upon it. It forms a curve, the concavity of which is downwards, scarcely perceptible in a normal pulse, but well marked in some forms of disease. The next elevation met with is the true diastolic wave of the pulse, c; the lowest part of the notch preceding it corresponds with the closure of the aortic valves, and is called the aortic notch. The systole of the heart here ends, and diastole begins. This elevation Dr. Sanderson has aptly called the "diastolic expansion or arterial systole." It is produced by the contraction of the elastic coat of the aorta which takes place at the termination of the ventricular systole. During the first part of the systole the blood is impelled throughout the whole arterial system, but the obstruction met with at the capillaries checks its onward current, and during the remainder of the systole the aorta becomes distended by the blood expelled from the ventricle. The contraction of the aorta, which now ensues closes the aortic valves, and sends a fresh wave of blood through the arteries. The conditions required for the increase or decrease of this wave are numerous and complicated; they will be considered below.

The remaining portion of the pulse-tracing shows a steady fall of the lever, indicating the gradual collapse of the artery, from the contraction of the elastic walls of the bloodvessels; it often presents another slight undulation in its course, again due to the efforts of the elastic walls of the arteries to overcome the capillary resistance to the blood current.

The pulse-wave may therefore be divided into two parts corresponding to the ventricular systole and ventricular diastole. The first portion is composed of two factors—i.e., the percussion and tidal waves; the second also of two—i.e., the arterial diastolic expansion and the (more or less) uninterrupted contraction of the elastic coat.

- | | |
|------------------|--|
| Ventric systole | { Percussion-wave. |
| | { Tidal wave. |
| Ventric diastole | { Diastolic expansion or arterial systole. |
| | { Contraction of elastic coat. |

There remains but one more point to be observed, and that is what is called by Marey the *ligne d'ensemble*, or may appropriately be entitled the respiratory line; it is formed by a line

drawn through the lowest points of the percussion upstrokes. It should be perfectly horizontal, but as it depends on the arterial tension it may vary under certain pathological conditions, being influenced by respiration.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

GUY'S HOSPITAL.

CASES UNDER THE CARE OF MR. BRYANT.

Lipoma, size of a walnut, on Plantar Surface of Second Toe.

JANE W., aged 44, came under my care at Guy's Hospital on September 27, 1866, for a swelling beneath the second toe of her right foot. It had been growing for fifteen years, and had been painless. It was troublesome only on account of its size. The tumour was apparently cystic and soft. Fluctuation could not, however, be made out. It was beneath the skin and soft, but not lobulated to the touch. I punctured it for diagnostic purposes, when nothing came away, and subsequently excised it. The tumour was made up of small lobules of loose fat. A good recovery followed.

Symmetrical Nævi in a Male and Female Twin.

Mary and John G., twin children, 8 years of age, were brought to me at Guy's Hospital on May 30, 1867. Each child was the subject of a nævus, the size of a sixpence, at the external angle of the right eye. The symmetry of the two growths was remarkable, being the same size and shape in both children. Mary was a very fair child, and John a dark one, and in features there was but a slight resemblance. The nævi were not apparently growing, so they were left alone.

Ulceration of the Cicatrix of a Burn following Ill-health.

William G., aged 48, came under my care at Guy's Hospital on January 18, 1866, for an ulcer of the right thigh. It had existed for five months, and was situated in the centre of a cicatrix, the result of a burn thirty years previously. It had come on after a serious illness, which had left him very feeble. He had had an ulcer on the same spot eight years previously from the same cause, which healed as soon as he had regained his health. Under tonic treatment the ulcer rapidly healed, and in one month he was well.

This case was a good one, showing how cicatricial or new tissue has a tendency to undergo degenerative changes or ulceration on any marked decline of a patient's powers making itself manifest.

Chronic Sloughing Ulcer on Leg (encircling the limb)—Necrosis of Tibia—Chronic Edema.

Elizabeth L., aged 38, admitted August 4, 1871; married thirteen years; no children or miscarriages. "No illness till 14 years old," then had severe erysipelas in left leg and foot; attributes it to getting wet. It became much swollen, and a Surgeon was sent for, who said it was rheumatism, and so treated it. Got worse; sent for another Surgeon, who said it was erysipelas, and lanced it in numerous places; blood escaped; leeches and poultices were afterwards used for six months, during which the leg remained swollen and painful. At the end of nine months it began to improve, when on the centre of the anterior surface of the right leg a small black spot appeared, which was painful, and quickly became a wound, for which five years ago she attended St. Bartholomew's as an out-patient. About three years ago the wound had increased to about half its present size; the foot became swollen and painful. Walked about till three weeks ago, when she fancied she over-walked herself, and the wound has since rapidly increased. There is now a very offensive discharge, and the bone exposed; the foot also is enlarged. Says the veins of this leg used to swell very much.

On Admission.—Patient looks worn out and thin; left leg healthy, right leg much swollen; skin of a purplish hue; midway between knee and ankle there is a large ulcerating wound encircling the limb; the tissues have sloughed about three inches, exposing part of the shaft of tibia, tendons, etc.; the foot is enormously enlarged, red, feels firm.

August 7.—Cataplasma carbonis, tonics.

8th.—Chloroform. Mr. Bryant amputated through the knee-joint; anterior and posterior flaps, the latter being rather longer

than usual; patella left *in situ*; torsion, and flaps retained by silk sutures, lint, short splint-strappings, and cotton-wool. On examination of the limb after amputation, the muscles and tendons were found to be sloughing. The pus burrowed in the course of the tendons, especially in the tibialis anticus, at insertion of which an abscess existed. The exposed part of tibia was about three inches long, and began two inches above the ankle. On vertical section of the tibia all appeared healthy except near the part exposed; the surface was necrosed and separating; the interior softer than elsewhere; the adjacent periosteum parchment-like and easily stripped.

November 16.—Convalescence has been delayed by several small abscesses, which formed about the stump. These were opened in due course, and she leaves the Hospital to-day in a very satisfactory condition.

ST. GEORGE'S HOSPITAL.

CASES UNDER THE CARE OF DR. JOHN W. OGLE.

Two Cases of Peculiar Rhythmical Muscular Movements in Adults (Chorea Oscillatoria).

THE first was a man, George A., aged 42, a clerk in an office. As a young man he had been athletic, but was now thin and pale, and sluggish in appearance. It seemed that for ten months he had been the subject of what he called "shaking fits," which he could sometimes, though not always, arrest by an effort of will, and afterwards they often returned with greater force. They seldom came on when he was walking. It was found that these shaking fits consisted of violent nodding movements of the head backward and forward, accompanied at times by violent upward and downward jerking of the right arm, as if he were hammering. The attacks were very irregular in their approach.

At first the patient was purged and took valerian, and had shower-baths, which, he said, made his attacks worse. Sulphate of zinc was subsequently given. On one occasion he so frightened and menaced a neighbouring patient in one of his "fits," that the patient threatened he would knock him down. After that he never had any very decided attacks, and left the Hospital. This patient had a brother who became insane, as he said, apparently "from excess of vanity."

The second case was that of a woman, Eliza S., aged 27, who had been much subject to asthma. Four years ago she had a fright, owing to a fire in her neighbourhood. A few months after that she began to feel far from well, and in a few months more she became affected by "nodding" of the head, which would come on and last all day, but always ceased during sleep. During the three years that she has had the attacks, she supposes that the intervals of immunity have been only half the whole time of her illness. The longest interval has been six months. For sixteen weeks before admission she had been perpetually troubled with the nodding movements, and unable to stand quite upright.

The catamenia had always been regular, and no disease of any organ was traceable. Under the use of valerian and assafoetida, with occasional aperients, followed by shower-baths, the noddings ceased entirely, and she became able to stand and sit much more upright. Having been free for three weeks, the patient left the Hospital.

Delirium Tremens simulating Typhus Fever.

T. A., aged 35, a very intemperate man, mainly drinking spirits, had had two or three threatenings of delirium tremens on previous occasions, and had been for fourteen days before admission very "shaky," having restless nights and troubled with ugly dreams.

When admitted the tongue was very coated, the hands tremulous, and the bowels confined. On the second day after admission the tongue became very dry, the pulse high, and the skin very hot; a mottled eruption over the entire body was also noticed—not, however, at all that of enteric fever. Delirium came on worse at night, and a great tendency to coma, and this existed for two or three days. The temperature ranged from 101° to 103.4°. He was purged, and salines with ammonia administered for two days. On the second day port wine was given, and ice applied to the head, and on the third opium was given at bedtime; on the sixth day after admission the temperature was normal, the tongue having cleaned much and become moist.

Ulcerative Endocarditis—Diseased Kidneys.

The patient, aged 42, single, was a fish-salesman, and stated that he had been drunk at least twice a week since he was 18;

years of age, always drinking beer, of which he required two gallons before he was intoxicated. He was admitted with anasarca and ascites, and much pain in the back and sides, and having great difficulty in retaining the urine long. He stated that he had spat blood occasionally. The urine was loaded with albumen. Physical examination showed enlargement of the heart and congestion of the lungs. He lingered for four or five days, having epistaxis on one occasion, and died somewhat suddenly. After death, in addition to œdema and congestion of the lungs, the heart was found to weigh eighteen ounces, and its muscular fibre was very fatty; the mitral and aortic valve-flaps were much thickened, and adherent to the segments of the latter was a thick layer of fibrine, which could be stripped off with ease, except at one part where it was dense and fibrous. Beneath this layer the endocardium forming the inner part of the valves was found to have been destroyed by ulcerative processes, and much calcareous deposit existed in the base of these valve-flaps. The liver was cirrhotic and fatty, and the spleen weighed twenty-four ounces. The kidneys were congested, and their tubules full of fatty epithelium.

Cases of Enteric Fever beginning with Pneumonic Symptoms.

The first case was that of a woman, aged 22—Sarah E.—who had been taken ill four days before admission, with sickness, pain in the back, and general *malaise*, and had had much tenderness in the right iliac fossa. On admission there was tenderness on pressing the abdomen, but no eruption on the skin existed. Auscultation and percussion showed indications of pneumonia at the base of both lungs, but especially the right one. There was, however, no expectoration. About five days after admission one characteristic "spot" was found on the side of the abdomen, but this disappeared in two days, and no others succeeded it. All this time the tongue was very dry and brown, and the teeth covered with sordes. For several days after admission the evacuations were only passed once a day, but were watery, and of a brown colour. The temperature was never higher than 103.2°. For several days the remission was in a morning, but afterwards the evening temperature was often lower than the morning. For some time the temperature kept up as high as 100° or 101° after the pulse had come down from 100 or 95 to 88 and 84; and when the temperature and pulse had got down to normal, and the patient was out of bed, there still existed much crepitation in the small bronchial tubes at the base of the lungs, especially the right one.

The second case was that of a boy, aged 12, who on admission had dulness at the base of the right lung, and moist sounds on inspiration. Two days after admission, typhoid spots were found on the abdomen, which was tender, the temperature being 104.4°, the pulse 108, and respiration 32 per minute. He went through a short course of fever, the lung symptoms gradually clearing up, and left the Hospital recovered. At first ammonia and salines with ipecacuanha were given, and warm poultices applied to the chest. Subsequently wine and mineral acids were given.

PROFESSOR VIRCHOW.—This renowned German pathologist, it is said, intends to leave Berlin and go to London. He has always been a great democrat in politics, and has in consequence suffered a good deal of persecution on the part of the royal authorities.—*New York Medical Record*, December 15.

THE PROFESSION IN VALPARAISO.—M. Garnier publishes in the *Union Médicale*, Jan. 27, a caution to those young Practitioners who have received invitations from the Intendant of the province, and which he characterises as a snare. It seems that a municipal ordinance has been issued that all Practitioners should in turns hold themselves for a week to attend gratuitously all patients who wanted their services between midnight and 7 a.m. Refusal would entail fines or forfeiture of licence to practise. All the European Practitioners, who constitute the majority in the town, have, as a protest against this arbitrary decree, spontaneously ceased to practise; and, consequent upon this, the autocratic Intendant has, through the Chili envoys in Europe, transmitted invitations to Practitioners to repair to Valparaiso, taking care, however, not to mention the cause which has rendered their services needful. He offers a free passage and 1000 fr. during the first three months, on their engaging to remain there for four or six years. The offer is, in fact, illegal, as no one can practise in Chili without having undergone an examination conducted in the Spanish language. "In face of Professional independence succumbing to violence, no Practitioner worthy of the name would favour this by accepting conditions so derogatory to his liberty of action."

SATURDAY, FEBRUARY 3, 1872.

SIR WILLIAM GULL'S ADDRESS TO THE CLINICAL SOCIETY.

THERE are in our Profession a goodly number to whom the name of Dr. Gull conveys only the idea of the fashionable West-end Practitioner—of one who, by some exceptional luck, has been able to secure a most enviable position; but there are others to whom the name conveys a totally different impression. These instinctively call to mind the hard-working clinical observer and the industrious pathologist, when as yet his future position could not even be dreamt of. In certain respects his election to the chair of the Clinical Society has been of service to Sir William Gull, for it has afforded him an opportunity of showing to those who little knew him what a shrewd Practitioner he is. His remarks have, as a rule, been short and pithy—epigrammatic and somewhat paradoxical; yet on that very account all the better fitted to stimulate the life of the Society, which sadly wanted some such stimulus, and which certainly of late has shown more signs of vitality than it was wont to do. The occasion of his re-election to the Presidential chair has, however, induced Sir William Gull to make a longer speech than usual, and certainly his remarks were both instructive and suggestive. What struck us as his main point was, that disease is no entity, to be exorcised from the body, but an abnormal fulfilment of the ordinary functions of the individual. Now, some people never do manage to carry on these functions in such a way as to give rise to no discomfort: in other words, to them ill-health is as natural as is sound health to the average of humanity. In any case, we are to study the individual, to ascertain as closely as possible what his ordinary condition is, and to keep that in mind alike in forming a diagnosis and a prognosis and in suggesting a line of treatment. It is the individual who is to be treated, not the malady.

And here it may be well to point out that Sir William Gull is not of the do-nothing school. Doubtless, he says, it would be a pleasant task enough to sit down and watch disease; but the work of the Physician is something very different. True, that in disease there is a tendency to a return to a state of equilibrium—that is, health; but it is the duty of the Physician to foster that tendency by every means in his power, and to watch that the patient, whilst getting well from the disease-process, does not die of something else.

As regards fevers, Sir William Gull's opinions are somewhat peculiar, and certainly they are well worthy of attention. In fever, he says, two sets of changes are going on—one set destructive, the other tending to health; but in this comparatively simple

process other manifestations than those of simple fever may make their appearance, such as pneumonia, bronchitis, and the like. These, says Sir William Gull, are part and parcel of the fever-process. Get the patient well of the fever, and these, also, will leave him. It is true that these complications may assume a severity such as to demand special attention and some special treatment, but in the main they are to be considered and dealt with as part of the fever.

Amusingly he drew attention to the existence of organs that in our bodies are superfluous, so far as we can make out, but which are perhaps more subject to disease on that account than are others. Tonsils, he thought, came in this category; and one might add a good many more. There is the coccyx, in females sometimes the seat of intense pain; the thymus, in adults often the origin of mediastinal cancer; persistent vitelline duct, as mentioned by the President himself, and many others which will suggest themselves to our readers. Let us hope, too, that the suggestion that such may be removed, perhaps with advantage, will not be lost sight of by Surgeons—some of whom have already taught us that people may live tolerably well without spleens, kidneys, and such-like organs.

It is not easy to give a good notion of such a speech as that to which we allude, for the manner often conveys as much as, or more than, the matter; but there were few persons who heard it, we venture to say, who were not in some degree benefited. Many, we know, would not agree with all Sir William said; but agreement is not always the best thing, especially in societies for discussion; and if some of the observations were of a nature to excite opposition, they were certainly such as would lead men to think. If the Clinical Society has reason to be satisfied with any one thing, that one thing is its succession of Presidents; and that the third in sequence should have attained the well-merited honour of a baronetcy must be pleasing to its members. For in the persons of their Presidents—pre-eminently working clinical teachers—their Profession has been honoured; not perhaps to the extent which might have been desired, yet, nevertheless, honoured as honours go. Finally, we do not know that we can do better than wish to Sir William Gull a long enjoyment of his well-earned dignity, and to the Clinical Society a long line of no less eminent Presidents.

INSENSIBILITY TO POSITION.

THE statement put forth by the experts in the Watson and Edmunds cases, that the "insensibility to their position" displayed by the respective prisoners was a sign of moral insanity, or, at all events, of some form of insanity, is one that demands careful examination, and must be received with a considerable amount of caution. A reception of the plea might go far to excuse all sorts of crimes, and cause much laxity in the administration of justice. Great criminals whose sanity has never been doubted, except by those who take up with the craze that all crime is an evidence of insanity, have—we might almost say as a rule—been callous and apparently insensible to their position. Lancettré, who for seven years pursued a course of deliberate crime and murder, Palmer, Rush, Müller, Ruloff (the New York murderer), and others, may be cited as signal instances. Feuerbach, in his work on German criminals, gives numerous examples of great criminals being singularly unaffected by their position. A recent writer has stated that if we were to expunge from the history of great crimes all those in which the criminal had shown great insensibility to his or her position, we should strike out of the list almost all which inspire the greatest horror, and those of most of the poisoners, from Brinvilliers to Edmunds. We may remark, in passing, that prisoners appear, as a rule, to be exceedingly callous and indifferent to the crimes they have committed. An habitual course of crime must, as a natural consequence, deaden moral sensibility. Every day we see how men harden in wickedness and vice: a few false steps are first

taken, perhaps not without some sharp twinges of conscience; the habit grows, and eventually a man or woman commits deeds, with no apparent compunction, that he or she would formerly have shrunk from with horror. It is a sad fact that people become as readily hardened in crime as in any other habit, and insensible to their position. Yet we should be loath to think that all these people who thus become callous and indifferent are insane. This earth would no longer be a safe habitation. Let humanitarians say what they will about the moral effects of punishment upon the criminal, and the reform to be effected by it, in a public point of view the deterrent effects of punishment are, in the interests of society at large, vastly more important. Criminals who are insensible to their position, if not clearly proved from other data to be insane, must be taught by their hard lot to recognise it; and would-be criminals must also be deterred from following their example. Many lunatics are known to be amenable to punishment; only when the person of unsound mind is so far dead to punishment that its infliction ceases to have a deterrent effect should it be entirely withheld. A morbid all-absorbing selfishness is just as good an evidence of insanity as that callousness which causes insensibility to position. All vicious propensities and evil tendencies are doubtless to be regarded as due to some defect—natural or acquired—of some part of the moral nature; but this deadness is not necessarily, or perhaps generally, innate; it is oftener acquired by slow degrees, and is, in its earlier stages at least, quite within the control of the individual. Dulness of sympathy and indifference to the opinion of others are generally signs of an increasing and culpable self-absorption. This is well seen in the history of great criminals. M. Ruloff, the Polish murderer, of New York, to whom we have already referred, was a signal instance of this. He organised a band of robbers and burglars with, as it appears, the sole object of procuring means for supporting himself whilst carrying on certain abstract studies. Those who are in the habit of frequenting our courts of justice must have been struck with the extreme indifference and insensibility to their situation displayed by criminals as a rule. We cannot be surprised, therefore, if lawyers look at this matter in a different light from Physicians, and refuse to acknowledge, in this indifference, any proof of insanity. Much as we wish to see an alteration in the law relating to insanity, and to have a new definition of this introduced more in accordance with Medical science, we are averse from seeing the safeguards of society relaxed, and the plea of insensibility to position accepted as a proof of unsoundness of mind.

THE WEEK.

TOPICS OF THE DAY.

It is understood that the meeting of the General Medical Council will take place about March 27. The chief business which will occupy the Council will, no doubt, be the consideration of such schemes for Conjoint Boards as may be submitted to it. We have already indicated our opinion as to the duty of the Council in reference to the scheme which has been agreed on by the Royal Colleges of Physicians and Surgeons in England. We think that they cannot accept it in its present form without laying themselves open to the serious charge of permitting the formation of a new body of Medical Practitioners, who will be prevented obtaining a Surgical diploma from any Examining Body in England without passing the examination of, and paying a large fee to, the Royal College of Physicians. To say nothing of this being in direct contravention of all the General Medical Council has said and done to insure the possession of a double qualification in Medicine and Surgery by all registered Practitioners, we may be certain that so monstrous a piece of injustice will never be permitted by the Legislature or by public opinion.

With regard to the scheme for England of the Royal Colleges of Physicians and Surgeons, we notice that it has been submitted to the Hebdomadal Council of Oxford, who have resolved—"That it is expedient to make such alteration in the Medical Statutes as may be necessary for the purpose of adopting the scheme in the University;" and it will be brought before Congregation on February 6.

The Royal College of Surgeons of Edinburgh has circulated amongst its Fellows a series of resolutions adopted at a meeting of the College held on January 23, 1872. It appears these resolutions were founded upon the report of a Conference of Delegates from the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, which was held at Glasgow on January 6, 1872, at which the Remit from the General Medical Council, with reference to the establishment of a Conjoint Examining Board, was under adjourned discussion. The following are the resolutions adopted by the Edinburgh College (the italics are ours):—

"1. That an examination by a Conjoint Board *for the purpose of testing clinically the knowledge of Medicine and Surgery, and the ability to practise them*, possessed by candidates for registration, should be established in each division of the kingdom, and that no one should be admitted on the Register who has not passed the examination of this Board.

"2. *That the examinations, double or single, of the Universities and Corporations be conducted as at present, with the exception of the examination in Clinical Medicine and Clinical Surgery, which may be superseded by the examination of the Conjoint Board.* That no candidate be taken on trial by the Conjoint Board who does not produce a certificate of having passed in Medicine and Surgery before Bodies legally entitled to grant licences to practise these departments. That, on the other hand, the Universities and Corporations bind themselves not to grant a degree or diploma to anyone who has not passed the examination of the Conjoint Board.

"3. That certificates of having passed the examinations of the Licensing Bodies in Schedule (A) to the Medical Act shall entitle the holder to present himself for examination before the Conjoint Board of any division of the kingdom; but provided always that in the case of a candidate being remitted by any one of the Conjoint Boards, he shall not be allowed again to appear for examination before any of the Conjoined Boards for a period of at least six months.

"4. That the Universities and other Corporations shall elect or appoint Examiners for the Conjoint Board in the same manner as their Examiners are at present elected or appointed.

"5. That the principles on which the Practical Examinations by the Conjoint Board are to be conducted, the periods at which they shall take place, and other general management, shall be arranged by a Committee of the General Medical Council, composed of English, Scotch, and Irish Members, and the Regulations afterwards approved of by the Council, so as to secure uniformity in examination in the three divisions of the United Kingdom."

We will not now stay to discuss at length a scheme, which, whatever be its merits—and we do not deny that it may have merits—is certainly not a scheme for a Conjoint Board in the sense in which the term has been hitherto understood. It does not appear on the face of the document circulated by the Edinburgh Royal College of Surgeons that the Scottish Universities have been taken into the councils of the three Scottish Corporations, or have given in their adhesion to any plan of combined action. If this be so, the scheme, as one for a Conjoint Examining Board, will certainly prove a failure. But the point on which we would insist is that such a plan would be practically useless. A Conjoint Examining Board should at least test the candidate in his knowledge of Medicine and Surgery as sciences, and not merely as arts, if it is to be of any real value. Moreover, a Conjoint Examining Board, for clinical examinations only, is merely the addition of another to the far too numerous examinations afflicting the Medical students of this country. Altogether, the Scotch College schemo is thoroughly worthy that canny nation. In the first place, it is evident that the Scotch Colleges do not in the least approve of the general

principle of a Conjoint Board in its full sense. In order, however, to avoid a rupture with the General Medical Council, they are ready to establish one which is to do as little as possible—merely to test the student's knowledge of clinical agenda—one which will leave each of the three Corporations to go on examining exactly as before. Of course the General Medical Council cannot accept this scheme, if it be determined to accept that offered by the English Colleges and Universities. To do so would be to render confusion worse confounded. The admission to the Profession in the two kingdoms, instead of being more uniform, would be placed on a perfectly different basis.

Dr. Lyon Playfair, M.P., on Wednesday last gave an address in the Queen-street Hall, Edinburgh, on the subject of "Teaching Universities and Examining Boards," which contained truths specially necessary and wholesome for the present time. Dr. Lyon Playfair has had the courage to attack the present Chancellor of the Exchequer upon his own ground, and to tell the truth about the University of London. Mr. Lowe, in a speech recently delivered at Halifax, shadowed out a policy for Ireland, and eventually for Scotland, which would convert the teaching and examining Universities into a single Examining Board for each kingdom, on the model of the University of London. Of course the Universities of England would follow in time. Oxford and Cambridge and Durham would be merged in one Examining Board already existing in the metropolis. Dr. Lyon Playfair shows in an able historical sketch that the French Revolution and Napoleon Buonaparte, "with the power of a military despot and with the professional instincts of a drill-sergeant," did the same for France, with the result on the science and intellect of the nation which all Europe has just witnessed. But Dr. Playfair goes farther. He shows that in no degree does the University of London justify Mr. Lowe's laudations of it. It is not a University in the European sense of the term—a teaching as well as qualifying body;—it is "far more related to the Examining Boards of China than to any European model."

"The London University prescribes no curriculum, and has no teaching functions, so it depends upon degrees as its only educational power. It is a University of modern foundation, and hence it would be unfair to test its achievements in its early years; I therefore leave the period from 1838 to 1860 without a close examination, and will chiefly rely on the ten subsequent years. The following points will be considered as fair tests of work:—

"1. Is the educational influence of the University of London extending, as shown by an increase in the number of its degrees?

"2. Is the proportion of degrees to matriculated students increasing or diminishing?

"3. Does the number of its degrees stand favourably with that of other Universities in the United Kingdom?

"It is only by distinct answers to such questions as these that we can find out whether a mere Examining University, dissociated from teaching functions, is capable of exerting an important, though indirect, influence on the higher education of a kingdom. It is usual to look at the degrees of Arts—representing, as they do, general culture in a university—as an index of its effect on higher education. I take the three last quinquennial periods of the London University in illustration. In the five years ending 1860, there is an annual average of 63 Bachelors of Arts; in the five years ending 1865, the average is 60; and in the last period ending 1870, the average is 65. About ten of these go up annually to the higher degree of M.A. This, then, represents the outcome and want of progression of the London University on the general higher culture of the United Kingdom and of the British colonies, including India; for the charter of 1849 added these to its province. It is a marked feature in the University of London, that its influence on all forms of higher education now appears to be practically stationary. There is no substantial increase in any one class of its degrees, either in Arts, in Science, in Law, or in Medicine.^(a) This is the more remarkable, when we recollect the large increase in its matriculated students, who have

(a) "In the two quinquennial periods ending 1865 and 1870, the number of graduates, including higher degrees, was respectively—for Arts, 69 and 75; for Science, 12 and 12; for Law, 13 and 10; for Medicine, 32 and 33."

risen from 265 in 1861 to 420 in 1870. If the influence of the University of London on higher education be progressive, a larger crop of students should, as in all healthy Universities, produce a larger crop of degrees; but this is not the case with that Examining Board, for its old and new degrees now remain stationary, though its enrolled students increase. From 1838 to 1862, four matriculated students produced a new graduate in Arts; for the last five years nearly six students are required for this purpose. Nor can it be said that increased severity of the examination explains the anomaly, because, during that five years (the only period comparable among its years on account of the institution of new degrees), the number of candidates is as stationary as that of its degrees. (b) If the standard of degrees be increased, so must the corresponding standard of matriculation; for whereas six candidates previously to 1862 produced five matriculated students, it now requires ten to pass the same number; yet with these presumably more highly qualified students augmenting in number the degrees are stagnant. The fact that a smaller proportion of candidates than formerly passes the matriculation examination has another important signification. If a mere Examining Board suffice to direct the course of superior education in a country, the London University has now had time enough to exercise its influence on the schools which attach themselves to it; yet we find that they have not responded to the demands for higher qualifications, because, though they have sent numerous candidates, these are in a worse state of preparation than formerly, as indicated by their increased proportion of failures. Thus, though matriculation candidates are more numerous, the candidates for degrees do not augment, nor do the graduates substantially increase in number. But one thing does increase in a notable degree, and that is, the ages of the graduates. If we take the three decennial periods of the operation of the University, this will be apparent. In the first period, the average age of Art graduates was less than 22; in the second, it was 22½; and in the third, it was close on 25 years. At this rate of increase, the time may come when the University of London will have to rule—as the Emperor of China has done in regard to its great Chinese prototype—that if a candidate regularly attend all examinations, though without success till he is 80 years of age, he then becomes a graduate *de jure*. The increase of age is not a good sign. It shows that, instead of being for the many, the ambition of the University of London is to become a fancy and select University for the few. This is the reason why the influence of that University, apart from its matriculation, is so singularly small in comparison with the area which it professes to cover. For the last ten years the average number of all its graduates, scholastic, scientific, legal, and Medical, is 130, while the Arts degrees alone in the two Irish Universities amount to 338; and yet the proposal has been made to reconstruct them on the type of the University of London, which would be to replace an excellent productive machine by a singularly unproductive one—a strange phenomenon in the history of human progress!"

There is no doubt that the conviction is gaining ground that the University of London, however useful it may be for the few who can bear the cramming process necessary to pass it, is not doing its duty to the many. It is not conferring on the people generally the benefits which were expected from it. It contributes little to the higher education of the country, and its influence is most limited and restricted. We are not disposed to undervalue it as a Medical Examining Board, but we maintain that it would be far more useful did it institute a thoroughly fair series of examinations, requiring only ordinary capacity and fair work for ordinary degrees, and reserve for its honour-papers questions which are simply gauges of the candidate's power of cramming.

A tract, violently libellous as regards the Profession, and unctuously fanatical—"On the Duty of Medical Men in relation to the Temperance Movement"—has been recently widely circulated amongst the Profession, together with a copy of the celebrated Medical Declaration on Alcohol, and the list of signa-

taries thereto. The author of the tract is a Dr. A. H. H. M'Murtry, of Belfast. Dr. M'Murtry assumes "that alcohol is a poison—always hurtful as a beverage, always useless as an article of diet, and always unnecessary, at the very least, as a medicine." He continues—"I have been assuming that the Medical Profession knows all this, but has allowed the people to remain in ignorance of it, to their great injury; and that, therefore, the Medical Profession is responsible for the consequences of this ignorance. The objection is that Medical men do not know all this, but positively deny some of it. Now, admitting, for the sake of argument, that they do not know what I supposed they knew, I reply that they *might* know it if they would, and that they are as responsible for the knowledge they might and should possess as for that which they already do possess. When a man's ignorance is inexcusable, the results of it are also inexcusable," etc. We wonder how the President and Senior Censor of the Royal College of Physicians, with the other signatories of the Medical Declaration, like the company in which they find themselves!

We have lately received an American paper containing an account of the cross-examination of Dr. E. Warren in the trial of Miss Wharton, who was accused of poisoning General Ketchum. The Doctor supported the theory of the defence, which was that the General had died from cerebro-spinal meningitis. The following sharp retort was made by Dr. Warren in his cross-examination by Attorney-General Syester:

"Attorney-General: A Doctor ought to be able to give an opinion of a disease without making mistakes.

"Dr. Warren: They are as capable as a lawyer.

"Attorney-General: Doctor's mistakes are buried six feet under the ground. A lawyer's are not.

"Dr. Warren: But they are sometimes hung as many feet above ground."

ILLEGAL QUALIFICATIONS—COUNTER PRACTICE—WHAT IS PRESCRIBING?

THE case of *Andrews v. Davies*, which our readers will recollect was adjourned to enable the plaintiff to give particulars of claim, and otherwise amend his bill, came before the County Court at Shrewsbury the week before last. As the plaintiff had only a foreign diploma, the judge decided, at the last sitting of the Court, that he was not entitled to sue as a Doctor, but gave him the opportunity of an adjournment to sue as a chemist and druggist for medicines supplied. This the plaintiff had done, and the case again came before the Court. Mr. Morris appeared for the plaintiff, and Mr. Chandler for the defendant. It will be remembered that the plaintiff was the defendant in a prosecution at the police-court for assuming the title of M.D., and was fined £20. Mr. Chandler said: We are freed from the payment of the bill by the Medical Act. Mr. Andrews, the plaintiff, was then examined. He said: This bill is for medicines supplied on the dates stated in the account. The defendant was then ill, and these medicines were supplied to him. The charges are the usual trade charges. Mr. Chandler: If I read this bill rightly, it contains something else besides charges for medicines. There are some portions of it in which you make no charge. The plaintiff replied in the affirmative. Mr. Chandler: Where is your diploma? Mr. Morris, the plaintiff's attorney, objected to this question. The Judge here said: How are you entitled to ask for his diploma? Here is a bill as a chemist and druggist. He claims, not as "Thomas Andrews, M.D.," but as "Thomas Andrews, chemist and druggist," and he charges for no more than what a chemist and druggist would be entitled to charge. Although there are some other things in the bill, he puts no charge to them. Does the mere fact that he entered these things in the bill, and that he entered some other service rendered to the defendant, although he has not charged for more than supplying the medicines—for he does not make any charge for service—make it a Medical man's bill, or entitle you to ask for his diploma? Mr. Chandler: No, it does not; but I will postpone asking for

(b) "From 1866 to 1870 inclusive, the candidates at all degree examinations are 615, 610, 649, 620, 631; while the degrees are 158, 131, 127, 123, 131. This period of five years is large in its Arts candidates as compared with the preceding five years—200 as against 158—yet the degrees are only 65 as against 60."

the diploma. To the plaintiff: When did you prescribe these medicines? The plaintiff: At the time. Mr. Chandler: You did prescribe them then? When did you compound them? Plaintiff: Perhaps one day, and he called for them the next, when the medicine was ready. He generally called in and said, "I shall want another bottle of medicine," and it was got ready for him. Mr. Chandler: You prescribed them one day and compounded them another? Plaintiff: Yes. The Judge: What I take to be the law is this: A chemist and druggist may prepare and dispense medicines, but he cannot give advice. I infer that although they may make up and dispense medicines they cannot prescribe medicines. Prescribing is not dispensing. Mr. Chandler: He has admitted that he prescribed them the day before he dispensed them. The Judge, after referring to the Act, said: I imagined the moment he said he had prescribed this medicine he was out of court. Mr. Morris: But I will show that all these medicines were sold in the ordinary way. In point of fact, these charges are those of a chemist and druggist. The Judge: Whatever these charges are, he has put himself on the footing of a Medical man. When a chemist takes upon himself to prescribe, he involves the province of a Medical Practitioner, and the plaintiff has said that he prescribed them. Mr. Morris: But a man may come into a shop and order a bottle of sarsaparilla. The Judge: That may be, but if the Doctor or would-be Doctor prescribes it, it is fatal to his recovering for it. There is a difference between supplying it and prescribing it. Mr. Morris: Then do I understand your Honour that it is no use going on with the case? The Judge: Not the least. Mr. Morris: Although the plaintiff has been in another court he thinks he has a right to sue in this court as a chemist and druggist for drugs supplied in the ordinary way of his trade as a chemist. The Judge: He has vitiated all claim to what he has supplied in consequence of his having prescribed them. Judgment for the defendant, with costs. Mr. Chandler: I did not ask for any costs before, and I do not ask for them now.

From the foregoing very important proceedings it will be seen that several points of great interest in reference to Medical law and the Medical Act were discussed and determined. The decision of the judge in regard to counter practice, or "prescribing over the counter," is of the last moment in reference to this kind of infringement of the Medical Act. As no "case" was asked for by the plaintiff's attorney, the decision—for the time, at least—must be regarded as law, but whether it would be so interpreted by the higher courts is a matter of doubt. We fear that the judges of the superior courts would regard the decision as too comprehensive and too favourable to the Medical Profession. However this may be, it is one consistent with common sense and common justice.

QUININE.

Our knowledge of the physiological and therapeutical actions of this invaluable alkaloid have been recently much extended by the labours of Binz, Ranke, Kerner, Zuntz, Scharrenbroich, and Schulte. We propose to lay before our readers a *résumé* of the chief results obtained.

Binz finds that quinine has the power of arresting the processes of putrefaction and fermentation in a high degree, and that it is an active poison for all low organisms, animal and vegetable. According to Cohnheim's views, pus, being mainly a collection of white blood-globules, which have passed through the walls of the vessels—further, quinine having the power of arresting the motions of the white corpuscles, and hence preventing their exit from the vessels—the alkaloid arrests, or at all events diminishes, the formation of pus during the course of inflammation. Moreover, it destroys the organising power of certain substances; and as the red corpuscles have this power, quinine in the blood probably diminishes oxidation of tissue, and lessens the production of heat. Ranke and Kerner, indeed, have found that quinine in large doses

diminishes tissue changes, as is shown by the smaller quantities of urea and uric acid excreted; and there are many observations to show that in fevers it produces a decrement in temperature. Ranke and Kerner's experiments do not show, however, how far the lessening of tissue-waste is due to the direct action of quinine on oxidation, and how far to the indirect action of the alkaloid through the nervous system. Two methods have been employed for ascertaining the direct influence of quinine on oxidation. Harley added quinine to the blood, and found that this, when so treated, took up less oxygen and gave off less carbonic acid than blood which had not been so treated. This method is inconvenient of application, and liable to error. Zuntz employed the changes in the alkalinity of the blood for arriving at the same results. Schulte has extended these researches. If fresh blood be drawn, a development of acid begins in it, and continues, at first rapidly, then more slowly, till putrefaction sets in. Of course this acidification depends on oxidations; and the diminished alkalinity of the blood, thereby produced, furnishes a test of the rapidity with which oxidation proceeds. Schulte has confirmed the observation first made by Zuntz and Scharrenbroich, that quinine and berberine lessen the production of acid. Harley's observation is thus confirmed. Cinchonine produces similar results to quinine, though in a very inferior degree. Picrate of sodium is nearly as powerful as quinine. Zuntz found, as Ranke and Kerner had previously done, that quinine in ten-grain doses lessens the daily excretion of urea by one-third or more. Unruh has found the same to occur when quinine is administered in fevers; but his observations are open to objection. Binz's experiments are curious, and show that when putrefying liquids are injected into the circulation the temperature of the body rises; but if the fluids be previously mixed with quinine, whereby the putrefactive processes are arrested or destroyed, the rise in temperature is either entirely arrested or considerably diminished.

We think that these experiments have an important bearing on practice, and that they are in accordance with the teachings of clinical observation. It has been too much the fashion to assume that the therapeutical actions of quinine are entirely different from its effects when administered in health. We apprehend that the true method of commencing the study of the actions of medicines is first to ascertain their effects in health; then to observe their results in disease.

Dr. Grace Calvert has also recently announced the discovery of the power of quinine in preventing the development of fungi. He appears, however, to have been unaware of Binz's previous publication of the fact.

TESTIMONIAL TO DR. M'KECHNIE.

A LARGE number of the most influential inhabitants of Paisley assembled in the County Hall, last week, to present a testimonial to Dr. William McKechnie, who is leaving Paisley, to reside in Edinburgh. Provost Murray, who presided, made the presentation. The testimonial included a vase, with tea, coffee, and fruit service. The inscription on the vase was as follows:—"Presented to William McKechnie, Esquire, by a few friends, on the occasion of his leaving Paisley, in appreciation of his Professional services. January, 1872."

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

A SPECIAL meeting of the Council and others will be held at the Medical Club, 9, Spring-gardens, W.C., on Monday, February 5, at 7 p.m. precisely, for the purpose of conferring with Mr. Corrance, M.P., as to the course to be taken by that gentleman, in the ensuing session of Parliament, in furtherance of the objects of the Association. Sir Dominic Corrigan, Bart., M.P., and Mr. McCullagh Torrens, M.P., have been invited to attend.

ARMY MEDICAL DEPARTMENT.

WE understand that several changes in the composition of the staff in the office of the Director-General of the Army Medical Department are impending, or actually in progress. The departure of Deputy Inspectors-General Massy and Crawford for India is already known to our readers. Dr. Rutherford, C.B. has arrived to succeed Dr. Crawford as head of the Medical branch. The Secretary of State has, we believe, decided that henceforth all appointments in the London office, with the exception of that of the Director-General, are to be held for five years only; they may be renewed on public grounds at the expiration of that time, but only under the authority of the Secretary of State himself. It will be remembered that during last session Mr. Cardwell stated, in reply to questions in the House of Commons, that these appointments were special, and not liable to the five years rule of military staff officers. In these days of reform, however, we have all of us ceased to experience the sensation of surprise—having, like "Mark Tapley," sold out our stock-in-trade of that article. The chief argument in favour of special appointments in the head-quarters office is, that men accustomed to the work attain a special aptitude in it, and are more likely to carry it on without a hitch. It must at the same time be admitted that this aptitude is acquired at the expense of a certain amount of Professional knowledge, which can only be maintained by practice. Another point is, that to a man with a family returning from foreign service, a five-years' berth in London is a very desirable thing, and this is an advantage which will be more generally diffused throughout the Service by the new arrangement. The first Medical officer to be affected by the recent change will, we are informed, be Staff-Surgeon Kidd, assistant in the statistical branch, who leaves the office on the expiration of his term of office in March next. Rumour has it in Aldershot that a Deputy Inspector-General of Hospitals is likely soon to be appointed to assist the Inspector-General in the Medical superintendence of the very large force in that camp. There can be no doubt that the thorough supervision in all Professional matters of more than thirteen thousand men, with the proportionate number of officers, women, and children, is more than one man can continuously carry on; and we shall be glad to learn that the report as to a projected increase of the administrative staff has been well founded. From Netley we learn that the Medical staff gave a farewell dinner, at which Sir Galbraith Logan was present, on the 31st ult., to Inspector-General Dr. Beatson, C.B., and Deputy Inspector-General Dr. Crawford, previous to their embarkation for India.

NITRATES IN POTABLE WATER.

DR. A. WAGNER (*Zeitschr. für Biologie*, vol. vii., p. 316) points out a fallacy in the means hitherto employed for the estimation of nitric acid in potable waters. When a sample of water containing nitrates is subjected to chemical examination without first destroying the organic matter present, the nitric acid is destroyed in part; and thus the amount of nitric acid found does not truly represent the acid present in the water. He proposes a method which obviates this defect, based upon an observation of Schulze's, that organic substances, when boiled with permanganate of potash in alkaline solution, are converted into oxalates. On cooling the solution and acidulating it, the oxalates are entirely converted into carbonic acid, and thus all organic matter is removed from the solution. The nitric acid can then be estimated by any of the ordinary methods. Considering that nitric acid in drinking-water is in great part, no doubt, derived from the oxidation of organic matter, and the uncertainty hitherto attending its estimation in such water, a new and simple method which obviates this difficulty is a boon to the analytical chemist and Physician.

ADDRESS AND PRESENTATION TO DR. WILLIAM STOKES, JUNIOR.

A REPRESENTATIVE deputation of the students, past and present, of the Richmond Surgical Hospital and the Carmichael School of Medicine, waited on Surgeon Stokes at his residence, Clare-street, Dublin, on the afternoon of Thursday week, the 25th ultimo, for the purpose of reading an address, and of presenting that gentleman with a valuable silver chalice. A numerous party of the heads of the Profession, including the Presidents of the Colleges of Physicians and of Surgeons, were also present on the interesting occasion. The address runs as follows:—

"DEAR SIR,—We, the students, past and present, of the Richmond Hospital and Carmichael School of Medicine, on account of the events which have lately occurred, consider this a fit and opportune occasion for presenting you with this address, as an earnest mark of the high esteem which your brilliant ability as a Surgeon has inspired us with, and also to show how fully we appreciate your uniform zeal for our Professional advancement, and your kindness and affability towards us individually. There are few on whom the arduous task of a Profession has devolved, who have been so eminently successful as you, who, by a happy combination of theoretical research and practical skill have made your lectures such as have been seldom equalled and never surpassed. We deem ourselves fortunate in belonging to an Hospital which counts amongst its Professors one whose name has been so long and intimately associated with the advancement of the science and Surgery of this country. Reflecting, as you do, the talents, ability, and genius of your illustrious father, we hope you may long continue our model and guide."

[Here follow the signatures of more than 100 students.]

The chalice bore an inscription which ran thus:—"Presented to William Stokes, by the students, past and present, of the Richmond Hospital and Carmichael School of Medicine, January 25, 1872." We heartily congratulate Dr. Stokes on this pleasing episode, which has so happily occurred after the anxious and harassing period he has passed through, and which will go far to mitigate the recollection of it. This demonstration of esteem and goodwill reflects credit alike on the earnest, painstaking clinical teacher, and on his intelligent and generous class.

SMALL-POX JOTTINGS.

THIRTY-EIGHT persons were attacked with small-pox in Berlin from the 20th to the 22nd ult., ten of which cases had a fatal result.—Ten new cases of small-pox and two deaths were reported to the Kensington Board of Guardians as having occurred last week. The disease was greatly on the increase.—Four cases of small-pox, one of which ended fatally, were reported to the St. Martin's-in-the-Fields Vestry at their last meeting.—At Mile-end Old Town four deaths occurred from small-pox in the past week.—In Wakefield House of Correction several cases of small-pox and one death are reported.—The Fulham Medical Officer reports the successful vaccination of fifty-four persons during the past week.—Small-pox cases are increasing in number and virulence in Birmingham, and it has been decided by the Board of Guardians to erect two additional convalescent wards for the accommodation of small-pox patients. On the 19th ult. there were in the Infirmary seventy-two patients; admitted since, twenty-five; died, five; discharged cured, nine; remaining, eighty-three. Of the remaining cases, there were—convalescent, fifty-six; severe confluent, thirteen; distinct and modified small-pox, fourteen cases.—Forty-three cases of small-pox are reported in the Stourbridge Union, and were principally above the pauper class. At present eight persons had recovered, and there had been only one case at the workhouse.—The Sheffield School Board declined to accede to the application of a deputation of anti-vaccinators last week, to rescind a resolution authorising the school managers to examine the arms of the children for the purpose of ascertaining whether they have been vaccinated. The Board insists that all the children shall have been vaccinated.

—John Charles Homes, of East-street, Manchester-square, was ordered by Mr. Mansfield, last week, to pay 10s. for Professional attendance, 2s. for costs, and 1s. nominal penalty, for refusing to allow lymph to be taken from his child, who had been successfully vaccinated by Dr. Summer, the Public Vaccinator for the Marylebone district.—Ten deaths from small-pox occurred in the Hackney district during the past fortnight.—In the Poplar district, last week, four deaths were registered from the disease, and twelve new cases had been brought under notice. In the same period fifty-five persons were vaccinated at the public stations. There were seventeen small-pox patients under treatment in the North-street Infirmary.—The deaths from small-pox in London, last week, were ninety. In the past six weeks the deaths from the disease in the metropolis have been all but stationary, ranging only between ninety and ninety-seven.—Dr. Aldis, St. George's, Hanover-square, "returned only one case of a woman, aged 22, vaccinated—an unfortunate, who lived with other women of the same class, and at first consented to go to the Hospital, then declined to do so, but at length, after much persuasion and delay, was removed there from the out-wards. Had she persisted in remaining, what a source of infection would have been prolonged!"

DAMAGES FOR SMALL-POX.

ALTHOUGH, according to the case of *Pritchard v. Huntington*, recently decided in favour of the plaintiff by Mr. Serjeant Wheeler (the judge of the Liverpool County Court), and referred to in last week's number of this journal, a landlord's liability for knowingly letting any house, room, etc., in which any person suffering from any dangerous infectious disorder has been, without having such house, etc., and all articles therein liable to retain infection, disinfected, under the Public Health Act, is not confined to the penalty for the public offence under the statute, but extends to the personal remedy for the private wrong at the suit of the party injured, it is much to be regretted that the law is still undecided as to the converse of the case—*i.e.*, the liability of persons, who are just recovering from an infectious disorder, coming into lodgings, and by so doing communicating the disease to others. Such a case was under discussion before the Court of Queen's Bench the week before last—in *re Best v. Stap*; but the Court came to no decision, and the parties were advised to go to trial, and ascertain the actual facts. It was necessary that a definite state of facts should be laid before the Court, because, if it should turn out that the taking of small-pox by the plaintiff's children, which was the injury complained of, was partly to be accounted for by their not having been vaccinated, it would tend to a further complication of the question. It is to be hoped that the matter will not be allowed to drop without a decision. The judgment of Mr. Serjeant Wheeler in the case of *Pritchard v. Huntington* is well deserving of perusal. It is as follows:—

"It is scarcely possible to exaggerate the importance of this case; for, if the contention before me be well founded, the position of a tenant in great towns like Liverpool and in crowded districts is one of vast peril and difficulty. But I do not concur in the view which the defendants, through their attorney, suggest as to the law of the matter. I am satisfied that a right of action does exist, and it is most righteous that it should. It is needless to travel beyond the statute into the question of common-law liability, though upon that point I should be prepared to state my opinion if it were necessary, because I think that the imposition by statute of a penalty for the doing of a particular act amounts to a statutable prohibition of that act, and makes it illegal. And if, by reason of such illegal act, injury arises to an individual, I think that the party injured has his personal remedy by action for the private wrong, and that without reference to the statutable penalty, which is intended to meet the public offence. I need only refer to the well-known case of *Couch v. Steel*, and to the more recent case of *Atkinson v. Newcastle and Gateshead Waterworks Company*. The legal objections failing, there remains only the question whether the plaintiff has proved his case,

and the conclusion at which I have arrived is that he has. He is, therefore, entitled to my verdict for the full amount which he claims, with costs."

DR. JENNER.

A VERY interesting memento of the discoverer of vaccination has recently been presented to the Royal College of Physicians by Sir John William Fisher. It consists of a cow's horn, beautifully polished, presented to Sir J. W. Fisher, in the year 1813, by Dr. Jenner, and polished by himself. The gift was made in grateful acknowledgment of services rendered to Jenner's sick children by Mr. Fisher, then a Medical assistant in Soho. The horn is now mounted in silver, and bears an appropriate inscription stating the circumstances under which it was presented to the College. Dr. Burrows, the President, in asking the acceptance of the horn, stated that it was probable—though there was no record of the fact—that the horn had been taken from one of Dr. Jenner's favourite cows on which he made his experiments on vaccination.

THE CHELMSFORD DISPENSARY.

WE publish in another column a letter from Dr. Nicholls, one of the late Surgeons to the Chelmsford Dispensary. That Dr. Nicholls has just grounds of complaint, may be gathered from the following facts:—It appears that the Dispensary for some years past has had two Medical Officers attached to it—Dr. Nicholls and Mr. Gilson. It has been customary annually to vote £20 each to these officers. A few months since Mr. Gilson resigned, and after some delay the Committee took advantage of the circumstance to issue a circular to the various Medical Practitioners of the town, asking them to give advice to the Dispensary patients gratuitously. The Profession very properly refused to listen to this appeal, with, unfortunately, one exception. This exception was in the person of Mr. Carter, who, at a meeting of the Committee on Tuesday last, was appointed to fill the vacancy, notices of motion being at the same time given to discontinue the allowance now made to Dr. Nicholls, and this without any reason being assigned for the unjust act. Now, we consider the conduct of the Committee to be most shabby and contemptible. We cannot exonerate Mr. Carter entirely. He is the one "faithless amid the faithful found," and, in acting in antagonism to his brethren in the town, has shown a want of the *esprit de corps* deeply to be regretted. We hope Dr. Nicholls will retire, and leave his new colleague "alone in his glory."

"DOCTOR MOORE, OF CANTERBURY."

WE suspect that the Attorney-General is hardly so clear in his facts as to the bleeding of R. C. Tichborne as he has been in most other parts of his very long and able address. He states that the operator on this occasion was "a Doctor Moore, of Canterbury," who is since dead. We believe Assistant-Surgeon Stuart Moore, of the 6th Dragoon Guards, to have been the Dr. Moore referred to—the same who was killed at the battle of Hindun Bridge, near Delhi, at an early stage of the Indian Mutiny in 1857.

LONDON WATER-SUPPLY.

DR. FRANKLAND, in his report upon the water supplied to the metropolis during the present month, calls attention to facts which "illustrate the utter unsuitability for domestic purposes of water derived from rivers flowing through highly manured lands, and receiving the sewage of a large population." The Thames has been in a state of flood during the whole of the month, and the water has consequently been in a "filthy condition." The system of filtering adopted by the water companies appears to have been entirely ineffectual in rendering this water fit for consumption. The West Middlesex was the only Company which was delivering efficiently filtered water. The

water delivered by the New River, East London, and Kent Companies, which principally draw their supplies from springs and deep chalk-wells, was, on the other hand, bright and transparent. The moral is, that every house ought to be provided with a fixed filter, through which all water used for drinking should pass.

FROM ABROAD.—THROMBOSIS OF THE INTERNAL CAROTID—CRYSTALLISED DIGITALINE—EPIDEMIC JAUNDICE—CASE OF UNIVERSAL TATTOOING.

At the Académie de Médecine, M. Verneuil related, at its meeting on January 16, a highly interesting and rare case of thrombosis of the internal carotid produced by external injury, and giving rise to anomalous symptoms and a faulty diagnosis. A man, 45 years of age, was brought on December 14 to the Lariboisière, having been a short time before extricated from beneath a railway waggon which had been overturned. On his admission he was the subject of excessive agitation, which prevented any account of his injury to be obtained from him. Gradually this disappeared, so that he was able to answer questions in the most clear manner. On examination, slight contusions on the vertex and elsewhere were found; but nothing could be discovered capable of explaining the signs of violent pain, the cries, disordered movements, and the great disturbance of respiration, of calorification, and of the circulation which he had exhibited on admission. These were regarded, therefore, as the effects of emotion; but in the evening he was seized with violent delirium, so as to require restraint, and this was followed in a few hours by profound coma and complete hemiplegia of the right side. His treatment, on account of his depressed condition, was merely expectant, and towards the fifth day he died. It was supposed that there had been laceration of a cerebral artery of small calibre, followed by slow effusion of blood; but at the autopsy not the slightest trace of effusion of blood or other lesion was at first discoverable. It was not until the base of the skull was examined that the true nature of the case was discovered. The internal carotid on its entrance into the cranial cavity was found to be filled with a thrombosis, which extended to all the ramifications of the middle cerebral artery, the carotid and Sylvian arteries seeming exactly as if they had been injected with suet. The anterior extremity of the left temporal lobe of the cerebrum was the seat of a widely extended ramollissement, fully explaining the hemiplegia observed. On following the track of the carotid downwards, it was found to be distended by a reddish, friable coagulum, until within a finger's breadth of the common carotid. From the base of the cranium to this point the artery was increased by at least one-third in its volume, suddenly diminishing in size there. On incising it at this spot, it was found that the internal tunics had been cleanly cut across, and, pushed back by the current of the blood, they had given rise to valvular folds, the free edge of which was turned towards the axis of the vessel. At this point the coagulated blood completely obliterated the calibre of the artery, the occlusion extending from below upwards to all the cervical and intracranial portions of the internal carotid, and also occupying the entire extent of the middle cerebral artery.

M. Verneuil suggests that it is probable that at the moment of the accident a laceration of the carotid was caused by a forcible twisting movement of the neck, although the arterial tissue exhibited no morbid alteration favouring this. At first, blood might have been able to enter the encephalon; but when occlusion was produced the cerebral accidents supervened. The ramollissement came on on the fourth or fifth day, at the time when the thermometer indicated a notable rise of temperature. M. Verneuil pointed out to pathologists the importance of a minute examination of the cerebral arteries in analogous cases. In many of these an absence of lesions has been believed in solely from not having taken this precaution, while a more complete examination would have exhibited the material lesion.

In a report to the Académie de Médecine by M. Baignet, on the essays sent in in competition for the Orfila Prize, he announces that the successful candidate (whose name is withheld until the time for the official declaration arrives) has made a discovery likely to be of very great utility in therapeutics and physiology. It is the production of crystallised "digitaline" in a state of absolute purity. The product has been submitted to a rigorous examination by the Prize Committee, and the superiority of the procedure adopted for the isolation of this active principle is admitted without hesitation. Splendid crystals resembling those of sulphate of quinine, and furnishing a bright emerald green when treated by hydrochloric acid, were exhibited at the last meeting of the Academy, and greatly admired. The chemical perfection of the product has been confirmed by its physiological and therapeutical effects in the hands of MM. Vulpian and Marrotte. Its promptitude and intensity of action are far greater than is the case with the digitaline of Homolle and Quévenne—three milligrammes administered in twenty-four hours producing saturation and intolerance, and one milligramme daily being ill-supported by most patients, so that more than half this quantity cannot usually be given. It is evidently an agent of tremendous power, which will require great caution in its employment, and may prove a fearful weapon in the hands of the poisoner.

M. Decaisne, at a recent meeting of the Académie, gave an interesting account of an epidemic of "essential jaundice" which prevailed last autumn in Paris and its environs. His personal experience relates to twenty-eight cases (occurring between October 15 and December 8), seventeen being men of from 21 to 61 years of age, and eleven women of from 17 to 45. With the exception of five of the cases, the disease appeared in the midst of health, and without apparent cause, the icterus first affecting the sclerotica, and spreading over the body in the course of four or five days. The *velum palati*, in almost all the cases, was of an uniform yellow. There was no fever or diminution of appetite; no pain or tenderness whatever was experienced in the hypochondrium. Under the use of mild aperients, or even mere expectation, the affection passed away in nine or ten days. In five of the cases there was much pain in the loins, itching all over the surface, desire to vomit, and obstinate constipation—symptoms which soon yielded to mild purgatives and abstinence. The persons attacked pursued different occupations, and were placed under different hygienic conditions. Many soldiers, also, of the regiments encamped around Paris, the sanitary condition of which was excellent, also suffered in just the same way. They applied for advice, in fact, not from feeling ill, but on account of their yellow colour.

The best account which we have seen of the extraordinary case of tattooing exhibited by Professor Hebra to his pupils has been furnished by Dr. P. A. O'Connell, in a letter published in the *Boston Medical Journal* of November 16. We transcribe some of the principal passages:—

"Standing upon the demonstration pedestal was a man of about five feet nine, perfectly naked, and of a remarkably fine physique. His form, attitude, and general appearance were such that at the first glance I supposed the figure to be a bronze statue—one of the masterpieces of some great artist who had used imagination to assist nature, and had produced a model of manly development. Vigorous, muscular, in the prime of life, his form alone would have made him an object of interest; while, in addition to this, there was a colouring of his skin which no doubt assisted the herculean symmetry of his form in giving me my first impression of his being a bronze figure. He was tattooed from head to foot, from top to toe. There was not a square inch—yea, not a square of even a quarter of an inch—that was free from the colouring, and the work had been done in the most beautiful style imaginable. The skin presented a very handsome appearance, far more beautiful, I believe, than any leopard's skin can be, and having an effect like the elegant tracery of an exceedingly rich cashmere shawl—only that the colouring was done with indigo principally.

with enough red inserted here and there to give it effect. His whole body, as it presented itself to view, was a 'work of art'; and when one pauses to consider the immense amount of labour, and the severe torture he must have undergone while this was performing, it will be easy to credit the statement that it was not a voluntary submission on his part that made him the subject of the artist's skill."

The man, a Greek by birth, was, it seems, taken prisoner during a marauding excursion in Chinese Tartary, and was branded in this way in order to show his character wherever he went—the colouring on the palms of his hands, consisting of beautiful lettering, describing the nature of his crime. It took three months of constant work to finish the job, and two companions died either during or subsequent to the process, which caused excessive suffering.

"The different designs were not each more than a few inches in size, and they were representations of elephants, lions, tigers, birds of all kinds, with letters worked in, referring, I presume, to his wickedness, each design being in itself a work of art, and the effect of the whole (with its thin outlines of natural skin, tinted here and there with red, and winding its tortuous course all over the body) being very beautiful. No part of the body, however private, was spared; and when he extended his arm over his head, the symmetry of design and the same elegance of execution showed in the axilla, as in the more noticeable and exposed parts of the body. A couple of dragons ornamented and glared at each other across his forehead. His cheeks had received their allowance of pigment, and his rough wiry beard half concealed and half disclosed the labour that had been expended in the ornamentation of that part of his person. . . . It is five years since the deed was done. His body swelled up very much at the time, was very sensitive to the weather, and continues somewhat so even now. While the artist was at work, it was necessary to chain him down."

As the subject of these curious operations, who is described as a complete rascal, contemplates making an exhibition-tour, we shall doubtless before long have an opportunity of admiring this novel "work of art."

ADDRESS OF SIR WILLIAM W. GULL, BART., TO THE CLINICAL SOCIETY.

SIR WILLIAM GULL, on the occasion of his re-election to the Presidential chair of the Clinical Society, took occasion to address the Society, and of this speech the following is the gist:—

In addressing you this evening, gentlemen, I have in some sort to throw myself on the forbearance of the Society, for, though I have been able to bring certain ideas together on the subject on which I desire to speak, I have not, for want of time, been able to adopt a form of words such as I should have liked. In some sense I am the spokesman of the Society as its President, in especial when laying before the public the objects of the Society as I would now do.

We, in our calling, differ from some theologians in one important respect: they look on this world as a decaying world, as much worse than it once was; we, as students of nature, are opposed to this view, for if we look to the history of nature we see we are ever advancing towards perfection, even if we are not likely to reach it. This is an improving world, and we are met to advance that idea. We believe that this world has something better in store for all than anything which has yet been seen, and are like to the convalescent, whose last day should always be the very best he has ever spent. Some men are apt to think that science has certain limits set to it, beyond which no man may go; but we believe that knowledge extends far beyond the strictly scientific limit. Doubtless, were the early lower animals assembled together in conclave, they would conceive it quite impossible to transcend their status; that when the world came to megatheriums, let us say, then it must stop. They could not conceive the possibility of such a being as man. But at this point we join the theologians again in accepting a metaphysical element, in forming conceptions of things of

which we can have no positive knowledge. In this way we may be said to worship nature, but only in a very limited sense. We look upon our being, not as perfect, but as becoming perfect, and we are here to-night—and at all times have it as our object—to improve these defects of nature, and to endeavour to perfect the human frame.

Respecting the object we work for—this living organism of ours—one great advance has of late been made. We are acquiring a physiological notion of disease. Disease is no entity; it is but a modification of health—a perverted physiological process; and this must at all times be insisted on. Were it not that we fear death, and dislike pain, we should not look upon disease as anything abnormal in the life-process, but to be as part and parcel of it. Few would nowadays venture on a definition of disease; for in reality it is but that course of nature in a living thing which is not health. In health the balance of function is even; incline it to either side, and there is disease. That being so, just as his life-process constitutes an individual and puts him apart from his fellows, so must any alteration in that process be individual, and not general. But to the ignorant disease is an entity—an evil spirit which attacks us and seizes us. Hence arises the word "seizure," which, though in a somewhat different way, we still use, but with a protest. To the charlatan, disease is a set of symptoms to be attacked by a variety of drugs—a drug for each symptom. To us, disease is a life-process of a perverted kind.

Many states are not now called diseases which used to be, and there are still some to be expunged. Some people are always ailing. Some have feeble stability, and to them it is as natural to be ill as it is to others to be well; but this is not disease. So, too, aged persons get ill; but this is not disease—in reality it is natural change simulating disease, and when we try to cure such we use all the farrago of the chemist's shop to prevent the sun from setting. So syphilis at last ceases in the system to be syphilis, and becomes an early universal decay.

It is curious to consider the various morbid agents at work within our bodies, the lines in which they work, and their seats of action. These as yet have been but little studied, and deserve attention. Thus, it is very doubtful if scarlatina begins in the blood, as we should all be apt to say, rather than in any other tissue or fluid. Let it be our object to find out where all these begin within the body, and how they enter the body. In future I hope comparative pathology, which is just beginning to be studied, will teach us much; for in our bodies we may have many organs which are of little or no use to us, and are only relics of a former state of being. What, for instance, is the comparative anatomy of tonsils? Were I to make a man, I do not think I would put tonsils in him. Yet these, and such-like organs, in accordance with the general law, are more prone to disease than are the others which are of real use in the system. I remember the case of a man who had a permanent vitelline duct. He had been out on a cold day, and the motion of the intestines twisted them in a mass round this persistent duct, and he died. I made a preparation of the duct, and wrote under it—"Cui vitam atque mortem dedit: diverticulum." Every part of the body is alive, and has its own individual life and pathology, whether it be immediately required or not; only, if not required, it is more prone to disease than if it were. I could, for instance, suppose a fœtus of four months going to the Doctor and saying—"I am going all wrong; my Wolffian bodies are disappearing, and kidneys are coming in their stead." Yet that is as much a condition of disease as some of those conditions of which I speak.

It is of the utmost possible importance, then, to be able to tell what we have and what we have not to cure. How often do we find people trying to do what is impossible! Some women have no more vital capacity than a canary bird; they are constantly ill, and it is useless to attempt to make them well. A man came to me, and said—"I don't know what to do with So-and-so. I have given her everything I could think of, and she will not get strong." "Why," I said, "you have been trying to put a quart into a pint pot! You cannot make her strong, and never will."

When a new instrument or some improved mechanical means of diagnosis is introduced, we must try to make ourselves masters of it, so as to be able to use it aright, even though this is troublesome to ourselves; only we must beware of applying the knowledge thus acquired too early to practice. Thus, as regards the thermometer, doubtless it yields us most valuable information, but we must beware of using it as a guide to our treatment until we have a more complete knowledge of the conditions of bodily temperature.

But after the physical comes the vital diagnosis. It is well

to know exactly what is the condition of each part of the system; but to what is the wrong due? That no weighing or measuring can give you—only experience. A man (say) has pneumonia; that is a fact too vague: what are the dynamics of the disease? One man with a pneumonia will get rapidly well and be right again in a few days, whereas another man will not get well at all. So, in different individuals, a form of disease apparently the same may be different from the beginning; and this we cannot always make out in our diagnosis, especially in internal disease. In skin diseases we can do better.

During the last week I have been called on, as most of you know, to form a diagnosis of the workings of the mind. Here the break-down may be the first sign of the diseased condition, just as it may be in heart disease, peritonitis, and a score of other diseases. A man, after racing up a hill, finds himself breathless and spitting blood. He comes to you, and you find heart disease. It does not mean that the heart disease was produced by running up the hill; it only means that an organ, equal to its ordinary duties, failed when unusual stress came to be laid upon it. So is peritonitis often the result of disease previously latent, but brought on by exposure to cold, or some such agency. Some men say that such cases as those of doubtful sanity should not be taken up by us—that ordinary men are quite as well fitted for finding out the truth as we are, with all our training. If so, all I say is that it is no honour to us.

Now, though the study of diseased conditions might be pleasant enough by itself, therapeutics is the end. We are sometimes twitted with letting Nature alone to do her work. We do not. And here, again, we join issue with the theologians. They say, "If it is God's will that a man die, so be it." But say we "God's will is to be found out; it is not a mere fate." We are no ignorant worshippers of nature, and whether a man is doomed to die or no, we know only by the result. We are corrective agents. We have to adjust and correct. We know the tendency to the recurrence to equilibrium—that is, health—and we endeavour to assist in adjusting this balance in each individual.

In fever, for instance, two things are promptly at work—destructive changes, and changes tending to recovery. In such diseases there are certain superficial accidents which we are apt to notice. In fever there are often complications; but these are really part of the fever process, and are not to be interfered with by themselves. Our study must be, how best to bring the condition to a safe ending: for a patient in fever may get well of the fever, and yet die of a bed-sore.

In conclusion, if I have spoken more as regards Medicine than as regards Surgery, I think the Surgeons ought to be indebted to me for hints towards the extirpation of superfluous organs—a grand prospect for the Surgeons of the future.

SIR HENRY HOLLAND, BART., M.D.,
F.R.S., D.C.L.(a)

WHATEVER objections may be raised to autobiographical recollections, it is certain that the specimens which we have of this kind of history of the members of our own Profession are few and far between. Looking to their interest and importance, I think it will be an object of regret to all that they have not been more numerous. Whatever may have been the shortcomings of Sir Benjamin Brodie's "Recollections," and however coloured (as they were) by personal bias and unquestionable prejudices, no one could rise from their perusal without being convinced that Brodie rendered good service to his brethren by their publication. Brodie had a practice as extensive, if not more so, than Sir Henry Holland, yet he confines his reminiscences to those with whom he was more immediately associated in the practice of his Profession. We have now to deal with a work of a very different kind. Fascinating, able, and graphic it undoubtedly is, and as the record of the life of a man who has filled a very important position, Sir Henry Holland's "Recollections" must be regarded as a most valuable contribution to the history of the age in which he lives. He was born at Knutsford on October 27, 1781, on the very verge of the French Revolution. He early imbibed a passion for travel,

and he describes with graphic power his journey to his maternal grandmother's brother at Newcastle-on-Tyne. He was for a year or two at a private school at Knutsford, and even then he made excursions round the neighbourhood in search of the picturesque and instructive. He was subsequently under the tuition of the Rev. Mr. Turner, at Newcastle-on-Tyne. During this period he made a journey to the summit of Blackstone Edge, and there he describes the emotions he experienced at the sight of the sea from the top of Tynemouth Castle. Soon afterwards he took a voyage to Jamaica, and describes with much power the effect of this voyage upon him. He subsequently took several pedestrian excursions round Newcastle. In 1803 he left Newcastle for a year, and was at the school of Dr. Estlin, near Bristol. He there became the head boy, succeeding Sir J. C. Hobhouse, afterwards Lord Broughton. Here he contracted an intimate friendship with Dr. J. Bright, for many years one of the Physicians at the Westminster Hospital. At the Christmas vacation he came to London, and passed some time with the celebrated Dr. Aiken, who resided at Stoke Newington, then a rural district near London. This was sixty-six years since. He has no recollection of Charing-cross, Pall-mall, or Piccadilly, but he has a vivid remembrance of the shooting fall at London-bridge, which was then, as in my own time, a perilous adventure. Tyburnia and Belgravia were then unknown, and he speaks in eloquent terms of the miserable Five Fields of Chelsea, and of the desolate wastes of Tyburnia which met his eye. He left Bristol on foot to return to Knutsford. When he was 16 years of age he was articled to a Liverpool merchant. Fortunately, he did not like mercantile pursuits, and determined to enter the Medical Profession. He passed two sessions at the Glasgow University, and there became acquainted with the celebrated Sir W. Hamilton. He states that when here he made his earliest contribution to literature, in the form of a letter to the *Morning Chronicle*.

It may be observed here that when at Edinburgh Mr. Holland formed acquaintance with most of the celebrated men who were then connected with that renowned seat of learning. Amongst others were Brougham, Sydney Smith, Walter Scott, Dugald Stewart, Jeffrey, Playfair, Henry Erskine, Dr. Thomas Brown, Leslie, Sir James Hall, and others. He early became identified with the leading Whigs and with the *Edinburgh Review*. It is probable that his Whig connexion favoured his appointment as Physician to the Princess of Wales, the Whigs at the time acting as her friends, in opposition to the Prince Regent, who had betrayed the party.

However this may be, Dr. Holland accompanied the Princess on her Continental tour, and gives a graphic and interesting account of many of the places and scenes which he visited whilst he was her Medical attendant. It was this connexion with the afterwards Queen Caroline that first brought Dr. Holland's name prominently before the public. In the memorable trial of the Queen, in 1820, the heart of the public was stirred in a manner which it is difficult to adequately describe. A Bill of "Pains and Penalties" had been brought by the Government in the House of Lords against her. The King was most unpopular, party feeling ran high, and the middle and lower classes, with many of the upper, sided enthusiastically with the Queen. The character of the King had been long a scandal; his profligacy was universally known, and it was generally believed that he had behaved with great cruelty and injustice to his wife. It is scarcely necessary to enter into further particulars of the state of the nation at this period, but it is certain that no event in our time caused so much excitement as the Queen's trial. One illustration may serve to show this in a marked manner. I was a small boy in a large school at Walworth. It is probable that not a boy amongst the hundred and twenty was in reality a "King's man"; but if we flagged in our amusements on a half-holiday, or wanted some extra excitement, some of the bigger boys

(a) "Recollections of a Life." By Sir H. Holland, M.D., etc. Longmans.

would suddenly raise a cry, "The King for ever!" The effect of this "call to battle" was instantaneous; the "Queen's men" immediately raised a defiant answer, "The Queen for ever!" Then ensued a general fight, which was sometimes carried on in so ferocious a spirit that many of the combatants were either carried to "Hospital" or placed *hors de combat*. The means resorted to by the prosecution were most offensive to the English people. Italian witnesses by dozens were brought over to give evidence, some of these of very questionable character. Sir Henry, in his "Recollections," speaks of having been "cognisant of certain unwarrantable means of obtaining evidence, which, so obtained, was reluctantly used by the counsel to whom it fell to employ it." Unquestionably, nothing could have been more disgraceful and disgusting than the evidence of the two principal witnesses, Theodore Majocchi and Madame Dumont. The "Non mi ricordo!" (b) of the former, and the filth of the latter, raised the just indignation of the people. Dr. Holland was called for the defence. The effect of his evidence was immediate and startling.

After the prevarications, the inventions, and the probable perjuries of the witnesses for the prosecution, Holland's evidence stood out, fortified by a straightforwardness and truthfulness which must have astonished the House as it did the nation. It was, in fact, the turning-point in the trial. With that evidence now before me, I cannot be surprised that its effects were so extraordinary. Nothing can exceed its plainness and its unequivocal honesty. Sir Henry states that he feared a severe cross-examination; but in this he was mistaken. He modestly observes (page 144)—"I was not detained more than an hour at the bar of the House, and encountered no difficulty which I was not prepared fairly to meet. Two or three congratulatory notes from peers present came to me immediately after the examination had closed." Sir Henry does not do himself justice in his brief notice of the Queen's trial. I have said that his evidence had a marked effect on the result of the trial. I have stated in one of my papers in this journal, that on one occasion, when dining with the late Lord Lyndhurst, at the house of a connexion of mine, the "Queen's trial" formed the subject of conversation; and I related a circumstance which occurred in the House respecting the great Lord Erskine. I ventured to recall Lord Lyndhurst's recollections of the evidence of Dr. Holland. "You cross-examined him?" "I did; but his evidence was not to be shaken. I feared to push my questions too far; the answers to those I put to him were damaging to us."

It is very difficult to follow the discursive narrative of Sir Henry; that very discursiveness which forms a principal charm of his remarkable work is sadly discouraging to one who attempts to "review" it. We must refer the reader to the book itself for the account of his most interesting travels, extending over a period of nearly seventy years. The perusal will amply repay the reader. He visited during this time many places, and sometimes at very long periods between. Immediately after taking his degree he spent a year and a half in travelling in Portugal, Spain, Sicily, the Ionian Islands, Greece, and some parts of Turkey. Whilst Physician to the Princess of Wales he travelled with her in Germany, Sicily, and Italy.

After he was established in practice, he made it a rule to travel for two months in each year, and this practice he has continued to the present time. He made up his mind early in life not to seek for a very large practice, and determined that his income should not exceed £5000 a year. Owing probably to his political connexion with the Whigs, Holland's practice very soon became remunerative, and in a year or two reached £1200. It was not long before it amounted to just under £5000, and with this he was content. It will be seen that Holland never really suffered in his early practice, as some men of eminence have done, from straitened circumstances, but commenced, as it were, free from pecuniary anxieties. He contends that he never lost anything by his annual excursions. They fitted him for renewed Professional work, at which he continued assiduously during the other ten months of the year. Moreover, he left London at a time when most of his patients were also away. Few men, particularly of our Profession, have travelled so much as Sir Henry Holland, or in such a diversity of places. In both the Old and New World he has visited the scenes of the great battles of ancient and modern times, from those of Marathon, Salamis, and Ther-

(b) In his cross-examination, Majocchi sheltered himself, when in a difficult position, by the invariable answer—"Non mi ricordo!" Dumont did not appear in a less disgraceful position.

mopylae, to Waterloo and Gettysburg. He also visited the classic places in Greece, Asia Minor, the Holy Land, and other places—not as a mere superficial spectator, or on a "railroad journey," to boast how many miles he had travelled in a given space of time, but with the laudable object of "seeing and verifying through natural features and by other evidences those unknown and doubtful localities which history has bequeathed to our research." In these visits his classical knowledge and his natural acquirements rendered him much service, and it is not too much to say he clothed with fresh interest most of the memorable places which he visited. Not the least interesting of his excursions and voyages are those which refer to the rivers and oceans of the New and Old World; of his following the course of the Danube from its assumed source to the Black Sea; his voyage down the Rhine; up the St. Lawrence for 2000 miles; his excursions on the Ohio, the Susquehanna, the Potomac, the Ottawa, and the Nile; his visits to volcanoes—to Stromboli, Etna, and Vesuvius. These travels are of the utmost interest, not only for the descriptions he gives of the localities, but from the reflections on, and deductions drawn from, the phenomena he observed. It is all but impossible in a notice of this kind to do justice to them; and, as we have observed, the book must be read in order that the full value may be known and appreciated. The most interesting portions of Sir H. Holland's book—that, indeed, which forms the chief portion of it—is his account of the persons with whom he has been on intimate terms of acquaintanceship, or to whom he has been merely introduced. If there be any drawback to the interest of this account, it is the occasional meagreness of the sketches of some with whom we should have been glad to have known more through his descriptions. When he does, however, give us a portrait, it is drawn from the life with a graphic fidelity which is absolutely charming. It is impossible to conceive anything more interesting than his sketches of Sir Walter Scott, Lockhart, Ali Pasha, Talma, Blumenbach, and Canning. If we were inclined to be critical we should take exception to his sketch of the late Lord Lyndhurst. That great man was not a mere lawyer, with only a lawyer's "parchment brain"—far from it; he was not only a finished gentleman but a man of erudition. He might, indeed, have had narrow views on some of the questions which occupied the attention of the Government during the time he was Lord Chancellor, but his views, if occasionally mistaken, were clear, and always expressed with a lucidity and power which were never surpassed. No man had greater influence in the Cabinet than Lord Lyndhurst. It was said to me, by one well able to form an opinion, that he, of all the other members of Sir Robert Peel's Government, was the only one who ventured to differ with that great Minister on important questions. (c)

Sir Henry Holland had the rare privilege of attending professionally six Prime Ministers of England. Unquestionably the most eminent and interesting of these was George Canning. Here is Sir Henry's account of his connexion with that extraordinary man:—"It is pleasant to me to recall, through the haze of intervening years, my many conversations with this most accomplished man on literary or political topics, such conversations often occurring when he was confined to his couch by gout or other illness. One of these, turning upon his favourite poet Virgil, is more strongly impressed on my memory from his presenting me at the moment with a copy of his own (a French edition in three volumes, 1754), lying on the table before him. He wrote his name, with mine, in each volume. This was immediately after a dangerous illness, in which I attended him in 1825. There was a charm in his fine countenance enhancing that of his conversation, and felt by all who knew him. His voice well harmonised with these endowments—an influence itself always powerful in private even more than in public life; surpassing that of mere beauty, and often surviving when all beauty is gone." In a note to this passage, Sir Henry says, in his happiest way, "Various well-known passages show the feeling of our great poets as to this charm of voice. But it is strange how little this happy endowment is generally recognised in the amount of grace and pleasure it imparts to social and domestic life, and how little is done or attempted to educate an organ which is susceptible of improvement even where Nature has dealt harshly with it in the beginning. Quintillian counsels well on the subject, as on every other." Sir Henry refers to a case of homicidal insanity in his sketch of Mr. Canning, which at the present time is of

(c) It is well known that Lord Lyndhurst was strongly opposed to the repeal of the Corn Laws. At the Cabinet Council at which it was determined to carry this great and beneficial measure, Lord Lyndhurst was absent. His absence was probably the result of a wish expressed to him by his chief. Whatever the cause, he certainly was not present on that occasion.

unusual importance when two cases of "murder" have attracted so large a portion of the attention of the public. The case is of peculiar interest, as coming from the pen of one of the most acute thinkers of the age, and one who has shed so strong a light on mental aberration. The lawyers would have been puzzled by such a case, had the unfortunate lunatic been tried for homicide. Would they have advanced the plea that the "moral aberration" did not affect the "intellect" of the murderer? Could they, in face of Erskine's famous defence of Hatfield, ignore the plea of insanity, and consign the wretched man to the scaffold? It is probable that they would have done so. The dictum of the law is, that if a man commit a crime, knowing that it is a crime for which, if he commit it, he will be punished, he is "legally" responsible. Now, let us see what Sir Henry Holland says on this subject. In our opinion, the dictum of such a man has more weight and cogency than the "eloquence" of advocates and the "ruling" of judges. Sir Henry Holland says—"Other recollections blend themselves with the name of Mr. Canning—one of them illustrating a very curious form of mental aberration. In 1825, as I think, when he was Foreign Secretary, and living at Gloucester Lodge, I was one morning called in haste to see a patient at Brompton. Scarcely had I entered the room of this gentleman (for such he was, and had filled a diplomatic office of some consideration) when he eagerly besought me to protect him against himself. He told me a propensity to kill Mr. Canning had come upon him suddenly, and so strongly that he had taken these rooms at Brompton to be in the way of satisfying the impulse. But against this insane will (induced by some supposed official injustice) a sounder feeling was struggling within him, and for the moment gained mastery enough to lead him to seek for instant restraint. I, of course, lost no time in providing it—warning Mr. Canning meanwhile to return to Gloucester Lodge by a different road. These strange cases of what may be called *duplicity* of the will are not rare in the long catalogue of mental infirmities. In a lighter and less critical form such incongruities enter into the most familiar moods of character and acts of life. But even here they need to be self-recognised and resisted, to prevent their gaining mastery over the mind. The consistent and firm command over the will ranks amongst the highest attainments of man." How does this anecdote, by its simple and "unadorned eloquence," demolish the fabric of "legal insanity" so elaborately built up by the twelve judges? The "legal mind," as it is called, is competent, no doubt, to deal with questions of fact; but the moment the lawyer has to decide upon questions of mental philosophy, he is "at sea." The only lawyer who at the present moment occurs to me as having risen to an elevated position with regard to mental aberration was Lord Erskine, in his memorable defence of Hatfield, in which he certainly did more to put the question of criminal insanity on a proper basis than any lawyer before him or since. We again quote from the "Recollections":—"Another recollection, again, is strongly impressed upon me. In February, 1827, I was called down to Brighton to see Mr. Canning, then suffering under very severe illness, the effect, I cannot doubt, of midnight exposure at the funeral of the Duke of York in the depth of winter. On my return to London, I hastened to Lord Liverpool, to report to him on what he himself strongly expressed to me as a matter vital to his Government. Having satisfied his inquiries as to Mr. Canning, he begged me to feel his own pulse—the first time I had ever done so. Without giving details, I may say that I found it such as to lead me to suggest an immediate appeal to his Medical advisers for careful watch over him. The next morning Lord Liverpool underwent the paralytic stroke which closed his political life. His pulse alone had given me cause for alarm; but there were one or two passages in our half-hour's conversation so forcibly expressing the harassing anxieties of his position, that I could hardly dissociate them from the event which then instantly followed."

Here is a graphic sketch of Talleyrand:—"My intercourse with Talleyrand was chiefly at Holland House, where I frequently met him at dinner, a meal to which he came with his animal appetites keenly awake to enjoyment. His face and figure have been often described; if I were to speak of them as they were when I knew him, I should simply say they were indescribable. His portrait at Holland House is placed between those of Mackintosh and Romilly—a contrast as strange as were the characters of the men. His conversation was also cast in a mould of its own, very unlike anything else—short, pithy sentences, poignant in their sarcasms upon men and events, witty without effort or the assumption of being so. In studying Talleyrand—and it is a curious study—a com-

parison often suggested itself to me in Cardinal de Retz. Their intellectual and moral qualities were of the same general stamp, and attested much in the same way, though on a very different scale of action. Their epigrammatic maxims have the same peculiar flavour, and their ecclesiastical positions the same relation to the actual religion of the two men. The Cardinal, however, doubtless stands lowest in the comparison. The petty incidents and passions of the '*guerre de la Fronde*' were little fitted to dignify a public character."

Two of the most interesting sketches are of two other Prime Ministers to whom Holland was Medical attendant, and with whom he was on intimate terms. He draws this able contrast between these two remarkable men:—

"Without infringing on my rule of abstinence from Professional anecdote, I may briefly notice the singular contrast of natural temperament between Lord Palmerston and Lord Aberdeen. The inborn vivacity and optimism of the former pervaded his life—both public and private—rescuing him in a great degree from those anxieties which press, more or less, upon every step of a Minister's career. He had a singular power of clear and prompt decision, and often had occasion to know; and was spared that painful recurrence to foregone doubt which torments feeble minds. Lord Aberdeen habitually looked at objects and events through a more gloomy atmosphere; he was wanting in that elasticity of body and spirit so influential in a public career. I recollect, on one occasion, to have seen them as patients in immediate succession for several days together, when this contrast was presented under those strongly marked colours which illness more especially discloses." Here are the reflections of Sir Henry on this contrast—reflections of high interest and value, especially to the Medical Practitioner:—"The practice of the Physician shows him, indeed, at every moment these strange diversities of human temperament—intellectual and moral—often concealed in part, and especially among the higher classes, by the outer usages and appliances of social life; but disclosed, or even intensified, by the conditions under which he regards them. Even where most obvious to common observation, they scarcely receive due attention in the practical conduct of life. The logic of one man's mind is not the logic of another; and their feelings and tastes equally differ in kind and degree. A rational allowance for these innate diversities of temperament might spare some of the conflicts and passions which disturb both public and private life. But reason is not often or readily invoked in cases of this kind."

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

EDINBURGH, January 23.

PUBLIC feeling is again running high on the question of female Medical education. The present fighting-ground is the Royal Infirmary. Your readers are aware that the supporters of this movement have lately succeeded, by small majorities, in electing managers favourable to their views, and in passing a motion admitting female students to the wards and classes of that institution. It must not, however, for one moment be supposed that this apparent majority represents a real growth of opinion in favour of this movement, and it is well that the Profession and the public not conversant with Edinburgh matters should know how a temporary victory has been achieved by a party doomed ere long to sink out of existence. Notwithstanding the constancy to this cause shown by many of its adherents, sensible people here have lately been growing tired of the troublesome innovation, and the movement, left to itself, would have died a natural death. A side wind has for the moment fanned into brightness the feebly flickering flame. When this subsides it will pass the more suddenly into utter extinction. What, and of what nature, is this side wind?

There are two parties strongly opposed to the erection of the new Royal Infirmary on the Watson's Hospital ground—firstly, those who have all along been opposed on general grounds to the new site; secondly, a number of the residents in the neighbourhood of the proposed building, who have local objections to an Infirmary in their vicinity. These parties have all along sought, and have at last managed, to pick a hole in the plans of the late managers. It now appears, from the statements of these parties, that the managers were about to erect an Infirmary on a scale which would cost double or triple the amount of the funds at their disposal, and so on. Upon

this *causa belli* they determined to drive the Infirmary—if they possibly could by fair means, or foul—off its newly chosen site, and back to its ancient ground. This it was quite impossible for them to do in a straightforward manner on the merits of the question itself; and how have they proceeded? From a new body of managers they might succeed in obtaining what they could not get from the old, especially if these new managers should feel that their tenure of office depended upon the votes of this band of dissentients. A new board of management could be secured by throwing in their influence on the side of the supporters of the female Medical movement, and thus this party have obtained their majority. To show that this was the case, I quote the words of one of the local objectors from a letter which appeared in the *Scotsman* on Monday, January 15. The writer concludes a long letter, exposing the mismanagement of the late managers, with the following words:—

“An opportunity will, on Monday, be indirectly afforded to contributors of expressing unmistakably whether or not the gentlemen who have had the administration of the affairs of the Corporation during the past year are worthy of their continued confidence. The question of the admission of lady-students will also be then under consideration. To this I shall make no further allusion than to express my conviction that, both as regards the Corporation and the contributors, it is of less present importance than the administration of the building fund. The doors of the institution can at any time hereafter be closed against the ladies; but should £50,000 be sunk in superfluous and unsightly buildings, neither the money of the citizens nor the amenity of the city can ever be restored. In these circumstances, all those contributors who still value the beauty of their native city should attend the meeting on Monday; and although some of them may have scruples as to the propriety of admitting lady-students, yet, if they desire to preserve their legitimate control over the funds of the institution, let them vote for the recognition of contributing firms as members of the Corporation.”

Thus, by a coalition of bodies which have no affinity for one another, right is overthrown and injury done to one of the noblest institutions in our city, and, through it, to our whole Medical school. Looking at the matter in this, the true light, sufficient justification is found for the following proceeding, which might otherwise be open to question. It has been felt that, at all hazards, an effectual stop must be put to the consequences of these recent votes. At the instance of three of the contributors, the Lord Ordinary has granted an interim interdict, prohibiting the Infirmary managers from declaring Andrew Coventry, James Cowan, David Masson, W. White Millar, and Alexander Nicholson (the managers recently elected by the majority of the contributors) to have been duly elected.

The pleas in law are as follows:—“1. The complainants are entitled to have suspension and interdict as craved in respect that the respondents, declared by the Lord Provost to have been elected as aforesaid, were not duly and lawfully elected. 2. Upon a sound construction of the Royal Charter, statutes, and Act of 1870, companies or firms are not entitled to vote at courts or meetings of contributors, and contributions given in the name of companies or firms do not afford a qualification upon which partners, mandatories, or others can vote at such courts or meetings. 3. Upon a sound construction of the said Royal Charter, statutes, and Act of 1870, numbers or classes of persons are not entitled to vote jointly, and contributions given in the names of numbers or classes of persons do not afford a qualification upon which any one or more such persons, or any mandatories, can lawfully vote at courts or meetings of contributors. 4. The complainants are entitled to the interdict as craved in respect that the gentlemen named in Dr. Maxwell Nicholson's motion were duly elected at the said meeting of January 1 by the majority of lawful votes. 5. The proceedings complained of being incompetent, illegal, and unauthorised, the complainants should have suspension and interdict as craved.”

Small-pox is still largely on the increase amongst us. On Sunday night the number of cases under treatment at the City Small-pox Hospital was 204. During the past week there were 39 deaths from this disease; of these only 12 occurred in the City Small-pox Hospital, the remaining 27 having occurred in private practice. Unless the mortality is much greater in private practice than in the Hospital, it indicates a large number of cases under treatment throughout the town. It is gratifying to learn that the revaccinated still appear to enjoy a perfect immunity from the disease. At the same time, it is surprising how many persons neglect to avail themselves of the protection afforded by this simple means.

The Medical Officer is actively endeavouring by all means at his disposal to stay the progress of the disease. Amongst other measures, the following intimation has appeared in the advertising columns of the daily papers:—

“*Public Health.*—The public are hereby warned against exposing articles of clothing and bedding which have been in contact with patients suffering from any infectious disorders. On application to the police, houses will be fumigated, and articles of clothing and bedding removed for special fumigation. Before clothes or bedding can be washed, they must be disinfected. An officer will be sent at any time to apply suitable disinfectants, so as to render the process of cleansing free from risk.—Sanitary Department, Police Chambers.”

GENERAL CORRESPONDENCE.

THE LATE ROBERT WADE.

LETTER FROM MR. HENRY SMITH.

[To the Editor of the Medical Times and Gazette.]

SIR,—As an old friend and colleague of the late Mr. Wade, I must thank “J. F. C.” for the true and honest words emanating from his kindly spirit and discerning judgment; and, without adding one word to the just tribute of praise already afforded in that able and interesting sketch, I cannot forbear giving my testimony to one point in Wade's Surgical career, to which prominent allusion has been made—I refer to his persistent advocacy of the use of potassa fusa in the treatment of the more severe forms of stricture. Having been his colleague at the Westminster General Dispensary for ten years, I had opportunities of becoming well acquainted with his views, and of testing the truth of his opinions on this much-vexed question in a practical manner. Without being an enthusiast, I hope I became a convert to Mr. Wade's views, and for twenty years I have employed the potassa fusa in the more severe forms of stricture with the utmost benefit; and I entirely agree with “J. F. C.” that Mr. Wade “snatched a valuable agent from oblivion.” It has stood its ground through good and ill report, and notwithstanding much ridicule and sarcasm; and I believe that it is one of the most valuable remedies we possess in the treatment of certain forms of stricture.

Wimpole-street. I am, &c., HENRY SMITH.

THE EDINBURGH INFIRMARY AND FEMALE STUDENTS.

LETTER FROM DR. BALFOUR.

[To the Editor of the Medical Times and Gazette.]

SIR,—As your anonymous Scotch correspondent has named me in my official capacity as “godfather”—whatever that may mean—to a certain proposal intended to favour the admission of female Medical students to the Edinburgh Royal Infirmary, by withdrawing a limited, and according to the present regulation insufficient, number of beds from the male students for the exclusive use of the females, you will, I hope, allow me to state that such a proposal never received any countenance from me; and though my warmest sympathies are with those who advocate free trade in Medicine, as well as in everything else, I have no doubt that in time this matter will be arranged without detriment to the students of either sex.

I am, &c., GEORGE W. BALFOUR.
Tweeddale-court, Edinburgh, Jan. 28.

A PIEBALD CHILD.

LETTER FROM MR. REILLY.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have at present under my care a child with congenital discoloration of patches of the skin, which is alleged to have been caused by a fright which the mother sustained when she was between three and four months advanced in pregnancy.

It appears that the mother, who is the wife of a milkman, when coming downstairs one morning, saw a man of colour stealing milk from a can which stood in the passage. She at once screamed loudly, and ran to the door after him, where he was met and caught by the husband, who chanced to be returning home, and who then and there inflicted summary chastisement on him.

Nine weeks ago the mother gave birth to a fully developed male child, but whose skin was disfigured by several ugly

black patches scattered all over the trunk and extremities, varying in size from a pea to a patch extending from the nape of the neck to the nates, and nearly encircling the chest and abdomen. The largest patch, shortly after birth, began to slough over the right scapula, but healed up rapidly on the application of a simple astringent lotion.

The mother has promised me that she will bring the child to the next meeting of the Beaumont Medical Society, which will be held at the Beaumont Institution, Mile-end, on Tuesday next, at 3.45 p.m., when I shall be very pleased to show it to any of my Professional brethren who may take an interest in the case. I am, &c.,

FREDK. J. REILLY.
Amesbury House, 68, Victoria-park-road,
South Hackney, Jan. 31.

THE CHELMSFORD DISPENSARY.

LETTER FROM DR. JAMES NICHOLLS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I send you this day's *Chelmsford Chronicle*; by it you will see how the Medical men of this our town are held by the Committee of the Dispensary. We are not only asked to work for nothing, but, as each out-patient has to pay twopenne per week, the Committee actually at this rate propose to make some £50 or £60 per year clear profit out of the gratuitous hard work of their Medical officers. This cannot be endured by at least one of their present officers—viz.,

Yours, &c.,
JAMES NICHOLLS, M.D., F.R.C.S. (exam.).

Chelmsford, January 26.

GRATUITOUS ADVICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—No one can doubt, who observes the demoralising effect of the abuses of the Hospital and Dispensary system, that Self-provident Dispensaries, as recommended by the Charity Organisation Society, are the only remedy.

The general Practitioner is sacrificed to the interests of—

1. The Practitioner who has made a large practice, and yet opens his doors to gratuitous patients.
2. The ambitious young Practitioner, who wishes to get practice by the same means.
3. The quack, legally qualified or not.
4. The homeopathist and water-cure doctor. And last, not least—
5. The druggist who prescribes in a shop blazing with gas and gold labels, infinitely to the injury of those who apply.

When will the Medical Council do their duty by putting down the "consulting-rooms" and "Medical advice before 11 and after 7 p.m." of the unqualified?

I am, &c.,

January 12, 1872.

A REFORMER OF ABUSES.

P.S.—Who can wonder at the condition of the general Practitioner, when in every street and house, almost, Mrs. A says to Mrs. B, "Why pay Mr. C for advice when Dr. D or Mr. E—such a clever man—will give it you for *nothing*?" How valuable the diagnosis and prescription in forty-five seconds!

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 25th ult., viz.:

Bethell, Alfred, L.S.A., Pelton, Somerset, student of King's College.
Cartwright, Henry Gordon, Burton-on-Trent, of Guy's Hospital.
Cawley, Thomas, Great Yarmouth, of Guy's Hospital.
Fordham, John William, L.R.C.P. Edin. and L.S.A., Stepney, of the London Hospital.
Foster, William James, Birmingham, of the Birmingham School.
Griffith, Richard Glyn, Bangor, North Wales, of King's College.
Moore, Arthur Jackson, L.S.A., Debenham, Suffolk, of the London Hospital.
Murdoch, Donald, L.S.A., Rotherhithe, of Guy's Hospital.
Oldman, Charles Edmund, B.A. Cantab., Cambridge, of Guy's Hospital.
Popham, Francis William Horne, L.S.A., Gawler, South Australia, of University College.
Rendall, William, L.S.A., Maiden Newton, Dorset, of Guy's Hospital.
Skaife, Frederic, L.R.C.P. Edin. and L.S.A., Easingwold, Yorkshire, of St. Bartholomew's Hospital.
Stokes, Henry Haldane, M.B. Dub., Tralee, co. Kerry, of St. Bartholomew's and Dublin Hospital.
Ward, Walter Alfred, L.S.A., Notting-hill, of St. Bartholomew's Hospital.

The following gentlemen passed on the 26th ult., viz. :—

Bland, George, L.S.A., Gerrard-street, Islington, student of St. Bartholomew's Hospital.
Hamilton, Alexander Macleod Stavely, M.B. Queen's Univ. Ireland, Ballymancy, co. Antrim, of St. Bartholomew's Hospital.
Magrath, John, L.S.A., Forest Raw, Sussex, of University College.
Matcham, Alfred, L.S.A., Lowestoft, of Guy's Hospital.
Palmer, Ambrose Myrie, Clapham, of St. Thomas's Hospital.
Pitt, Isaac, L.R.C.P. Edin. and L.S.A., Willenhall, of the Birmingham School.
Ross, William Grahame, M.D. McGill, London, Ontario, Montreal, of the Canadian School.
Russell, Ebenezer Geer, L.S.A., Poole, Cornwall, of Guy's Hospital.
Steele, Edward Harry, L.S.A., Dorchester, of Guy's Hospital.
Wade, Reginald, L.S.A., Cross, Somerset, of St. Bartholomew's Hospital.
Wallace, Thomas, M.D. Queen's Univ. Ireland, Cardiff, of the Belfast School.
Weatherhead, John Fraser, L.F.P. & S. Glasg. and L.S.A., Holloway, of St. Bartholomew's Hospital.
Williams, Alfred Henry, M.B. Aberd., Brixton, of the Aberdeen and St. Thomas's Hospital.

Thirteen candidates passed the examination in Surgery, and, when qualified in Medicine, will be admitted Members of the College, and twenty-one were referred to their Professional studies for the usual period of six months, including one candidate examined under the old regulations, who was detected copying. The total number of candidates amounted to ninety-two. Of this number there were twenty-eight holding the L.S.A.; three L.R.C.P. Edin. and L.S.A.; two M.D. Queen's Univ. Ireland; one M.D. McGill, Toronto; one M.B. Cantab.; one M.B. Dub.; one M.B. Aberd.; one L.R.C.P. Lond.; one L.R.C.P. Edin.; and one L.F.P. & S. Glasg. and L.S.A.

Arts Examination.—At the recent Preliminary Examinations for the diplomas of Fellowship and Membership of the Royal College of Surgeons, 289 candidates presented themselves, of which number 195 passed—viz., for the Fellowship the following :—

Adams, J.	Granger, F. M.	Payne, H. P.
Apthorp, E. P.	Griffith, W. S. A.	Phillips, E. J. M.
Barnes, J. J. F.	Haig, P. de H.	Revell, R. C.
Beddoes, C. C.	Hansell, W. C.	Richards, T.
Bennett, W. H.	Hawken, F. J.	Ross, J. H.
Benson, P. H.	Hawkins, A. F.	Russell, A. P.
Besant, W. H.	Hill, M. M.	Shaw, H. G.
Bonsall, G. R.	Hodgson, G. G.	Speed, H. A.
Brock, A. C.	L'Anson, W.	Tarrant, W.
Brock, C. de L.	James, A. C.	Thanc, G. D.
Burton, H. C.	James, W. C.	Thomas, A. A.
Candler, W. J.	Johnson, W. B.	Tredennick, E.
Carter, R.	Laey, A. G.	Tudge, J. McD.
Clubbe, C. P. B.	Mackenzie, J.	Vincent, O.
Cripps, W. H.	Merriman, J. W. C.	Ward, W. C.
Dixon, J. F.	Moore, H. W.	Webber, W. L.
Eceles, A. S.	Munro, H.	Weiss, H. F.
Edwards, R.	Nicholls, H. A. A.	Wherry, G. E.
Evans, T. C.	Owen, C. W.	Whitlock, E. W.
Friend, H. E.	Page, A. A.	Young, A. H.
Galloway, A. W.	Paul, F. T.	

The following gentlemen passed for the Membership, viz. :—

Addison, C. J.	Florigny, L. E.	Poynder, J. L.
Alden, E. W.	Fox, L. W.	Prior, E. T.
Anderson, A. R.	Gascoigne, H.	Proffitt, W. J. W.
Andrew, J. E.	Godfrey, W. E.	Pullon, H.
Armstrong, W.	Hains, J. C. L.	Raitt, A. G. E.
Astley, H. J. D.	Harding, A.	Rees, A.
Atkey, W. T.	Harries, J. G.	Richardson, R. T.
Baber, J. A.	Harris, S. C.	Richardson, T. W.
Bailey, A. J.	Hart, R. A. H.	Ritchie, J.
Baillie, J. H. J.	Hawks, R. S.	Roberts, W. S.
Bain, D. S. E.	Heald, R.	Rodwell, E. M.
Ball, W. M.	Heelas, J.	Rusher, J. B.
Barton, G. H.	Hicks, E.	Salkeld, C. A.
Batty, W. E. L.	Hicks, H. G.	Sharples, C. W.
Bell, M. L.	Houghton, J. H.	Smale, M. A.
Bennett, H. J. L.	Jeans, F. A.	Snell, E. G. C.
Bennett, St. J. C.	Jefferson, W. D.	Spofforth, J.
Blackman, J. G.	Jones, C. C.	Stacpoole, C. A.
Blaikie, W.	Jones, H. O. P.	Stokes, R. L.
Blaker, T. F. I.	Judkins, E.	Tarleton, P.
Bruce, R.	Kelham, H. R.	Telford, J.
Burd, G. V.	Kendale, P. S.	Thomas, D. H.
Caffyn, S.	Kidd, A.	Thompson, E. J.
Calcott, L. B.	Lalor, G. J.	Treadgold, F. C.
Castle, H.	Lewin, E. T.	Tribe, H. T. B.
Chadwick, W. F.	Lewis, D. G.	Turner, W. P.
Christie, W. A.	Lewis, W. A.	Vasey, J. A.
Clarke, W. H.	Ling, C. A. S.	Vasey, S. W.
Cleveland, F. W.	Logan, T. T.	Wallis, P. E.
Coleman, G. E.	Lush, J. S.	Walsh, W. A. S.
Coles, D. A.	Macdonald, H. M. W.	Walter, E. W.
Collington, J. W.	Maile, C. E. D.	Ward, G. S.
Cooper, P.	Marsh, W. A.	Whistler, C. W.
Crane, C. R.	Mason, C. R. S.	Whitcombe, W. P.
Cripps, C. C.	Merriman, W. S.	Wickham, H.
Cumil, H. B. S.	Middleton, C. F.	Wild, J. L.
Dresser, A. K.	Moore, G. R.	Willows, R. G. E.
Dunn, H. P.	Morgan, W.	Wilson, W. T.
Evans, J. D.	Nockolds, S. W.	Winn, A. T.
Eve, F. S.	Parker, A. C.	Wood, P. M.
Farmar, E. D.	Parker, G. N.	Woods, J. F.
Feltham, W. P.	Popert, A. J.	Womersley, J. K.
Field, C. H.	Potts, L.	Wright, H. A. K.
Fisher, T.	Pound, F. J.	

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At the ordinary quarterly meeting of the College, on Thursday, the 25th ult., the following gentlemen, having passed the required examinations, were admitted Members:—

Berkart, Isidor B., M.D. Wurtzburg, 33, Harley-street, W.
 Ralfe, Charles Henry, M.B. Cambridge, 26, Queen Anne-street, W.
 Vanderstraaten, Julian Louis, M.D. St. Andrews, Civil Medical Service, Ceylon.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, January 25:—

Clague, John, Isle of Man.

 Seth, Harry, Holsworthy.

The following gentleman also on the same day passed his first Professional examination:—

Spurgin, William Henry, Guy's Hospital.

At the Preliminary Examination in Arts, held at the Hall of the Society on January 26 and 27, fifty-six candidates presented themselves, of whom nineteen were rejected, and the following thirty-seven passed, and received Certificates of Proficiency in General Education, viz.:—

In the First Class, in Order of Merit.

1st. John Manley.
 2nd. Frederick de Caux.
 3rd. Henry Thomas Batchelor.
 4th. James Francis Henry Bottrell and Ernest William Livesey.
 6th. Alfred George Bernard, Charles William Gay, and Joseph Hampson.
 9th. James Harris Lilley.

In the Second Class, in Alphabetical Order.

Anderson, F. C.	Hughes, David Arthur.
Baldwin, Frederick.	Hustler, James D. W. L.
Banfield, Harold W.	Ingram, E. Fortescue.
Buxton, Alfred St. Clair.	Munns, Frederick George.
Clegg, John Hague.	Palmer, Harold Lewis.
Davenport, Harold.	Pease, Douglas Clifford.
Floyer, Hubert M.	Peck, Frederick Hamilton.
Glynn, Herbert Arthur.	Peskett, Henry.
Gordelier, John Thos.	Simpson, Philip William.
Gordelier, William Gibbs.	Thomson, Herbert W.
Green, Alfred Pierce.	Vickery, Alice.
Haincs, William John.	Walker, William.
Hairsinc, Hudson.	Wheaton, Francis D. W.
Headland, Alfred.	Wise, Alfred T. Tucker.

APOTHECARIES' HALL, DUBLIN.—At an Examination in Arts held on January 18 the following gentlemen received certificates entitling them to commence their Medical studies:—

Brownrigg, Robert Percival G.	Kerin, Michael W.
Carmody, Michael.	Nagle, Pierce Patrick.
Carmody, M. Henry.	Patterson, Gerald Walter Cecil.
Castles, Henry.	Peyton, Andrew.
Fitzmaurice, John Louis.	Walter, Matthew James.
Kelly, Michael Francis.	

The following have obtained the Licence to Practise:—

Cremin, Patrick J.	Murphy, John.
Harvey, Arthur G.	Vickery, George.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BRETT, ALFRED THOMAS, M.D. St. And., M.R.C.S., L.S.A.—Medical Officer to the London Orphan Asylum, Watford.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Mr. M. Norris, on or before March 1. Election on the 7th.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Andover Union.—Mr. Fredk. Eldridge has resigned the Third District; area 6124; population 687; salary £20 per annum.

Holywell Union.—Mr. J. H. Wolstenholme has resigned the First Division of the Whitford District; area 9459; population 4490; salary £35 per annum.

West Ward Union.—Mr. Andrew C. Johnston has resigned the Shap District; area 48,640; population 2174; salary £25 per annum.

APPOINTMENTS.

Bedford Union.—George A. Hicks, M.R.C.S. Eng., L.R.C.P. Lond., to the Harrold District.

Belford Union.—Wm. Magill, L.R.C.S. Edin., L.R.C.P. Edin., to the East District.

Blackburn Union.—Albert Louis Peacock, M.R.C.S. Eng., L.S.A., to the Harwood District.

Gainsborough Union.—Richard H. Dawson, M.R.C.S. Eng., L.S.A., to the Newton-on-Trent District.

Guisborough Union.—John E. Chalmers, M.R.C.S. Eng., L.S.A., to the Danby District.

Kendall Union.—John C. Smith, L.R.C.P. Edin., L.F.P. & S. Glasg., to the Burton District.

Keynsham Union.—Henry Skelton, L.R.C.P. Edin., M.R.C.S. Eng., to the Mangotsfield District.

Leighton Buzzard Union.—Charles Etheridge, M.R.C.S. Eng., L.S.A., to the Upper District.

Pateley Bridge Union.—R. S. Veale, M.D. Univ. Edin., L.R.C.S. Edin., to the Eastern District.

Ripon Union.—Wm. E. Ledgard, M.R.C.S. Eng., L.R.C.P. Edin., to the Third District.

West Fife Union.—Henry C. Holman, M.R.C.S. Eng., L.S.A., to the Third District.

DR. CÆSAR has been appointed Medical Officer of Health in the Mile-end Old Town district, vacant by the death of Dr. Robinson.

DR. CLAREMONT has been appointed temporarily the Medical Officer at the St. Pancras Infirmary, at a salary of ten guineas a week, *vice* Dr. Ellis, resigned.

THE Limehouse Board of Works have resolved to proceed under the "Artisans' and Labourers' Dwellings Act" against the owners of the Houses in Victoria-place, Limehouse, the Medical Officer of Health for the district having reported the houses to be unfit for human habitation.

THERE is at present an unusually large amount of sickness in Fraserburgh, especially among the younger portion of the community, measles and hooping-cough being extensively prevalent. These maladies, however, seem as yet to have presented a comparatively mild type.

THE Board of Trade have declined to accede to the suggestion of the Association of Medical Officers of Health to institute an analytical inquiry into the water-supply of London, which the Association considered to be necessary in view of the probable approach of cholera.

AT Guildhall, on Monday, a meeting of representatives of riverside parishes and local boards was held, when the best means of preventing the introduction of cholera into the metropolis was discussed. The arrangements made, it was stated, would secure the isolation of cholera patients arriving in the river, and treatment by an experienced Medical staff.

HANNAH STEELE, head nurse in the lunatic ward of the Manchester Workhouse, charged with having wilfully murdered Mr. A. Harris, Senior Resident Surgeon at the Workhouse Hospital, by the administration of poison, has been committed for trial.

AT the Quarterly Middlesex Session, on Thursday, a petition from the St. Pancras Guardians, praying the Court to support their representations to the Home Office on the subject of the numerous and, as they thought, unnecessary inquests held in the parish on the bodies of paupers, was referred to the Parliamentary Committee, for them to take such steps as they might deem advisable.

IT appears, from a minute published by the Council of the Edinburgh University Club, in London—in reply to a statement recently made by the Chancellor of the Exchequer as to the number of those students who came to London after passing the Medical examination at the Edinburgh University—that since 1839, when the degree of Doctor of Medicine was first conferred by the University of London, the names of only fourteen Edinburgh Medical students have been enrolled in its calendar, though thousands of young men have during that time received their education in the University of Edinburgh.

MR. DARWIN'S name has been placed first on the list for the forthcoming election at the French Academy of Sciences of a Corresponding Member in Zoology.

AN application was made by the Sanitary Inspector of St. George's-in-the-East, on Monday, to the magistrate at the Thames Police-court for an order to remove a dead body in the district. The Inspector said he went to No. 5, Blacksmith's Arms-place, St. George's, and discovered four persons and the deceased in a small room. It was enough to breed a pestilence in the neighbourhood. The magistrate said he had no power to order the removal of the body, but the coroner had, and he had no doubt if there was any trouble in the matter the police would protect him in the discharge of his duties.

COLLEGE OF SURGEONS EXAMINATIONS.—The following are copies of the Surgical and Medical papers submitted to the candidates for the diploma of Membership of the Royal College of Surgeons at the examinations just concluded:—1. What are the causes of acute synovitis? Mention the symptoms pointing out those which are diagnostic of each variety; and describe the pathological changes and treatment. 2. Supposing a man to be stabbed in the medial line of the abdomen, midway between the ensiform cartilage and the umbilicus, and the instrument to pass straight to the spine, mention in order the parts likely to be pierced. 3. Diphtheria: Its nature, symptoms, complications, and treatment. 4. Describe the different methods and means that have been recommended in the treatment of cases of apnoea from drowning. 5. What are the symptoms, course, results, and treatment of gonorrhoeal ophthalmia? 6. Describe the course and relations of the internal jugular vein on both sides of the neck; what veins open into it?—1. A young woman is seized with pain in the abdomen, which you diagnose to be due to peritonitis. Why do you come to this conclusion? State under what circumstances the attack might occur, and what would be your treatment? 2. A patient has dropsy, which you believe to be due to mitral regurgitation. What are the signs and symptoms which lead you to this opinion? How do you treat the case? If the patient should die, state briefly the post-mortem appearances of the principal organs. 3. Write prescriptions in full for the following complaints:—Bronchitis, diarrhoea, chlorosis, gastrodynia, chorea, eczema.

PROFESSOR WILSON, F.R.S.—The following is the syllabus of the course of lectures which this gentleman commences this day (Friday) in the theatre of the Royal College of Surgeons, at four o'clock, *viz.*:—*Common Inflammation of the Skin.*—Review of the past; groundwork of investigation; foundation of inquiry; first principles; physiology, pathology, diagnosis. Summary of the nature of eczema; illustrations of eczema; new models of eczema. *Lichen planus*; signification of the term "lichen." General characters of eczema. *Erythematous Affections* (their general pathology; special forms).—*Erythema*: fugitive, fixed, migratory, and tumescent forms; therapeutical indications; *erythema arsenicale*, *erythema copaibicum*, *erythema pellagrosum*, *erythema porphyricum*. *Erysipelas*: pathological phenomena; therapeutical indications. *Urticaria*: pathological phenomena; therapeutical indications. Therapeutical diagnosis of *eczemata* and *erythemata*; therapeutical treatment of the *erythemata*. *Phlyctenous Affections* (*pemphigus* and *herpes*).—*Pemphigus*: pathology of; *pemphigus iris*; *pemphigus vulgaris*. *Herpes*: signification of the term; pathology of *herpes*; *herpes zoster*. Therapeutical indications of the *phlyctenous affections*. *Furunculous Affections* (their general pathology).—*Ecthyma*; *hordeolum*; *furunculus*; *anthrax*. Therapeutical indications. *Traumatic Affections*—extensive and varied range of the group; pathological effects of arsenic; arsenical ulcer; pathological effects of the coal-tar pigments. *Adenoma*, from cutaneous irritation. *Specific Inflammation of the Skin.*—*Exanthematous affections*: *rubeola*, *scarlatina*, *variola*. *Syphilitous affections*: general pathology; *erythematous syphilis*; *papulous* and *tuberculous syphilis*; *pustulous* and *ulcerous syphilis*; *degenerative syphilis*. *Radesyge*—*syphilis of the tongue*; *syphilis of the hair*. Therapeutical treatment of *syphilis*.

MR. D. W. CROMPTON, F.R.C.S. ENG.—Some friends and admirers of this gentleman having had his portrait painted, as a permanent record of his long and valuable services to the General Hospital, Birmingham, presented it to the Weekly Board, upon which they passed the follow resolution:—"That this Board, on behalf of the Governors of the General Hospital, accept with great pleasure the portrait of D. W. Crompton, Esq., late Honorary Surgeon, and now Consulting Surgeon, to this Institution. The Board desire to

tender their best thanks to Mr. George Whateley, and the other friends and admirers of Mr. Crompton, for so valuable a gift; and they have much pleasure in complying with the wish of the donors, by giving to the portrait of one so deservedly esteemed a local habitation among the worthies who already grace the walls of the Board-room."

CHELSEA HOSPITAL FOR WOMEN.—This new institution is just opened at Markham House, King's-road, and is intended chiefly for respectable women of "limited incomes," who are unable to bear the expense of Medical attendance and nursing in the case of their being affected with internal disease. The number of beds for such patients in the existing Hospitals is quite insufficient for purposes of charity or of science; and much as may be said against special Hospitals, there can be none against giving a temporary asylum during sickness to that class of the community which is above all to be pitied—genteel poor women. Dr. Barnes and Mr. Curling form the consulting, and Drs. T. Chambers and Aveling the ordinary Medical staff.

SCHOLARSHIPS AND EXHIBITIONS FOR NATURAL SCIENCE AT CAMBRIDGE IN 1872.—The following is a list of the Scholarships and Exhibitions for proficiency in Natural Science to be offered in Cambridge during the present year:—

Trinity College.—One or two of the value of about £80 per annum. The examination will be on April 5, and will be open to all undergraduates of Cambridge and Oxford, and to persons under 20 who are not members of the Universities. Further information may be obtained from the Rev. E. Blore, Tutor of Trinity College.

St. John's College.—One of the value of £50 per annum. The examination (in chemistry, physics, and physiology, with geology, anatomy, and botany) will be on April 12, and will be open to all persons who are not entered at the University, as well as to all who have entered and have not completed one term of residence. Natural science is made one of the subjects of the annual College examination of its students, at the end of the academical year, in May; and Exhibitions and Foundation Scholarships will be awarded to students who show an amount of knowledge equivalent to that which in classics or mathematics usually gains an Exhibition or Scholarship in the College. In short, natural science is on the same footing with classics and mathematics, both as regards teaching and rewards.

Christ's College.—One or more, in value from £30 to £70, according to the number and merits of the candidates, tenable for three years and a half, and for three years longer by those who reside during that period at the College. The examination will be on March 19, and will be open to the undergraduates of this College, to non-Collegiate undergraduates of Cambridge, to all undergraduates of Oxford, and to any students who are not members of either University. The candidates may select their own subjects for examination. There are other Exhibitions, which are distributed annually among the most deserving students of the College.

Caius College.—One of the value of £60 per annum. The examination will be on March 19, in chemistry and experimental physics, zoology, with comparative anatomy and physiology, and botany, with vegetable anatomy and physiology. It will be open to students who have not commenced residence in the University. There is no limitation as to age. Scholarships of the value of £20 each, or more, if the candidates are unusually good, are offered, for anatomy and physiology, to members of the College. Gentlemen elected to the Tancred Medical Studentships are required to enter at this College. These Studentships are four in number, and the annual value of each is £113. Information respecting these may be obtained from B. J. L. Frere, Esq., 28, Lincoln's-inn-fields, London.

Clare College.—One or more of the value of £50 per annum. The examination (in chemistry, chemical physics, comparative anatomy and physiology, and geology) will be on March 19, and will be open to students intending to begin residence in October.

Downing College.—One or more of the value of £40 per annum. The examination (in chemistry, comparative anatomy and physiology) will be early in April, and will be open to all students not members of the University, as well as to all undergraduates in their first term.

Sidney College.—Two of the value of £40 per annum. The examination (in heat, electricity, chemistry, geology, physiology, and botany) will be in October, and will be open to all students who may enter on the College boards before October 1.

Emmanuel College.—One or more of the value of £40 to £60 per annum. The examination on March 19 will be open to students who have not commenced residence.

Pembroke College.—One or more of the value of £20 to £60,

according to merit. The examination in June, in chemistry, physics, and other subjects, will be open to students under 20 years of age.

St. Peter's College.—One from £50 to £80 per annum, according to merit. The examination, on April 4, in chemistry, comparative anatomy and physiology, and botany, will be open to students who will be under 21 years of age on October 1, 1872, and who have not commenced residence.

Although several subjects for examination are in each instance given, this is rather to afford the option of one or more to the candidates than to induce them to present a superficial knowledge of several. Indeed, it is expressly stated by some of the Colleges that good clear knowledge of one or two subjects will be more esteemed than a general knowledge of several. Candidates, especially those who are not members of the University, will, in most instances, be required to show a fair knowledge of classics and mathematics, such, for example, as would enable them to pass the Previous Examination. There is no restriction on the ground of religious denomination in the case of these or of any of the Scholarships or Exhibitions in the Colleges or in the University. Further information may be obtained from the tutors of the respective Colleges. It may be added that Trinity College will give a Fellowship for natural science once, at least, in three years; and that most of the Colleges are understood to be willing to award Fellowships for merit in natural science equivalent to that for which they are in the habit of giving them for classics and mathematics.

A LUNATIC ASYLUM IN BELGIUM.—The proposal which was recently made in the Belgian House of Representatives, that madhouses should be placed under supervision, was suggested by the abuses that were found to exist at the establishment of Evère. This institution is situated in the environs of Brussels. Towards the close of the year the authorities made an impromptu visit there, and the result of their investigation was most unsatisfactory. The disclosures of cruelty and mismanagement have excited great indignation at Brussels, and the Government has ordered the immediate closing of the establishment.

MUSÉUM D'HISTOIRE NATURELLE DE PARIS.—The Professors have, by a majority of two, voted for the maintenance of the Chair of Palæontology, vacant through the death of M. Lartet, and the continuance of which has been seriously threatened. Suppress the only public Chair of Palæontology which exists in the country of Cuvier! We can scarcely comprehend how such questions can be raised, and seriously discussed.—*Révue Scientifique*, January 13.

THE CONCOURS FOR AGRÉGÉS OF THE PARIS FACULTY.—There are seventeen candidates for the seven vacancies in the Section of Medicine. The jury is composed of five Professors of the Faculty (MM. Tardieu, Chauffard, Gubler, Hardy, and Vulpian), an *Agrégé* (M. Jaccoud), and a Member of the Academy of Medicine (M. Roger). No one can complain of such a jury, but the mode of choosing the juries is very objectionable. This is in the hands of the Minister of Public Instruction, on the designation of the Inspector of Medical Studies (M. Dénonvilliers). How much better would it be that the Faculty, the *Agrégés*, and the Academy of Medicine should respectively choose the members, who would thus acquire more weight, and be independent of all Ministerial connexion. It is a liberal reform, of incontestable utility, and one easily effected.—*Révue Scientifique*, January 13.

TO MEDICAL MEMBERS OF THE FRENCH NATIONAL ASSEMBLY.—Twenty-two Medical men, who are Deputies, have, on the proposition of M. Roussel, formed themselves into a Medico-Political Society, which meets every Monday. At their first meeting they chose Professor Bouisson, of Montpellier, as President, and M. Mahy, of the Ile de la Réunion, as Secretary. The principal object the Society has in view is to submit to a preliminary discussion all subjects involving Medical interests that are likely to be brought before the Assembly, and in legislating on which Medical science may prove of great utility. The first topic to be treated of is "Medical Assistance in the Country;" and "Drunkenness," "Hospital Administration," "Medical Education," etc., will follow.—*Gaz. Méd.*, January 27.

DETACHMENT OF THE PERIOSTEUM IN GUNSHOT WOUNDS.—M. Desprès, reporting on some cases of gunshot wounds to the Society of Surgery, called attention to the great detachment of periosteum at a distance from the fracture which sometimes takes place, and which he attributes to the concussive action of the ball on the bone, but which others refer to the effusion of blood near the seat of fracture. How-

ever this may be, extensive consecutive necroses take place, which may be followed by extensive reproduction of bone. Such detachment easily and almost completely takes place in spite of there being a great number of splinters, and constitutes an additional reason in favour of the precept of never amputating for a comminutive fracture of the leg or arm, however numerous the fragments may be, providing the arteries and nerves are not seriously damaged.—*Union Méd.*, January 27.

BREAD MADE WITH SEA-WATER.—M. Rabuteau calls attention to the importance of this article. In the first place it is very pleasant eating, also increasing the appetite and stimulating digestion. On board ship bread so prepared has been found very conducive to the preservation of health during long voyages. It also exerts important medicinal effects, especially in dyspepsia. In phthisis and in scrofula the author states it is a powerful adjuvant.—*Union Méd.*, January 6.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. W. Yeats, M.B.—Your paper has been received, and shall appear shortly.

The late Robert Wade, F.R.C.S.—We are requested to correct an inaccuracy which crept into our obituary notice of Mr. Wade. He died at the age of 74, not at "84," as stated last week.

Puckmura.—We have the greatest pleasure in complying with your request. The work referred to has been looked out, and the reference shall be added in the proper place.

A Parish Surgeon.—About the middle of June, at the College of Surgeons. The fee is £2. Write to the Secretary for the Regulations, which will give you the subjects of the examination.

Mr. J. Reed, Pentridge.—Your letter, with enclosure, has come safely to hand. The numbers lost at sea will be forwarded by next mail. Dates as follows:—September 9, 16, 23, 30, October 7, 1871. If more are required, please advise us.

AN ETYMOLOGICAL QUERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—There are two words, I presume of Greek origin, which puzzle me much. One is *myringitis*, which signifies the same as tympanitis; the other is *spagyric*, used in the seventeenth century to signify remedies new and chemical, not old and Galenic. Please tell me *unde derivantur*.

I am, &c.,

TYRO.

Melbourne.—On a perusal of the evidence adduced in the case of Turner v. Van Hemert, we cannot think that the jury arrived at a perfectly just verdict. It is clear that the case was beset with some difficulties, and the plaintiff suffered from causes beyond the reach of the skill of the Surgeon. We regret that the Supreme Court refused a new trial, because it is probable that a further inquiry might have tended to elucidate more fully the facts of the case. It is proverbial that "Doctors differ," but it is an axiom of law to make all doubts tell in favour of the defendant. It must be some consolation for him to know that he is supported by his Professional brethren in Victoria. We quote the following from the *Melbourne Argus*:—

"A largely attended meeting of the members of the Medical Society of Victoria took place (November 29 last) at the hall of the Royal Society, to consider the recent action of Mrs. Turner v. Van Hemert, tried some few days since at the Supreme Court, and the result of which was that Mr. Van Hemert, a Medical Practitioner at St. Kilda, was heavily cast for damages (which, with costs, made up £700), for alleged unskilful treatment of the plaintiff's leg. Professor Halford, President of the Society, took the chair, and, together with several of the leading Surgeons and Physicians of Melbourne, expressed a strong opinion that Mr. Van Hemert was by no means to blame. Resolutions were then passed, declaring that a wrong verdict had been given, expressing regret that a new trial had not been allowed, proffering sympathy with the defendant, and finally appointing a committee for the purpose of calling a general meeting of the Profession to organise a fund to recoup the defendant's losses."

KILLING NO MURDER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With your permission, I would supplement a former communication with a few additional remarks. Being merely one in the ranks of the Profession, with no "*stat nominis umbra*" as the badge of a superior, I can only plead the interest I feel in what concerns the rights of humanity, justice, and truth in matters relating to Professional influence on questions of insanity. That the cases of Watson and Edmunds have much engaged public attention cannot be denied, as well as the influence of our Profession in abating and commuting the sentence of the law so as to make virtually, in a responsible sense, "killing no murder." That the reverses of Mr. Watson, and probable domestic irritations, made him under passion rush upon the outrage of murder would appear clear; but where was the insanity? That Miss Edmunds, unsuspected, and exhibiting at middle-age (up to it) no evidence of insanity, artfully contrives the deaths of others, and takes every care to elude detection, should also, with Mr.

Watson, obtain the same clemency—again may be asked, Where was the insanity? I should be sorry, with all humane persons, to advocate Draconian laws to meet crime; but there are many, like myself, who think that, until capital punishment may be done away with, philanthropists and Doctors are somewhat apathetic in interesting themselves so charitably for the perpetrators of mischief, and paying so little attention, at the same time, to the unfortunate victims and their sorrowing relatives and friends.

But what, may be reasonably and justly asked, should be insanity in respect of murder or crime according to law? Irresponsibility, or responsibility, can be the only answer, and this, of course, must involve investigation of the particular case. A reckless and wanton man—from habits of drink or the indulgence of passion—commits murder. Everybody adjudges him guilty; but if hereditary taint be hinted at, and proved, then comes forth (too often, we think) some learned member of our Profession to the rescue. A drunken or vicious man may become insane, his mental condition may have been much influenced by hereditary taint, and then he is fairly open to legal consideration, although I think, under the Divine law, if he may not have resisted serious and growing propensities of evil, he may be held responsible.

I would further beg leave to observe, although I would not disparage learned Doctors who have written on insanity, and who preside over asylums, and who may in consequence contend for their better title to diagnose and treat insanity, yet, as they cannot explain that mechanism of brain connected with mind, I contend that they are as much outside the interior of the subject as other well-educated men, and that they, therefore, can only be custodians of the insane, and advisers and guardians of their general health.

I am, &c.,

THOMAS STOKES.

Nailsworth, January 29.

Health of Marylebone.—Dr. Whitmore, in his monthly report on the health of Marylebone during December last, makes the following observations on sewer ventilation and sewer flushing:—

"It has struck me as a singular omission that although the writers of the numerous letters which have recently appeared in the *Times*, on the subject of 'Sewer Ventilation,' are very fertile in expedients for carrying off the poisonous gases from our sewers, it has occurred to none of them to suggest that a possible mode of overcoming the difficulty would be by getting rid of the fetid deposits which generate them. 'Remove the cause and the effect will cease,' is a trite axiom, and I cannot help thinking that if a well-devised system of sewer flushing were resorted to at frequent intervals, it would be found that the present method of ventilation by air gratings would be sufficient for all sanitary requirements. How this is to be efficiently done must, of course, be a subject for the consideration of sewer engineers, but that it can be done, and that it has frequently been done in this parish, I myself can testify. I have instructed the inspectors, in their future sanitary inspections, to examine the waste water-pipes in cisterns and other water receptacles. It has been recently discovered that in many of the largest and best-appointed houses in the parish these pipes enter directly into the house-drains or closet-pipes, and are not trapped: the consequence is, that foul and poisonous gases ascend through them, to be absorbed by the water in the cistern, if the cistern be covered, or if not, then to find their way into the house, and invariably into those rooms where fires are burning. In either case injury to health, and possibly an outbreak of fever, may be the result; it is therefore of the highest importance that every householder should at once examine his waste water-pipes, and if he finds them connected with either the drains or closet-pipes, he should at once sever such connexion, regardless of whether they are trapped or not, and allow the overflow from the water receptacle to run down upon the area pavement, or anywhere rather than directly into the drain. The ventilation of house-drains and closet-pipes requires to be carried out with considerable care and judgment; there is no doubt considerable risk and danger in keeping foul air pent up in the drains and closet-pipes, but to discharge it, except at a considerable distance from the house, would be attended with equal danger, unless it could be previously disinfected with charcoal, or in some other mode equally efficacious. Where the height of a house admits of it, the foul air can be allowed to escape through a pipe which passes upwards to some little distance above the roof, but where this is not practicable the advice of a competent person should be first taken."

THE YOUNG FAMILY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Our Profession has boasted of several eminent members of the name of Young. There was, for instance, of late a Surgeon in Sackville-street of some eminence, and brother to Sir Charles Young, Garter King-at-Arms. These were, I believe, sons of a Dr. Young, an eminent Physicist, and Physician to St. George's Hospital. There is a very interesting book now in circulation, "The Memoirs of Charles Mayne Young," in which it is stated that his father was an eminent Surgeon and Anatomist in London at the end of the last century; and that his brother, George Young, made £8000 a year as a Surgeon, and retired early in life with a fortune of £60,000. Can any of your genealogical readers tell me whether any connexion existed between these two families? I am, &c., X.

PHTHISIS IN MELBOURNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—For the third consecutive month, I send you the usual list of deaths (exclusive of natives) that have taken place in the Melbourne Hospital during the month (as published for the outgoing mail summary by the *Argus* of this date), for the purpose of enabling you to determine for yourself whether or not my statement of the extent of the prevalence of phthisis here is borne out by authenticated facts. Of a total mortality in the Hospital for the month of twenty-seven deaths from all causes—that is, exclusive of natives—there were sixteen from phthisis, or nearly 60 per cent. In Melbourne and suburbs during the same period there was a total mortality from all causes, at all ages, of 280, of which number forty-two were from phthisis, the ratio being exactly 15 per cent. The Registrar's returns are not yet out, but I have ascertained particulars at the office, and will forward the tables by next mail. I trust you will excuse my thus troubling you, should you not consider the importance of the question somewhat justifying it. It will be unnecessary to send you any more of these monthly reports, sufficient having been shown in vindication of their impugned veracity. In a few weeks more the census papers will be completed, when, as already promised, I shall finish the analysis and forward the result.

South Yarra, November 6, 1871. I am, &c., WILLIAM THOMSON.

COMMUNICATIONS have been received from—

A. PARISH SURGEON; DR. ARDING; MR. HALLIWELL; DR. NICHOLLS; DR. PORTER SMITH; DR. ROGERS; MR. F. P. STAPLES; MR. STOKES; MR. J. T. RUDALL; MR. F. J. REILLY; MR. W. W. REEVES; DR. McKECHNIE; DR. ALDIS; MR. YEATS; DR. BALFOUR; DR. CATON; MR. C. WOODCOCK; DR. J. D. ADAMS; DR. LYON PLAYFAIR; MR. T. M. STONE; MR. J. A. WANKLYN; DR. SEATON; MR. F. A. MAHOMED; DR. C. J. B. WILLIAMS; MR. J. CHATTO; DR. J. MATTHEWS DUNCAN; DR. R. H. COLLYER; DR. PHILLIPS; MR. HENRY SMITH; MR. W. G. WADE; MR. G. WAIT.

BOOKS RECEIVED—

Urban-Dubois' Household Cookery Book—Report of the Tenby Cottage Hospital—The Life of Thomas Geeran, a Centenarian—Rindfleisch's Text-book of Pathological Histology.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Pharmaceutical Journal—Chelmsford Chronicle—Gardener's Chronicle and Agricultural Gazette—Melbourne Herald—Melbourne Age—Melbourne Argus—Manchester Courier—Monthly Microscopical Journal—Medical Press and Circular—Monthly Homœopathic Review—Food, Water, and Air—Hardwicke's Science Gossip—Canada Lancet.

APPOINTMENTS FOR THE WEEK.

February 3. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Mr. Wm. B. Donne, "On the Theatre in Shakespeare's Time."

5. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Third Lettsomian Lecture, by Dr. Habershon—"The Bile and the Bile-ducts."

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Anniversary Meeting.

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

6. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Mr. Christopher Heath, "Fibro-cystic Tumour of the Lower Jaw." Dr. King, "Aneurism of the Aorta perforated by a Fractured Rib, and associated with Embolism of the Middle Cerebral Artery." Dr. Thorowgood, "Biliary Calculus." Mr. Jabez Hogg, "Madura Foot." Dr. Moxon, "Subacute Yellow Atrophy of the Liver;" "Expansion and Softening of small Grey Tubercle." Dr. Nunneley, "Congenital Oclusion of the Hepatic Ducts." Dr. Greenhow, "Embolism and Softening of the Left Anterior Cerebral Lobe: Aphasia."

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

7. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

OBSTETRICAL SOCIETY, 8 p.m. Dr. Phillips, "On Retroflexion of the Uterus as a frequent Cause of Abortion." Dr. Bantock, "On the Use of the Sponge Tent in Menorrhagia." And other Papers.

ROYAL MICROSCOPICAL SOCIETY, 8 p.m. Anniversary Meeting.

SOCIETY OF ARTS, 8 p.m. Meeting.

8. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

9. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Adjourned Discussion on Mr. Cooper Forster's Paper "On the Treatment of Popliteal Aneurism." Mr. Hulke, "On the Therapeutic Value of Condurango as a reputed Cure for Cancer." Mr. De Morgan, A supplemental paper on the same subject. Mr. Bryant, "Two Cases of Recto-vesical Fistula successfully treated by Colotomy."

QUEKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Objects only.

ROYAL INSTITUTION, 9 p.m. Prof. Humphry, F.R.S., "On Sleep."

VITAL STATISTICS OF LONDON.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29'13 in. The highest was 29'77 in. at the end of the week, and the lowest 28'21 in. on Wednesday morning.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

† Through an error which was discovered on the revision of the enumerated numbers at the Census Office, the correct population of Manchester at the middle of 1871 was 351,171, and not 356,099, as published in recent Weekly Returns. The number for the middle of 1872 (352,759) shows, therefore, an increase of 1271 upon the corrected number for 1871.

PROTECTED BY ROYAL LETTERS PATENT. SPECIALITY FOR THE MEDICAL PROFESSION.

AGNEW'S COD-LIVER OIL JELLY,

Guaranteed to contain not less than 70 per cent. of the finest Newfoundland Oil,
AS SUPPLIED TO HER MAJESTY'S NAVY FOR HOSPITAL SERVICE,
Commands a large sale, and is extensively ordered by the Medical Profession in private practice and in public institutions.
Sold in Half-pints, 2s.; Pints, 3s. 6d.; Quarts, 6s. 6d.

J. AGNEW, INVENTOR AND PATENTEE.

Manufactory and Principal Wholesale Depot, 278, Great Homer-street, Liverpool.

London Agents:—Evans, Lescher, & Evans; Barclay & Sons; Sanger & Sons; Millard & Sons; Edwards; Newbery & Sons; and all Wholesale Houses

PEPSINA PORCI.

Messrs. BULLOCK & REYNOLDS

Beg to direct the attention of the Profession to the experiments upon Medicinal Pepsin by Professor Tuson, recorded in the "Lancet," Aug. 13th, 1870, which incontestably prove the very great superiority of their preparation in point of digestive power over every other Pepsin, British or Foreign. Dose—Two to four grains.

Messrs. BULLOCK and REYNOLDS will be happy to forward a Reprint of Professor Tuson's Paper on application.

3, HANOVER-STREET, HANOVER-SQUARE, W.

HUBBUCK'S PURE OXIDE OF ZINC.

See *Pharmaceutical Journal* of May 1, 1856.

Sold in Stamped Boxes of 14 lbs. each, by the following Wholesale Druggists:—

Messrs. Baiss Brothers & Co.	Messrs. Geo. Curling & Co.	Messrs. Hearon, Squire, & Francis.	Messrs. Southall, Son, & Dymond.
" Barron, Harveys, & Co.	" Drew, Barron, & Co.	" Herrings & Co.	Mr. James Woolley.
" Battley & Watts.	" Evans, Lescher, & Evans.	" Hodgkinsons, Stead, & Treacher	Messrs. Wright, W. V., & Co.
" Burgoyne, Burbidges, & Co.	" Evans, Sons, & Co.	" Langtons, Scott, & Edden.	" Wyleys & Co.
" Cox, Gould, & Co.	" Samuel Foulger & Son.	" Preston & Sons.	Glasgow Apothecaries' Co.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;

and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

SILVER MEDAL AWARDED 1867.—JUROR 1862.

MORSON'S PREPARATIONS OF PEPSINE.

MEDICINAL PEPSINE

(Poudre Nutritive, or "Pepsine Acide Amylacée" of the French Codex)

Contains the active digestive principle of the gastric juice, purified and rendered permanent and palatable. Dose—15 to 20 grains.

PEPSINA PORCI,

A concentrated and NEUTRAL preparation of Pepsine, free from any disagreeable taste or smell. Dose—5 to 10 grains.

These preparations of Pepsine are carefully examined and tested by a professional Chemist, and certified to answer to the tests indicated. Every bottle containing the preparations named, and bearing the Trade Mark of T. MORSON AND SON, is sold with a guarantee to that effect.

PEPSINE WINE, PEPSINE LOZENGES, PEPSINE GLOBULES,

Are convenient forms for the administration of Pepsine.

SACCHARATED WHEAT PHOSPHATES,

A Dietetic Preparation, supplying an important deficiency in the ordinary Food of Invalids and Children.

Manufactured by **T. MORSON and SON, Pharmaceutical Chemists,**

31, 33, and 124, SOUTHAMPTON-ROW, LONDON, W.C.

NEPENTHE.

PREPARED EXCLUSIVELY FROM OPIUM. (Dose the same as Tinctura Opii.) Price 8s. per lb.

From the "Lancet," Dec. 18, 1869.

NEPENTHE, OR ANODYNE TINCTURE (PREPARED BY MESSRS. FERRIS AND CO., BRISTOL).

This preparation really consists, as stated, solely of opium, resembling somewhat the liquid extract of the British Pharmacopœia. It is claimed for it that it does not produce headache, stupor, giddiness, depression of spirits, diminution of nervous energy, prostration of strength, nor constipation; it is doubtless less stimulating than those preparations of opium made with the solid and crude drug; and a further commendation of Nepenthe is its uniformity of strength. The Nepenthe intended for subcutaneous injection is of double the ordinary strength; and that it is really so we have verified by analysis.

May be procured direct from the Sole Manufacturers,

FERRIS, BOORNE, TOWNSEND, and BOUCHER,
Wholesale Druggists, Bristol,

And through all leading Wholesale and Retail Chemists in Great Britain and the Colonies.

NOTICE.—Notwithstanding the enormous and increasing advance in Opium, the price of Nepenthe remains the same, and it is now the cheapest as well as the best preparation of this important drug.

N.B. Two Pounds NEPENTHE, or One Pound NEPENTHE and Three Pounds Ferris and Co.'s SYRUP of CHLORAL, will be sent, Carriage Paid to any Railway-station on receipt of P.O.O. for 16s.

ORIGINAL LECTURES.

LECTURES ON THE
PRINCIPLES OF THE TREATMENT OF
FEVER.

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE III.

THE ADMINISTRATION OF LIQUIDS, FOOD, AND STIMULANTS IN
THE FEBRILE STATE.

Liquid.—During the feverish state there is usually much thirst, and patients crave for drink. Considerable quantities of fluid may be taken with apparent advantage, and, at least in the majority of cases, the yielding to the desire for cool liquids seems to do no harm. I have known many patients take more than twelve pints of fluid in the twenty-four hours. Broth is probably of use in fever, mainly on account of the water it contains, and the same remark is applicable to much of the beef-tea that is given, as well as to the diluents in favour. In cases, however, in which the stomach is distended and the abdomen tympanitic the Physician should not permit a very large amount of fluid to be swallowed. Sometimes, even when taken in very small quantities, the fluid is not absorbed, and by accumulating in the bowels stretches their coats, and thus paralysis of their peristaltic action may be occasioned. I have known a strong man destroyed in the course of twenty-four hours in consequence of paralysis of the muscular coat of the intestine, the cavity of which was found after death to be enormously distended with liquid.

In dieting a fever patient the actual quantity of fluid which is to be given should always be carefully stated. From two to four ounces an hour is a good allowance, and more than sufficient in most cases; but this proportion is often greatly exceeded, particularly in Hospital practice—many a patient during the twenty-four hours taking as much as two pints of milk, about the same quantity of beef-tea, besides water almost *ad libitum*. And in the majority of cases this free swallowing of liquid does not seem to be disadvantageous. The liquid is absorbed as fast as it is introduced, and the greater part soon escapes from the blood as perspiration; some, however, passes off in the breath, and a considerable proportion is excreted by the kidneys—the activity of these organs often increasing considerably after the first few days in cases where the malady runs a short and favourable course.

In all forms of fever it is important to prevent the patient from drinking considerable draughts of cold water, milk, or other fluid; but small quantities even of ice-cold water given at intervals of half an hour or more do no harm, and are extremely grateful to the patient. By the frequent introduction of small proportions of fluid (one or two teaspoonfuls) the blood is diluted, the solution of the noxious materials formed during the feverish state is effected, and the removal of these by the skin and kidneys promoted.

Food to be given during Fever.—Although in the feverish condition, by the free action of the secreting organs, the state of the blood may be much improved, and the nutrient fluid rendered more fit to traverse the vessels, it must be obvious that, unless new materials be introduced to compensate for those removed, the nutritive powers of the blood will fail, and the patient may die from sheer exhaustion. Hence it is very necessary to consider how food may be given without causing derangement of the digestive organs, and what kind of nutritious matter is most suitable under the circumstances.

It is of great importance that the nutritious matters given in fever should be such as will be not only readily absorbed, but quickly assimilated—matters capable of being taken up and applied to nutritive purposes without undergoing those slow preliminary changes which are requisite to convert the less soluble constituents of ordinary-health diet into a fit state for nourishing the tissues. In fever the solvent secretions are not only very scanty, but their properties are altered. The saliva, the gastric juice, the bile, and the pancreatic fluids are all defective, and the organs which secrete these important solutions, as well as the numerous glands in every part of the digestive tract, are seriously affected, and their action impaired. For these reasons great care should be taken in the selection of the food, and the utmost precaution

exercised in preventing the patient from having any particles not likely to be readily digested, or anything that has commenced to undergo the slightest putrefactive change. In hot weather the nurse should be particularly observant on the latter point, for the most digestible foods very soon undergo decomposition, and sometimes good beef-tea will be tainted in a single night. For this reason it is important not to use the patient's sick-room as a larder, the air of which, irrespective of its temperature, is prone to hasten putrefactive decomposition, and is no doubt loaded with germs of fungi ready to multiply.

As I have already suggested, in the slightly feverish condition, the treatment of which is now under consideration, little food is really required. Mutton broth, weak beef-tea, camomile tea, and infusion of many herbs (some of which are undoubtedly nauseous enough) have been very strongly recommended for their curative properties; but their efficacy is mainly dependent upon the quantity of water they contain, as has been already mentioned. But, on the other hand, the Physician must never forget that in many very bad cases of fever in which nutrient matter is much required little can be taken, and life may be thereby endangered. The patient not unfrequently rebels against every kind of food, and if any be swallowed, distressing vomiting is immediately excited, or the food accumulates in and distends the stomach, doing harm in many ways. Under these circumstances, we have in some cases to feed the patient by enemata, while in others we may rely for a time almost entirely upon stimulants of some form or other, until the state of the stomach improves. But it will be more convenient to consider the question of giving stimulants in low feverish conditions under the head of alcoholic treatment.

Occasionally every kind of food is spat out forcibly as soon as it is taken into the mouth, and unless the nurse displays good judgment and care, this rejection becomes a habit, and in very bad cases is continually repeated while the patient remains in a half delirious or even totally unconscious state. When this troublesome symptom is first noticed, it is better to change the food. Milk alone may be offered, or iced milk, or even pure water only, for a time given.

Whenever it can be obtained, well-made beef-tea, made from fresh beef, should be tried. The "essence of beef" (sold by Brand and Co., Little Stanhope-street, Hertford-street, May-fair) is a most valuable preparation, and almost always liked by patients. It may always be obtained quite fresh, and can be forwarded daily into the country. This most excellent preparation for invalids should not be kept more than three days in winter, or two in summer. Next to these freshly made essences may be mentioned the extracts of meat which are now largely sold. During the last few years Liebig's extract has much improved in quality; and the meat extracts made by Messrs. Whitehead are extremely good. A very palatable form of beef-tea is made by merely adding boiling water to two teaspoonfuls of Liebig's extract, placed in a tea-cup. In some cases it is necessary that whatever is given should contain very little salt; for, in consequence of numerous cracks upon the tongue, and the presence of little superficial sores in different parts of the mucous membrane of the mouth, this substance causes great pain, and sets the patient against food. The fresh beef-tea and Brand's essence contain much less salt than the inspissated extracts. Some forms of solid beef-tea also are made without any salt being added.

In the treatment of all febrile diseases we must never lose sight of the fact that the action of the stomach, like that of other organs of the body, is much deranged. Should the stomach be irritable, ice, a little dilute hydrocyanic acid and soda, and other remedies may be tried. Although in slight cases there is usually no harm in yielding to the patient's disinclination to take food, this must certainly not be permitted during the early period of any of those febrile diseases which we know will probably last for many days; and even in the mildest attacks the convalescence is often much reduced in duration if only the patient can be fed during the whole period of the malady. In long and severe cases the regular introduction of small quantities of nutritious, easily digestible food at short intervals of time is most important. At the least two or three tablespoonfuls of good strong beef-tea or milk should be given every two, three, or four hours, or one tablespoonful at much shorter intervals if the case is a bad one. If we try the experiment of treating an ordinary cold, when there is complete loss of appetite, with good beef-tea or soups, with a little wine administered every three or four hours, and then on another occasion try the starving process, we shall be able to decide, by studying the effects upon our own organism, which plan is the more efficacious. In many very slight

cases of fever only a moderate quantity of food is required. The brod-suppe and butter-suppe of the Germans may be given, and the patient will do perfectly well. In fact, the principal of treatment often adopted in such slight cases is that of giving diluents; for weak beef-tea, etc., consists almost entirely of water, and it would be absurd to suppose that the very small quantity of solid matter contained therein really compensates for the material removed from the body by the secreting organs. We know, indeed, that it does not, and that the patient loses weight, and loses weight fast. In a short time the feverish state passes off; the secreting organs begin to act again freely; the salivary glands and the stomach resume their function; healthy secretions are produced in considerable quantity; the nutrient constituents of the food are freely dissolved; and the loss of tissue which had occurred during the feverish period of the malady is speedily repaired, and not unfrequently more than repaired—for it is not unusual to find that for some time after a patient has recovered from a feverish attack, he improves in health, and becomes stronger and more robust and vigorous than he had been at any antecedent period of life.

Milk is one of the most valuable forms of food, not only in cases of low fever, but in almost all forms of disease. Sometimes it is desirable to dilute the milk with an equal quantity of water. If there should be nausea or sickness it may be iced, and a few drops of hydrocyanic acid may be added. If a little lime-water or a few drops of *liquor potassæ* be mixed with milk it will often be retained, even though the stomach be in a very irritable state. There is no objection to mixing ammonia and other medicines with the milk, and any wine or brandy to be given may be added to it. In the case of sick children, milk is by far the best article of diet, and oftentimes the only one which can be successfully used as a vehicle for the administration of medicine.

During the last few years we have had the advantage of being able to employ the concentrated Swiss milk, which, when properly diluted, is a most pleasant drink, and perhaps less liable to cause sickness than ordinary fresh milk. In some cases, however, milk is altogether refused. Whey, from which the curd has been separated, may be tried; but if this does not suit, we must depend upon simple nutritious soups, eggs cooked in various ways, beef-tea, and the extracts of meat already referred to.

The digestion of milk and all animal soups is promoted by putting into each cupful three or four grains of pepsin. If a mixture of beef-tea and pepsin be allowed to stand in front of the fire for a couple of hours, artificial digestion will have commenced, and if for a somewhat longer time, it may have been completed, and the fluid will be in a state favourable for absorption, the weakened digestive power of the stomach not being taxed in any way whatever. The solvent action of the pepsin is much increased by the addition of from ten to twenty drops of dilute hydrochloric acid. The casein, which in the case of milk may remain undissolved, may be strained off with some of the oily matter. Phosphoric acid or lactic acid may be also employed; but these act less powerfully.

For many years past I have been in the habit of adding *pepsin and hydrochloric acid* to the beef-tea that is given in very bad cases of fever, and I am sure with the greatest advantage. The stomach is relieved, and a comparatively large amount of nutrient matter digested and absorbed within a given time. By this plan the tympanitic state of abdomen, which is sometimes so distressing, is relieved in the course of a few hours, and its recurrence prevented during the illness.

The pepsin used for this purpose, and generally employed by me in medicine, is prepared according to the plan I devised more than fifteen years ago; and as the process is but little known, although simple, it will, I think, be practically useful to give an account of it in this place.

PEPSIN OF THE PIG.

On the Preparation of Pure Digestive Powder or Pepsin from the Pig's Stomach.—Various chemical processes more or less complicated have been employed in the preparation of pepsin. Partly in consequence of these being tedious and difficult of performance, and the results uncertain, and partly from the sale of perfectly useless preparations, the remedy has to some extent lost its reputation. Many years ago, when engaged upon some experiments on artificial digestion, and after having met with considerable difficulty in obtaining clear solutions that would filter, I tried various new plans of preparing digestive fluids; and from the circumstance that the pig was an omnivorous animal, with a very strong digestion, and his stomach to be easily procured for a small

sum, I was led to try his pepsin in preference to that of any other animal. The following mode of preparation was found to answer very satisfactorily. It is very simple, and free from many of the objections to which other processes are liable.

The mucous membrane of a *perfectly fresh* pig's stomach was carefully dissected from the muscular coat, and placed on a flat board. It was then lightly cleansed with a sponge and a little water, and much of the mucus, remains of food, etc., carefully removed. With the back of a knife, or with an ivory paper-knife, the surface was scraped very hard, in order that the glands might be squeezed and their contents pressed out. The viscid mucus thus obtained contains the pure gastric juice with much epithelium from the glands and surface of the mucous membrane. It is to be spread out upon a piece of glass, so as to form a very thin layer, which is to be dried at a temperature of 100° over hot water, or in vacuo over sulphuric acid. Care must be taken that the temperature does not rise much above 100°, because the action of the solvent would be completely destroyed. When dry the mucus is scraped from the glass, powdered in a mortar, and transferred to a well-stoppered bottle. With this powder a good digestive fluid may be made as follows:—

Of the powder	5 grains.
Strong hydrochloric acid	18 drops.
Water	6 ounces.

Macerate it at a temperature of 100° for an hour. The mixture may be filtered easily, and forms a perfectly clear solution very convenient for experiment.

If the powder is to be taken as a medicine, from two to five grains may be given for a dose, a little diluted hydrochloric acid in water being taken at the same time. The pepsin powder may be mixed with the salt at a meal. It is devoid of smell, and has only a slightly salt taste. It undergoes no change if kept perfectly dry, and contains the active principle of the gastric juice almost unaltered.

The method of preparing this pepsin was communicated to Mr. Bullock, of the firm of Messrs. Bullock and Reynolds, 3, Hanover-street, Hanover-square, who at once adopted it for the preparation of medicinal pepsin, and soon improved upon it in some particulars. (a) Gradually the usefulness of this preparation of pepsin of the pig was found out, and it had to be prepared in increasing quantities. I should be afraid to say how many pigs' stomachs have been used of late years during the winter season.

In 1857 Dr. Pavy carefully examined the pepsin prepared and sold by many different firms, and found that this dried mucus of the pig's stomach was the most active of them all (*Medical Times and Gazette*, 1857, vol. i., p. 336). In 1863, Professor Tuson instituted a still more careful comparative examination, and with a similar result (*Lancet*, August 13, 1870); for he found that this preparation was *twenty-five times stronger than some others that he obtained for examination*.

I have purposely abstained from writing about the value of this preparation since the note I first published concerning it in 1856. It has, however, been used largely by many Practitioners ever since, who are thoroughly convinced of its usefulness. I have often given it to patients, who did not know what they were taking, but were quite satisfied of the improvement which resulted; and I have tested its usefulness in many different ways. It is often extremely valuable in treating the diseases of young children, and I believe that persons greatly advanced in age may sometimes be kept alive by it.

(To be continued.)

LIVERPOOL NORTHERN HOSPITAL.—At the annual meeting of the Northern Hospital, Liverpool, an alteration was made in the rules, under which, in future, no candidate will be eligible to serve on the hon. Medical staff unless he shall have been engaged in private practice for three years.

ELISÉ RECLUS.—This eminent scientific scholar, for whom a petition was forwarded from England to the Government at Versailles, has, we are happy to say, had his sentence commuted to banishment from France.

(a) Mr. Bullock supplies genuine pepsin at the rate of 2s. per drachm. The dose is from 2 to 4 or 5 grains. *Test*: 8 grains of this pepsin, with ten drops dilute hydrochloric acid and an ounce of distilled water, dissolve 100 grains of hard-boiled white of egg in from twelve to twenty-four hours. In the body probably twice this quantity of white of egg or even more would be dissolved in a comparatively short space of time. The digestive powder prepared from the pig's stomach retains its activity for any length of time if kept dry. I had some which had been kept in a bottle for upwards of five years, and still retained its active power unimpaired. The solution made with this pepsin and hydrochloric acid was nearly tasteless and inodorous. One pig's stomach, which costs 6d., will yield about forty-five grains of the powder prepared as above described.

ORIGINAL COMMUNICATIONS.

A FEW WORDS IN EXPLANATION OF THE MEANING OF PAIN.

By C. B. RADCLIFFE, M.D., F.R.C.P.,

Physician to the Westminster Hospital, and to the National Hospital for the Paralysed and Epileptic.

ON various occasions during the last dozen years I have had occasion to call attention to the history of pain. I ventured to think that the facts demanded a very different interpretation to that commonly put upon them; and, notwithstanding all that Dr. Chapman has recently urged to the contrary in the pages of this journal (December 23, 1871, and January 20, 1872), I still venture to do so. I see plainly enough that I might have taken my stand more firmly; I see, in what is said, no reason whatever for shifting my ground.

The history of pain in gout, I take it, may well supply the key to the history of pain in all cases; and what this history is, so far as concerns my present purpose, a short quotation from what I have already written will serve to show. "About two o'clock in the morning," says Sydenham, who, from personal experience knew full well what to say, 'the patient is awakened by a severe pain in the great-toe, or, more rarely, in the heel, ankle, or instep. This pain is like that of a dislocation, and yet the parts feel as if cold water was being poured over them. Then follow chills and shiverings and a little fever. The pain, which was at first moderate, becomes intense; and with its intensity the chills and shivers increase.' After tossing about in agony for four or five hours, often till near daybreak, the patient suddenly finds relief, and falls asleep. Before falling asleep the only visible change in the tortured joint is some fulness in the veins. On waking in the morning, the part has become swollen, shining, red, tender in the extreme, and more or less painful; but this painfulness is as nothing when compared to the torture of the night past. It seems, indeed, as if the pain which now exists must be referred to the mere tension and stretching of the inflamed ligaments, for it may be relieved or even removed by judiciously applying support to the toe and to the sole of the foot. On the night following, and not unfrequently for the next three or four nights, the sharp pain in all probability returns, re-appearing and disappearing suddenly, or almost suddenly, and resulting in the discovery of additional inflammatory swelling upon awaking in the morning. The pain in these relapses, like that in the first attack, is accompanied by chills and shivers, and by the most distressing irritability and excitability; but, until unequivocal signs of inflammation are developed in it, the painful part is not tender in the true sense of the word. The inflammation is attended with no fever, or by very little; or if it be otherwise, as it is occasionally, and the inflammation runs higher than usual, *the characteristic pain is less urgent than usual.*"

Here then is pain *before* the establishment of local tenderness, heat, and swelling; and pain of another kind *after* the establishment of local tenderness, heat, and swelling—the former kind violent, neuralgic, paroxysmal, coming and going suddenly without apparent cause; the latter kind, though often severe enough, only accidental, depending solely upon some disturbance of the tender part by pressure, stretching, or the like. Here is pain, which must be regarded as a symptom of the cold stage of the inflammation, going hand in hand with the rigors and shiverings of this stage, and in association with a state of circulation which is more akin to collapse than true fever, and pain which belongs to the stage of reaction in the circulation—in the hot stage of the inflammation, in fact. Nothing can be more different than the belongings of these two kinds of pain; nothing can be more certain than that the paroxysmal pain is not a symptom of the inflammation in the sense in which the accidental pain is a symptom. Accidental pain may be a symptom of the inflammation; paroxysmal pain, on the contrary, instead of being such a symptom, points to a state of vascular contraction rather than to a state of vascular relaxation—a state which may pass on into inflammation, but which, while it lasts, is in every way opposed to inflammation. Instead of being a symptom of inflammation, indeed, it would even seem that paroxysmal pain is antagonised by inflammation.

And this, as it seems to me, is the history of all pain, not even excepting that which is connected with inflammation of the brain, or spinal cord, or sensory nerves. In all cases, as

it seems to me, true paroxysmal pain—the pain which is other than accidental—is connected with a state of circulation which is more akin to collapse than to vascular reaction; and the only conclusion which I can draw from the facts is, that this pain, instead of being a symptom of inflammation, is a proof that such inflammation is not yet established, and a reason for supposing that the remedial measures needed are those which are calculated, not to check, but to promote, reaction in the circulation.

Dr. Chapman, however, is not disposed to accept this view. He will have it that pain "other than accidental" is the symptom of symptoms of inflammation of the great nerve-centres. He will have it, also, that there must be a state of vital excitement of the vaso-motor centres in the cold stage of inflammation in any case, and that in order to the existence of this state of excitement there must be a surplus of blood in these centres—a surplus which, of course, is by no means incompatible with the opposite state of things in the superficial vessels of the body. And he appeals to his experience with his ice-bags as being contradictory to my notions. But really I cannot see the force of these objections.

Dr. Chapman asserts that all other writers are against me as to the symptomatology of inflammation of the great nerve-centres, in that pain is always given by them as the most prominent symptom of such inflammation. I can only answer that the facts, so far as I myself have been able to observe them, are as I have stated them to be—that *pain is by no means the prominent symptom which it is believed to be in these affections*; that true paroxysmal pain, when it is present, is in the cold stage prior to the establishment of the inflammation; that such pain disappears on this establishment; that, in short, true paroxysmal pain, instead of being a symptom of these inflammations, is rather a symptom of those affections of the nerve-centres which are non-inflammatory in their nature. It is simply a mistake, so far as my experience goes, to suppose that violent paroxysmal pain, any more than spasm, is a symptom of symptoms in inflammation of the membranes of the spinal cord, for example; the simple fact being that such pain, when it is present, is obviously in the cold stage of the disorder, and that any other pain which may be present afterwards is as obviously only accidental, in that it is absent if the movement of the back which gives rise to it be avoided. Can Dr. Chapman, from his own experience, contradict what I have myself observed in these matters? And for the rest, I will only state my belief that the question at issue has been prejudged by all in assuming that pain, like spasm, is a symptom of inflammation or of a condition akin to inflammation, and that much confusion would have been avoided if many writers on systematic Medicine had been less content to copy their predecessors, and if their predecessors had observed for themselves rather than copied the notes taken by young and inexperienced clinical clerks, who have not always been careful to discriminate between the symptoms proper to the cold stage of inflammation and those proper to the hot stage.

Nor can I agree with Dr. Chapman in thinking that there must be a hyperemic condition of the vaso-motor nerve-centres to account for the contraction of the vessels present in the cold stage of inflammation. I can find a different explanation (not quite that which Dr. Chapman gives for me) for this contraction in electro-physiology, but not one short enough to be introduced here. But the main question is not as to the condition of the vaso-motor centres during pain: it is as to the condition of those centres which take cognizance of pain. Are these more bloodshot than they should be? Is paroxysmal pain accompanied by any signs indicating "determination of blood" to the head? Quite the contrary, say I; and what I have said remains unanswered, so far as I know. Moreover, I may add here, as an argument to the same effect, that in several cases in which I have looked into the matter with the ophthalmoscope, the deep arteries of the retina seem smaller, and the deep veins larger, during a bout of violent neuralgia than they are found to be after the paroxysm is at an end.

And as to the ice-bags there surely need be no great difficulty. No doubt pain in the spine may in some cases be relieved by this means. But what of this? May it not be sometimes that the cold relieves the pain by "driving the blood inwards," rather than by lessening the blood in the spine? May it not be sometimes that the pain is relieved by the cold benumbing certain afferent nerves? And what of those cases—not a few—in which the ice-bag cannot be borne with, because severe paroxysmal pain is set up by it?

The case, no doubt, is somewhat complicated. The subject, indeed, is more than sufficient, not only for a short article like

the present, but for many long chapters; and, therefore, my best course is to come to a stop at once, and refer for the rest to what I have written elsewhere, more especially in a book having the title of "Dynamics of Nerve and Muscle," and to the article on Diseases of the Spinal Cord in Dr. Reynolds's "System of Medicine."

NOTES

ON THE PATHOLOGY OF MALIGNANT NEW GROWTHS.

By HENRY ARNOTT, F.R.C.S.,

Assistant-Surgeon to St. Thomas's Hospital, and Joint Lecturer on Morbid Anatomy in the School.

V.

SARCOMA.—(Continued.)

Round- and Oval-cell Sarcoma—Small Round-cell Sarcoma—Myeloid Sarcoma.

Round- and Oval-cell Sarcoma.—Besides the spindle-cell growth which constitutes the bulk of most of the sarcomata, certain of these tumours are made up of cells of a still lower type—embryonic cells—consisting merely of little lumps of nucleated protoplasm, which, held together by a nearly fluid connecting-material, show but little tendency to assume an elongated form by regular pressure on the sides, but remain as soft, spherical or ovoid cells, like those met with in granulations, although occasionally considerably larger; hence the name "granulation tumour," which has been suggested for this form of growth. Tumours possessing this structure are generally very soft, and from their consistence and general appearance, as well as from their microscopic characters, are more liable than any other form of neoplasm to be mistaken for medullary carcinoma. These tumours are very vascular, the vessels being usually simple channels through the cell-tissue, with walls formed by the same cells; and hence the very frequent rupture of the vessels, and escape of blood into the substance of the tumour—sometimes to such an extent as to give rise to a large "blood-cyst," which by its size may mask the real nature of its origin. The cells themselves are also very fragile, so that it is unusual to prepare either a scraping or a section of one of these growths without allowing a large number of free nuclei to escape. Seen in section, it is often even more difficult to recognise the precise form of the cells than in the fusiform variety. The usual appearance is that of an amorphous or granular substance in which large or small round or oval nuclei, with bright nucleoli, are embedded. At the edges of the section the rounded outline of the soft cells may be recognised, and in little detached bits of the section their shape becomes yet more distinct. The size and shape of such detached cells (see Fig. 14) suggest at once the occasional difficulty in distinguishing these tumours from carcinoma.

FIG. 14.

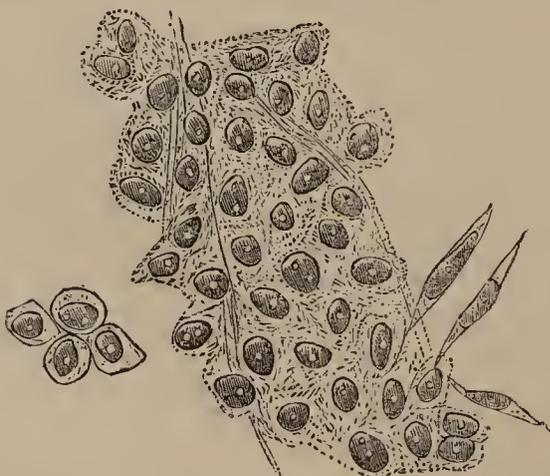

FIG. 14.—Section of large oval-cell sarcoma, with detached cells resembling those of carcinoma. Magnified 220 times.

The cells are, indeed, somewhat plumper and less like epithelial elements than are the ordinary cells of carcinoma, and there is usually some amount of visible intercellular substance; but where the stroma is fibrillated—as is sometimes the case—and fibrillated in such a way as to suggest a meshwork like the alveolar stroma of carcinoma, the distinction between the two is one of the most delicate points of pathology. Billroth has suggested the name "alveolar sarcoma" for this latter form. It is, fortunately, rarely encountered, and its accurate distinc-

tion is a matter of pathological interest rather than of clinical importance, for about its grave malignancy there can be no doubt. I have seen a patient dying with upwards of a hundred of such tumours scattered through her body, chiefly in the subcutaneous cellular tissue, but also affecting lymphatic glands, breast, and kidney. In this case most of the growths contained more or less of black pigment, the pigment granules lying in large round cells, and in sufficient quantity to render most of the growths distinctly melanotic.

The more usual form of round-cell sarcoma is made up of much smaller cells than those just described, cells closely resembling leucocytes or the first cells of a granulation; and since these minute cells are mostly about the size of blood- or lymph-corpuseles, the distinction between this form of growth and lymphoma (to be presently noticed) is sometimes as difficult to draw as is the distinction between the larger oval-cell sarcoma and medullary carcinoma. This small round-cell tumour differs from true lymphoma mainly in lacking the fine reticulated stroma of the latter neoplasm. The cells or corpuseles are separated by a variable amount of semi-fluid granular substance; but occasionally an appearance as of fine fibrille branching amongst the cells is met with, and when this is the case the growth is to be distinguished from lymphoma by the absence of minute nuclei in the angles of the network, to be hereafter described as characteristic of that structure. Round-cell sarcoma is a distinctly infiltrating growth, as may be seen in the subjoined sketch (Fig. 15), taken from a thin

FIG. 15.

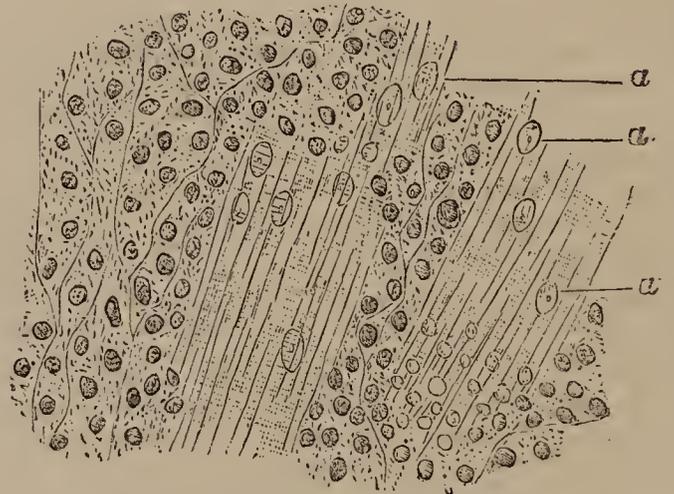

FIG. 15.—Small round-cell sarcoma infiltrating muscle; *a a a*, nuclei of the striped muscle-fibres. Magnified 220 times.

section of one of these tumours springing from the fibula and blending with the muscles of the calf. Remains of striped muscle-fibres broken up and invaded by the new growth sufficiently attest its destructive character, and show that the muscle is not merely wasted by the pressure of the increasing mass in its neighbourhood.

The structure of this tumour closely resembles what is to be met with in the vicinity of nearly all active new growths. As these advance, they send before them, so to say, "feelers" of this "indifferent granulation material," which stretch out into the surrounding structures, and form the first histological indication of the march of the morbid change. Reference has been made to this tissue in the description of the early stages of carcinoma. The peculiarity about the growth now occupying our attention is, that the whole bulk of the possibly enormous mass is made up of the same simple small corpuscular structure. To establish this fact it is of course necessary to take a scraping or section from three or four different parts of the tumour under examination. Such an investigation may show the prevailing type of cell to be of another kind, these small round corpuseles merely spreading about the margins of the growth; and so the tumour may receive a different name, and perchance a corresponding difference may be required in the prognosis of the case.

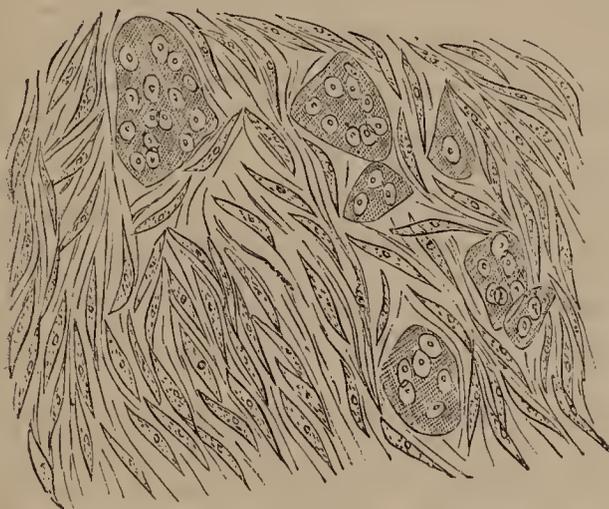

These round- and oval-cell sarcomas are usually very soft, white— or variously mottled by the results of blood-extravasations—blending intimately with the structures amongst which they lie, and readily exuding a creamy juice filled with the cells and escaped nuclei of the tumour. They are far more apt to infect lymphatic glands than are the spindle-cell varieties, and, as a general rule, are also far more rapid in their destructive course.

MYELOID SARCOMA is a form of the spindle-cell variety in which a distinctive feature is given to the growth by the

presence, in considerable number, of the large plate-like masses of nucleated protoplasm normal in the foetal marrow of bones. But it must be borne in mind that these singular cell-masses are met with under many different circumstances besides the tumours springing from the medullary cavities of bones. It is probable that few spindle-cell sarcomas from any part of the body could be thoroughly examined, bit by bit, without some "myeloid" cells being encountered; and Dr. Payne has described the occurrence of similar cells in certain early stages of lymphatic gland enlargement. But in certain sarcomatous tumours springing from bone, and especially from the medullary cavity of the bone, these cells occur in such number as to offer a convenient characteristic by which to classify the growths exhibiting them.

These myeloid growths are usually much firmer than the other varieties of sarcoma, approaching more nearly to the density of fibromas; their cut surface has a smooth, fleshy look, unlike the fasciculated appearance of the firmer spindle-cell varieties, and they yield a scanty juice to the knife scraping them. They are very commonly met with springing from the periosteum of the jaw (where they are usually styled fibrous epulis) and about the ends of the long bones, but they may be met with in other situations. They are probably less malignant than many forms of sarcoma, but they are very apt to recur after apparently careful removal, and secondary growths have been occasionally met with in the lymphatic glands, lungs, etc.

FIG. 16.

Myeloid sarcoma from an epulis. Magnified 220 times.

Microscopically the diagnosis of this form of sarcoma is sufficiently simple. Embedded in a tissue made up of small oat-shaped cells (with which small round and oval cells may be mixed) are large pale irregular cells (Fig. 16) containing small bright oval nuclei with nucleoli. These last cells have the appearance of flat plates rather than spherical or ovoid masses of protoplasm, and vary in size from a tiny cell containing a single nucleus, to a very large mass holding a score or more of similar nuclei.

(To be continued.)

CLINICAL REMARKS ON THE SEVERAL FORMS OF PULMONARY PHTHISIS.

By R. DOUGLAS POWELL, M.D., M.R.C.P.,

Senior Assistant-Physician to the Hospital for Consumption and Diseases of the Chest, Brompton;
Assistant-Physician to the Charing-cross Hospital.

(Continued from page 704, vol. ii., 1871.)

Fibroid Phthisis, its characteristic signs and pathology summarised; reasons for selection of term as most applicable—A disease secondary to some parenchymatous affection of the lung, doubtful if pleurisy or bronchitis alone will give rise to it—Relations to other forms of phthisis—Example related—Summary—Remarks on diagnosis, prognosis, and treatment.

CERTAIN forms of pulmonary phthisis of various origins are attended by such an amount of interstitial fibrous growth as to give them clinical features of a very peculiar type.

The prominent symptoms and signs by which such cases are distinguished—increasing contraction and immobility of the side, dragging pains, traction of organs to that side, deadened

percussion-note, and weakened respiration of more or less bronchial quality (intensely so, or cavernous, at parts), breathlessness, paroxysmal cough, occasional hectic, but general absence of fever, very chronic progress, long-continued one-sidedness of the disease, and correspondingly slow failure of nutrition—show them to come within the definition of phthisis, but phthisis of a special kind.

The conditions presented to us, post-mortem, of a contracted, toughened, indurated, and usually pigmented lung, surrounded by a greatly thickened adherent pleura, containing one or more rigid, dense-walled cavities, dilated bronchi, and cheesy encapsuled nodules, are confirmatory of this view. On minute examination, we further discover this condition of lung to have been produced by a growth of two kinds pervading it. 1. Connective tissue proliferation, resulting in the formation of bands and processes of fibrous tissue, derived from the sheaths of vessels and bronchi, and the sub-pleural and interlobular tissue of the lung. 2. A more important nuclear growth leading to the formation of broad tracts of fibroid tissue, thickening the walls of the alveoli, compressing, and finally effacing them, unless they shall have been previously stuffed with their own catarrhal products; this fibroid structure being very possibly derived from the lymphatic elements normally pervading the lung.

The products of these two processes become intimately mingled, but it is the latter which is the phthisical element in the disease, for mere connective tissue growth does not lead to organic destruction of the lung. This is also the element which specially gives to the disease its peculiar clinical features, and renders the name "fibroid phthisis" applicable to it.

The term "fibroid phthisis" has been productive of much discussion. Originally introduced by Dr. Andrew Clark as "embracing all those cases, whether local or constitutional, which are anatomically characterised by the presence, in a contracted and indurated lung traversed by more or less dilated bronchi, of fibroid tissue, and of tough fibrogenous substance, together with cheesy deposits or consolidations, and usually small cavities, commonly found about the middle and lower parts of the affected organ"^(a)—it has been objected to as signifying too definitely the existence of the disease as a substantive or idiopathic one. Dr. Clark is, however, convinced that it may, and often does, appear as a primary affection, in which view he differs from most contemporary authorities. Still, the term is such a neat, concise, and clinically useful one, that it has been very generally accepted with the above reservation. Dr. Clark argues, with much force, that these cases are indisputably cases of phthisis, while all their special characters are due to the pervasion of the affected lung by a contractile fibroid and fibrogenous tissue. These two facts cannot, I think, be controverted; and when it is further urged, as I think it may truthfully be, that this fibroid tissue is indistinguishable in situation and development from chronic tubercle, a very fair case may be made out for the preservation of the term "fibroid phthisis," though its distinguished author would, I fear, not admit this latter argument. I ventured, in a paper read before the Clinical Society in October, 1868 (*vide Clinical Transactions*, vol. ii., p. 193), to question whether this term was advisable, since the pure constitutional disease was of such rare and doubtful occurrence. Later reflection and the observation of a good many cases have, however, led me to think that this objection, though by no means weakened (see article by Dr. Fox, *loc. cit.*, p. 772), is not sufficient to render the term clinically inapplicable, since "fibroid" only corresponds with other adjective terms—"catarrhal," "tubercular," etc.—in describing the predominant character of the variety of phthisis thus distinguished; for in all cases of chronic phthisis the morbid processes are more or less of mixed character. Dr. Wilson Fox, in his exhaustive article on "Chronic Pneumonia" in Reynolds's "System of Medicine," vol. iii., includes under that term all cases of pulmonary fibrosis uncomplicated by tubercle; his chronic pneumonia would therefore agree with Dr. Clark's fibroid phthisis, except that he does not admit the disease as a primary or constitutional one. On the contrary, he contends that it is always associated with (and dependent upon) catarrhal pneumonia; hence his adoption of the term "chronic pneumonia." Dr. Fox, though thus characterising the typical disease as essentially one of pneumonia affecting the lobules of the lung, not the connective-tissue which binds them together, acknowledges that freedom from tubercle is very exceptional. Dr. Bastian would include all these diseases under the old term "cirrhosis of the lung." Cases

(a) *Clinical Transactions*, vol. i. p. 188.

to which the term "cirrhosis" is strictly applicable, in which there is no catarrhal pneumonia or tubercle, nor any true organic destruction of the lung are, however, so rare as to render the name a misleading one.

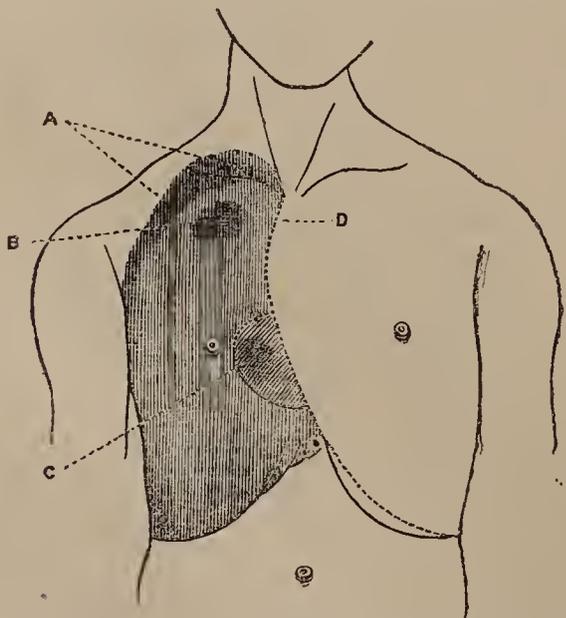

This disease, then—fibroid phthisis—is in the great majority of instances, so far as my own experience informs me, of a truly secondary nature, supervening upon some more or less acute inflammatory affection of the lung, whether simple, basic, or broncho-, or catarrhal, or tubercular pneumonia. It is very doubtful whether pleurisy or bronchitis alone can give rise to it without the intervention of lobular pneumonia or tubercle. Local injury or pulmonary abscess may form the starting-point of the disease, but are not alone sufficient to cause any extensive fibroid invasion of the lung beyond their own immediate limits. (b)

Numerous examples may be found of this somewhat inclusive disease, ranging from the most typical cases to those which are indistinguishable from ordinary chronic phthisis. In the third paper of this series is described a case of catarrhal-pneumonic phthisis, in which the transition into one of fibroid phthisis or pulmonary fibrosis is traced. It would not be difficult to find examples in which the reverse takes place, the clinical characters of fibroid phthisis being gradually changed by subsequent pneumonic processes, and all the features of the special variety becoming merged in the diffuse pulmonary destruction.

Cases of fibroid phthisis may be roughly divided for convenience of clinical exposition into three varieties:—1. Those in which the disease has its starting-point at the apex of the lung, and is proceeding downwards. 2. Those in which it commences at the base, and advances upwards. 3. Those in which the most marked signs are discoverable about the middle of the lung. Of the first variety the following case is a fair example:—

George P., a sawyer, aged 43, came first under my notice as an out-patient at the Brompton Hospital in August, 1868. He was a thin man, with dark hair, having no hereditary predisposition to lung disease, except that his father had suffered from "asthma." In the preceding January, having suffered from slight cough for years, he was laid up for six weeks with "inflammation of the right lung." Since that time the cough had been continuous, and three months ago had been attended with slight hæmoptysis. The cough was now paroxysmal, causing retching and often rejection of food; expectoration difficult, abundant, and of a pink tinge. He had got thinner lately. The digestive functions were fairly good; the pulse a little hurried; no fever.

On inspecting the chest, cardiac pulsation was visible at the fourth right interspace, c, to left of right nipple. This side was diminished in size and much restricted in movement, the intercostals deepening with inspiration; while the left side expanded freely, with an uplifting movement of the shoulder. On careful examination, the apex of the heart was found a little to the left of the ensiform cartilage. On percussion, the left side in nipple-line anteriorly was dull to the second rib, comparatively resonant to the fourth, and below this point again toneless. To the left of the line of sterno-clavicular

articulation, at the level of the second and third cartilages, there was good resonance continuous across median line with

(b) Vide first paper of present series, June 10, 1871.

that of opposite side. The line of this resonance, D, sloped upwards to the episternal notch, being displaced in a downward direction by cardiac dullness at the fourth cartilage. Hepatic dullness barely reached the costal margin. There was dullness throughout the axillary region and posteriorly from apex to mid-scapula, the note having a tubular quality in this latter region. Below mid-scapula there was fair resonance to the ninth rib, though less and harder than on opposite side; the lower two or three inches on the right side gave a flat note on percussion.

The percussion-note over the whole left side, including the region of normal cardiac dullness and extending across the median line, as above indicated, was full and good in front and behind.

The auscultatory signs were in agreement with those of percussion. Above the clavicle the respiration was amphoric, dry; below the clavicle weak and bronchial to the base, with some rather large, moist rhonchus, friction, and bronchophony. At one spot corresponding with the second and third ribs nipple-line, B, the breath-sound was of tracheal quality, with scanty cavernous clicks and pectoriloquy. In the upper axillary region the respiration was amphoric, and the voice-sound pectoriloquous; in the supra-spinous fossa and interscapular regions, cavernous blowing, with pectoriloquy. Blowing respiration extended to the angle of the scapula, where it became weaker, and gradually annulled at the base. The vocal fremitus was generally increased on the right side. Respiration throughout left lung exaggerated, vesicular.

February 27, 1869.—Patient has improved in flesh and appearance; stronger than before, but complains much of cough, and expectorates much pink phlegm. Breath short on exertion; cough causes retching, but does not bring up food now; appetite fair; digestion not very strong; bowels regular. Continues medicine (oil with nitro-muriatic acid and cinchona). Fingers noted (February 13) to be clubbed. The additional physical signs noted at this date were, a distinct short systolic bruit at the point of maximum cardiac impulse, not appreciably increased by pressure nor confined to that spot, being also audible at the apex. Measurements of chest: From mid-sternum to nipple, right side, 4 inches; semi-circumference, $15\frac{1}{4}$ inches; expansion, $\frac{1}{4}$ inch. Left sterno-nipple-measurement, $4\frac{1}{4}$ inches; semi-circumference, 16 inches; expansion, $\frac{1}{2}$ inch.

We may, by way of summary, aided by a glance at the above-figure (reduced as accurately as possible from a sketch taken at the time upon an outline diagram used by Dr. Sanderson), interpret the above detailed physical signs as indicating general induration of the right lung, with much contraction, its anterior margin having receded considerably from the median line, exposing the pericardium, and also shrinking away from the upper surface of the liver. Its upper and a portion of its lower lobes are extensively excavated, the cavities being old, tolerably dry, and shrunken with the general contraction of the lung. The pleura (from the hardness of percussion, feebleness of breath-sound, and great fixity of walls) is probably greatly thickened. The liver is drawn up within the costal margin, and the heart considerably displaced to the right, its axis being, however, but little altered. At a later examination a murmur is heard over the heart.

Subsequently to the last note I repeatedly examined his chest during the many months of his attendance at the Hospital, but beyond some variation in the dryness of the sounds there was no important change in the physical signs. I fancy I examined the urine more than once, but the only note I have of it was taken in April, 1869, when it was acid, became slightly turbid on boiling, but cleared on adding a drop of nitric acid. The left lung remained healthy, and, though the patient continued thin and cachectic-looking, with a troublesome cough, he held his ground fairly well, and rather improved in general health. At times the expectoration would become very abundant, and occasionally of a pink colour (I thought due to fresh irritation and slight sanguineous discharge from the walls of the old cavity). The most troublesome symptom throughout the case—and one which is common in greater or less degree to all those cases of phthisis in which indurated thick-walled cavities are present—was the paroxysmal cough terminating in vomiting, occurring especially after meals. No doubt the mechanical conditions of such a cavity, rendering the removal of expectoration very difficult, have much to do with the production of vomiting, and render it a particularly common symptom in these cases; but the reception of food into the stomach has seemed to me to be in many cases so constantly followed by cough, ending in vomiting, as to render this mechanical explanation insufficient, and in 1869

I was led to attribute it to an undue reflex irritability of the pneumogastric nerve, (c) and proposed strychnia as the best remedy. I have since, in many cases, found this remedy valuable, but by no means invariably so.

On leaving off attendance at the Hospital in May, 1869, the patient continued for a time to improve, though not free from cough; but he soon afterwards began again to emaciate, and the vomiting with cough returned. He again attended in January, 1870, resumed the oil, and used carbolic acid inhalations, and left March 30, improved. Since this time I have heard nothing of him.

The above-related case represents very well the main features of fibroid disease of the lung. The indurative disease supervened presumably upon an acute apex (tubercular or catarrhal) pneumonia, and did so with tolerable rapidity, the characteristic symptoms and signs being fully developed within six months of the termination of the acute disease. The question as to the rapidity with which this disease may advance is one of great interest, and requiring further observation. I cannot but think that, reasoning from the morbid appearances found post-mortem, we are apt to regard such diseases as older than the clinical history will warrant us in believing; on the other hand, though it is very probable that the fibroid induration of the lung may proceed with great rapidity to such a stage of shrinking as to produce very marked clinical signs, its subsequent progress is very slow and difficult to measure, consisting mainly in the further hardening of an already indurated lung, the gradual widening of the bronchial tubes, and filling up of the loose oedematous areolar tissue between the separated pleural layers by dense fibrous growth.

There are a few points for consideration in the *diagnosis* of the above case.

That it is not simply a case of contracted cavity is evident from the contraction of the side being general, from the heart being displaced laterally, not specially drawn up towards the right apex, from the weakness of breath-sound, and dulness at the base, with raising of the liver. The presence of considerable excavation at the apex would be in favour of the disease having commenced there as an apex (phthisical) pneumonia, and not being secondary to basic pleuro-pneumonia or empyæma. It would also negative its being a case of simple cirrhosis of the lung. The resonance of the opposite lung extending across the median line would emphatically exclude cancer, which the history of the case, and many other signs, particularly the kind of cardiac displacement, would also negative. While in certain cases of mediastinal cancer the heart is fixed in about its normal position, it is, I believe, never displaced towards the side most affected. In regarding the signs of cardiac displacement, however, it is important to avoid taking the point of maximal impulse as necessarily the apex-beat. In this case the real displacement of the heart is much less than a first glance would lead us to believe. The absence, while the patient was under observation, of any evidence of complication of other organs would be in favour of the disease being of local origin.

In calculating the *prognosis* in these cases, we have to bear several things in mind—the cachexia of the patient, the size and freedom of communication with external air of any cavities present, and the evidence of disease of other organs, especially of the opposite lung. The cachexia is occasionally very manifest; without very marked emaciation the anæmia is apt to become great, and the complexion of a straw-tint, reminding one of that seen in certain cases of cancer or in women suffering from uterine disease. A cavity of considerable size, and freely communicating with outer air, is a more hazardous condition for the patient than one which is small, or which we may presume to have become flattened and partially or completely closed. In the former condition the patient is constantly liable, on exposure to cold, etc., to recurrence of irritation and fresh ulceration of the cavity-wall, causing profuse secretion and hectic, as in the present case, or laying bare vessels which may at any time rupture and cause death from hæmoptysis. (d) When the opposite lung is affected, it is most generally by grey tubercle, and it in most cases becomes so sooner or later, unless the patient be cut off too soon by some intercurrent affection. We must, however, not give a too hastily fatal prognosis from mere physical signs in such cases,

(c) *Practitioner*, vol. i., p. 312. Dr. Hughes Bennett (Reynolds's "System," vol. iii., art. "Phthisis," 1871) regards this as a cause of vomiting in the later stages of phthisis.

(d) Out of eight well-marked cases of which I have made post-mortem examinations, this has been the cause of death in two. For an account of one of these, Downer, *vide Clinical Transactions*, *loc. cit.*, p. 181; the other is referred to in a Table on Hæmoptysis, *Pathological Transactions*, vol. xxii., p. 53, Case 1, F. W.

for the course of the tubercle is disposed to be very chronic and indurative, and the signs may again subside and long remain in abeyance. But when attended with decided elevation of temperature, the prognosis is most grave, for pulmonary tuberculosis is perhaps the most common cause of death in these cases. Dr. Clark regards albuminoid degeneration of other organs—the liver and kidneys—as commonly supervening in the later stages of this disease. Of the three purest cases of which I have made post-mortem examinations, in which there was no obvious grey tubercle in the other lung (though islets of peribronchial induration were present in all), in one there was extensive albuminoid degeneration of liver and spleen, with granular kidneys; in another of the spleen only, with ulcerated intestines. Albumen in the urine, absent in the present case, affords us the earliest clinical evidence of this degeneration. Though the prognosis is always, in cases of fibroid phthisis, a precarious one, from the circumstances above mentioned, yet the course of the disease may be very long, and may, with due precautions, in some instances be almost indefinitely extended. The condition of health and *physique* maintained by some patients is remarkably good. In this respect the example above related is an unfortunate one; I have notes, however, of a postman presenting exceedingly well-marked signs of this form of phthisis, who almost entirely lost his cough while attending the Hospital, and was able to resume his duties, walking fourteen or fifteen miles a day; and I might mention two or three other patients capable of considerable physical exertion on level ground.

The management of this variety of phthisis is not very peculiar; the prevention of fresh catarrhs by judicious clothing, the selection of climate when practicable, the avoidance of night-air, and protection from irritating fogs or cold or damp winds by respirators, are, with a nutritious but not stimulating diet, the hygienic measures to be adopted. Iodine frictions, soothing or antiseptic inhalations (carbolic acid being particularly useful when there is any fetor of expectoration), seem the best local remedies; while the general condition, including that of digestion, the nature of the cough, and profuseness of expectoration, supplies us with indications for the administration of appropriate drugs—iron, cod-oil, strychnia, alkalies, tonics, etc.—or the abstention from all medicines.

The very full consideration of the above example of fibroid phthisis, and of the general bearings of the disease, renders it perhaps unnecessary for me, even if space would permit, to enter further into those variations in the signs of this form of phthisis which depend upon its seat of origin.

(To be continued.)

A MODE OF PROMOTING CONSTANTLY THE DEVELOPMENT OF COW-POCKS UPON HUMAN SUBJECTS, BY MEANS OF ANIMAL VACCINE LYMPH.

By Dr. BEZETH,

Member of the Society of Vaccination, and Director of the Animal
Vaccine Department at Rotterdam.

(Communicated, at Dr. Bezeth's request, by Dr. SEATON.)

THE well-known, sufficiently expounded difficulty with regard to inoculation of humanised Jennerian vaccine lymph is the profound dislike of a great many people against its application, and not only against its inoculation, but equally so against the taking of lymph for further supply, however constantly eruptive humanised vaccine lymph may be. (a)

Further, the well-known grievance of vaccinators against inoculation of animal lymph in human subjects—which, however, is tolerated with much less dislike by the public—is the inconstancy of eruption of cow-pocks, not only with regard to entire failures, but also to the number of pustules. This inconstancy has been observed till now chiefly in using preserved animal lymph, though immediate vaccination from calf to human individuals has also in this respect been not quite satisfactory. For the confirmation of this point may be consulted the last annual reports (1870) from Rotterdam and Amsterdam. (b) The same inconstancy is noted in the last communica-

(a) *Vide* Marson's standard in "Handbook of Vaccination," p. 160. By Dr. E. C. Seaton. London. 1868.

(b) *Nederlandsch Tydschrift voor Geneeskunde* 1871, 1ste Afdeel, page 25, 155, and 582—Conf. Report by Dr. Seaton on so-called Animal Vaccination in France, Belgium and Holland, in Twelfth Report of the Medical Officer of the Privy Council, p. 171. London. 1870.

tions from other countries by impartial reporters, such as Delpech(e) in France. Dr. Seaton, in England (Twelfth Report, etc., *loc. cit.*, p. 189), writes—"Still, I am bound to say I do not in the least think it likely, putting all the facts together, that with any amount of experience or pains the virus will take nearly so kindly when transferred from the animal to human subject as when transferred from one human subject to another."

Consequently, it remains our permanent aim to promote the development of cow-pocks upon human individuals in a constant way; and this by means of animal vaccine lymph, as well as by humanised lymph, because we continue to think it recommendable that the inoculation of animal lymph should maintain itself on even terms next to vaccination of humanised lymph, and this especially in countries like Holland, where vaccination is not compulsory by general law.

We continue to think it recommendable, too, with regard to the quintessence of all vaccination in human subjects—viz., precaution against small-pox. To the question whether inoculated animal vaccine lymph is in this respect as trustworthy as humanised virus, we may answer with the following facts:—1. That in the Register for 1870 of our Society of Jennerian and Animal Vaccination, fourteen observations, purposely made as experiments, are stated, on children who were vaccinated from arm to arm, without notable result, after having been inoculated successfully from the calf a few weeks before. This proves, at least, that such animal lymph secures against the effect of vaccine virus itself. 2. During and after the late violent epidemic of small-pox at Rotterdam—1870 and 1871—no case has offered itself, or was made known to us, of small-pox in persons who, in sufficient time before the incubation of small-pox, had been vaccinated successfully from our calves.

Strengthened in our confidence by these facts, we, in the experimenting way, got acquainted with a mode of operating which proves itself most favourable to the desired purpose—viz., the acquiring by means of animal vaccine lymph of a (in every respect) constant and abundant eruption of cow-pocks upon not vaccinated human subjects. Properly speaking, we ought to denominate it a renewed but modified mode of operating, because, long since, Negri, at Naples, followed nearly the same way, by taking the vaccine lymph on his lancet out of the tissue itself of the inoculated animal vesicles.(d) This mode procures efficacious vaccine virus, not only more constantly, but at an earlier period of the evolution of the animal eruption. According to Lanoix's statement, forty-eight hours only after the vaccination of the heifer, Negri applied successfully upon human subjects the lymph drawn out of the growing pock itself. We, too, may assert that by a similar manner we have obtained well-developed cow-pocks upon several children, with animal vaccine lymph taken out of the tissue of the pocks three days after the favourable inoculation of the calf. The lymph we then used had even been preserved between glasses.

However, we do not snip away the pustule, and then hold it between the fingers to scrape strongly the hindermost surface, as is done roughly by Negri,(e) but we make the pock rise up a little by a pair of draw-forceps, compressing its base till it opens on the outside of the cutis and gives issue to a minim of lymph. In this respect we still follow Lanoix, Depaul, Warlomont, Pissin. But our present method is to introduce a lancet into the tissue of the pock through the opening thus made in the cutis, and to draw out repeatedly the contents of the pustule itself on the lancet; after which we vaccinate with it immediately on the arms, or strike it off on a bit of glass for stored lymph or for mediate application. Points (Coely,(f) Warlomont) may also be charged more actively in this way.

Formerly—like our French, Belgian, and Prussian predecessors—we practised with the "flow" of less certain lymph, which is driven out to the ruptured surface by the effect of the squeezing pair of forceps. We also formerly placed the glasses or points on or within this mixed fluid. Further, in order to fill entirely our usual bulbed capillary tubes, we formerly compressed rather more the environs of the pock, and thereby squeezed out the required (but then so much less certain) lymph, as more was drawn out of the circumference of the pustule. "It is quite evident, however, that the lymph cannot, in such cases, be obtained pure and unmixed with other animal products; and this is probably one reason of the un-

success which attends vaccination with this lymph, and of the difficulty of preserving it."(g)

The fact that our former usual method produced vaccine lymph of inconstant action, may further be explained by the circumstance that the contents itself of the animal vesicle are not easily inclined to come forth. It is certain that by only puncturing the pock—as in human Jennerian pocks at the eighth day—generally very little is obtained, especially on the fourth, fifth, and often even on the sixth day of evolution of the eruption on the calf—viz., the period in which the animal lymph usually is taken for use. It is on account of the difficult evacuation of these pocks that the employment of forceps has been adopted—after Negri—by our predecessors (Depaul, Lanoix); but this instrument presses much more lymph out of the surrounding tissues than may be desirable for the vaccination to be constantly successful.

According to our new mode of operating, it is not quite possible to fill capillary tubes entirely and exactly at the proper period—usually five days after the vaccination of the calf—without taking up ineffective lymph out of the circumference of the pock. Here, indeed, the often-described method of Dr. Müller, at Berlin, may be followed,(h)—viz., to strike off on a glass the contents of several vesicles (animal, in our mode), and to mix accurately the gathered vaccine lymph with some pure glycerine and pure water, after which the absorption in capillary tubes for stored virus is easily performed. Their application procures us the most excellent results, and well next to the immediate vaccination from calf to human subjects and calves. It was a pleasant observation for the vaccinator to see how not only the usual punctures did develop cow-pocks, but even the wounds accidentally added by the same lancet; so that eighteen to twenty pustules upon both arms of several children are registered, and will be enumerated in our following annual report.

After all, indeed, it may be accepted without difficulty, that lymph from the calf drawn out of the pock itself at the proper period, must be the proper vaccine virus for inoculation; in other words, that such lymph must contain the proper virulent vaccine corpuscles—Beale(i)—not too much rarefied by other inactive matters (Chauveau). We have, moreover, observed many a time that with our mode of acting it is not necessary that the animal pustules have quite exquisitely succeeded in evolution to give still a good result on human subjects and calves.

It ought to be said that our new simple mode of operating is applied on calves without any observable painful or bloody injury, or other bad consequences. Generally, only a small brownish spot is found the following day, in lieu of the pock itself. But it is requisite that the animals, some months old, be firmly fastened during the operations.

We have still to add, that by means of our corrected manner, the evolution of a great number of cow-pocks upon our calves—females and males—is now regularly successful by inoculation on the shaven abdominal region, if the animal be healthy,(k) well provided for, properly fed, and vaccinated according to the rules of experience—to calf from calf, or out of capillary tubes which had been well sealed and wholly filled either with genuine animal or with humanised vaccine lymph (retro-vaccination).

Let it be remembered that the retrovaccination, or "the inoculation upon heifers with vaccine virus derived from the human subject, and the use of pocks thus produced for human vaccinations," was already systematically practised in the beginning of this century—shortly after the Jennerian arm-to-arm vaccination—by Dr. Galbiati, at Naples.(l) On the other hand, the propagation of natural, genuine cow-pocks by successive inoculations upon the heifer, and from this upon the human individuals, was effectively and regularly executed by Professor Depaul at Paris, in 1866.(m) During the last six months our Society not only pursues, as usual, the practice of arm-to-arm vaccination, and of vaccination from animal to human subjects, by means of Depaul's genuine regenerated vaccine lymph, but we maintain also the retrovaccination entirely separate, and this certainly not with the less success upon heifers and human subjects.

It may be regarded as indifferent, whether human indi-

viduals—to secure them against small-pox—be vaccinated either by humanised vaccine lymph, or by genuine regenerated lymph of cow-pocks, or by retrovaccinated vaccine virus, if only, according to the disposition of the human constitution, it contributes to develop a constant and well-looking eruption of cow-pocks. We say *contributes* to develop, because the virus of cow-pocks alone, even the most virulent, is not able to do so, as may be observed by everyday's experience. For this aim a *pyrogene(n)* and *phlogogene* alliance (Otto Weber, Billroth) with an innate something is requisite, which Dr. Ballard(o) denominates *pabulum*—food. By this alliance in the process of vaccination, the food for pocks can be consumed either totally or partly, either made unfit for ever or temporarily(p) as *pabulum* for the *virus variolosum*. By itself, *virus variolosum* is equally unable to produce variola; the same food out of the organism, the same alliance, is wanted for this purpose. In this way eruption of cow-pocks originated from any vaccine virus whatever can secure against small-pox.

In this way also, the necessity of revaccination is evident, in order to render the residue of the *pabulum* inactive for the development of small-pox. But when has the proper period for revaccination arrived? On account of its want of determination, the author of these lines begins to perform it in every case of his private practice, if possible, on the eighth day after successful primary eruption, and this most easily out of the cow-pocks themselves of the inoculated person. In the institutions of vaccination in our town, at Amsterdam, and at the Hague, this mode of revaccination on the eighth day is only practised, however, when the eruption of vesicles with regard to the number of punctures has been incomplete. The primary cow-pocks pursue their course in the usual way. Most, but not always, the secondary eruption, if it arises, consists in abortive pustules, this being exactly what we desire to complete the process of protection against small-pox, and to certify the constitutional effect of the primary inoculation—the modified Bryce's proof.(q)

All these facts ought to be practised and experienced in many cases, in order to judge of their usefulness and to arrive at the proper understanding of the matter.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

NECROSIS OF TROCHANTER MAJOR—REMOVAL OF DEAD BONE.

(Under the care of Mr. HENRY SMITH.)

The patient, a woman of middle adult life, had been operated upon some years previously in King's College Hospital, and carried the marks of former disease in the same region, in the form of an old depressed scar below and behind the trochanter major on the left side. At the time of operation there were two sinuses, opening upon a depression of the surface of the thigh, over the lower and outer part of the trochanter, through which dead bone was felt. Mr. Smith made two incisions from these sinuses, one an inch and a half backwards, and a shorter one downwards at right angles to the first, and then removed a portion of the trochanter with the bone-forceps and gouge. While using the latter instrument its brittle extremity snapped off, and a fragment of the metal, Mr. Smith said, remained in the wound. This was sought for, but could not be detected, and therefore, as Mr. Smith remarked, it was most probable that suppuration would follow, owing to the irritation which would be provoked by the presence of the steel.

CLEFT PALATE.

(Under the care of Sir WILLIAM FERGUSSON.)

This was a fissure of the whole of the soft and two-thirds of the hard palate in a young person. Sir W. Fergusson performed the operation upon the soft palate in the manner which he himself first proposed, dividing the muscles of the soft palate

previous to paring the edges of the cleft. Chloroform was administered, and a new form of gag used, which consisted of two grooved plates to fit the teeth of the upper and lower jaws, connected by a horseshoe-shaped spring; this, being placed on the teeth of one side of the mouth, was quite out of the way of the operator during his manipulations. Four sutures were employed to bring the edges of the soft palate accurately into apposition. The sutures were passed in the ordinary way; but an excellent plan is adopted by Sir W. Fergusson, who, to facilitate the adjustment of the sutures, uses them of two different colours, passing sutures of the same colour on the same side of the cleft, so that one colour indicates those to be withdrawn and the other those to be retained. In his remarks, after the operation, he referred to the use of chloroform in these operations, and said that the danger of giving much was owing to the loss of sensitiveness of the upper part of the larynx, and the consequent trickling of blood down the trachea and bronchi without corresponding reflex attempts to prevent it. The fact that even after the administration of chloroform some irritation was produced in the larynx and about the palate by the blood, was the cause of the restlessness shown by the patient, but this diminished during the later stage of the operation, when the parts became more tolerant of the cause of excitement in them.

SINUSES FOLLOWING EXCISION OF KNEE-JOINT—SINUSES LAID OPEN AND SETON PASSED.

(Under the care of Sir W. FERGUSSON.)

This patient was a young girl of good appearance, but with a somewhat strumous aspect, who had undergone excision of the knee-joint, about twelve months previously, for synovial degeneration of the joint. Some sinuses now existed on the inner side of the ankylosed bones, which were laid open, and a curved and deep incision was made on the outer side, and some grumous-looking matter removed. A probe threaded with a seton dipped in carbolic water was passed from the outer to the inner side behind the extremity of the femur, and left to promote granulations.

Sir W. Fergusson said that this was an example of an excision performed under adverse circumstances, with abscesses around and sinuses extending high up along the thigh; still, as a basis of excision, it had proved satisfactory, and the two limbs were now well-nigh symmetrical. There were three sinuses remaining, with some thickening about the parts; bony ankylosis was, however, quite complete. Formerly, in the early period of the history of excision, no allowances were made for such sequelæ, and amputation was frequently resorted to; but there could, he thought, be no doubt that excision, with such treatment for resulting sinuses or fistulæ as he had adopted, was infinitely preferable to the sacrifice of the limb.

LONDON HOSPITAL.

MR. MAUNDER'S CLINIC.

AMONG others are two cases of disease of the rectum. *Case 1* is a young woman, about 25 years of age, who has been under Mr. Maunder's observation for two years, with tertiary syphilitic ulceration of the lower bowel. Neither mercury nor iodine has been beneficial, and at the present moment a sanguineous muco-purulent discharge is as copious as when she was first seen. On one occasion the bowels were locked up for fifteen days with opium, but without avail. The canal is gradually becoming narrowed. The question of lumbar colotomy may possibly be entertained.(a) *Case 2* is a male, about 45 years old, the subject of scirrhus cancer, narrowing the bowel very much and encroaching upon the urethra. Incontinence of feces and retention of urine exist. Little can be done to relieve this poor fellow at present. The bladder can be emptied by catheter, and there is not sufficient bowel-obstruction, nor pain, nor ulceration, nor hæmorrhage to justify colotomy.

Case 3, a female, 75 years old, has been in the Hospital more than five weeks with severe compound fracture of the leg. Sloughs and portions of bone have come away, and as a result, in great measure, of the care and attention bestowed upon the case by the House-Surgeon, Mr. Stanley Gill, there is every probability of a satisfactory issue.

Case 4 is a man of spare habit and sallow complexion, who, three months ago, had his ankles jammed in a door. Three weeks after a swelling arose. This swelling now occupies the front of the ankle-joint, and conceals to some extent both

(a) This has since been had to recourse to.

malleoli. It is painless, soft, and very elastic, but cannot be markedly diminished in size by direct pressure, as well as by compression of the femoral artery. It has a distinct expansive impulse, which ceases when the above artery is compressed. Mr. Maunder thinks the swelling consists of a mass of cells (probably soft cancer) very freely supplied with arterial blood.

Case 5 is a young man, 23 years old, who, four months ago, at sea, broke his thigh across the middle of the shaft. Little was done for the first month, but subsequently a starch bandage was worn for ten weeks. The limb is now three inches short and perfectly useless. The extremity of the upper fragment projects forwards, and is just under the integument; the end of the lower fragment is less prominent, but can be felt in the back of the thigh, and on rotation of the leg it moves quite independently of the upper fragment. The two ends are widely separated by a firm mass of inflammatory effusion. The questions of non-interference, of attempting to approximate the ends of the bone by operation, or of amputation if the latter fail, must be entertained.

WESTMINSTER GENERAL DISPENSARY.

[We are indebted to Mr. Sewell, the House-Surgeon, for notes of some interesting operation cases at this Dispensary.]

ABSCCESS WITHIN OR AROUND THE SHEATH OF BRACHIAL PLEXUS, SIMULATING MEDULLARY TUMOUR—PUS EVACUATED—RECOVERY.

(Under the care of Mr. CHURCHILL.)

J. S., aged 36, a printer's pressman, had suffered for some months from severe gnawing or stabbing pains extending from the shoulder down the inner side of right arm and forearm to the tips of the fingers. He had been treated at other public institutions for rheumatism. He was admitted under the care of Dr. Waite, who, after inquiry into the antecedent history and occupation of the patient, found that the pain he complained of was deep-seated, and most severe about the neighbourhood of the axilla and supra-clavicular region. The elbow- and shoulder-joints were also at times very painful, which, associated with some pyrexia, probably induced the belief that the patient was suffering from subacute rheumatism. While under Dr. Waite's care he was treated with bicarbonate of potash, iodide of potassium, and opiates; but the most powerful local and general sedatives failed to procure relief from the severe pains in the course of the nerves. He had little rest day or night—in fact, the nocturnal exacerbations were most severe. Dr. Waite attended him at his own home, and in a week or two after the application of large poultices to the shoulder the pain became somewhat less severe. On tracing up with the finger the course of the ulnar nerve to the apex of the axilla, a firm, hard, deep-seated, circumscribed swelling could be felt, as also in the supra- and post-clavicular regions. The natural inference was that a tumour of rapid growth, implicating and pressing upon the nerves of the brachial plexus, was the cause of the deep-seated pain and pyrexia. Mr. Churchill met Dr. Waite in consultation, and, after careful examination, was unable to obtain any evidence of fluctuation. The rapid growth, the febrility, and the decided increase of pain at night led to the suspicion of inflammatory mischief, although unaccompanied by local increase of heat or tenderness. The tumour was punctured with a large trocar and canula, and about two ounces of pus evacuated. The patient was instantly relieved, but the stabbing pains continued very severe. It was evident that pus was reaccumulating in the sac of the abscess, and about a week later Mr. Churchill made a more extended incision, and gave free vent to the pus. The scalene muscles near their attachment to the transverse processes of the central cervical vertebræ were included in the abscess, which was now somewhat diffuse. The abscess healed from the bottom in the course of a few weeks, and his health rapidly improved. He was dismissed cured two months later.

FATTY TUMOUR IN THE SITUATION OF RANULA BENEATH THE TONGUE, SUCCESSFULLY REMOVED FROM AN OLD MAN 86 YEARS OF AGE.

(Under the care of Mr. CHURCHILL.)

H. T., aged 86, of strong constitution, but with marked senile atrophy and arcus senilis, was admitted under the care of Dr. Waite for eczema rubrum of the leg, dependent upon venous obstruction of the cutaneous capillaries on the anterior aspect of the leg below the knee. The incisive teeth in lower jaw were intact, and situated just behind these was a movable, apparently pedunculated tumour, about the size of a walnut.

The surface of the mucous membrane was smooth and uniform; it was becoming chafed and painful from friction against the sharp edges of the teeth. He had noticed the swelling for twenty-two years; but, according to his own account, it became somewhat diminished in size after clear fluid had squirted out of it. This statement led to the suspicion of ranula. Probably, however, the fluid did not escape from the ranula-like cyst, but from the temporarily obstructed follicles of the sublingual gland. He was afraid that the tumour was "a cancer." The sac being opened, and the tumour exposed, it was carefully dissected out.

Mr. Paget mentions having removed a fatty tumour simulating ranula, which appears to have resembled this in almost every particular. It may now be seen in the Middlesex Hospital Museum. Mr. Churchill's tumour was about a quarter of an inch longer than Mr. Paget's—*i.e.*, one inch and three-quarters in length. There is no such tumour in the Museum of the Royal College of Surgeons, and it is doubtful if there is another specimen in London. (For a full description of the microscopic character and pathological import of this tumour, *vide Medical Times and Gazette* for December 23, 1871.)

Remarks by Mr. Churchill.—The benign character and slow growth of lipomatous and encysted tumours, especially in this situation, together with the exceedingly rare occurrence of a lipoma simulating ranula, are sufficient to justify the diagnosis formed in this case. Then, again, the occasional squirting of fluid from beneath the tongue, as described by the patient, appeared *inter alia* to justify the diagnosis formed of the fluid character of the tumour. It would seem that the remarkably inappropriate term "ranula" has been indiscriminately employed to characterise tumours of a totally different nature and rapidity of growth. Mr. Holmes Coote describes ranula as "a fluctuating, semi-transparent, livid-blue swelling, situated under the tongue" (Holmes' "Surgery," vol. iv., p. 223). Such a definition is aptly descriptive of the cystic tumour of the sublingual gland, usually understood as ranula. But if we are to include under this head, as Mr. Coote has done, various encysted growths in the floor of the mouth, as "enlarged bursæ which may extend down the neck" (*op. cit.*, p. 224), such a definition cannot be held descriptive of growths originating in so many various ways. "Some cysts, as many ranulæ, should not be retained in the list of tumours," says Mr. Paget, "for their growth appears to be due only to the accumulation of the contents of the tube or sacculus." Bearing in mind the anatomical relationships between the submaxillary and sublingual glands, it seems right to conclude that structurally and physiologically each constitutes an inseparable part of the salivary apparatus. If we trace up the Whartonian duct from the submaxillary gland round the border of the mylohyoid muscle, we find that, after passing over the vertical muscles of the tongue, it is joined by the Bartholinian duct, which issues direct from the sublingual gland of the same side. The common ejaculatory duct for the two opens into the floor of the mouth just behind the incisive teeth. There are, in addition, numerous short ducts of the sublingual gland which discharge their contents directly into the mouth. It would seem, however, desirable that some well-defined distinction should be made between the semi-transparent, livid-blue swelling indicating simple obstruction and dilatation of a salivary follicle or duct, and the large encysted growths occurring in the floor of the mouth, usually from obstruction of the Whartonian duct. Mr. Coote states that cysts may form in this situation from four sources: dilatation of Whartonian duct, of a sublingual duct, of a mucous follicle, or of a bursa mucosa. As some reference has been made to the time which these tumours take to grow, it would appear by the accounts given of similar cystic formations, especially where so deep-seated as this, that some have taken many years to develop.

MELANOTIC PEDUNCULATED GROWTH DEVELOPED UPON A MOLE—EXCISION—RECOVERY.

(Under the care of Mr. CHURCHILL.)

E. W., aged 45, had noticed a slight button-like elevation of the skin over the lumbar spine from childhood. It was of a dark brown colour, flat, and smooth. In July, 1870, she fell downstairs and injured her back. The mole-like growth, which had previously remained stationary, now increased rapidly. Two months later, the tumour was as large as a grape, prominent, and pedunculated; a watery discharge oozed out from the base. She had failed to strangulate it by twisting a silk thread round the neck of the tumour. The growth was removed by including it in a spindle-shaped incision through healthy integument wide of the growth. There has been

involving the greatest variety of climate and of race. There is the "Bengalee living in a humid, steamy, and malarious atmosphere all the year round, and feeding almost exclusively on rice and fish." There is the Rajpoot on his dry, sterile soil, living on wheat and dhal. The Puthan lives in a colder, higher, and rainier district, living on wheat and flesh; and amongst these it is found that a liberal diet is the best means of holding leprosy in check. But with regard to grain from uncultivated land—

"A grain merchant, who came to Dr. Farquhar's Dispensary in the cantonment of Sealkote, suffering from leprosy, stated a fact in regard to his food of much significance. The village he lived in was surrounded by cultivated land, the wheat-grain from which he was in the habit of receiving for sale. In the neighbourhood, however, there were vast tracts of uncultivated land, over which a nomadic race, living in tents, wandered with their flocks. When rain fell plentifully in any particular spot at a propitious season of the year, these people set about turning up the soil, to the depth of an inch or two, with primitive ploughs, consisting of stout sticks burnt at one end, and tied on to bullocks by strings.

"The wheat-grain was then cast into the ground, covered over, and in due time yielded corn. The area thus sown was too great for the few people to reap the straw from, so only the ears of corn were plucked from the stalks and gathered into sacks. The grain seller added, that he bought this inferior-looking grain from these people, and because his customers, as a rule, disliked it, he lived upon it himself, and sold all his good grain. The idea struck Dr. Farquhar that this uncultivated and poor grain might have something to do with the leprosy, and following up the thought, he found in other parts of the country what appeared abundant proof of leprosy being associated with the consumption by the population of inferior grain. He found the disease to be common in another district in the Punjab, where a large uncultivated plain was near to a long line of villages, near a cultivated district. This plain was sown only at intervals of a year or two, when the rain fell, and no manure or other care beyond the ploughing and reaping, as above described, was bestowed on the soil.

"Leprosy, Dr. Farquhar noticed, was comparatively absent in those districts of India where there was long-established cultivation of a higher order, where the fields are properly cared for and manured, and where man lives industriously by 'the sweat of his brow.'

"In the rice country of Bengal, where cultivation has been long established, there appeared to be an argument against the 'uncultivated grain' theory of leprosy. On inquiry, it is found, however, that the Bengal ryot exhausts his soil by drawing yearly sometimes three crops from it, and that the grain (rice) produced at one season of the year is known among the people to be unwholesome.

"In the Upper Provinces of India, where unleavened cakes of wheaten flour form the staple of the food of 60,000,000 or 80,000,000 of people, *calculus vesicæ* is a very common disease, while, in the rice-feeding 30,000,000 of Bengal Proper, this affection is comparatively very rare.

"The extraordinary statement, also, that in the 'Patna' district of Bengal leprosy exists in a large proportion of the population in a slight form, should be further and specially investigated and reported on.

"It may turn out, after all, that the use of grain grown on uncultivated land is not of much moment in regard to the cause of leprosy; and that it is only coincident with residence in an undrained and marshy (malarious) locality, which, also, may have nothing to do with the genesis of leprosy. Some observers declare that the subsidence of leprosy and ague go on *pari passu* with the introduction and extension of drainage in localities in which leprosy has been endemic.

"The late Dr. Kinlock Kirk supposed, as the result of his observation, that the use of the leguminous seeds, common in India under the name *dāl*, is capable of giving rise to something like leprosy."

So far, all the evidence as to leprosy bears witness to the benefits derived from civilisation—in the careful culture of the soil, the selection of fine grain, and the general improvement which results from artificial methods of culture. Under a second head, we might descant on the protective influence of clothing; under a third, the protection that might be afforded by that artifice a filter, in order to purify water from the host of animal and vegetable parasites which it contracts when left

to the care of "nature." But we have said as much as our limits allow, and only hope that the Practitioners to whom this volume is sent will assist in solving the questions it puts before them.

PROVIDENT DISPENSARIES AND THEIR EVILS.

SOME little time ago the Charity Organisation Society held a conference in the house of the Society of Arts, the subject of discussion being, "The best methods of checking the Abuses now incidental to Out-patient Hospital Relief, with special reference to the expediency of extending the Provident principle." Such was the programme; and on the telling platform of Hospital abuses there were some speeches from men to whom we might well listen—men of good Professional standing, of high social position; but hardly, nevertheless, men of genius. We are no devoted advocates of the so-called Provident system, and, frankly, we have no great confidence in the regeneration of the British working-man at the expense to himself of something like three-halfpence a week. But neither are we so hugely enamoured of the present system of out-patient departments and Dispensaries as to maintain either their perfection or their perfectability.

First, as to the vices of out-patient departments, against which the great outcry is raised. We are convinced that these are not nearly so much abused as are the Dispensaries connected with no Hospital; and for much that is bad the complainants have themselves to blame. It is worthy of notice that a goodly number of men possessed of vast experience have carefully held aloof from this agitation, partly because talkee-talkee will not mend matters, and partly from the well-known fact that it began with those most culpable in fostering the abuse of charitable institutions. Those who have joined in the cry say, "People come to Hospitals and are treated who should not do so." This nobody is prepared to deny, but the remedy is simple—Don't see them! Assuredly the authorities will hold the officers scathless for so doing. They say, "So many people come, only a few moments can be bestowed on each;" again we say, "Why see so many?" And there is one rule all-important: never on any pretence sign a certificate. But in the meantime we have to do with the system which some propose to substitute for those named Provident Dispensaries.

Now, so far as we can make out, there are certain Medical evils connected with the Provident system, as ordinarily worked, which are fairly well represented in the following document, which has been forwarded to us, we presume, for publication:

"ROYAL VICTORIA DISPENSARY, NORTHAMPTON.

"Statement of Result of Operations for the Year 1871:—At the meeting of the Committee of this Institution, held on January 12, the Honorary Secretary reported that the total number of paying members during the past year was 5578, representing 12,820 persons who were entitled to receive Medical relief from the institution.

"The amount contributed by these parties was £2005 16s. 8d., a larger amount than had ever been subscribed before. Out of this sum a portion had been applied towards the general expenses, as provided by the rules, and £267 4s. 10d. had been paid for drugs and corks. The net balance was divisible amongst the Medical officers in the following proportions:—

	£	s.	d.
Dr. Barr	730	6	9
Mr. Moxon	511	1	11
Mr. Evans	378	4	9
	£1619	13	5

"This sum represented, therefore, the net remuneration of the Medical officers for the year, after deducting all expenses. The Secretary also reported that the Honorary Fund, which last year exhibited a deficiency of nearly £40, was now out of debt.

"The detailed report will be presented as usual at the annual meeting in February."

Here we have the working of, probably, the largest institution of the kind in the kingdom, and it reveals a state of

things which is at least instructive. Northampton is not a very large town, and it is not a very rich town. It is the head-quarters of the shoemaking trade, so that it contains a large number of artizans earning fair wages. We read that already more than 12,000 of these, including their wives and children, are entitled to Medical relief from the institution; and we have seen it stated that, according to the rules of this institution, about 30,000 of the inhabitants of the town are in a position to entitle them to its benefits, provided they become paying members. As a result of their labours, three Medical men divide among them the sum of upwards of £2000, giving them from this source alone incomes decidedly above the average of English Professional earnings. But what becomes of the other Practitioners in the town? This Provident Dispensary apparently absorbs—or is ready to absorb—in its all-devouring maw most or all of the working population of Northampton. These three Practitioners cannot do all the work; they are not inclined to add to their number, but rather to do the work by underpaid assistants. In short, we see this so-called charitable institution erected into a monopoly for the benefit of those connected with it, and to the exclusion of all new-comers. This surely is a perversion of charity not contemplated by those who look on such institutions as a panacea for pauperism and all the unnumbered woes.

To look at this matter from another point of view, we take it for granted that the institution in question would be called a charity. On whom, then, is the charity bestowed? Surely on the gentlemen who are supplied with the means of carrying on practice from funds not coming out of their pockets, and thus enabling them to compete advantageously with their less fortunate brethren. If these things are good for the public, they are not good for our Profession, which is thereby pauperised with a vengeance.

For carrying on these institutions aright two things are absolutely necessary—first, a thoroughly efficient committee, prepared to find out exactly the position of everyone who applies for admission to the benefits of the institution. In a place like London such an inquiry is hardly possible, however easy in narrower localities. Still more important is it that all the Medical men of a town or a district shall be on an equality, so far as the institution is concerned, so that the patient may apply to any Medical Practitioner he or she thinks proper; without this, those not belonging to the institution must be infallibly handicapped in the race of life.

THE WEEK.

TOPICS OF THE DAY.

THE prospects of Medical legislation in the present session of Parliament are not at present as good even as in the last session; and yet, we believe that a short and simple Act, which would enable the different Corporations and Universities in each division of the kingdom to combine, without prejudice to each other, for the purpose of forming a Conjoint Board of Examinations, which would reduce the number of members of the General Medical Council, and would provide more stringent remedies against the illegal assumption of Medical titles, would be an enormous boon to the Profession. The danger, however, in appealing to Parliament is that an endeavour would certainly be made by one party to place the Profession under a department of Government, and by another to introduce the direct representation of the Profession into the General Medical Council. As we should regard the realisation of either of these projects as a great disaster, we confess that we are not sanguine or particularly anxious for immediate Medical legislation. The Profession has waited so long that it may well wait a little longer. Better to bear present ills than to fly to others which we know not of. If the Corporations and Universities of the three kingdoms were actuated by the interests of Medicine as a Profession rather than by their own—if they would be con-

tent to combine on fair and equal terms, and not endeavour to impose conditions which they know will be distasteful on other Corporations—Medical legislation would be unnecessary; the Profession would reform itself. But whilst the endeavour seems to be on the part of each Corporation to subserve exclusively its own interests rather than those of the Profession at large, and to exalt itself by endeavouring to depreciate or extinguish its rivals, we confess that we can only look to the action of the Legislature for an equitable settlement. But, as we have already said, our condition is one that may be made far worse by over-medication than by expectant treatment.

The Syndicate of the University of Cambridge appointed to consider various questions connected with the study of Medicine and Medical legislation have recommended that the sanction of the Senate be given to the scheme for a partial Conjoint Board drawn up by the Royal College of Physicians of London and the Royal College of Surgeons of England. Friday, the 9th inst., was fixed for the meeting of the Senate, when the report of the Syndicate would be discussed. We notice amongst the list of signatories to the report of the Syndicate the name of Dr. Paget, the President of the General Medical Council. It cannot, however, be too widely known that, should the General Medical Council, over which Dr. Paget presides, give its sanction to this scheme, it will favour the formation of a body of Practitioners who will possess no Surgical diploma, or will encourage all English Medical students who are not desirous of taking the diploma of the London College of Physicians to travel to Scotland or Ireland for a diploma from the Scottish or Irish College of Surgeons. We may be pretty well assured that whatever Conjoint Scheme may be adopted in Scotland and Ireland, it will not be of a kind to exclude English Medical men who can pay the necessary fees from obtaining Surgical diplomas in Edinburgh or Dublin. But we ask whether this is a state of affairs which the General Medical Council is prepared to countenance? Will it be in accordance with its previous policy, or with the spirit of the Act of 1858, which it was called into existence to administer?

A Congregation of the University of Oxford have accepted a resolution in favour of the scheme by a majority of seventeen to ten. The opponents of the resolution objected to any abandonment of the ancient privileges of the University and to Medical trades-unionism. The Vice-Chancellor explained that the resolution was of the nature of a *Prejudicium*, and that details would have to be settled by subsequent statute.

The Senatus Academicus of the University of Aberdeen has circulated the following Minute relative to a Conjoint Examining Board in Medicine and Surgery for Scotland. It will be seen that the authorities of the University of Aberdeen are by no means agreed with those of the Edinburgh College of Surgeons as to the object and scope of the proposed Conjoint Examination:—

“In consequence of the recommendation of the General Medical Council, of date July 7, 1871, urging the formation of Conjoint Examining Boards, the Senatus has again taken the matter into its consideration. A Committee was deputed to meet and confer with representatives of the other Medical authorities of Scotland. While a general concurrence was found to exist as to the possibility of forming such a Board, it appears that considerable difference of opinion exists in regard to what the nature of the proposed Examination should be, some being of opinion that it should be restricted to a Clinical Examination. The view as to this point taken by the Senatus is, that, while Clinical Examination should form part of the final Examination, a Clinical Examination merely would not be sufficient, and scarcely a fair test of a student's work in connexion with the various departments of pathology and practice. It appears to the Senatus that the draft scheme already, it is understood, agreed on for England by the Universities and Corporations of England, is a well-considered one, and might safely be taken as a basis in the formation of a Board for Scotland.

"The Senatus desires it to be understood that it adheres to the view formerly expressed, that the evils complained of in regard to Medical licensing may be met simply by the combination, under the 19th clause of the Medical Act, of the Medical and Surgical Corporations, to form an Examining Board in each of the three divisions of the kingdom, thus conferring a complete qualification, while those who sought the higher qualifications conferred by the Universities would, as at present, register on their degrees. It appears to the Senatus to be not only unnecessary, but oppressive, to subject the University graduate to the expense and inconvenience of having, in addition, to pass a minimum examination, as a sacrifice merely to the name of uniformity. But if it must be so, it is reasonable that this hardship to the University graduate should be reduced as much as possible, and that, accordingly, under any scheme, the provision formerly proposed shall be secured—that his University examination in the fundamental sciences shall be accepted, and that he shall be admitted to whatever examination of the Conjoint Board he is to be required to pass on payment of a small fee.

"In the event of its being considered expedient to form a Conjoint Board for Scotland, before which University graduates shall be required to appear, the Senatus would approve of its being formed in accordance with the following conditions:—

"1. That a Conjoint Board be formed by the co-operation of the Universities and of the Medical and Surgical Corporations of Scotland, for the purpose of testing the knowledge of Medicine and Surgery, and the ability to practise them, possessed by candidates for registration; and that no degree or diploma entitling to registration shall be issued except to those who have passed the examination of the Board.

"2. That every matriculated student of a University who shall have completed the curriculum of study, and shall have passed an examination or examinations at his University in the fundamental sciences, shall be admissible to the examination by the Conjoint Board on payment of a fee not exceeding five guineas.

"3. That a Committee of Management be chosen, to consist of an equal number of representatives appointed by the Universities and the Corporations.

"4. That the Committee shall have power to fix the number of examiners, the period during which they shall hold office, the times and places of examination, and the division of the subjects, and shall elect as examiners the most competent men who can be found. That no member of the Committee shall be eligible as an examiner.

"5. The Senatus sees no objection to the proposal that candidates who are certified to have passed the first Professional examination of the Conjoint Board in one division of the kingdom, should be admissible to the final examination of the Conjoint Board of either of the three divisions of the kingdom."

The representation of the Society of Apothecaries in the General Medical Council, vacant by the resignation of George Cooper, Esq., F.R.C.S., has been conferred by the Master, Wardens, and Court of Assistants on Mr. E. Bradford, F.R.C.S., Deputy Inspector-General of Hospitals, late Chairman of the Court of Examiners, and Honorary Surgeon to the Queen.

The Queen's speech, in a paragraph of two lines, which follows at the tail of "Education in Scotland," "the Regulation of Mines," "the Amendment of the Licensing System," "the Superior Law Courts," "the Ballot," and "Administrative Improvement for Ireland," promises that "legislative provisions, founded on the Report of the Sanitary Commission," will be laid before Parliament. We have no doubt that, in the eyes of her Majesty's Government, sanitary matters are of infinitely less importance than the Ballot Bill. The illness of the Prince of Wales, however, has taught a lesson which is not yet forgotten by Parliament or by the people; and unless there be any political convulsion which will frustrate all chance of domestic legislation, we may reasonably expect an important Sanitary Reform Bill in the present session.

The *Cheltenham Examiner* of February 3 contains a copy of a Declaration on Alcohol, signed by Dr. Rumsey, Sir William Linton, and the leading members of the Profession in Cheltenham, which we observe commences with an important modification of the text of the unlucky Declaration which was fathered by the officers of a temperance society and the editor

of a Medical contemporary upon the Profession in London. The chief modification which the Cheltenham Medical men have adopted was suggested some weeks ago in this journal, and completely changes the character of the Declaration. The first sentence of the original Declaration, it will be remembered, implied a libellous charge on the great body of Medical Practitioners. This characteristic is obliterated by the substitution of the words "frequently asserted" for "believed" in the first line of the sentence, and the word "would" for "should" in a subsequent line. The sentence in the Cheltenham Declaration is perfectly unobjectionable. It stands thus:—

"As it is *frequently asserted* that the inconsiderate prescription of large quantities of alcoholic liquids by Medical men for their patients has given rise, in many instances, to the formation of intemperate habits, the undersigned, while unable to abandon the use of alcohol in the treatment of certain cases of disease, are yet of opinion that no Medical Practitioner *would* prescribe it without a sense of grave responsibility."

The Declaration of the Cheltenham Medical men is defensive; its London predecessor was simply offensive.

A Mrs. Robinson, residing in the Lewisham Union, has been fined £5 and £2 costs, or, in default of payment, one month's imprisonment, for sending her servant, who was suffering from small-pox, in a cab to the Lewisham Union without giving notice to the proprietor of the cab of the nature of the case. The cab was used for ordinary purposes on the same day.

Sir William Gull has, it is announced, purchased the estate of Relugas, in Morayshire.

PHYSIOLOGY AT THE ROYAL INSTITUTION.

In his second and third lectures on the Circulation, Dr. Rutherford showed some beautiful experiments upon the heart. The motions of the frog's heart and Cyon's experiments upon the effect of heat upon the movements were demonstrated by means of the electric light. The shadow of the beating heart was thrown upon a screen; and the acceleration of the cardiac action by heat, and the retardation produced by cold, were thus rendered evident to all. The rhythmical action of the auricles and ventricle of the frog's heart was demonstrated by means of mirrors and the electric light. From a small mirror moved by the auricles, and from another moved by the ventricle, a beam of light was reflected upon a screen, and the order and duration of the motions exhibited in the most striking way. The inhibitory action of the vagus was also demonstrated in the same ingenious manner. The innervation of the heart was discussed, and the circulation of the blood in the frog's web demonstrated upon a screen by means of a microscope and the electric light. This exhibition, together with that of a number of beautiful transparent injections of bloodvessels of the different organs and tissues, demonstrated in the same brilliant manner, formed one of the most novel and startling demonstrations ever given at the Royal Institution. It appears, however, that this mode of demonstration is only suited for things which do not require a very high magnifying power. The want of light prevents the use of the higher powers. Nevertheless, from this demonstration we know that very much of the structure of the body can be satisfactorily shown in this way. No diagrams could compare with the beautiful pictures of the spinal cord, brain, lung, liver, kidney, skin, intestine, tongue, etc., which were thrown upon the screen. Many of the injections were prepared by Dr. Carter, of Leamington, who had lent them for the occasion.

PROFESSOR ESMARCH, OF KIEL.

We learn on excellent authority that Professor Esmarch, of Kiel, the son-in-law of Professor Stromeyer, and well known amongst us by his work on the "Use of Ice in Military Surgery," is about to be married to the Princess Henrietta of Schleswig-Holstein, sister of Prince Christian, who married our Princess Helena.

THE MEDICAL SOCIETY OF LONDON.

At a meeting of this old Society, especially convened for the purpose, it was decided that the following congratulatory address should be presented to her Most Gracious Majesty the Queen:—

"We, the President, Council, and Fellows of the Medical Society of London, in special meeting assembled, desire to approach your Majesty with feelings of deep thankfulness to give utterance to our humble and earnest congratulations that it has pleased the Almighty to raise up his Royal Highness the Prince of Wales from a bed of sickness; and thus to avert from your Majesty's House, and from your Majesty's loyal people, a calamity, of which the possibility had filled all hearts with apprehension. We rejoice that it has been the privilege of honoured members of our own calling to be the instruments, under Providence, by which this great blessing has been conferred upon the nation; and we pray that the Great Disposer of the issues of life and death may extend His continued protection to your Majesty and to his Royal Highness, and that your Majesty may long reign over a devoted and loyal people.

"Signed on behalf of the Council and Fellows of the Society,

"ANDREW CLARK, M.D., President.

"George-street, Hanover-square, January 20, 1872."

RESIGNATION OF ONE OF THE MEDICAL OFFICERS TO THE QUEEN ADELAIDE DISPENSARY.

DR. WELCH, of the Hackney-road, has resigned the office of Physician to the Queen Adelaide Dispensary, after seventeen years' connexion with that institution. The reasons of Dr. Welch's resignation are—first, that he was prevented from seeing his patients by the Rev. Mr. Coke, the visitor, on one occasion, on the ground that he (Dr. Welch) had attended at the Dispensary at ten o'clock instead of at 9 a.m.; and, secondly, that the Rev. Mr. Coke, as Chairman of the Committee, had said to Dr. Welch—"I do not know if you are aware of it, but for some time past I have given orders that your prescriptions should not be dispensed with the medicines you prescribe, because they are too expensive." We need not say that under these circumstances Dr. Welch was justified in sending in his resignation; in fact, if he had not done so, he would have been wanting in his duty both to himself and his patients. We should think the Governors of the Dispensary will not let the affair rest where it is.

THE DUTY OF THE CORONER.

DR. LANKESTER lately held five inquests at the "College Arms," St. Pancras, four of the cases being those of paupers in the St. Pancras Workhouse. It appears that the St. Pancras Guardians have complained to the Middlesex magistrates that unnecessary inquests have been held. The Clerk of the Magistrates had told them that, unless the expense of the inquests in Dr. Lankester's Court were diminished, he should recommend the magistrates to lay the case before the Home Secretary. Dr. Lankester asserts that he is in nowise responsible to the Home Secretary; and although the Coroner attended the meeting of the magistrates to rebut the charge of the Guardians, but could not be heard as having no *locus standi*, he is as independent of the magistrates as of the Home Secretary. Dr. Lankester, in addressing a jury on the subject, said:

"He reminded them of the inquiries he instituted three years ago into the disgraceful state of the St. Pancras Workhouse, and the amount of good he had effected. He did not regard an investigation by Government inspectors as worth anything at all. He asked them to look at the result of the Hampstead Small-pox Hospital inquiry. Government inspectors conducted it, and Government men defended officers appointed in all such Government inquiries. He thought it right to say that that inquiry would never have taken place at all had not he and a jury held an inquest on the body of a child who had died in the Hospital; and when they went to view the body, another body was shown them, the real child having been buried in the confusion. Another child had either been buried or lost, and had not been found yet. He found out that in several cases persons had been found dead in that Hospital,

and it was the duty of the Medical officers to report all such cases to him; but instead of that they buried the bodies. Was it not the duty of the Coroner's Court to find out the cause of all sudden deaths? He had written to the Commissioners, pointing out the neglect of the Medical officers, and the Commissioners, in their report on the late inquiry, never referred to that fact. There was an attempt, on the part of persons in authority, to screen their improper practices from the public by excluding the action of the Coroner's Court."

SMALL-POX JOTTINGS.

FIVE new cases of small-pox in the Medical district of Islington were reported during last week. There had been two deaths as against one the week before.—Mr. Abel Heywood, jun., read a report to the Manchester Board of Guardians, last week, on the small-pox cases treated in the Canal-street Hospital, in which it was shown, that while the mortality among unvaccinated patients was $55\frac{1}{2}$ per cent. of the total number attacked, it was only $4\frac{1}{2}$ per cent. in the case of those who had been vaccinated.—Small-pox is rapidly diminishing in Rome.—In Aberdeen, since the outbreak of small-pox, the deaths amount to 50. In the Infirmary and Small-pox Hospital there are 70 cases, and in private practice 30; total 100. As usual, the popular impression greatly exceeds the fact; at the same time, these figures, which include the city, but not the suburbs, are formidable enough, and few parts of the town have been or are exempt from the disease, which has been no respecter of persons as to age, sex, or social status.—The Registrar-General, in his quarterly report ending December 31, states that small-pox, owing to defective administrative arrangements, was, in spite of the Compulsory Vaccination Act, more fatal than any other epidemic; of it more than 6000 died, chiefly children.—In Marylebone four small-pox patients were removed during last week from the parish to the Hospital. Mr. A. Emery, of 66, Great Portland-street, was fined 20s. and costs for refusing to have his child vaccinated.—At Limehouse, during the past fortnight, four deaths occurred from small-pox, and nine fresh cases are reported.—Ten deaths from the disease were reported in the last fortnightly return to the Camberwell Vestry.—The Medical Officer of St. George's-in-the-East, in his return to the Vestry, states that "during the past month small-pox had in no instance been fatal."—At Sheffield twenty-four cases of small-pox were reported in the workhouse, against forty-two the week before. The stipendiary magistrate, Mr. Davis, in giving judgment a few days since on a small-pox prosecution, said he had learned on the best authority that the town was in a frightful state, in consequence of the filthy and neglected condition of the ashpits and closets. It would be the duty of someone to apply to the authorities in London, unless some very vigorous efforts were made by the local sanitary authorities.—Dr. Lankester reports to the St. James's (Westminster) Vestry two deaths from small-pox, and since the last report sixteen new cases had been brought under notice, making in all 266 cases and thirty-seven deaths since the outbreak of the epidemic. He adds—"The epidemic still rages in the parish, and was as far off cessation as in the month of May last year. As no efforts were being made to prevent its extension by the Government, they might expect the disease to continue its ravages."—In the Homerton Small-pox Hospital during the past fortnight, there have been sixty-four admissions; seventeen deaths, and fifty-two discharges, the number remaining being 120.—In the Stockwell Small-pox Hospital in the same period there had been ninety-eight admissions, and there were now 195 patients, being a large increase upon the preceding return.—At the Hampstead Hospital during the last fortnight 115 fresh cases were received, and the number remaining was 245, as against 279 at the last report.—Small-pox has broken out at Toddington, Bedfordshire. Several deaths have already occurred.—The disease has also appeared at Leamington and Warwick.—

Small-pox is greatly on the increase in Leeds.—The *Oswestry Advertiser* observes, "from returns presented to the Directors of the Oswestry Incorporation, on Monday week, that of 2662 children whose births were registered in the Incorporation in 1868, 1869, and 1870, only six cases of default in vaccination are returned. A clearer bill, we imagine, could be returned by no union in the country. The Anti-Vaccination Association must look elsewhere for facts and victims, and allow us to congratulate ourselves that we are so well protected against small-pox."—At Kettering, since the commencement of the small-pox epidemic in October last, there have been 200 cases, nineteen of which ended fatally. The opening of the Hospital has been attended with the most satisfactory results; the disease has since gradually declined. Only five out of the nineteen deaths presented any satisfactory evidence of vaccination. A striking piece of evidence of the value of revaccination is that in families where the disease had broken out revaccination has uniformly prevented its further spread, whereas in families where this precaution had not been taken the exact opposite has been the invariable result. There are now only ten cases under treatment in the town and ten in the Hospital, most of whom are convalescent.—In Berlin during the week ending the 1st inst. there were sixty-six deaths from small-pox; in the two previous weeks the numbers were 107 and 109.—In the metropolis last week fifty-two deaths from the disease are reported, as against ninety the week before.—Dr. Aldis, St. George's, Hanover-square, reported two patients, both vaccinated, in the in-wards.

TYPHOID FEVER AND BAD DRAINAGE.

SEVERAL of the persons employed in the winding-room at the mill of Messrs. Woods and Hampson, Swillbrook, Preston, were, a few days ago, taken suddenly ill, and compelled to cease work. An examination of the premises revealed the existence of a very defective drain, from which noxious and, in this case, deadly exhalations were emitted, filling the whole atmosphere of the room, and rendering it highly poisonous. Medical aid having been obtained for the sufferers, it was found that they were all in a highly dangerous state of typhoid fever. One of the young women, Alice Christian, aged 19, has just died in the Preston House of Recovery, and three others have succumbed to the deadly effects of the gases at their own homes in Walton-le-Dale and the neighbourhood. Seven others have had narrow escapes, if indeed they are yet out of danger. On the discovery of the cause of these fatalities, steps were taken to cleanse the defective drain, and to prevent the recurrence of so sad an event.

PRESCRIBING DRUG-SELLERS.

IT seems impossible, under the present law, to prevent the practice of Medicine by illiterate vendors of drugs. The evil is more prevalent in the poorer neighbourhoods, and notably in the East-end of London. Mr. Humphreys is entitled to commendation for the very decided manner in which he treats the cases of persons who have died under the hands of drug-sellers, and on whom inquests have been held. But the law is too indefinite, and no coroner, however energetic, can deal successfully with a class of offenders who inflict so much misery on the living and destroy so many lives under the pretence of "doctoring" the patients. Last week an inquest was held by Mr. Humphreys on the body of an infant, aged 1 year. The mother deposed that the child had been ailing for some time, and that she had called in a "chemist" to attend him, and that he had attended and prescribed for some time, charging sixpence for a visit and medicine. She always thought that he was a regularly qualified Doctor, and he never told her to the contrary. The child gradually got worse, and at last was so bad that she called in Dr. Riley on the Friday evening, but the child died the next morning. Dr. Riley stated that he saw the deceased on Friday evening, and found him suffering from

congestion of the lungs. He died the next day. If he had seen the case a few days before, he had no reasonable doubt he could have pulled him through, as he was healthy and well-nourished. The Coroner, addressing the jury, said: "Unfortunately, this is a sample of many inquests which I have to hold; for druggists openly defy the law, thereby endangering the life of the patient. There is no earthly reason why this child should not have grown up to manhood. Some active steps ought at once to be taken to abate this evil, and I sincerely trust the press will help to expose it." The verdict was, "Death from natural causes"—the jury expressing their concurrence in the opinion of the Coroner.

TRIBUTES OF RESPECT TO THE LATE MR. WADE.

A FORTNIGHT since we recorded the death of Mr. Robert Wade, of Dean-street, Soho. We are pleased to announce that at the meeting of the Vestry of St. Ann's, Soho, held last week, the following resolutions were passed:—"That this Vestry has heard with unfeigned regret of the death of Mr. Robert Wade, who for upwards of fifty years has resided in this parish, during the last forty years of which he has filled the office of Surgeon to the Westminster General Dispensary." "That the Vestry has also observed the devotion and kindness which prompted his gratuitous exertions in alleviating the sufferings of the sick poor during so long a period, and takes this opportunity of expressing its sense of the great loss which the public, whom he served so ably and unselfishly, has sustained by his death. It further tenders to his widow and family its sympathy with their bereavement." A similar vote of condolence to the widow and family of Mr. Wade was passed by the Committee of the Westminster General Dispensary.

MR. CORRANCE AND POOR-LAW MEDICAL RELIEF.

THE Council and members of the Poor-law Medical Officers' Association held a meeting at the Medical Club, on Monday, to confer with Mr. Corrance, M.P., as to the course to be taken by that gentleman in the ensuing session of Parliament in furtherance of the objects of the Society. Resolutions were passed declaring the present Poor-law Medical Service to be ill-regulated and deficient in many important respects, and demanding improvement. That the establishment of public Dispensaries, in accordance with the recommendation of the Sanitary and Poor-law Inspectors' special reports, is necessary and desirable, and that a deputation wait upon the President of the Local Government Board, to impress upon him the necessity of introducing clauses in any Sanitary Act embracing these opinions.

THE WATER-SUPPLY OF LAMBETH.

DR. CORMACK made his first sanitary report to the Lambeth Vestry on Thursday last. He stated that he had made a careful analysis of the water supplied to the parish by the Lambeth, the Southwark, and Vauxhall Companies. In each case the water had been drawn from the main. He found the water strongly impregnated with sewage and other organic matter to an alarming extent, and declared that the water supplied by the above Companies was utterly unfit for human consumption. It was resolved that the report be printed for the use of the Vestry, after which the subject would be taken into consideration.

LUMBAR COLOTOMY.

ON Wednesday, January 31, at the London Hospital, Mr. Maunder performed the above operation in the left loin, in order to favour the healing of tertiary syphilitic ulcers in the rectum, associated with a free discharge of bloody mucus. The patient, a female, aged 25, had been under observation for more than two years, and the disease had resisted many modes of treatment. She is doing well.

FROM ABROAD.—EPIDEMIC VARIOLA AT MILAN IN 1870-71—
DISCUSSION ON DIPHThERIA.

DR. FELICE DELL'ACQUA, Medical Officer of the Milan Municipality, has published in the *Gazetta Medica Italiana-Lombardia* (January 27) a report on the epidemic of small-pox which has recently prevailed in that city, and which, indeed, still prevails there, although to a diminished extent. We extract some of the particulars. The account relates exclusively to the cases observed within the municipal limits, and does not embrace those which occurred in the adjoining communes. The epidemic commenced in the spring of 1870, and continued to increase during the rest of the year. In the early part of 1871 its prevalence diminished; then, again, as is usual with this disease, to greatly increase again; so that the cases reached, in September, October, and November, 1871, the respective numbers of 756, 739, and 676. In December these sank again to 345, and in the first fortnight of the present January 125 cases only occurred. Unfortunately, the reporter does not state the portion of the native population of Milan (217,310 in 1871) which the municipality comprises. In 1870 the entire number of cases was 1287 (646 males and 641 females), the ordinary number in Milan being between 200 and 300. In 1871 the number increased to 4467—2381 males and 2086 females. In 1870, of the 1287 cases, 881 were treated in Hospital, furnishing 93 deaths; and 406 in domicile, with 59 deaths. There were thus 152 deaths, or 14 per cent. Of the 1136 recoveries, 789 took place in Hospital and 347 in domicile. In 1871, of the 4467 cases, 3286 were treated in Hospital and 1181 in domicile; and while in the Hospital there were 2686 recoveries and 600 deaths, there were in domicile 915 recoveries and 266 deaths. In the total of 4467 cases there were 866 deaths, or 19 per cent., and 3601 recoveries. The mortality in both years would have been much less had not popular prejudices prevented so many of the cases coming early under the management of the sanitary authorities.

The municipal authorities, at all events, did their part well and actively, and with no stinted means, and, while seeking out and tending those attacked, diffused gratuitous vaccination and revaccination far and wide to all they could get to accept it. As Milan is one of the head-quarters of "animal vaccination," it is that form which was resorted to by the municipality. In 1870 there were 4228 persons vaccinated (*i.e.*, 1267 vaccinated and 2961 revaccinated) at the municipal expense; and in 1871 there were not less than 17,069 subjected to the operation; of these 1504 were vaccinated and 15,565 (7720 males and 9349 females) revaccinated. In 10,597 cases in which the results were verified, these were as follow:—In 1309 vaccinations the results were genuine in 1270, spurious in 4, and wanting in 35; in 9288 revaccinations they were genuine in 5039, spurious in 435, and wanting in 3814. Among 4467 cases of small-pox observed in 1871, only 76 persons were found who had been revaccinated, and these, for the most part, several years before, and almost always without result. Of these 76 individuals only 8 died, while the majority suffered only a light form of varioloid. Of these 8 cases, 4 had been revaccinated five, six, nine, and ten years before, and the other 4 had been revaccinated twice more recently, but without effect.

Milan, in fact, suffered relatively much less from the epidemic than smaller places—as, for example, Brussels and Genoa; and the reporter attributes the comparative lightness of the epidemic to the excellent arrangements of the municipality and the large number of vaccinations put into force. The Local Vaccine Committee practised 21,601 vaccinations, while, in private, Practitioners were most active in the practice; so that it was calculated that altogether about one-fourth of the entire permanent population of Milan was vaccinated.

In the garrison of Milan there occurred, in 1870, only 5 cases of variola in a force of 9000 men, and in 1871, in a force of 7000, there occurred 18 cases. All these had been vaccinated in their infancy, and revaccinated without result on joining the

army. In 1870 there were 1541 revaccinations performed in the garrison, and 1657 in 1871.

Dr. Dell'Acqua terminates his report by again eulogising animal vaccination, which has, he says, spread so rapidly throughout Italy. After having been practised for many years in Naples, it was introduced into Bologna in 1868, and Milan in 1869, and has since been adopted in all Italian towns. One alone—Venice—has proved recreant, and he visits with most withering language the municipality of that city, which, notwithstanding the splendid results obtained by its own sanitary commission, has, led away by prejudice and routine, retrograded to the old practice of arm-to-arm vaccination. For this he holds it up to the indignant scorn of the more advanced municipalities.

On the occasion of one of the internes relating at the Lyons Medical Society several cases of diphtheria which have occurred at the Hospice de l'Antiquaille, an interesting discussion arose, which we find reported in the *Lyon Médical* for January 21 and February 4.

M. Delore observed that the disease is frequent at the Charité, where it may be observed affecting the skin and mucous membranes, the surface of wounds, blisters, erosions, etc. Among the mucous membranes those of the pharynx and larynx are specially affected, and of wounds those after operations. He has met with it seven or eight times after harelip operations; and what is remarkable about it there is, that it occupied only the surface of the lip, and not the incised portions, so that, in spite of the complication, union could be obtained. It has frequently occurred, also, after autoplasty, and so great is its frequency and gravity, that autoplasty is a more dangerous operation at the Charité than amputation of the thigh. M. Delore cannot admit the assimilation that has been attempted between puerperal fever, diphtheria, and erysipelas, although these diseases may sometimes coincide. At the Maternité he has witnessed several epidemics of puerperal fever, and only rarely diphtheria; and while in the Surgical wards he often meets with diphtheria, he rarely sees erysipelas. Diphtheria is very contagious, and the epidemics which so often occur in the Charité can almost always be traced to a child with croup. A morbid condition of the mucous membranes predisposes to the contagion; and thus angina, laryngitis, bronchitis produce an alteration in the membrane which facilitates the absorption of the diphtheritic contagium. For the treatment of the disease he does not believe that there is any specific, all means having been attended with some success, while sometimes the affection stops short of itself without obvious reason, recurring, too, in other cases even after the application of the actual cautery, just as in hospital gangrene. It is, in fact, with this latter disease that diphtheria has most analogy, so that in some cases the differential diagnosis is difficult.

M. Icard wished to direct attention to the importance of the diagnosis between diphtheritic angina and the anginas which, under the name of *angine couenneuse*, are often confounded with it. Among these are the pultaceous, herpetic, and ulceromembranous angina; and the confusion thence arising brings Medicine into discredit. The characteristic symptoms of diphtheritic angina is a more or less thick false membrane, which is of a greyish-white colour, elastic, and cohesive, and adheres pretty closely to the mucous membrane, having also a tendency to invade the air-passages, and being accompanied by a more or less serous general condition, which has nothing peculiar in itself. In *pultaceous angina*, which is nothing but an inflammatory angina with epithelial desquamation, there are white, soft, thin, irregular patches, which are easily detached, and have no tendency to invade the air-passages. *Ulceromembranous angina* is characterised by circumscribed and superficial ulcerations, which are covered by a greyish, pultaceous, non-cohesive matter, easily bleeding, and almost always

coexisting with analogous ulcerations along the free edge of the gums, the lips, and inner surface of the cheeks. It has been observed as an endemo-epidemic among the military, and readily yields to the internal use of chlorate of potash. But in *herpetic angina* the difficulties of diagnosis are increased. It commences with small vesicles, which are succeeded by erosions of the mucous membrane, which becomes covered by small, thin, white circular and adherent pellicles. When these become confluent, they are sometimes not to be clinically distinguished from diphtheritic angina. The coexistence of herpes labialis is of some help in the diagnosis. Where there is doubt the prognosis should be guarded; but we should be careful in not resorting too readily to the use of cauteries in this and the above-mentioned forms. Even in the true diphtheritic form cauterisation will not arrest the development of the disease, and many excellent Practitioners have renounced its employment, relying only on general treatment.

M. Horand was of opinion that M. Delore had confounded *diphthéroïde* and diphtheria, as if they were two forms of the same disease. The former is a local affection of the buccal parietes, frequently met with in infants. It is found in the form of greyish ulcerations, and if the wound is pressed between the fingers, as is done when we wish to ascertain the induration of a chancre, a slight discharge is produced. The affection has no disposition to extend, and does not occupy even the whole interior of the cheek. It is more frequently met with in boys than in girls. It is neither contagious nor inoculable, and is not propagated to wounds. M. Boucaud fully recognised the great difficulty there is in the differential diagnosis of diphtheria and Gubler's herpetic angina. It would seem that there are also mixed cases, as in gout and rheumatism. M. Soulier admitted four species of diphtheria—the malignant, infectious, local, and chronic—the malignant also having two varieties, in the one of which the disease has a pernicious form from the beginning, false membranes already filling the throat when the symptoms had not caused any suspicion of danger; in the other variety, the disease is of grave form without being pernicious, the symptoms being in general proportionate to the extent of the lesion. It is the infectious form of the disease that is generally observed, the accidents, which at first seem local, being speedily followed by an infection of the entire economy. The third form is generally benign, especially affecting the larynx, and tracheotomy performed for it is often successful. In regard to diagnosis, it may be observed that at one time diseases of a pseudo-membranous character were multiplied too much, and then, a reaction ensuing, a generalisation took place, and diphtheria of various forms was admitted. Most of the so-called diphtheritic anginas are evidently herpetic anginas. M. Dron believed that a complete separation must be admitted between diphtheria and ulcero-membranous stomatitis, which has of late been called *diphthéroïde*—a term only calculated to create confusion. During five years at the Antiquaille, in a children's service of 240 beds, he has met with no case of diphtheritic laryngitis or angina, while he has seen more than 200 cases of ulcero-membranous stomatitis, which is, so to say, endemic there. The local characters of deep ulceration and pultaceous secretion covering this, as well as its ready cure by the internal use of chlorate of potash, prove that it is a disease radically different from diphtheria.

PARLIAMENTARY.—PUBLIC HEALTH.

In the House of Commons, on Wednesday,

Sir C. Adderley gave notice that on the 16th inst., on the occasion of the introduction by the Government of the promised measure relating to the public health, he should ask leave to introduce his own measure of last session for consolidating and amending all the laws relating to public health now existing and applicable to England and Wales.

MEDICAL REPORT OF THE SMALL-POX AND VACCINATION HOSPITAL FOR 1871.

PRESENTED TO THE ANNUAL GENERAL COURT OF THE GOVERNORS HELD ON FRIDAY, FEBRUARY 2, 1872.

THE epidemic of small-pox, to which we had to ask your attention in our last annual report, has not yet entirely ceased. Its influence was evinced in varying degree throughout the whole of the year 1871—markedly so in the first half of the year, and in minor degree in the second half. The monthly admissions of patients into the Small-pox and Vaccination Hospital during the year 1871 were as follows:—

January	137
February	117
March	125
April	130
May	109
June	88
July	61
August	39
September	21
October	35
November	40
December	60
Total	962

Of the 962 patients thus admitted into the Hospital in 1871, 950 were labouring under small-pox, and 12 under varied forms of eruptive or febrile disease—not small-pox, but assumed to be so, and on that assumption sent to the Small-pox Hospital. Of the 950 cases of small-pox, 870, or 91·5 per cent., of the whole cases of small-pox had been vaccinated; and 74, or 7·78 per cent., were unvaccinated. Six of the patients were reported to have had small-pox previously.

Of the 74 unvaccinated cases, 49 died, being a mortality for that class of 66·2 per cent. Of the 870 vaccinated cases, 130 died, or 14·9 per cent. Of the 6 cases classed as small-pox after small-pox, 2 died, or 33·3 per cent. Ten deaths in the vaccinated class were caused by superadded disease, viz.:—

Bronchitis	1
Gangrene	3
Erysipelas	3
Cellular inflammation and pyæmia	1
Diarrhœa and glossitis	1
Diarrhœa	1
Total	10

Fourteen patients admitted last year are still in the Hospital under treatment, and one of these is yet in some danger.

The general mortality for the year 1871 has been 181, or 18·8 per cent. of all admitted. Excluding the twelve cases not small-pox, none of which were fatal, the mortality was 19 per cent.—a death-rate largely in excess of any that has occurred at the Hospital during the last twenty years, and not attributable in this instance (as a heavy death-rate on many former occasions has been) to the number of unvaccinated children suffering from small-pox who have been admitted into the Hospital (for of such there were very few in the year 1871), but due to the severity of the disease, and especially to the number of cases of malignant small-pox, the proportion of which to other cases has been very largely in excess of anything within the previous experience of either of your Medical officers. In this respect the small-pox epidemic of 1870-71 has deviated from the ordinary course of epidemics. As a rule, the proportion of severe cases is the largest, and the mortality consequently greatest, during the earlier portion of an epidemic, the disease becoming milder, the proportion of severe cases less, and the mortality diminishing, as the epidemic approaches its termination.

But in the case before us this rule has been reversed, for the proportion of severe and fatal cases increased as the epidemic advanced. In 1870—the first portion of the epidemic—in a total of 1285 cases of small-pox, there were 19 malignant cases, or rather less than 1·5 per cent.; whilst in 1871—the latter portion of the epidemic—in a total of 950 cases of small-pox, there were 42 malignant cases, or 4·4 per cent. In the 74 unvaccinated cases there were 6 malignant, or 8 per cent.; in the 870 vaccinated, 36 malignant, or 4·1 per cent. All the malignant cases, without exception, proved fatal. In fine, the mortality, both in the vaccinated and unvaccinated, has been

nearly double what was the average of a series of sixteen years—viz., from 1836 to 1851 inclusive—as may be seen by a comparison of the return of 1871 with the tabulated reports made public by your Resident Surgeon in 1853. 965 persons have been vaccinated at the Hospital during the year 1871, and 732 charges of vaccine lymph have been supplied to the members of the Medical Profession at home and abroad, besides several large supplies in tubes for the colonies.

WILLIAM MUNK, M.D., F.S.A.,
Physician to the Hospital.

J. F. MARSON, F.R.C.S.,
Surgeon to the Hospital.

London, Feb. 2.

THE CONTAGIOUS DISEASES ACTS QUESTION IN A NUTSHELL.

It is surely high time that some agreement should be come to between the supporters and the opponents of these Acts. New statutes may be framed so as to include all the solid advantages which the former claim for them, and at the same time to exclude provisions which give ground, or seem to give ground, for the argument that these Acts may be used to promote moral, whilst attempting to repress physical evil.

Some of the objections against the Acts must be admitted to be unanswerable, because they seem rather to belong to the department of lunacy than of common sense.

1. One of them is the plea that venereal disease was intended as a punishment for sins of the flesh, and that to do away with the punishment will take away the prudential motives which restrain some men from sin. There may be some truth in this; but still, if such an argument is to be acted on in one case, why not in more than one? Lice and the itch are punishments for want of cleanliness; diarrhoea and typhoid for want of proper modes of disposing of ordure; rheumatism and gout, pneumonia and pleurisy, are all punishments. But who would begrudge a pot of brimstone ointment to a man with itch, lest other people should be encouraged in the sin of dirtiness?

2. A second is, that women have a right to do what they like with their own, and that laws against disease are infringements of liberty. According to this, we should abolish our legislature against small-pox.

3. Next comes the objection that, by simply attending to the health of public women, and neglecting their morals, a kind of Government stamp is given to two pernicious principles. One, is that indulgence is a matter of necessity for the one sex; and the other, that the "State" should make provision that this indulgence may be safe.

Now, spite of all the accusations made against the Medical Profession, we do not believe that it as a whole, or any more than that most insignificant fraction who in so large a body may be expected to hold eccentric and unusual opinions, ever promulgates any doctrine, in public or in private, contrary to sound morality. Of this we can adduce one remarkable instance:—

In the interesting volume issued by Dr. Dobell ("Reports on Progress of Medicine in various parts of the World," vol. ii., p. 228) we find a report from an English Physician at Java. This gentleman, in describing the moral and physical peculiarities of the population, says that all the unmarried Europeans either keep mistresses or resort to the public women. He speaks of resistance to the sexual passion as attended with bad consequences to health. When asked by young men in this difficulty—"What am I to do, Doctor?" his advice is *not* that which we will say, unhesitatingly, would be given by respectable men in this country. But to show that this is his private opinion only, and that our Profession cannot be accused of sanctioning immorality, let us quote further. "I will not dilate further," he says, "on this subject, falsely called 'delicate' by some, but which, I think, ought to be openly and honestly handled by the Profession, and more especially by professors to their pupils. I think I never heard this subject even mentioned, much less lectured on, during the whole course of my Medical studies; and this is very unfortunate for the young Doctor afterwards."

Here we see the force of the proverb, "*Exceptio probat regulam.*" This gentleman holds opinions and gives advice which he considers physiological, but most of us immoral; and he complains that these opinions are *not* taught in the schools.

It must be confessed that the other part of this accusation—

viz., that a department of the State is organised for the purpose of making vicious indulgence safe—might be held with some show of probability if some of the statements of the special supporters of the Acts were taken too nakedly. We hear it said that "the Medical Profession has nothing to do with morality"; that a Surgeon who undertakes the private visitation of a brothel is only exercising his skill legitimately. We find a late writer (Dr. Rogers) in behalf of the Acts stating as follows:—

"A matter of hygienic and police importance might also fairly be considered, and well deserves attention—as to the dwellings of this unhappy class. Admitting, as we must, that the evil exists, and, so far as we can see, *will exist*, it seems cruel to drive them into the most unhealthy and noisome slums. Apart from the effects of the disease itself, there is thus also its implantation in a system under the worst hygienic influence to be considered, and which will, in all probability, reflect itself in the recipients of the contagion. Better far to allow some tacitly acknowledged retreats in healthy parts of the town, under police surveillance."

If this proposition means anything, it means that public women are not only to be treated medically at the public expense, but that their dwellings are to be placed under police and sanitary care superior to that bestowed on the honest working-classes, who, we suppose, are to be left to the full benefit of the "unhealthy and noisome" slums, from whose influence the women and their customers are to be protected by the "State."

The substance of what is desired is, that prostitution—open, brazen-faced, public prostitution—in public places shall be repressed by the police; that any prostitute under 21 be sent to a reformatory; and that the repression of syphilis be made, as it should be, a subordinate but essential work of the machinery for the suppression of open prostitution; whereas at present the disease is put into the first place, and morals left out.

We must here do full justice to the persons employed in carrying out these Acts, and acknowledge that although, technically speaking, it is disease, and not vice, which is their subject-matter, yet that, in the actual discharge of their duties, vice has received a large share of repression. We refer with pleasure to a pamphlet "On the Working of the Contagious Diseases Acts at Cork and Queenstown," by James G. Curtis, jun., Visiting-Surgeon, 1871—a work evidently dictated by views as clear of the necessity of discountenancing vice as those of anyone who opposes the Acts on the plea of morality.

"When first the Acts came into force," says Mr. Curtis, "the streets of Cork were a disgrace to any civilised community. Nearly 400 Phrynes of the lowest type nightly paraded the chief thoroughfares, so sunk in vice that one could scarcely fancy them human beings. No virtuous female, even when accompanied by a male relative, dared to traverse the streets without incurring the risk of being saluted with the vilest obscenity, and disgusted by scenes of frightful inebriety; in fact, the streets of Cork at night were as faithful a representation of Pandemonium as need be. What is now the case? Cork is, for its size, as orderly a city at night as any in the world. No gross obscenity or drunken ribaldry offends the ear; and the most practical proof of the efficacy of the Acts is, that out of this large number of prostitutes (400) there now remain in the district but 181, of which latter there are usually in Hospital, prisons, and workhouse 104; leaving the actual number at present in Cork, Queenstown, and an area around them of ten miles, but 77 at large. Well may I be asked, Where are the rest? Have they gone elsewhere to carry on their sinful trade? A very small number indeed have; but the majority have not only left the streets, but have left their degrading life, and become virtuous."

If all advocates of the Acts had written in the gentlemanly and moral tone of Mr. Curtis there could have been no vestige of ground for the accusation that their sole care was to make vicious indulgence safe.

We say, in conclusion, "Repress open flaunting prostitution, which is the tree, and not merely syphilis, which is the fruit." If the police can take cognisance of public women, and if they can be subjected to moral influence when diseased, why not before they are diseased? As for *extinguishing* prostitution, that is Quixotic; but we can make it hide its face. We will wind up with a cutting from the *Daily Telegraph* of October 16, 1871, headed "Jack Ashore," and describing life at Wapping. Let us say that a police that is to exterminate syphilis had better begin with such prostitutes ("scores and hundreds, from 15 to 50") as anyone may see at Wapping.

"Here," it says, "are the old taverns where jolly Jack Tar,

both of the navy and of the mercantile marine, used to drain his can of flip, as well as several of modern build, and they are ablaze with gas and plate-glass, and there are announcements of concerts and dancing-rooms. Men in reefing jackets pass in and out, some alone, and some in close companionship with females in ball-room attire. There is the sound of music within, and shrill female laughter. This is promising. Let us enter the 'Old Frigate' and see how the modern Jack ashore disports himself.

"A first look round somewhat damps one's expectations; the more so, because it is evident at a glance that the male customers who cluster about the extensive bar are seafaring men, and that the females present are their consorts. A terrible-looking lot the latter—brutal, bleary-eyed, savage-looking, from *fifteen to fifty* and over, all with a thirst for gin as ferocious as that of the tiger for blood, and with as little consideration for the victim who supplies it. No blandishment or 'blarney' with these bruised and bloated black-eyed Susans; no ogling or make-believe of affection, or even of affable toleration, for the men whose pockets they are draining. They demand more gin or rum with the air of a Whitechapel fighting man in female disguise, and spill it down their capacious gullets without so much as a bare 'thanky.' But perhaps these are not fair samples of the modern 'lass that loves a sailor.' The 'concert-hall' was at the end of a passage; a curtain screened the entrance to it; and no doubt within its more secluded precincts Jack ashore, and in search of that lovely charmer, a few hours in whose blissful society give ample reward and consolation for weeks of toil upon the raging main, is more fortunate.

"Delusive hope! The 'concert-hall' was as melancholy a place as could well be imagined. At the end of the room there was a raised platform, with a shabby attempt at scenic decoration, and a fiddle and a harp; and at intervals a female 'came on' and favoured the company with a song, not much more indecent than many to be heard at any music-hall. Afterwards the singer, with her low-necked frock, and her short skirt and 'fleshings,' moved among the audience with cigars and tobacco, and received its congratulations, together with any odd pence it might please to bestow on her, over and above the price of the havanahs. That was all the 'fun,' if so it may be accounted. . . . They were dull and stolid, and good for nothing but drinking.

"This, at least, was evidently what the women thought—drinking and fleecing. A heartless, cold-blooded set of ogres! I do not speak exclusively of those assembled at the 'Old Frigate,' but of the scores and hundreds besides who were to be found that night, or any night, haunting Ratcliff and Shadwell, and lying wait like beasts of prey for spoony modern Jack ashore, to hocus and pillage him. They are a peculiar breed of females, I believe, that have their lairs in Tiger Bay, and Backchurch-lane, and Palmer's Folly, and other awful places contiguous to the Docks. They appear different from the vilest creatures of any other part of London, and they act differently. The grit of vice seems to have scoured their natures bare of all that is womanly, while it gives the keenest edge to their cunning and rapacity. Jack ashore has wonderfully altered with the times. He sits like a fool, and allows a tigress of the 'Bay' to get drunk at his expense. Should he be too wary to let her dip her hand into his pocket, and so 'drink him dry,' she will permit him to accompany her to her den; and he is a remarkably lucky Jack if he escapes therefrom with the clothes on his back. Occasionally, once or twice a week, these cases of robbing and stripping are brought under the notice of the police magistrates; but it is a fact which the police of this infamous district could corroborate, that if the plunderers were prosecuted in every instance, his Worship on the bench would find his time pretty constantly occupied with them. Jack ashore, however, has no love for the police or for police-courts, and would rather bear the loss than risk the ridicule of his ship-mates."

Will anyone dare to advocate the repression of mere disease, and to leave this abominable public profligacy as it is?

It is understood that the Waynflete Professorship of Chemistry at Oxford will shortly become vacant by the resignation, through ill-health, of Sir Benjamin Collins Brodie, M.A., of Balliol and Magdalen Colleges. Professor Brodie was elected to it in 1855. The Professorship is worth £600 a year, and is in the gift of the Chancellor of the University.

SOME REMARKS ON DR. MAUDSLEY'S BOOK, "BODY AND MIND."

By Dr. F. A. HARTSEN.

OF modern philosophical publications which have lately appeared, England has given by no means the least important contingent; and among these "Body and Mind," by Dr. Maudsley, is decidedly one of the most attractive. We wish to make some remarks upon that part of his book which is especially consecrated to the theory of vitality.

The characteristic of Dr. Maudsley's theory of vitality is this: that he considers the different modes in which life appears as so many kinds of *force* (vital forces) and, definitively, transformations of *physical* forces (warmth, electricity, etc.).

From a theological point of view, the theories of Dr. Maudsley have already been attacked. We wish to attack them from a logical point of view, and more particularly so his theory of vital force.

The idea of considering vital forces as transformations of physical forces is certainly very ingenious and seductive. But, we regret to say, it is rather the consequence of a poetical than of a scrutinising mind. It is inspired by the spirit of Goethe rather than by that of Newton or Whewell.

Dr. Maudsley has a very strong love of *generalisation*, and his theory is the offspring of his worship to this divinity. Not that we would wish wholly to banish generalisation from science, but, surely, in this matter great caution is required, and one should never in generalising "sell the bear before she is killed." For instance, in physics it is a law that heat, electricity, and chemical affinity are never destroyed, and that, if one of them appears to have been destroyed, it is present in another form. Thus it is admitted that those phenomena can be transformed the one into another. From this Dr. Maudsley infers—"Though it may seem difficult to avoid the conclusions that there is fundamentally but one natural force which manifests itself under different modes, yet such a supposition at present transcends the domain of science."—(P. 152.)

Dr. Maudsley, who abhors the idea of force which produces itself, is not in earnest shocked at the idea of one single force taking different forces—nobody knows why!

But wait a little. What is in reality transformed? Dr. Maudsley and Physicians say *force*. But let us ask: is this exact? What is heat, and what is electricity, and what is chemical affinity? Are they not modes of motion? *Motion*, so it seems, not *force*, is transformed. Is real force, which is an *action of an atom*, (a) ever converted into another? We doubt it. Who has ever stated that a real force—*gravity*, for example—was transformed?

Admitted that heat, etc., were real forces, we have no right to assert that even among the physical forces the law of transformation is without exception. The utmost we may do is to allow it to those forces which are not inherent to a special atom, or, rather, which do not form its substance.

But Dr. Maudsley, it seems, sets aside all atoms, and, in fact, all *positive individuality*. To him the whole world is an agglomeration of forces which can merge the one into the other. He abhors creations out of nothing, but at the same time he allows one substance to be transformed into another, as if this did not suppose both destruction and reconstruction!

Dr. Maudsley not only generalises extravagantly, but (in contradiction to all rules of science) ends by constructing the particular from his own generalisation. In short, his theory of vitality is evidently a deduction from this argumentation. If the axiom that force, like matter, is not capable of annihilation be accepted, and we find, as we do, that organic bodies incorporate, or somehow cause to disappear, inorganic matter and force, and thereby themselves increase, it is an unavoidable conclusion that the organic matter and force must represent the converted inorganic matter and force (p. 167), etc.

Here, as minor, another axiom is supposed—namely, this: when a thing appears while another disappears the former is necessarily a transformation of the latter. But this axiom we must declare wholly arbitrary. By the same rule Dr. Maudsley could go a step farther, and declare that each effect was *nothing but the transformation of its cause*. If he means that this would be too much in opposition to facts, we could make the same objection to his own theory. Nobody denies that

(a) That which we call "matter" is evidently nothing else but *force*. See on this subject the "Psychology" of Professor Ulrich, the publications of Professor v. Fichte, Mr. Drossbach, and others.

the force and matter which organic beings incorporate are lost. But does it follow from this that they are *transformed* into vital force?

It is possible that an action is necessary to another without there being any transformation of the one into the other—that is, without destruction of individuality. For instance, if I order my servant to lift a heavy weight, two activities are manifested: firstly, my volition, and secondly, the muscular activity of the arm which lifts the weight. According to Dr. Maudsley's theory, the latter activity would be the transformation of my volition. This evidently is not the case. Let us analyse the origin of the muscular activity, and it will never be brought back to my volition. The muscular activity may be transformed chemical affinity of substances in the servant's blood, substances emanating from his food. Allowing them to be transformed volitions of the *servant*, they have nothing to do with *my* volition. For my volition is not transformed into the servant's volition. My volition has only given the impulse to my organs of speech. These have brought the air into movement, and this movement has communicated itself, through the ear of the servant, to his mind. Each keeps his own volition. And even if the little force necessary to produce the vibration in the air which conveys my order to the servant were transformed volition, *his* volition is not a transformation of that force. Thus, the muscular activity which lifts the weight at my command would be at the utmost a transformation of the *servant's* volition, not of *mine*. But it is *not* a transformation of his volition. No; for, as it is between me and the servant, so it is between the molecules of which the servant is constituted. The force displayed by the fibres and atoms of his muscles has by no means its *origin* in his volition, but in his blood, and finally in his food. His volition is not transformed into the volitions (so to speak) of the molecules of his arm, but it *commands* the molecules of his *brain* as I command my servant. Consequently, the molecules of his brain command to the molecules of his *peripheral nerves*, and these latter command (by vibrations?) to the molecules of his muscles. So each molecule acts by itself, and *keeps* its own force.

If really the muscular activity were transformation of volition, there would be a *proportion* between the volition and the activity displayed in consequence of it. Now, this is by no means the case. It does not require a greater expenditure of volition to command a large army than a small one, and a child can command his muscles to lift up 1000 kilos as well as an athlete. If the command be not obeyed, it is the fault of the muscles, not of the volition. We see by this that the quantity of motion or physical force displayed by a volition is not proportionate to its own expense of activity, but to the *place* it occupies, and to its instruments of action.

And so it is with all vital force. The soul, whatever may be its nature, needs physical force for its manifestation. But the real *source* of this force is the body, not the soul itself. The soul is not transformed into physical force, nor physical force into vitality. But Dr. Maudsley admits no soul as a substance. He considers the soul as a production of the organisation. We may ask Dr. Maudsley . . . whence this organisation itself?

However, even the strongest materialist cannot explain the world as a Proteus-like transformation of a force. He is at least obliged to admit *fixed centrum*s (atoms) of force. And though these centrum's may change their relations towards each other, though they may exhibit movements according to certain laws, it would be an upset of all science to admit that a force could be detached from one atom and reappear in another atom in a different form.

We can admit that an atom itself—the soul, for instance—changes its form of action, according to the manner in which it is affected by other atoms; but this is quite a different matter. (b)

PORT OF SPAIN, TRINIDAD, January 17.

THE EPIDEMIC OF SMALL-POX IN TRINIDAD.

THE epidemic, of which I very briefly described the commencement, has now reached what we hope is its height in

(b) After having written these lines we made the acquaintance of the "Psychology" of Professor Herbert Spencer, and were agreeably surprised in finding our own arguments in his interesting book.

Port of Spain. There have been reported to the Health Office up to the present date (January 16) 1740 cases and 310 deaths. There are many more deaths than these, but they have not all been reported. One day last week twenty-seven deaths from small-pox took place, and this out of a population of 23,000. This was at the rate of nearly 43 per cent. per annum. The cases have lately assumed an exceedingly malignant form, many petechial and hæmorrhagic cases having occurred, all of which proved fatal. The extraordinary amount of eruption in some of the negroes is astounding; the whole body is one single pock—that is, the whole of the epidermis is raised in one smooth, even mass, without even the marks of division into pocks, except, perhaps, on the abdomen. These cases, of course, die in a few days of blood-poisoning; they never reach the pustular stage. The epidermis is rubbed off as from a blister in large masses by the patients rolling about; and they present a horrible spectacle. Very many corymbose cases have come under my observation. I have found that in these, and severe confluent or semi-confluent cases with a copious eruption, nothing does so much good as opium. At the Small-pox Hospital, which is under my charge, I treat the secondary fever in these cases with bark mixture and opium, and certainly some have recovered who seemed hopeless at first. Ten minims of the tincture every four hours is the usual dose, with a little compound tincture of cinchona, and two grains of quinine. Delirium is exceedingly common, and the patients are very violent and troublesome. Chloral seems to do no good unless pushed to larger doses than would be safe. Morphia given in repeated small doses answers better. It has often been necessary to give nourishment in these cases per rectum, as they refuse everything.

As a rule, all the bad cases come from certain well-known localities, where every possible sanitary defect exists, especially fearful overcrowding. I suppose the densest slums of London are not now so overcrowded as many parts of Port of Spain are. At night the people are packed together on the floors as thick as they can lie.

One case of secondary small-pox has occurred. It was in a coloured girl, who lives in one of the most unwholesome streets in the town. She had small-pox in the epidemic of 1861. Attacked with the discrete form in this epidemic, she had petechiæ over the whole of the body; she died after five days' illness. What is curious is, that the petechiæ appeared *before* the eruption, and during the primary fever. This led me to suppose that it must be typhus. Three other cases have occurred in the same house.

It is unfortunate that the measures taken by the Board of Health at the commencement of the epidemic were of such a feeble and inefficient character. They are now beginning to wake up, and are adopting more energetic measures. The Medical Officer of Health, Dr. Bakewell, resigned on January 2, partly because he found the work too much for him, he having charge of the Small-pox Hospital, and being Vaccinator-General also, but chiefly because he was disgusted by the continued opposition made at the Board of Health to the plans he proposed for treating the epidemic, and which he deemed essential if it was to be in any degree checked. Dr. Crane, the Surgeon-General, has been appointed to succeed him.

I regret to say that pernicious fever has made its appearance, and typhoid has caused some deaths lately. Diphtheria is also somewhat prevalent. Altogether this is about the unhealthiest colony in her Majesty's dominions, and now we are all shut in here, as none of the steamers will take passengers from this island on account of the quarantine regulations.

PROVINCIAL CORRESPONDENCE.

IRELAND.

DUBLIN, January 27.

At the last meeting of the Dublin Obstetrical Society, held on Saturday evening, January 20, a most valuable paper was read by Dr. George Johnston, the present Master of the Rotunda Lying-in Hospital. The communication to which I refer was a report of the practice of that institution during 1871. Since he entered upon office Dr. Johnston has laboured to bring the sanitary working of the Lying-in Hospital into a most efficient state, and his efforts have so far been crowned with success. A perfectly pure atmosphere in the wards, secured by allotting a large cubic space to each patient and by a system of thorough ventilation, the maintenance of strict cleanliness in every particular, and the judicious management

of the cases under treatment have worked marvels in raising the health-standard of the Hospital.

In the year which has just drawn to a close, characterised as it was by the prevalence of epidemics—more or less severe—of scarlatina, typhoid fever, and, lastly, small-pox, the healthiness of the Lying-in Hospital comes out in still bolder relief. During the year ending November 5, 1871, 1161 intern labour cases were treated, of which 403 were those of primiparæ. In 963 instances the labour was in every respect natural. There were 19 cases of tedious labour, 56 of preternatural labour, 39 of complex labour, and there were 24 abortions. The deaths amounted to 33—a number higher, indeed, than that of the former years, but, as appears from an examination of the causes of death, in no way to be attributed to defective sanitary arrangements. Of the 33 deaths from all causes, 21 were referable to zymotic diseases, of which peritonitis with 8 deaths heads the list. Of the remaining 13 deaths from zymotic causes, 8 were due to accidents attending the puerperal state. One death resulted from typhoid fever, 2 from bronchitis, and 1 from scarlatina. The number of cases of zymotic diseases under treatment during the year was 50, of which, as before stated, 21 terminated fatally. Nearly one-half of these 50 patients—namely, 23—were unmarried, the victims of seduction or the votaries of prostitution; and this fact speaks volumes for the influence of mental agitation or other depressing circumstances on lying-in patients. The second portion of Dr. Johnston's report is devoted to an analysis of the operations performed, or the complications met with in the same period. In 64 cases delivery was effected by the forceps; craniotomy was performed in 6 instances, and version was practised on 7 occasions. Prolapse of the funis occurred 8 times; there was 1 case of placenta prævia; accidental hæmorrhage was met with in 8 instances, post-partum hæmorrhage in 5 instances; there were 2 cases of eclampsia, 12 of mania, and 9 of retention of the placenta from morbid adhesions.

At the same meeting, a most remarkable case of quadruple birth was described in a paper by Dr. Cuppaidge. The mother was only 19 years of age, and was five months and a half advanced in pregnancy when labour occurred. The first two children were alive when born. A foot-presentation took place in the case of the second foetus, a breech in that of the third, and the fourth presented with the nates. Two distinct placentæ existed.

As was to be expected, from the still increasing proportions and formidable character of the small-pox epidemic now prevailing, the recent meetings of the Medical Society of the College of Physicians have been chiefly devoted to a consideration of the leading topics connected with that terrible disease. The subject was introduced on December 13, in an able paper on "Treatment," by Dr. Stokes. To obviate the untoward effects of pitting, the local treatment by poulticing, and in some instances by depletion, was advocated, and the great advantages derived from the use of the warm bath in certain instances were enlarged upon in this most valuable communication. The subject of variola was again taken up at the January meeting of the same Society, in a paper from the pen of Dr. Malachi Burke, entitled "Some Observations on the Present Epidemic of Small-pox." Dr. Burke traced the history of the outbreak from its commencement in the spring of last year, and dealt with the principal questions relating to the subject in a manner eminently suggestive and introductory to the subsequent discussion.

The debate has already extended over two evenings, and has been again adjourned. The speakers have chosen very varied stand-points from which to view the question, the topic most frequently treated of being, perhaps, the efficacy of revaccination as a preventive measure. Drs. Beatty, Kidd, Atthill, Hayden, and others directly, and Dr. Grimshaw indirectly, have borne testimony in favour of the repetition of the operation. The clinical aspects of variola have engaged the attention of Dr. William Moore, Dr. MacDowel, and others. Of the speakers mentioned, Dr. Moore called attention to the early appearance of the eruption in many cases—within thirty-six hours from the first development of symptoms; while Dr. MacDowel spoke of the purpuric tendency observed in so many cases—perhaps connected with the recent prevalence of malignant purpuric fever in our city. Again, statistical information has been brought forward by Drs. Grimshaw, Hayden, and MacDowel, all of whom have devoted attention to the influence of contagion in spreading the disease. I may say that, in the case of the two largest fever Hospitals in Dublin, the earliest cases of small-pox last year were clearly traceable to importation from England, Scotland, or Wales. As to the

mitigating influence of vaccination on the virulence of disease, the striking fact came out in the discussion, that while the mortality of protected persons attacked averaged only from 6 to 9 per cent., that of the unvaccinated amounted to 50 per cent. and upwards.

So far a great difficulty, having reference to the too early dismissal of small-pox patients from Hospital, has existed. There seems to be now good hope of having this drawback removed, as accommodation is being prepared for convalescents dismissed from the wards of the South Dublin Union. It is to be hoped that similar steps will be taken by other public bodies, so as to prevent the dissemination of the disease among the relatives and friends of the convalescent.

The remarkable displacing influence of a prevailing epidemic on diseases of a kindred type is at present well exemplified here. In many Hospitals the fever wards are, and have been for some time back, almost empty; and though scarlatina is so frequently met with as nearly to assume the proportions of an epidemic, yet it is generally of a comparatively mild nature, in pronounced contrast to its character of a year or two ago.

GENERAL CORRESPONDENCE.

TREATMENT OF HYPERPYREXIA BY CONTINUOUS IRRIGATION.

LETTER FROM DR. RICHARD NEALE.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—Much has lately been written upon reducing the temperature in hyperpyrexia, and many have been the ingenious contrivances to effect that purpose; but in no paper have I seen allusion to a plan so familiar to myself that I presumed everyone else knew of it, and which has, in my hands, for years past produced the result desired—*cito, tuto et jucunde*,—I allude to continuous "irrigation" of the head.

During several years' active practice in Java, where one has daily to combat fevers of the greatest intensity, it was my custom to treat in this manner cases where the fever, from its intensity, threatened to overwhelm the cerebral system. The patient was brought to the edge of the bed, or, if young, placed on a table, with oil-cloth (if at hand) underneath—generally it was a plantain-leaf—a roll of linen in the hollow of the neck, and the head over the edge of the bed or table, a vessel to catch the water below, and, if obtainable, a tea-urn placed above with a piece of elastic tubing. Generally I had to use only beer-bottles, filled with water out of the coldest well or iced (this rarely), with a slit cut in each side of the cork, so that a stream as large as a crowquill could continuously issue. The effect was magical. The delirious patient passed into a quiet slumber; the comatose into a healthy sleep. The hand placed on the pulse could feel the effects, and although the thermometer was not then used as now, the hand told the difference in temperature. After a very short period, indeed, you could bring down the temperature as low as was consistent with safety. Cease the irrigation, and, unless the fever were abated, the previous temperature would soon be again reached. Of course remedial agents, such as quinine (generally combined with iodide of potassium if the brain were much implicated), were simultaneously employed.

Patients have been thus irrigated for thirty, forty, or more hours—one of my own children for thirty-six. One child, aged 10 years, with frightful convulsions, due to tubercular meningitis, complicated with acute dysentery and violent remittent fever, was for eight or ten days and nights continuously, or with short intermissions, under the tap, where she slept as peacefully as in health; but, the stream ceasing, soon the convulsions returned with all their former violence, only to be calmed by "re-irrigation," until death released her.

Dr. Wilks alludes to a case in the *Medical Times and Gazette*, August 1, 1868, page 115, where the results of this plan were most beneficial. I have read, too, of a patent "infant nursery" (the locality has escaped me). It consisted of a ledge under a waterfall, where the native women laid their young children on going to work, so arranged that a stream of water, conducted by a bamboo, fell on each forehead. The child slept quietly until fetched by the mother, her work being done.

It has only once fallen to my lot to employ the above treatment since my return to this country, and then the results were most happy.

One point I ought to mention is, that when the irrigation has

been kept up for thirty or forty hours, the scalp has occasionally peeled afterwards. I am, &c.,

RICHARD NEALE, M.D. Lond.

60, Boundary-road, St. John's-wood, N.W.,
February 5.

TYPHUS FEVER.

LETTER FROM DR. FRANCIS R. HOGG.

[To the Editor of the Medical Times and Gazette.]

SIR,—Accidentally dropping in at Guy's Hospital, and taking a seat amongst attentive students, the great pleasure was afforded me of listening to Dr. Wilks. Amongst other subjects, in an interesting lecture, he reminded us of the difference between typhus and typhoid fever, distinctions which cannot be repeated too often. Although every Practitioner has a library, memory is proverbially treacherous, and continuous reading in the distraction of practice but seldom congenial; whereas, the casual perusal of the Medical journals, in addition to discussing the discoveries of the present, will recall to recollection the lessons and teaching of the past. Briefly, then, typhus, an epidemic contagious fever, originating in dirt, destitution, and overcrowding, commences suddenly after an incubation of nine days, the duration of fever about fourteen, the rash appearing about the fourth—mulberry, petechial, continuous, universal; the patient stupid, the tongue brown, the abdomen natural, the evacuations dark. On the other hand, typhoid—endemic—a non-contagious fever of the better classes, depending on defective drainage and poisoned water—creeps on insidiously after incubating about thirteen days, the fever three weeks, the rash out on the tenth day, rose-coloured, lenticular, non-petechial, and sparsely scattered in successive crops; the patient flushed and animated, the tongue glazed, fissured, and red, the abdomen tumid, the evacuations ochrey. During the leisure of a month's leave, analysing certain statistics, it appears that the deaths in England from typhus typhina, typhina, taking the mean average from 1850 to 1869, amounted to 17,960 annually; the deaths to 10,000 persons living, about 9·18; the proportional number to 1000 deaths being 41.

In 1865 the Registrar-General records 23,034 deaths, and in 1860 only 13,012. Examining the London Fever Hospital reports, the typhus admissions from 1862 to 1870 run:—1827 (in 1862), 1319, 2497, 1961 (in 1865), 1735, 1383, 1971, 1260, and 631 (in 1870); the deaths being 365 (in 1862), 203 (in 1863), 435 (in 1864), 402, 343, 275, 297, 259, and 117 (in 1870). Total number admitted 14,584, of whom 2696 died. The majority came from miserable localities. The mortality under the age of 20 less than 5 per cent., but above the age of 50 exceeding 50 per cent. Excepting April, 1862, and July, 1870, the admissions highest in November, December, and January, but low in April, June, and August. Excepting the year 1862, female admissions invariably in excess; and as to mortality, from 1862 to 1870 the males 1375 to 1321 females. The characteristic eruption noticed in the following percentage:—94 (in 1862), 96, 97, 93, 85 (in 1866, curious), 95, 96, 97, and 92 (in 1870).

Complications.—Out of 981 fatal cases, the principal complications were—Pulmonary, 470; diarrhoea, 68; convulsions, 46; parotid swellings, 34; erysipelas, 20; gangrene of the feet, 10; scarlet fever, 1; cholera, 1. Calculating from nearly 8000 other cases, the complications and results run somewhat thus:—Pulmonary 1264, deaths 458; diarrhoea 430, deaths 101; dysenteric ulceration 3, deaths 2; obstinate vomiting 15, deaths 7; of 96 instances of parotid buboes (single and double) and submaxillary swellings, 37 died; erysipelas and pyæmia 39, the deaths 11; retention of urine 108, deaths 51; convulsions 76, of whom 69 died; brain disease 9, deaths 4; gangrene of the feet, nose, ears, chest (principally of the former), 15 instances, 8 deaths; cancrum oris, 3 instances, all fatal; various hæmorrhages 12, the deaths 9; bedsores 49 (chiefly begun prior to admission), 13 deaths; epistaxis 3, 1 death; jaundice 3, 1 death; cardiac disease 3, of whom 2 died. Single fatal instances are recorded as complicated with phthisis, pericarditis, hæmatemesis, catalepsy, and keratitis. As to pregnancy, out of 52 women it is very satisfactory to find that only 3 died; 1 went her full time in Hospital, and 22 aborted.

Non-fatal Complications.—Phlegmasia dolens, tonsillitis glossitis, phlebitis, laryngitis (1 of tracheotomy), diabetes, ague, thrombosis of femoral vein, hysteria, albuminuria, carbuncle, otorrhoea, various abscesses and excoriations.

Health of Officials.—Out of 30 Medical men in 34 years, none died; the last fatal case up to 1866 was that of Dr. Dill, in

1832. However, in 1866 Dr. Wyber, and in 1870 Mr. J. C. Skinner, died of typhus. From 1862 to 1870 ten other Medical officers attacked (this event happening every year excepting 1868), recovered. The deaths of two bath-women and two scrubbers are recorded; also of an engineer (in 1864), who had been employed in the Hospital for sixteen years, and who had never before had fever, although his duties brought him daily into the wards. A small number of patients—about 48—suffering from other ailments, contracted typhus. Now about the nurses: from 1862 to 1870, out of 162 attacked thirty-three died—a terrible state of things until the question is fully considered. When it is a matter of fact that nurses have been known to enjoy good health in the Fever Hospital for twenty years after their first attack of typhus, the remedy appears very simple—only to employ young seasoned nurses, and to pay them well—it becomes simply a question of finance. Money, people say, will buy everything but health and happiness; in this case, it will restore health, possibly, to many patients; and, after full consideration, no institution in London appears more deserving of support than a Fever Hospital. Think for a moment of the frightful mortality when cases of typhus are treated in a general Hospital, or allowed to remain in the garrets and hovels of the poor, or in the kitchens and attics of the rich. At great personal inconvenience and neglecting legitimate work, with the hope of learning something, the Hampstead Hospital Inquiry was once or twice attended. An immense establishment, worked by a Naval Surgeon and three lads, where a number of patients gave an infinity of trouble without contributing one farthing, appeared severely taxed. The other day, a crowd of foolish people broke through the ice whilst skating. Their gratitude for life-preservation was represented by a few shillings, and complaints as to the quality of the brandy-and-water. On the subject of typhus, at some distant period of leisure, I hope to be allowed to give my own views and experience. I am, &c., FRANCIS R. HOGG, M.D.

HORSE AND CATTLE SICKNESS AT THE CAPE.

LETTER FROM MR. W. S. BLACK.

[To the Editor of the Medical Times and Gazette.]

SIR,—In Dr. Egan's letter from the Cape, reference was made to the prevalence of horse-sickness and pleuro-pneumonia in cattle in Caffraria, as well as to its intractable nature. This I can fully corroborate from what I saw myself, as also the great mortality resulting, and the pecuniary loss entailed upon owners of stock of both descriptions. Notwithstanding these melancholy prospects, there still exists a possibility of successful treatment, if the means were commensurate to the object in view. The catarrh of the horse is of the most fatal character, and rapidly extends to the trachea and bronchial tubes, and causes death by suffocation induced by the immoderate flow of secretion forced into the air-passages.

Bleeding has been repeatedly tried, but the depression following it is always prejudicial to the strength of the animal, and death results in spite of it. Purgative balls, again, are equally unsuccessful; they induce debility, and (if persisted in too far) cause inflammation of the intestines. On the other hand, antimony and sulphur appeared to have a more salutary effect in diminishing the abundant secretion by causing diaphoresis. This was further tried to be aided by covering the animal with blankets, and abundant perspiration used to follow. Diuretics, as nitre, tended subsequently to confirm this good effect on the disease by inducing full urination and relieving the tendency to the watery secretion from the lungs. In horses there was always coryza preceding the congestive bronchitis, and when the disease was established, the mucus flowed in streams from the nostrils, and suffocation soon resulted from its accumulation and non-expulsion.

In cattle there was a distinct solid pneumonia, with serous and gelatinous pleurisy seen on post-mortem examination. The favourite remedy at the Cape was inoculation of the tail with the virus or effused products of the disease in the lungs; and it generally succeeded, as testified by numerous tailless oxen living afterwards. In cattle the disease was slower in progress, and unattended by the profuse secretion from the nostrils, as in the horse, and was manifested chiefly by loss of appetite and debility. A great many cases were successfully treated by saline purgatives, which did not appear to do the same harm as in the horse. In oxen the irritating morbid agent seemed to pass down to the air-cells of the lungs without acting on the bronchial tubes and nasal passages, as in the horse. Death resulted more from asthenia than from apnoea,

and the vital powers succumbed more from failure of the circulation than from its obstruction.

The cause of both diseases lay, probably, in some morbid agent in the air, like to what produces influenza in England; but many cases were referable to the morbid secretion being swept up off the grass by the animals feeding over places that had been grazed over by affected animals.

Medical officers at the Cape were frequently called upon to attend barracks on the loss of officers' horses, and on the deaths of slaughter-cattle for the use of the troops there from this disease, which rendered the meat unwholesome.

Preventive measures were, however, always salutary in both horses and cattle, which on the appearance of an epidemic ought always to be brought in from grass and kept stall-fed till it has passed.

I am, &c.,
February 1, 1872. W. S. BLACK, Staff-Surgeon.

THE REVIEWER'S REPLY TO DR. DONKIN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I had no desire to reply to Dr. Donkin had you not thought it advisable that I should do so; for, indeed, all the writing in the world cannot alter the facts of the case or make Dr. Donkin's book a good one. I know nothing of Dr. Donkin personally; nor have I any means of deciding whether his book is good or bad beyond what itself contains. Furthermore, I have been careful to separate in my own mind those parts which deal with the treatment of disease by skim milk from those of a more strictly scientific kind; and I repeat that Dr. Donkin's attempts to improve the treatment of diabetes deserve every credit. It is to the quasi-scientific pages of the book I took exception, and, as I believe, most justly. The book apparently claims to give "a sufficiently full account of our present knowledge of the subject (diabetes), and to embrace the numerous and highly important observations concerning the disease made of late years, and scattered amongst a host of British and foreign Medical journals and other publications." One is, therefore, quite entitled to inquire how far these promises are borne out by the character of the work, and, if it falls short, to say so.

Dr. Donkin errs when he supposes the errors formerly adduced were the only ones contained in the volume. To give a full list of them would be, even now, too much; but on the principle "*Ex pede Herculem*," some samples were given and commented on. The impeachment I brought against Dr. Donkin was—that in a work of great scientific pretensions there was not a single quantitative analysis, and it was taught that specific gravity, taken in conjunction with quantity, supplied "a very reliable practical guide as to the quantity of sugar voided in any particular case of the disease"—a guide on which Dr. Donkin seems exclusively to have relied. Now, specific gravity alone is the reverse of a safe guide. Let Dr. Donkin refer to Dr. Bence Jones's "*Lectures on Pathology*," page 49, and he will find facts and figures to convince anyone on that head—which, indeed, I had believed to be patent to all men. But in one case narrated by Dr. Donkin at page 227 of his book, I noted that the quantity of sugar passed in the twenty-four hours was given (it was also stated to be given in the table, but one cannot find it); therefore I was fain to turn back to the case as it appeared in the *Lancet*, and there the mystery was explained. I found that Dr. Donkin had *by means of a table calculated* the amount of solid matter contained in the urine, its specific gravity being known. "If from this," says he, "we deduct about 600 grs., or 10 drs., as the normal quantity of solids daily in the urine, we arrive at the quantity of sugar present." And this is scientific accuracy, treating an abnormal secretion as a normal one, taking no heed—to mention one thing—of the fact that almost invariably the urea is in diabetes greatly increased! Surely Dr. Donkin cannot have known Roberts's method of estimating sugar, which is both simple and accurate, or he would not have had recourse to such perversely ingenious devices. I will not bandy words with Dr. Donkin, nor discuss the complexity—save the mark!—of Fehling's test; yea, I will commiserate with him on a printer who will spell *Dr. Ringer Mr. Ringer* three separate times; who will print *carnivora, carnivoræ*, and generally make mischief. Perhaps both Dr. Donkin and the printer will be more careful another time.

I am, &c.,
THE REVIEWER.

FEVER has broken out with great virulence in the Budwoa, Hooghly, and Nuddea districts.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 3.

Dr. J. BRAXTON HICKS, F.R.S., President, in the Chair.

THE following gentlemen were elected Fellows of the Society:—Dr. Bridgwater (Harrow), Dr. Fox (Birmingham), Dr. Gardner (Montreal), Mr. W. Harding, Dr. R. H. Hilliard, Mr. E. M. James (Melbourne), Mr. Jalland (Horncastle), Mr. J. Lattey, Mr. D. B. Rankin (Melbourne), Dr. Vanderstraaten, and Dr. W. C. Wise (Plumstead).

Dr. BANTOCK exhibited a specimen illustrating the Changes which take place in the Pedicle of an Ovarian Tumour when treated by Ligature. The specimen had been obtained at a post-mortem examination performed twelve months after the operation. When the parts were exposed, no trace of the pedicle could be seen, and the upper border of the broad ligament formed a continuous line with the fundus uteri; but close to its edge could be felt a small body as large as a hemp seed, covered by peritoneum, and about one inch and a half distant from the uterus. The hard body was found to be formed of the knot of the ligature, the loop and ends having disappeared. Dr. Bantock referred to the experiments of Spiegelberg and Waldeyer on this subject, and said that the course of events would appear to be as follows:—When the ligature is applied it forms a deep constriction, which by the bulging of the tissues on each side causes the living to come in contact with the strangulated tissues. Plastic lymph is thrown out, gluing together the opposing surfaces, and its organisation establishes a vital connexion between the two, so that sloughing is prevented. This result is also favoured by the fact that, by displacement of the tissues immediately embraced by the loop of the ligature, in course of time the loop ceases to exert any force; and it is probable that the capillaries ultimately become pervious. Subsequently the absorbents begin their work, and remove not only such portions of the tissues as are unable to maintain their integrity, but the ligature itself yields to the forces at work. Dr. Bantock considered that the extra-peritoneal method by the clamp was the best method of treating the peduncle; still, this case demonstrated the safety of the ligature.

Dr. PLAYFAIR read a paper "On the Treatment of Empyema in Children." The author described the peculiarities of pleurisy in children as contra-distinguished from the same disease in the adult. He then referred to the change of opinion which had of late years been observed with regard to the operation of paracentesis. This operation, in ordinary serous pleurisy, evidently stood on a very different footing from the same operation in empyema; since, in the former, we only sought to relieve the distension by removing some of the fluid, and allowing the remainder to be more readily absorbed; while, in the latter, the chance of absorption was diminished to a minimum, and it would be a great gain if we could effect continuous drainage of the pleural cavity, and at the same time effectually exclude the entrance of air. The author then described the method of drainage by Chassaignac's tube, with illustrative cases. He then described the method of continuous subaqueous drainage he advocated, and related the history of three cases successfully treated by it. The results of these were very satisfactory, and contrasted remarkably with the cases treated by pneumatic aspiration by Bouchut. (The paper was illustrated by drawings of the chests of five children, taken by Dr. Gee's eystemeter, which showed how much greater the chest deformity was when air had been allowed freely to enter the pleural cavity.)

Dr. HILTON FAGGE said that it was hardly necessary for him to state that he approved of the method, as two of the three cases were under his care, yet he felt bound to mention to the Society that he had recently had a case in which the same method had been employed, and with results not entirely so satisfactory. The pus had in this instance made its way by the side of the indiarubber tube, and continued to discharge. It was of great importance that the tube should be tightly grasped by the skin; and for this reason it was better to remove the canula before introducing the indiarubber tube, which should be of the same diameter.

Dr. F. T. TAYLER mentioned a case of empyema treated in a similar manner. The chest was tapped with a syphon-trocar. An indiarubber tube was affixed to the canula, and carried into a basin of water. The canula and the tube were retained

twenty-four hours, and then a piece of elastic catheter, with a smaller indiarubber tube, was inserted through the canula, which was withdrawn. The tube was retained for fifteen days.

Dr. SEDGWICK approved very much of the plan of subaqueous paracentesis. He had himself occasionally, during the last fifteen or sixteen years, carried out the same principle. He had used a canula, the tube of which projected externally an inch beyond the shield, on which he slipped a long indiarubber tube, with the other end dipping into a dish of water. The plan of introducing the indiarubber tube into the chest was much better than leaving the canula in. Dr. Sedgwick had adopted the same plan in a case of paracentesis abdominis, where the patient was exceedingly weak, and the abdominal walls were as thin almost as parchment. The rapidity of the flow was entirely under control by means of pressure on the tube.

This meeting being the annual meeting of the Society, Dr. Graily Hewitt said that he had much pleasure in proposing to the Society a very important resolution, to the effect that the Society should at once institute an examination for midwives. The Council began seriously to consider the subject while he had the honour of holding the office of President, and the proposed plan was the result of the continuous and matured consideration of the matter by the Council. The plan recommended involved the institution of an examining board, composed of six Fellows of the Society, the examination to be held quarterly, to consist of a practical testing of the competency of the candidates to practise as midwives, and of the possession, on their part, of such an amount of knowledge as would enable them to recognise the presence of difficulties, and the necessity for at once procuring competent Professional aid for their patients. It would hardly be necessary for him to dilate on the great ignorance and incompetence of vast numbers of practising midwives, nor of the loss of life which thus resulted. The attention of the Society had been forcibly drawn to that in the reports on the subject of infantile mortality procured recently from London and the provinces. It might possibly be said that the institution of such an examination was the duty of the Government, or of the Royal College of Physicians or Surgeons, or of the Society of Apothecaries. He was afraid that little was to be hoped from Government action at present, though ultimately it might be hoped that this action of the Society would result in legislation on the subject. Nor was it to be expected from the general Medical bodies. Under the circumstances, the Society proposed to step forward to initiate what was, he believed, universally admitted to be a laudable object—one, indeed, of pressing necessity. The Society was instituted for the promotion of knowledge in all that relates to obstetrics and the diseases of women and children. This examination would, he felt sure, do very much practically to carry out that great object.

Dr. ROUTH seconded the proposition. He stated that his first impression was that this measure belonged more to some College than to the Society. On reflection, however, and judging from the long delay that the Colleges would not take it up, he thought some other learned body ought; and if so, what body better qualified than the Obstetrical Society? Dr. Routh then referred to the large number of lives lost through the ignorance of midwives, and to the advantages which would result from having well-educated ones. He could speak with praise of some educated by Dr. Hall Davis. Again, strong-minded women were on the increase, and sooner or later many would be found in the ranks of the Profession. He only hoped when they were in it there would be found more than the two French ladies, whose names would be handed down to posterity with honour. He alluded to Madame Boivin and Madame Lachapelle. But if the better class of strong-minded women entered our ranks, we might rest assured that they would find imitators in a lower class, which would invade the province of midwifery. If so, it was important to test more accurately their knowledge, and certainly this Society could do it well. Under the circumstances, Dr. Routh thought the Society did well to take the initiative.

The motion was supported by various speakers, and was carried *nem. con.*

The Reports of the Treasurer and the Librarian were read, and the President delivered the annual address. The ballot for election of officers then took place, and the following gentlemen were declared to be duly elected:—*Hon. President*: Sir Charles Locock, Bart., M.D. *President*: J. Braxton Hicks, M.D., F.R.S. *Vice-Presidents*: John Clay, Esq. (Birmingham); H. Gervis, M.D.; H. M. Madge, M.D.; G. C. P. Murray,

M.D.; D. Ll. Roberts, M.D. (Manchester); and John Scott, Esq. *Treasurer*: E. J. Tilt, M.D. *Hon. Secretaries*: W. S. Playfair, M.D.; J. J. Phillips, M.D. *Hon. Librarian*: A. Wiltshire, M.D. *Honorary Members of Council*: W. Tyler Smith, M.D.; H. Oldham, M.D.; Robert Barnes, M.D.; J. Hall Davis, M.D.; Graily Hewitt, M.D. *Other Members of Council*: J. H. Aveling, M.D.; J. W. Black, M.D.; John Brunton, M.D.; Brendon Curgenvin, Esq.; J. Fowler, Esq. (Wakefield); G. Gaskoin, Esq.; S. Day-Goss, M.D.; T. T. Griffith, Esq. (Wrexham); W. E. Image, Esq. (Bury St. Edmunds); J. R. Kirkpatrick, M.B. (Dublin); D. Mackinder, M.D. (Gainsborough); J. B. Potter, M.D.; Adolph Rasch, M.D.; W. R. Rogers, M.D.; Henry Savage, M.D.; L. W. Sedgwick, M.D.; Heywood Smith, M.D.; H. W. Sharpin, Esq. (Bedford).

THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 16.

Mr. HILTON, F.R.C.S., President, in the Chair.

REPORTS were read on Mr. Norton's Tumour of the Larynx, which was declared to be an epithelioma; on Mr. Hickman's supposed Green Pea, by Dr. Bristowe, which was described as composed of lowly vegetable organisms, and no pea at all; on Mr. Arnott's specimen of Scrofulous Testicle, the description of which was confirmed; and on Dr. Southey's specimen of Supra-renal Capsules, which were described as characteristic of Addison's disease.

Dr. GREENHOW then brought before the Society an Isolated Mass like a billiard-ball, which lay detached in a pouch in the cardiac end of the stomach of a woman aged 50. The mass had no appearance of any attachment, but rolled out when the abdomen was opened. In its centre the mass was opaque and yellow; its outer portions were white and something like a uterine fibroid. This part was made up of a network of fibres. There were two other and very similar masses, but much smaller, attached to the great omentum. One ovary was enlarged, and a cyst in it contained hair. Mr. Shaw had shown a billiard-ball tumour similar to this removed from the sac of a hernia, but the specimen was smaller than this.

Mr. J. WOOD had examined Mr. Shaw's specimen, and had found other specimens in the London museums. He thought they were formed from the appendices epiploicæ, which seemed to furnish a nucleus. Dr. Wilks, who examined the specimen along with him, differed as to their further mode of growth. He had met with two instances of such masses in hernial sacs, and diagnosed them. He was inclined to believe that they grew by accretion from the fluid of an irritated peritoneum.

Dr. CAYLEY said this one was not so formed, inasmuch as it had a distinct peritoneal layer; besides, two smaller ones were seen attached to the omentum.

Mr. GAY said he had found some tumours like these in veins, apparently from clotted blood. They were shiny, and had a coat like peritoneum.

Mr. HULKE had examined one smaller than this, and was led to confirm Virchow's notion that they originated in the appendices epiploicæ. One of these bodies became fatty, and formed a nucleus; on this a sub-peritoneal fibrous coat was formed. Their appearance was totally different from the bodies described by Mr. Gay.

Mr. ARNOTT thought a good deal was to be said for Mr. Wood's view, inasmuch as the mass contained no nuclei and no vessels. An appearance resembling an epithelial covering might be formed on its surface without attachment; and there was no appearance of a pedicle. He had seen the same structure in old lymphomata.

Dr. GREENHOW, in support of his opinion, referred to the existence of other tumours still *in situ*. The centre of this mass was calcareous; not a blood-clot, as described by Mr. Gay.

The SECRETARY read from the *Transactions* the account of Mr. Shaw's case; and the specimen was referred to the Morbid Growth Committee.

Dr. FAGGE then showed, for Dr. Kitchener, an enormously Hypertrophied Kidney from a newly-born calf. It was cystic, and contained urine in the cysts.

Mr. GEORGE LAWSON narrated the sequel of an already recorded case of Blood-cyst of the Thigh. The leg had been amputated and examined by Mr. Arnott, and the cyst found filled with spindle-shaped cells. The patient died in 1871, after the glands of the neck had enlarged, and the stump had been ecchymosed and fluctuating. Just before death there

was most troublesome shortness of breath; and after death a large quantity of brain-like cancerous matter was found in the mediastinum and right thorax, springing from the lung. There was much clotted blood in the stump, and a cyst of cancerous matter with grumous contents in the same situation.

Mr. LAWSON also showed a Tumour of the Eyeball, giving rise to what he thought was not an uncommon history. The patient complained of loss of eyesight, and became glaucomatous. Iridectomy had been performed, but that was of no use; so the eye was extirpated, and found to contain a tumour of the choroid. The eye was set in a jelly of glycerine and calf's-foot jelly, with a little creasote—a very good plan, which seemed likely to succeed. It had kept six months.

Dr. CAYLEY said ordinary glycerine jelly became yellow and opaque by keeping.

Mr. HOGG said it also decayed.

The form of the secondary cancer-cells could not be elicited.

Mr. WARREN TAY had observed a similar case in the London Hospital. The loss of sight came on slowly, and glaucoma was induced. The eye was removed, and the tumour found.

Dr. LEARED exhibited some Renal Calculi of Cystic Oxide. The patient was a domestic servant, who from time to time had passed these calculi for ten years. Recently she had had four or five attacks. She only suffered from pain during the attack, which seemed limited to the left kidney.

Mr. T. NORTON exhibited a Malignant Growth from the Thigh, removed by amputation. The patient suffered from great pain and swelling. The limb was increased in size, and seemed likely to suppurate. There were intervals of great pain, then ease comparatively. (Referred to the Morbid Growth Committee.)

Dr. GREENHOW exhibited a Lung from a patient, aged 30, who died of Capillary Bronchitis. In the right lung was a large cavity lined with false membrane, and not apparently communicating with the tubes. There were three similar but smaller cavities on the left side. There were no symptoms of phthisis.

The same gentleman also exhibited the Lung of a Female, aged 56, who had suffered more or less from Bronchitis since she was 30. Latterly the cough had been constant, and she had several attacks of pleurisy. She died suddenly of hæmoptysis. The left lung was very small, the right enlarged; and there was one large cyst in the left, opening into the bronchus. In this was the open mouth of a considerable vessel. He fancied there had been pneumonia, then breaking-down of the lung substance.

Dr. GREEN said, in the first specimen the lung was very considerably invaded by fibrous tissue.

Dr. LEARED asked if the small lung was cirrhotic.

Dr. GREEN again remarked on the curious absence of induration, though much fibrous tissue was present.

Dr. C. T. WILLIAMS had seen several lungs like the first—few of the second form. What was the diagnosis in the second case?

Dr. BAÜMLER asked if there was contraction of the side in the second case.

Dr. GREENHOW, in reply, said there was no cirrhosis, and the diagnosis was imperfect. The left bronchus was plugged.

Dr. THOROWGOOD exhibited a Salivary Calculus, removed by Dr. Prosser James. The mass began twelve years ago, and ultimately caused an abscess, which opened externally. The calculus consisted mainly of phosphate of lime.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, JANUARY 20.

Dr. DRUITT, President, in the Chair.

Dr. CORMACK, Medical Officer of Health for Lambeth, was proposed as an Ordinary Member, and Dr. Sneade Browne as an Associate Member.

Dr. DUDFIELD, Medical Officer of Health, brought before the meeting the subject of the keeping of pigs in the metropolis, and described in detail a district in his parish in which this trade was carried on on a large scale, to the detriment of a large surrounding population. He had immense difficulty in dealing with the nuisance; in fact, he was obliged to secure the attendance of six policemen when he went to inspect the place. He thought the same regulations ought to be enforced in respect of piggeries as was done in the case of cow-houses. There was not only the nuisance arising from the pigs them-

selves, but one even greater was occasioned by the boiling of their food. He contended that under present Acts the evil was difficult to get at. The men in question were well-to-do, and laughed at the infliction of a slight fine.

Dr. STALLARD had inspected the locality in question, and did not find it in such an unsatisfactory state as had been described. He thought it would be difficult to prohibit entirely the keeping of pigs in the metropolis. Besides this, people had something in the nature of vested interests which ought to be taken into consideration. The wisest plan would be to attack the system on the ground of a general nuisance whenever pigs were not properly kept.

Dr. CRACE CALVERT, F.R.S., then delivered an address "On the Effects produced in Protoplasmic Life by the Action of Heat and Concentrated Solutions of various Chemical Substances." After describing the minute care he had taken in making the various experiments, the speaker said that he should limit himself to his own experiments and observations. Speaking first of spontaneous generation, Dr. Crace Calvert said his experiments were against it. He found that the best substance to experiment with was distilled water, after having, with great care and trouble, destroyed all trace of organic matter, so that he could keep it for months without life appearing. He then introduced some of this water into small tubes and placed them near putrid meat, and from time to time opened and examined the tubes, until life was observed. In the distilled water in his flask no life appeared, whereas he found that in the water of the tubes life appeared in twenty days. If the production were spontaneous, why, he asked, did not life appear in the liquid contained in the enclosed flask as well as in the tubes which had been exposed to the atmosphere, or where means of impregnating with germ were permitted? The next subject was that of the influence of temperature. Taking some putrid gelatine and other solutions containing substances in a state of decay, he enclosed them in small tubes and heated them successively to 100°, 200°, 300°, and 400°. Microscopic life was destroyed in most cases at about 200°, there being only one class of vibrio life surviving the heat of 300°. Pursuing his experiments upon disinfectants, he dipped some calico into a putrid solution and inserted it in a tube. At 300° the calico was slightly softened; still there was life. He then took the white of egg, and mixed one part of albumen with four parts of water, and experimented with them in adding one-thousandth part of thirty different substances—acids, alkalies, chlorides, sulphates, phosphates, etc. The details of these results were represented in a large diagram. With respect to bleaching powder, Dr. Crace Calvert mentioned that he had for years regarded it as antiseptic. Being on a visit to Paris, the Inspector-General of French Cemeteries told him that not only was it not a disinfectant, but that it actually aided putrefaction. Hardly able to believe this, he, on his return to Manchester, made a series of experiments, and found the assertion correct. Proceeding to give the results of his experiments with the thirty different substances, he said that in some vibrio life developed itself, but fungus life did not until some days later. In some vibrio life abounded, but there were no fungi. An interesting point was to notice that acids promoted fungus life. With alkalies the case was reversed; vibrio life appeared, but no fungi. The substances ranged themselves under four distinct heads:—1. Those which absolutely prevented both vibrio and fungus life. These consisted of only two substances, carbolic and cresylic acids. 2. Those which presented vibrio but not fungus life. Of these, also, there were only two—chloride of zinc and bichloride of mercury. 3. Those in which there appeared vibrios, but no fungi. To this class belonged seven substances out of those he studied—sulphate of quinine, pepper, turpentine, prussic acid, etc. 4. Those which presented neither vibrio nor fungus life. This class was by far the most numerous, numbering no less than twenty-seven substances. The last class might be further subdivided into those emitting a decomposing smell and those that did not. Dr. Crace Calvert also made another series of experiments with putrid solutions of albumen and gelatine, adding to them a one-thousandth part of each of the thirty substances above alluded to. He examined them at the time of inserting the germs, again after twenty-four hours, again after six days, and again after sixteen days. The acids, generally speaking, seemed at first to paralyse low life; but after twenty-four hours most of the animals began to assume their usual movements. Of the alkalies, soda alone affected their vitality. After a few days there was a small quantity of life, and the odour became offensive. Dr. Crace Calvert examined several chlorides, but principally dwelt on the interesting fact that little or no change was produced by

chlorine and chloride of lime when first added. After several days there was a large quantity of life in the solution and a putrid smell. The most powerful substances were the chlorides of zinc and mercury, carbolic acid, and cresylic acid. Although they prevented the production of life, they never entirely destroyed it, a certain percentage constantly remaining. With sulphate of quinine locomotiveness was almost destroyed for a time, but returned completely after a few days, showing that this substance does not prevent vibrio, but does completely prevent the production of fungi. Charcoal did not destroy vibrio life, but completely prevented the production of noxious odours. In concluding, Dr. Crace Calvert said he was making two other series of experiments—one on putrefaction, the other on the decomposition of eggs. These he would be happy to bring before the Association on a future occasion, when the results were fully matured.

The thanks of the meeting were cordially voted to the speaker for his interesting address.

Dr. LETHEBY, while acknowledging their great indebtedness to Dr. Calvert, remarked that the results arrived at by him differed from those of Dr. Sanderson and other authorities. The discrepancy arose, no doubt, from the immense difficulty of excluding disturbing causes while performing this delicate experiment. To this probably was due the different degrees of temperature assigned by different people as that at which these animals were destroyed. As to what was said by Dr. Calvert about chloride of lime and other substances tending to increase putrefaction, every agent, he said, that tends to develop oxygen does so. Many of the experiments made by Dr. Calvert were very remarkable, especially that with sulphate of quinine. He thought his result might be due to the sulphuric acid rather than to the quinine. It was a great step to discover what hindered and what developed microscopic life, yet they must be on their guard against jumping to the conclusion that the results of disease depending on the supposed development of low organisms in the blood were equally controllable.

Dr. BARCLAY believed that vibrio and fungus life had very little to do with disease. He believed disease arose from putrefactive change in dead animal tissue, and from this, while undergoing a special process of change, being introduced into the living tissue, and superinducing a similar change in the living tissue.

The CHAIRMAN said he had been deeply interested in Dr. Calvert's address, and he gathered from it that it was easier to prevent the development of low organisms than to destroy them after development.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 23.

Surgeon-Major BOSTOCK, Vice-President, in the Chair.

Dr. WILLIAM RUTHERFORD communicated a paper "On the Excitability of Different Parts of the Trunk of a Spinal Nerve, with a 'Schema of the Circulation.'" In this communication Professor Pflüger's experiments regarding the excitability of different parts of the trunks of the motor fibres of spinal nerves are described, and his "avalanche hypothesis" founded thereon criticised. The faulty character of his experiments is pointed out, and those performed by the author are narrated. The latter conclusively show that Pflüger's explanation of his experiments is untenable; that the avalanche hypothesis regarding the transmission of nerve-force has no fact in its support; and that the excitability of both the *afferent* and *efferent* fibres of a spinal nerve is inversely as the distance from the spinal cord. The possible explanations of this singular and novel fact are considered, and the bearing of this discovery upon our ideas regarding the nature of the influence which travels along a nerve is indicated.

Mr. HENRY POWER always considered Pflüger's hypothesis fraught with difficulty—that force should gain by being expended. Did Dr. Rutherford think the increased excitability due to the thinness of the coats of the medullated fibres near the spinal cord?

Dr. RUTHERFORD was glad of the suggestion; meantime, he had not made up his mind.

Dr. RADCLIFFE was glad to hear a refutation of Pflüger's views. Did not the fact that nerves die centripetally explain something?

Dr. RUTHERFORD sometimes cut the nerve at the distant

electrodes, when the cutting for a time caused the excitability to increase, so as almost to equal that of the other and cerebral end.

Mr. POWER asked if Dr. Rutherford had seen Schiff's experiments, which went to show that the excitability of the pneumogastric was greatest near the brain?

Dr. RUTHERFORD had done so. They confirmed his view.

A paper by Deputy Inspector-General C. A. GORDON, M.D., C.B., was communicated by Mr. BERKELEY HILL, on "Proposed Forms of Surgical Returns and Reports to be used in War." The object of the proposed forms is to present information regarding wounds received in battle and operations performed in their treatment in a manner calculated to facilitate comparison regarding their severity, results, prevalence, and fatality of complications usually met with, and also to arrange observations upon subjects of Surgical interest in a definite manner. Table No. 1: In this form wounds are arranged (a) according to their position, (b) according to severity, and (c) the deep parts of importance implicated. The different columns into which the form is divided indicate the circumstances under which wounded have been admitted, the several conditions in which they are discharged, and, in regard to those who die, the causes of death, distinguishing particularly the cases of mortality by hospital diseases and complications. Table 2: This form is intended to contain a record of the various operations performed. The operations are arranged according to their kind, as—(a) amputations, (b) excisions, (c) resections, (d) ligatures, (e) trephining, (f) extractions, (g) other operations. The first four classes are severally arranged according to region or part of the body, and in regard to each case the return will show the manner in which it was admitted, period of operation, the circumstances under which the patient is discharged, and, in cases of death, the precise cause, as far as practicable, of the fatal termination. Form 3, or Report: This presents different "headings" under which information may be arranged for the purpose of being subsequently collected and condensed. These headings include the following points—viz., (1) those referring to Form 1; (2) those referring to Form 2; (3) conditions of individual Hospitals; (4) as to certain diseases that may appear among the wounded; (5) as to the important question of hæmorrhages; (6) as to the relative success of primary and secondary operations; (7) as to other Surgical points of interest, some of which are enumerated; (8) as to the character of wounds by new projectiles and other arms; and (9) such other general subjects as are not included under any other of the above heads.

The CHAIRMAN thought that, as an Army Surgeon, he ought to tender his thanks to Dr. Gordon.

Mr. WYATT said that the more succinct the form of notes to be taken in actual campaign, the more likely were they to be accurate. One would hardly be able to note all the points suggested by Dr. Gordon under such circumstances. He had drawn up a form which was approved of in the operations before Paris. It was important to have a form which would be available for use afterwards. In all the civil Hospitals of Paris one definite form was used. It would be well could we have a similar one adopted in London.

Dr. CHARLES MAYO agreed with Mr. Wyatt as to the difficulties in the way of filling up these forms. Field statistics were very uncertain, especially when the army was constantly moving on. Then it would be impossible to fill them up, however desirable to do so.

Dr. RUTHERFORD next demonstrated the uses of a New Schema of the Circulation, and the meeting adjourned.

OBITUARY.

GEORGE EDWARD DAY, M.D., F.R.S.

LAST week we recorded the decease of this amiable and scientific Physician, and valued contributor to our pages, which took place at Andersey, Torquay, on January 31.

George Edward Day was born on August 4, 1815, at Tenby. He was the son of George Day, a gentleman of fortune, who owned an estate in Glamorganshire known as Mauruabon. His misfortunes began early in life, for his father was induced, in 1825, by an old schoolfellow, to join him in the bank at Swansea, and in six months the bank failed, and Mr. Day lost £60,000. His mother, *née* Miss Jane Hale, was a lineal descendant of Sir Matthew Hale, the famous Chief Justice. She was connected with the Wigbys, Greswolds (of Malvern Hall), St. Johns, Perrits, and other good Worcestershire and Gloucestershire families.

Our deceased friend, the eldest son, was sent, after the Swansea Bank failure, to live with his grandmother, Mrs. Hale, at Hopley Court, near Hereford. This house was his home, and here he was educated by a private tutor till he went to Cambridge, where he was entered at Trinity College, and migrated to Pembroke; graduated B.A. in 1837, and M.A. in 1840. On leaving Cambridge, in 1837, he went to Edinburgh to study Medicine.

During his connexion with this University and the Extra-Academical Schools he distinguished himself in all his classes, taking Dr. Handyside's Gold Medal for Anatomy in the sessions of 1838-39 and 1839-40; Dr. Simpson's Silver Medal in the Midwifery class, 1840-41; besides Dr. Skae's and Dr. Atkin's prizes in 1840 and 1841.

During his residence in Edinburgh he was intimately associated with John Goodsir, Edward Forbes, George Wilson, James Forbes, and other distinguished men of that period. In 1842 he became a Licentiate, and in 1848 a Fellow of the Royal College of Physicians. In 1849 he took an M.D. degree at Giessen to qualify him for the Chair of Medicine at St. Andrews, which he obtained in the same year. In 1857 he met with the accident which broke down his health; he fell through a horizontal chimney connected with the white-lead mines at Helvellyn, and after remaining three hours unable to extricate himself, he was saved by some young men, who had heard his occasional calls for help. He fractured the right arm at the surgical neck of the humerus and two inches above the elbow, and dislocated the elbow. The upper fracture remained disunited, and gradually caused complete deformity of the shoulder. Eighteen months after the accident acute rheumatism affected the right knee as the result of his having stood on damp ground; the joint became implicated, synovitis came on, and he never recovered the power of using the leg. In 1863 he relinquished the chair of Medicine and came to Torquay, but never regained his health.

Both before and after this lamentable accident his industry was untiring. He wrote a work on the "Diseases of Advanced Life," and on "Chemistry in its relation to Physiology and Medicine;" he translated Simon's "Animal Chemistry" and part of Rokitsansky's "Pathological Anatomy" for the Sydenham Society, Lehmann's "Physiological Chemistry" for the Cavendish Society, and most of the Medical and scientific articles in "Chambers' Encyclopædia." His scientific and Professional knowledge was vast and exact, and his judgment sound and temperate. Almost up to the last he retained his habit of literary work, though struggling against increasing debility and exhaustion, which, however, was not to be traced in his writings. Few who read the reviews and scientific notices in our own columns could have surmised that they were written by an invalid disabled by ununited fracture of one arm, helpless upon the legs, and distracted by a host of minor sufferings arising out of his state of rheumatism and prostration. His handwriting was most peculiar, done as it was with an arm that had to be lifted on to the writing-table. At last, about Christmas, he caught severe influenza, and, though not entirely confined to his bed for more than three days, he never rallied, and spite of the affectionate care of those who long had nursed him and watched his growing feebleness, he expired on the last day of January.

WILLIAM RAYNER, M.R.C.S. ENG., L.S.A. LOND.,

CARRIED on practice in Uxbridge from the year 1826, succeeding his father. He held appointments under the Poor-law Board from its establishment—at first the district of Ickenham Russlip and Eastcot; this he gave up, and for the last twenty-three years was Medical Officer to the Workhouse. Many years ago he took great interest in a volunteer corps, of which he was successively captain and captain-commandant, and of which he, at the time of his death, held the colours. It was mainly owing to his exertions that a literary and scientific institution was formed in Uxbridge, and in connexion with which he delivered several series of lectures (popular) upon the senses and comparative anatomy, illustrated by diagrams enlarged by aid of a magic-lantern and drawn in water colours by himself. He also took a prominent part in the establishment of the present Local Board of Health; but although he worked very strenuously till the Board was formed, the inhabitants had so little regard for his services, that he was not even elected on it as a member. He was a great lover of natural history, and at one time had a very considerable number of English birds confined together in a large aviary, and he wrote many articles upon their habits in several periodicals. In later years his taste was occupied in the cultivation of

plants, and he had the honour of flowering for the first time in England the "Lily of the Empress," as it is called in its native country, the Brazils, and it has been named after him by Dr. Hooker. He operated successfully for strangulated hernia upon an infant only six weeks old, probably the youngest case on record. He also amputated at the knee-joint, for compound comminuted fracture of tibia and fibula, the leg of a woman who was over 80 years; she also had compound fracture of the arm of the same side, the result of the same accident. She is still alive, and is now upwards of 90. During the last few years of his life his sight became very much impaired, so that he was quite unable to read or write.

A few years ago he met with a very unusual accident—rupture of the rectus femoris—and this occurred again last year, but in the other leg. He was attacked last autumn with the malady (angina pectoris) which has now terminated his life, after many months of great suffering and distress, at the age of 70.

ABRAHAM P. BALDERSON, L.S.A.

MR. BALDERSON was a well-known Surgeon in general practice in London, but more particularly so as the "assistant of the late Sir Astley Cooper," as the notices of his death in the newspapers style him. Mr. Balderson received his Medical education at Guy's Hospital, and became a Licentiate of the Society of Apothecaries in 1826. He commenced practice in Poland-street soon after, and for many years had a very extensive general practice. He subsequently removed to Great Marlborough-street, where he was joined in partnership with Mr. J. D. Tucker, who now carries on the business, Mr. Balderson having retired altogether some years since. It is a remarkable fact that he did occasionally represent Sir A. Cooper in Conduit-street, and saw patients for him, and yet was never a qualified Surgeon—was never a member of the College of Surgeons. Sir Astley was of great service to his *protégé* in recommending him wherever or whenever he could. His estrangement with his nephew Bransby may explain, but scarcely justify, his conduct. Mr. Balderson was a man of slender acquirements, but of good common-sense and unflagging industry. He was kind-hearted and charitable, and spent the last few years of his life in doing good. He died in Woburn-square at the age of 66.

DR. WILLIAM BAIRD, F.R.S., F.L.S.,

DIED on January 27, after a long and painful illness. He was born at Eccles, in Berwickshire, in 1803; educated at Edinburgh, Dublin, and Paris, for the Medical Profession. He received in 1823 an appointment as Surgeon from the East India Company. This gave him an opportunity of visiting India, China, and many other countries, the natural history of which he carefully studied. In September, 1841, he was appointed an assistant in the zoological department of the British Museum, in which capacity he remained till his death. He was a great author, and has made most valuable contributions to science by his publications. His most important work was a "Natural History of the British Entomozoa," which was published under the auspices of the Ray Society in 1850. An excellent naturalist has, by his death, been lost to the world of science. He was highly esteemed by all who knew him for his kindly and genial nature.

MEDICAL NEWS.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, February 1:—

Breeze, Richard Goodwin, 197, Euston-road.
Mahomed, Fred. Henry Horatio Akbar, Brighton.

The following gentleman also on the same day passed his first Professional examination:—

Barron, Fred. William, St. Bartholomew's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BRADY, J. B. J., L.R.C.S.I., L.K. & Q.C.P.I., L.M.—Junior House-Surgeon to the Sunderland Infirmary, *vice* S. H. Whitcroft, L.R.C.P. Edin., etc., resigned.
MATHESON, L. M., L.F.P.S. Glasg.—Medical Officer for the Parish of Kilmuir, Skye.

WADDY, H. E., L.R.C.P. Lond., M.R.C.S.E.—Surgeon to the Gloucester Lying-in Charity, *vice* T. S. Ellis, M.R.C.S.E., L.S.A., resigned.

MILITARY APPOINTMENTS.

60TH FOOT.—Staff Assistant-Surgeon William Godfrey Martelli, to be Assistant-Surgeon, *vice* William Silver Oliver, M.D., promoted on the Staff.

MEDICAL DEPARTMENT.—Assistant-Surgeon William Silver Oliver, M.D., from the 60th Foot, to be Staff Surgeon, *vice* Alfred Hooper, placed upon half-pay; Assistant-Surgeon John Henry Hughes, M.D., from the 38th Foot, to be Staff Assistant-Surgeon, *vice* William Godfrey Martelli, appointed to the 60th Foot.

BIRTHS.

ADAMS.—On February 1, at Martock, Somerset, the wife of J. Dixon Adams, M.D., of a daughter.

HAMILTON.—On February 1, at St. Mary's-terrace, Peckham, the wife of Dr. M. Hamilton, R.N., of a daughter.

LEVICK.—On January 29, at West Ham, Essex, the wife of George Levick, Surgeon, etc., of a son.

MOORE.—On January 28, at Cambridge-heath, the wife of Dr. Moore, of a daughter.

ROSE.—On February 5, at Mile-end, the wife of Dr. C. Rose, of a daughter.

SMITH.—On January 29, at 18, William-street, Regent's-park, the wife of Dr. Walter Smith, of a son, stillborn.

STEPHENSON.—On January 29, at Beverley, Yorkshire, the wife of W. Stephenson, Surgeon, of a son.

MARRIAGES.

BLANDY—BAIRNSFATHER.—On January 30, at St. Andrew's, Wells-street, Frederick John, son of William Blandy, Esq., of Westwood, Tylehurst, Berks, to Anne Jane, second daughter of the late George Bairnsfather, M.D., 101, Harley-street, late Physician-General, Bombay.

BOSWORTH—HALL.—On February 1, at St. Nicholas Church, Sutton, John Routledge Bosworth, Surgeon, second son of John Bosworth, Esq., of the War Department, to Emily Sophia, youngest daughter of John R. Hall, Esq., J.P., of The Grange, Sutton.

CARLESS—OGSTON.—On February 1, at 9, Golden-square, Aberdeen, by the Rev. Henry Cowan, Edward Nicolls Carless, M.B., C.M., Devizes, to Amelia, youngest daughter of the late Alex. Ogston, Esq., of Ardoe.

GLENCROSS—BRICKWELL.—On January 18, at Sawbridgeworth, Herts, Frederick John Glencross, Thurlby, Bourn, Lincolnshire, Surgeon, to Caroline, youngest daughter of John Brickwell, Esq.

INGLIS—FEENEY.—On February 1, at the parish church, Edgbaston, Alexander Inglis, M.D., Worcester, to Florence, second daughter of the late John Frederick Feeney, Esq., Edgbaston, Birmingham.

LACEY—KIRBELL.—On January 31, at St. Michael's Church, Chenies, Bucks, Thomas Warner Lacey, L.R.C.P. Lond., of Plumstead, Kent, to Sarah Anne (Daisy), youngest daughter of Mr. Edward Kirbell, of Latimer, Bucks.

LLOYD—TARRANT.—On February 1, at the parish church of St. Marylebone, Henry James Lloyd, M.D., of 57, Margaret-street, Cavendish-square, to Florence, third daughter of the late William Tarrant, of Westcroft-place, Hammersmith.

MONRO—MARGAREY.—On February 1, at Stoke Church, Devonport, Edward William, second son of Henry Monro, M.D., of Cavendish-square, London, to Arabel Sophia, second daughter of P. J. Margarey, Esq.

PORTER—WILLIAMS.—On Tuesday, February 6, at Ardingly, Sussex, William Elliot Porter, Surgeon, of Lindfield, youngest son of the late Rev. J. T. Porter, formerly of The Cose, Salisbury, to Julia Martha, only daughter of the late H. W. Williams, Esq., solicitor, and granddaughter of the late Thomas Gibbs Crawford, Esq., of Paxhill-park, Lindfield, Sussex.

SNELL—CHAPMAN.—On February 1, at Holy Trinity Church, Brompton, Ebenezer Snell, Surgeon, of Barrowden, eldest son of H. H. Snell, Esq., of Leeds, to Annie, third daughter of John Chapman, Esq., of South-street, Brompton.

DEATHS.

BALDERSON, A. T., L.S.A., for many years assistant to Sir Astley Cooper, at 37, Woburn-square, on February 3, in the 68th year of his age.

DALTON, ANN, wife of Wm. Dalton, M.R.C.P. and F.R.C.S., late of Cheltenham, at Peachley, Bournemouth, on February 2.

HAMBERTON, THOMAS, Esq., late of 112, Piccadilly, W., at Cheltenham, on February 2, in his 84th year.

LOWDELL, SUSANNA, relict of Joseph Lowdell, Surgeon, at 217, Brixton-road, S.W., on January 31, in her 85th year.

QUEKETT, ISABELLA MARY ANNE, widow of the late John Quekett, F.R.S., F.L.S., etc., Professor of Histology at the Royal College of Surgeons, at 13, Delamere-crescent, Westbourne-square, on February 6, aged 55.

ROBERTS, MATILDA EUPHEMIA, the beloved wife of Charles Roberts, Surgeon, at Uxbridge, on February 1.

ST. JOHN, CHARLES, M.R.C.S.E., of 2, Cambridge-gardens, Kilburn, elder son of the late Charles St. John, Esq., of Barbadoes, at 28, Maryland-road, W. (the residence of his brother-in-law), on February 1, aged 33.

TOWNSEND, CHARLES, Surgeon, of Pakenham-road, Edgbaston, and Temple-row, Birmingham, after a short illness, on January 29.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BLOOMSBURY DISPENSARY.—Resident Medical Officer. Must be duly qualified. Applications to the Secretary, on or before February 17. Election on the 19th.

DENTAL HOSPITAL OF LONDON, 32, SONO-SQUARE.—Dental House-Surgeon. Applications and testimonials to the Honorary Secretary, on or before February 14.

KENT AND CANTERBURY HOSPITAL.—Dispenser and Assistant House-Surgeon. Must be duly qualified and registered. Applications to Mr. T. Southee, on March 15. The duties will commence on March 31.

MARGATE ROYAL SEA-BATHING INFIRMARY.—Resident Surgeon. Must have some legal qualification to practise. Applications to the Secretary, on or before February 29.

MIDDLESEX HOSPITAL, W.—Physician. Full particulars may be obtained upon application to Mr. H. M. Evans, Secretary-Superintendent, on or before February 20.

MILE-END OLD TOWN UNION.—Medical Officer for the North District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications to Mr. E. J. Southwell, Guardians' Offices, Baneroff-road, Mile-end, E., on or before February 15.

NEWARK HOSPITAL AND DISPENSARY.—Resident Medical Officer and Secretary. Candidates must possess both Medical and Surgical qualifications. Applications to the Secretary, on or before February 13.

NORTH WALES COUNTIES LUNATIC ASYLUM, DENBIGH.—Assistant Medical Officer. Must be duly qualified and registered. Applications and testimonials to Mr. John Robinson, Clerk to the Visitors, on or before February 20.

NOTTINGHAM DISPENSARY.—Resident Surgeon and Assistant Resident Surgeon: Double qualifications necessary. Applications to the Secretary, on or before February 12. Election on the 26th.

WESTMINSTER GENERAL DISPENSARY, GERRARD-STREET, SOHO, W.—Hon. Surgeon. Must be F. or M.R.C.S.E., not practising pharmacy or midwifery. Applications and testimonials to the Secretary, on or before February 19. Election on the 22nd.

WESTMINSTER GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified and registered. Applications and testimonials to the Secretary, on or before February 19. Election on the 22nd.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Mr. M. Norris, on or before March 1. Election on the 7th.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

St. Thomas's Union.—Mr. Philip C. Hayman has resigned the Woodbury District; salary £65 12s. per annum.

Settle Union.—Mr. Francis Green has resigned the Workhouse; salary £18 per annum.

Uxbridge Union.—The Workhouse is vacant; salary £50 per annum.

APPOINTMENTS.

North Bierley Union.—Edward Bryan, M.R.C.S. Eng., L.S.A., to the Sixth District.

Poole Union.—Edward P. Philpots, M.D., B.M., M.C. Univ. Aberd., to the Third District.

Toxteth-park Township.—Thos. F. Morrish, M.R.C.S. Eng., L.S.A., to the Second District.

DR. JOHN BUSKLEY BRADBURY, of Downing College, has been appointed Linacre Lecturer in Physic at St. John's College, Cambridge, *vice* Dr. Paget, appointed Regius Professor of Physic.

MESSRS. BURGESS, RICHARDS, AND JARVIS have been re-elected District Medical Officers of Health for Bethnal-green.

THE GOVERNMENT has sanctioned a liberal expenditure, extending over two years, for investigating the causes and nature of cholera in the Jubbulpore district.

At a special meeting of the Association of Medical Officers of Health, held on Thursday last, the 8th inst., at the Scottish Corporation Hall, Crane-court, Fleet-street, a paper was read by Mr. Wm. Acton, on the question "Whether the Contagious Diseases Act shall be Repealed, Continued, or Extended to the General Population, founded on the Minutes of Evidence lately given before the Royal Commission."

THE Vice-Consul of Her Britannic Majesty at the city of Bolivar writes to the Consul-General at Caraccas—"An old woman, named Mariquita Orfile, has discovered an efficacious remedy for the yellow fever and black vomit, which has completely cured several persons. This remedy is the juice of the leaves of the vervain plant, which is obtained by bruising, and is taken in small doses three times a day. Injections of the same juice are also administered every two hours until the intestines are completely relieved of their contents. All the Medical Practitioners here have adopted the use of the remedy, and consequently very few, if any, persons now die of those terrible diseases referred to. The leaves of the female plant are used."

DINNER GIVEN BY DR. BUTCHER, OF DUBLIN.—On Monday, the 5th inst., Dr. Richard G. Butcher, Lecturer on Operative Surgery at Sir P. Dun's Hospital, and Examiner in Surgery in the University of Dublin, entertained about one hundred members of the Profession at dinner in the Ancient Concert-rooms, Dublin. Sir Dominic Corrigan, Bart., M.P. (the President of the King and Queen's College of Physicians), Dr. Banks, Sir William Wilde, the Rev. Professor Haughton, Dr. George H. Porter (Surgeon to the Queen), and many other

Leading Medical men were among the guests. The healths of Her Majesty the Queen and of the Prince of Wales were drunk with enthusiasm. In proposing the health of the host on the occasion, Sir Dominic Corrigan spoke of the necessity for combined action on the part of the Profession in securing a high social position in the community. Some admirable part-singing pleasantly diversified the evening's entertainment, which was in every respect a complete success.

HUNTERIAN ORATION.—At a meeting of the Council of the Royal College of Surgeons of England on the 8th inst., Mr. Henry Hancock, the Senior Vice-President, was nominated, and consented, to deliver the Hunterian Oration in the ensuing year.

THE FRENCH INDEMNITY SUBSCRIPTION.—The subscription set on foot by the ladies of Alsace towards the raising of the fund for the indemnity, seems spreading fast in France, and in the *Union Médicale* of February 3 is an eloquent letter from Madame Jeannel, the wife of Dr. Jeannel, addressed to her *consœurs*, calls on the wives of Medical Practitioners in the name of the "ardent patriotism" which she says sentimentally, if not quite accurately, "distinguishes women, and especially French women," to organise a special subscription in aid of the effort "to speedily liberate our invaded brethren and reconquer our independence." In the National Assembly the proposal for a national subscription has been brought forward by Professor Bouisson, of Montpellier, who promises to contribute himself 10,000 francs. In political circles, however, the proposed subscription is looked upon as a futile procedure.

PROFESSOR WILSON, F.R.S.—This gentleman will bring his course of lectures on "Dermatology" to a close on Wednesday next, the 14th inst., and be succeeded by Professor Flower, F.R.S., who will deliver eighteen lectures on the "Modifications of the Organs of Digestion in the Vertebrata," commencing on Friday next, the 16th inst. The following is Mr. Flower's programme, viz.:—"The parts which will come under consideration in this course are the mouth, lips, cheeks, palate, tongue, salivary glands, fauces, pharynx, œsophagus, stomach, intestinal canal, liver, and pancreas. The modifications of the structure and functions of these parts will be treated of in detail in the various animals composing the class Mammalia, in the following order:—Primates, Lemuroidea, Carnivora, Insectivora, Chiroptera, Rodentia, Ungulata, Hyracoidea, Proboscidea, Sirenia, Cetacea, Edentata, Marsupialia, Monotremata. If time should permit, a review of the principal variations of the same parts in the other vertebrata will follow." The lectures will be illustrated as fully as possible by specimens from the Museum and by diagrams. The course will conclude on Wednesday, March 27; and some time in June next Professor Holmes will commence his course of lectures on the "Surgical Treatment of Aneurism in its Various Forms."

THE FEMALE MEDICAL STUDENTS.—Miss Jex Blake has protested against the recent decision of the Edinburgh University Court on the female Medical student question. A reply to her protest has been forwarded to Miss Jex Blake by the Secretary of the University Court. After referring to various points in the protest he says—"On the assumption that while you at present decline the offer made by the Court with reference to certificates of proficiency, you now ask merely that arrangements should be made for completing the Medical education of yourself and the other ladies on behalf of whom you write, I am to state that the Court are quite ready to meet your views. If, therefore, the names of extra-academical teachers of the required Medical subjects be submitted by yourself, or by the Senatus, the Court will be prepared to consider the respective fitness of the persons so named to be authorised to hold Medical classes for women who have in this or former sessions been matriculated students of the University, and also the conditions and regulations under which such classes should be held. It is, however, to be distinctly understood that such arrangements are not to be founded on as implying any right in women to obtain Medical degrees, or as conferring any such right upon the students referred to."

DEMONSTRATION OF THE STUDENTS OF THE UNIVERSITY OF EDINBURGH.—At the conclusion of Sir William Sterling Maxwell's address, a large body of the students assembled outside the Music-hall, and, headed by a band improvised for the occasion, the principal instruments in which were penny whistles and children's trumpets, marched by way of Prince's-street to the quadrangle of the University. Here a programme was speedily drawn up, and immediately carried into effect. To the number of three or four hundred, the students proceeded in procession, four abreast, to St. Andrew-square, and, opposite

the premises of the Lord Provost, they set up a terrible hooting and yelling, to indicate their disapprobation of his Lordship's actions in regard to the education of the lady Medical students. At the conclusion of this unwelcome serenade, the processionists marched along Queen-street, and when passing the Merchaut Maiden Schools they gallantly cheered the inmates, many of whom acknowledged the compliment by waving their handkerchiefs. Continuing their progress westwards, they arrived at Professor Lister's house, in Charlotte-square, and a deputation, consisting of Messrs. Rees and A. D. Stewart, went up to the door, and acquainted the Professor with the nature of the demonstration. Professor Lister then came forward and briefly addressed the crowd. He said he did not know whether the demonstration was or was not intended as a compliment to him. If it were complimentary to all the Professors of the University then he was glad to see them, but it would have pleased them more had the students behaved better to the rector of their own choice. Although what he had said might not please them, his words were meant in good part. Having given three cheers for Professor Lister, the students next visited in succession Professor Spence's, in Ainslie-place, Sir Robert Christison's, Dr. Bell's, and Dr. Annandale's. They subsequently marched back to the University, and on passing the *Scotsman* office, in Cockburn-street, gave vent to their feelings by continued groans and hisses. Coming up the High-street the students congregated in front of the *Courant* office and cheered lustily. Going in a southerly direction, they gave three cheers for Mr. Livingstone, bookseller, and then proceeded by way of Nicholson-street to Buccleuch-place, on a visit to Miss Sophia Jex Blake. Naturally enough, people turned out in all directions to witness the somewhat unusual sight of 300 or 400 students in procession. In Buccleuch-place a good-looking young lady was standing at her own door, watching the demonstration. Such a temptation could not be resisted. Two or three students made a rush up the steps, and one of them succeeded in obtaining the much-coveted kiss. The students then went to Miss Jex Blake's house, and, although they pulled the door-bell with much vigour, that lady did not deign to acknowledge their presence. Shortly afterwards the procession broke up.—*Edinburgh Courant*.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN JANUARY, 1872.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
<i>Thames Water Companies.</i>						
Grand Junction	21.57	0.094	0.126	0.008	15.1	3.8
West Middlesex	20.27	0.034	0.119	0.001	15.3	3.3
Southwark & Vauxhall	20.77	0.115	0.119	0.008	15.0	3.8
Chelsea	21.43	0.098	0.120	0.004	15.4	3.9
Lambeth
<i>Other Companies.</i>						
Kent	26.83	0.013	0.312	0.000	20.4	6.0
New River	20.47	0.021	0.119	0.002	15.4	3.6
East London	23.00	0.068	0.136	0.003	16.0	4.0

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—namely, in the case of the Grand Junction and of the Southwark and Vauxhall Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 102,446,507 gallons; and the number of houses supplied was 487,230. This is at the rate of 31.4 gallons per head of the population daily.

NOTES, QUERIES, AND REPLIES.

Be that questioneth much shall learn much.—*Bacon.*

We are glad to see that our "young friend" Mr. Neale, who expressed himself as so well satisfied with the Matriculation Examination of the University of London, obtained the second place in the honour list at the last examination, *exceptis excipiendis*.

Fothergill tells us that four years ago Mrs. F. went into the Samaritan Hospital with an ovarian tumour, and went successfully through the operation of ovariectomy. On January 22, 1871, she was safely delivered of twins by Dr. Skegg, M.D., Northumberland-street, Strand. The mother and twins are doing well.

Chelmsford.—Yes; the quarrel is a very "pretty one as it stands." We have no desire to enter into local squabbles. We dealt with the question in its relation to the public and the Profession, and we do not see any reason to modify the opinion expressed in the last number of this journal. We may state that we think the *Chelmsford Chronicle* has behaved well in the matter.

THE "YOUNG" FAMILIES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A correspondent, in your last number, inquired if there was any family connexion between the celebrated Dr. Young and his son or nephew the late Mr. Young, of Sackville-street, and Mr. George Young, of the City. I can answer that there was not. Mr. George Young was the brother of the celebrated actor, Charles Young, and was for many years in extensive practice in Frederick's-place, Old Jewry, in the next house to that which has been occupied by Mr. Coulson for nearly forty years past. On the retirement of Mr. Young, his house was taken by Mr. E. A. Lloyd, of St. Bartholomew's, who subsequently removed to Mr. Abernethy's house in Bedford-row. I am, &c., J. F. C.

COMMUNICATIONS have been received from—

Mr. BALMANNO SQUIRE; Mr. DALE; Mr. A. MACLEOD; Mr. COWLAND; Mr. SNELL; Mr. F. P. STAPLES; Dr. VINEN; Dr. STEVENSON; Dr. RADCLIFFE; Dr. MUNK; Mr. E. MORGAN; Mr. WADDY; Mr. M. NORRIS; Mr. GLENCROSS; Dr. NEALE; Dr. RUMSEY; Mr. G. REID; Mr. R. EDIS; Mr. J. W. BLACK; Mr. H. C. LAWRENCE; Mr. RAYNER; Mr. J. TEASDALE; Mr. H. R. BELL; Dr. THOROWGOOD; Dr. MOORE; Mr. MAUNDER; Dr. LETHBY; Dr. ANDREW SMART; Mr. ROWAND; Mr. C. A. FOX; Mr. C. WELCH; Dr. BAKWELL; Mr. H. ARNOTT; Mr. F. A. MAHOMED; Dr. R. D. POWELL; Mr. J. CHATTO; Dr. LIONEL BEALE.

BOOKS RECEIVED—

Cobbold on Worms—Supplement to Wats's Dictionary of Chemistry—Antisepticity in Surgery, by E. Lund, F.R.C.S.—Lund's Suggestion for a Ready Method of Recording Surgical Cases in Hospital Practice—Transactions of the Odontological Society—Report of the Northumberland and Durham Medical Society—Dyson Wood on the Present Condition of Political Liberalism in England—Dyson Wood on Social Politics—Report of the Board of Health of the City of New York—Harris's Principles and Practice of Dentistry.

PERIODICALS AND NEWSPAPERS RECEIVED—

Pharmaceutical Journal—Chelmsford Chronicle—Kettering Monthly News—Borough of Marylebone Mercury—Nature—Practitioner (February)—Temperance Record—Cincinnati Clinic—Philadelphia Public Ledger Almanac—Medical Press and Circular—East London Observer.

APPOINTMENTS FOR THE WEEK.

February 10. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Mr. Wm. B. Donne, "On the Theatre in Shakespeare's Time."

12. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. Silver, "On Mitral Stenosis" (communicated by the President). Mr. Walter Coulson, "On Lithotomy after Lithotripsy."

13. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

14. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

EPIDEMIOLOGICAL SOCIETY, 8 p.m. Mr. J. N. Radcliffe, "The recent Diffusion of Cholera in Europe."

SOCIETY OF ARTS, 8 p.m. Meeting.

15. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Clinical Meeting. Dr. Wynn Williams, "Case of Artificial Anus consequent upon Unbilical Hernia."

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

16. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 9 p.m. Dr. Gladstone, F.R.S., M.R.I., "On the Crystallisation of Silver and other Metals."

VITAL STATISTICS OF LONDON.

Week ending Saturday, February 3, 1872.

BIRTHS.

Births of Boys, 1292; Girls, 1216; Total, 2508.

Average of 10 corresponding weeks, 1862-71, 2245.5.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.70 in. The highest was 29.99 in. on Sunday morning, and the lowest 29.40 in. on Thursday morning.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

† Through an error which was discovered on the revision of the enumerated numbers at the Census Office, the correct population of Manchester at the middle of 1871 was 351,171, and not 356,099, as published in recent Weekly Returns. The number for the middle of 1872 (352,759) shows, therefore, an increase of 1271 upon the corrected number for 1871.

THE BLOW-PIPE GAS CAUTERY.

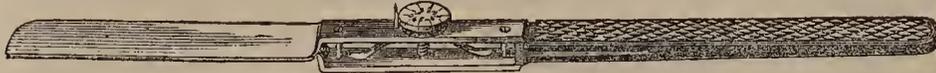

(The late Mr. BRUCE'S.)

The Instrument consists essentially of two tubes connected together, one of which may be attached to a gas-receiver or to an ordinary gas-jet, and serves as the burner; the other tube is inclined to the former at a slight angle, and serves as a Blow-pipe. The accessory parts of the Instrument consist of the following:—

1st. An indiarubber ball, capable of containing about 110 cubic inches of gas, which may be readily filled from any ordinary gas-jet by means of a pump-ball. In cases in which the gas-jet is conveniently situated, this receiver may be dispensed with, and the burner connected directly with the pipe by means of an elastic tube.

2nd. Three or more small platinum cups of various forms, adapted to the different purposes for which the Cautery may be applied. One of these cups is hemispherical, one conical, and one terminates in a probe-like extremity. Other forms adapted for special purposes have been made, but are not contained in the ordinary cases. To facilitate removal of the cups whilst heated, a small metal clip has been introduced.

3rd. Shields of different forms to protect the surrounding parts during the application of the Cautery. These consist of discs of metal and ivory, mounted upon handles, and perforated by holes of various sizes, and a plate, with a slit in the centre, to allow the Cautery to be applied along a line.

NEW SECTION KNIFE,

FOR MAKING MICROSCOPIC SECTIONS.

This improvement upon Valentin's Knife is adjusted for parallelism by the central screw, the flat head of which is divided into ten equal parts. This enables the blades to be readjusted at precisely the same distance apart. The thickness of the section is, therefore, known. The central part of the knife is strongly gilded, to prevent rust attacking the steel. Upon removing the short blade of the instrument and the adjusting screw, a capital razor-blade is formed, which may be used separately.

Inventor, Patentee, and Sole Maker, HAWKSLEY, 4, Blenheim-street, Bond-street, London, W.

SECOND-HAND SURGICAL INSTRUMENTS.

The LARGEST ASSORTMENT IN LONDON is at C. BAKER'S Old-Established INSTRUMENT WAREHOUSE, 244 & 245, HIGH HOLBORN. Every description of NEW supplied at the Wholesale prices. Second-hand Instruments of all kinds Purchased or taken in Exchange.—Observe, 244 & 245, HIGH HOLBORN (Opposite Day and Martin's).

NEW PATENT.

MESSRS. BLAISE and CO. (late SAVIGNY and CO.) beg to inform the Medical Profession that they are manufacturing URINOMETERS, &c., of Vulcanite, which far surpass those made of glass or metal, being proof against acids, and not liable to break; and they invite inspection at 67, ST. JAMES'S-STREET, and 276, WESTMINSTER-BRIDGE-ROAD. (*Vide* "British Medical Journal" and "Lancet" of October 28th, 1871.)

Second-hand and New Surgical Instruments at greatly Reduced

PRICES.—A great variety of SECOND-HAND MICROSCOPES, TELESCOPES, and OPERA GLASSES, MAGIC and DISSOLVING VIEW LANTERNS, PHOTOGRAPHIC APPARATUS, CAMERAS, LENSES, &c., by the best makers.

Address, WM. LAWLEY, 78 Farringdon-street, City, London.—Enlarged and Revised ILLUSTRATED SURGICAL CATALOGUE forwarded for 6 Stamps.

PRIZE MEDAL,
1862.

JOSEPH F. PRATT,

PRIZE MEDAL,
1865.

SURGICAL INSTRUMENT MAKER, ORTHOPÆDIC MECHANICIAN TO ST. BARTHOLOMEW'S HOSPITAL,
420, OXFORD-STREET, W.

SOLE AGENT FOR DR. E. STÖHRER'S GALVANIC APPARATUS.

ELASTIC STOCKINGS, LADIES' ABDOMINAL BELTS, IMPROVED WATER-PAD TRUSSES FOR SCROTAL AND UMBILICAL HERNIA.

MILLIKIN & WALTERS

(Late J. MILLIKIN),

7, SOUTHWARK-STREET, BOROUGH
AND
12, Palace-road, Lambeth.

Mr. F. WALTERS (of 16, Moorgate-street) begs to inform the Medical Profession that, having taken over the Stock, Plant, and Business of the late J. MILLIKIN, he is prepared to execute all orders for Surgical and Orthopædic Instruments with which he may be entrusted, on the shortest notice and in the most workmanlike manner.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;
and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

ORIGINAL LECTURES.

SKETCHES OF
SUCCESS AND FAILURE IN MEDICINE.BEING THE SUBSTANCE OF THE
LUMLEIAN LECTURES AT THE LONDON ROYAL COLLEGE OF PHYSICIANS
IN 1862.

By CHARLES J. B. WILLIAMS, M.D., F.R.S.

(Continued from page 122.)

PART IV.

EXAMPLES OF SUCCESS AND FAILURE IN PRACTICE.

Pneumonia: Treatment—General Plan: Extremes to be avoided, but Treatment varied with the Type: Failures: Successes: Evil Consequences of Excessive Use of Stimulants.

Treatment.—In the early stage of acute pneumonia, during the feverish reaction after the chill or period of collapse, in young and vigorous subjects, I have still no doubt of the superior efficacy of antiphlogistic remedies over all others. As Consulting Physicians, we do not often see the disease in this early stage, and in such subjects; and therefore we may join in the remark now often made, "How rarely bloodletting is ever employed!" But I cannot subscribe to the sweeping condemnation of this measure made by my lamented friend the late Dr. Todd and his followers in this matter; nor do I by any means approve of the highly stimulating practice which he substituted for it. Referring to an earlier period of my practice, I can recall to mind cases in which pneumonia in its first stage, with rusty expectoration, fine crepitation, strong pulse, and ardent fever, was cleared away and cured in a few hours by bleeding, general and local, aided by tartar emetic and salines. The effect was too immediate to admit of a doubt; and I would contrast these prompt and unequivocal results with the tardy and doubtful cures described by the advocates of the stimulating plan. Tartarised antimony is a most valuable aid to bloodletting at the same early stage; and in most ordinary cases may be substituted for it. I first observed the use of this agent in the practice of my illustrious teacher, Laennec; but he gave much larger doses than appear to be necessary. Doses of from the eighth of a grain to half a grain every two, three, or four hours are as effectual as larger doses, and are more easy and safe in administration. It may properly be exhibited in an effervescing saline of citrate of potash with nitre, to the diuretic and cooling properties of which I attach much importance. In fact, I find these diuretic salines of great utility through the whole inflammatory period of the disease, and I believe they help to restore to the renal secretion its proper constituents, the absence of which is a prominent feature of the disease.

No sooner does the inflammatory engorgement begin to pass into hepatisation, than bloodletting and the other sedative means lose their efficacy, and, with increasing weakness of pulse, may be absolutely injurious. At this period mercury (particularly calomel with a little opium) is more useful, together with large and repeated blisters; and these, together with the salines, now improved by the addition of carbonate of ammonia, are the best remedies for this stage. It has appeared to me that the useful operation of mercury is connected with its action on the liver and intestines more than with its affecting the gums, the appearance of the bilious or dark green stools being often followed by improvement in the symptoms. As hepatisation proceeds (and in cases not arrested early it will proceed in spite of treatment) the skin cools and the pulse fails in strength; and then frequent liquid nutriment, together with wine and other stimulants (particularly carbonate of ammonia), are required to keep up the powers of circulation, respiration, and expectoration; and the improvement which will often follow their use is very striking. I suppose we have all of us seen patients rescued from an approach to sinking by a timely and judicious use of stimulants and nourishment at the proper period; and observe—this treatment, which for the sthenic forms of inflammation in the young and robust is fit only for the after-stage of the disease, is necessary even from the first in the asthenic type, and in feeble and aged subjects; and the only antiphlogistics to be ventured on then are blisters, mild mercurials, and saline diuretics with ammonia. There is doubtless in pneumonia, more than in some other severe inflammations, a tendency to pass into an asthenic or typhoid

state; and this I take to be due to the manner in which the blood becomes affected, both by the retention of the excrementitious matter already noticed, and also by the manner in which it becomes contaminated with the products of inflammation developed in so large a vascular plexus, and so near the centre of the circulation.

Thus, the sources of danger in pneumonia, and therefore the causes of failure and death, are not only in the lung itself, by interruption to respiration from obstruction in the air-cells and tubes, and to the circulation, by coagulation of blood in the pulmonary vessels, but also in the blood generally, by cachæmia and pyæmia, and in the heart and system at large, by asthenia. You can perceive, therefore, why, in the treatment of pneumonia in its successive stages, or in its different forms, we have to use, and use freely, the most opposite remedies (bloodletting and stimulants), and yet be rational and consistent in our practice.

Pneumonia is undoubtedly a formidable disease, and, according to the reports of French authors, the mortality ranges from 9 per cent. in ages from 10 to 30, up to 60 and 80 per cent. in ages from 60 to 80; but I cannot find in my notes evidence of anything like this mortality. The cases of which I have notes, within the period from which I take my samples, are not numerous—not exceeding thirty—and the recorded deaths are only three. The history of these three will show that treatment had not a fair chance.

One was the case of a lady, about 30, whom I was requested to see by the late Dr. Darling. He had been called in only the day before, *the patient previously having been treated homœopathically*—in other words, had not been treated at all; and the disease had advanced to extensive hepatisation, with collapse of the vital powers, beyond the reach of Medical aid. She sank the following day—the victim, I truly believe, of homœopathic quackery.

The second case was that of a gentleman, aged 34, seen in the winter of 1849. Six days before, after prolonged exposure to wet and cold, he was attacked with severe rigors and pains in left chest, and great oppression; and although he had been actively treated by cupping, tartarised antimony, calomel and opium, and blisters, I found him unrelieved, and expressing his conviction that he could not recover. In truth, the chances were fearfully against him; for, in addition to the signs of double pneumonia, there were friction-sounds in the left back and accompanying the heart's motions, with a weak and rapid pulse, and clammy skin. And he did sink in two days—an example of the failure of Medicine from the overwhelming amount of disease. On post-mortem examination, both lungs were found extensively hepatised, and the pericardium as well as the pleuræ coated with lymph. But such cases are very rare—I do not recollect more than three or four in other periods of my experience.

The third fatal case belongs to a group that are not so uncommon—pneumonia of the aged. An old lady of fourscore had a shivering fit, followed by pain of the side, cough, and great oppression, frequent unsteady pulse, and slight delirium. I saw her on the second day after the attack, and found the fine crepitation in both lungs, with the loud large tubular sounds denoting consolidation over a great part of the right back. The circulation was beginning to fail, and, although stimulants were freely and assiduously given, there was no power of resisting the disease, and death took place the next day. Chomel used to say that he rarely knew an instance of recovery from pneumonia after the 70th year; but I can recall at least half a dozen instances of recovery at and above that age, one being an old lady of 83, another a veteran general officer of 88. But then our practice in such cases is very different from that commonly pursued in France. At this age the vital powers are so apt to succumb to disease that it is necessary from the first to sustain them by continued stimulation and nutrition, even whilst we are using mild mercurials, saline eliminants, and large blisters to derive from the lungs. My experience has taught me to put great faith in large blisters, both in asthenic pneumonia and in bronchitis, and I am confident that I have seen many lives saved by their means. Instead of being lowering, they give a salutary excitement to the labouring circulation; and the copious serous discharge which they produce from the skin tends to relieve the congested lung without wasting the red blood that is so needed to sustain the functions. Small blisters tease as much as large ones, and are far inferior in the relief they afford.

Passing now to the list of *successes* in pneumonia, I shall only detain you by a brief notice of a few severe cases in which the pneumonia was double, affecting both lungs.

In February, 1851, I was called to see a lady, aged 38, with

pneumonia, in the first and second stages, occupying the whole of the right lung. It had come on a week before, after weaning her infant and much anxiety; and, in addition to the usual symptoms, there was occasional delirium, and the urine was albuminous, but of high specific gravity. I considered these symptoms to be mutually connected, and to have reference also to the recent weaning. In a few days the left lung was also attacked, and became considerably hepatized; but fortunately the right lung began to clear before much of the left was involved; and after some days of extreme danger the urine became abundant, and with copious deposit, and the patient made a gradual and complete recovery—the lungs at the end of two months being quite free from deposit. The chief remedies employed were local bloodletting and antimonial salines at first; then mercurials, salines, and blisters; lastly, mineral acids and other mild tonics: nutrient diet with mild stimulants being continued throughout.

A gentleman, aged 40, in March, 1853, after six weeks of gonorrhoea and orchitis, was severely chilled, and had extensive pneumonia of the right lung. The symptoms had begun to abate after the use of venesection and tartarised antimony, but a more expectant treatment having been substituted by a Physician called in, the inflammation returned with great severity, attacking both lungs, but again yielded to mercurials, antimonial salines, and free blistering; and the patient was well in four weeks, and has enjoyed good health since.

I have notes of several cases of boys at Harrow and other schools, at ages from 12 to 17, becoming the subjects of double pneumonia of a formidable character. These boys get heated at football or some other violent exercise, and then throw themselves on the damp grass, or take off their coats to cool themselves, or stand about "keeping base"; and the chill operating on the exhausted body causes extreme congestion in the lungs, the circulation of which has been weakened by the previous violent respiratory efforts. The result is pneumonia, generally of asthenic type, commonly double, attended with much prostration of strength, sometimes slight delirium, much coated tongue, sordes on the teeth, and other indications which exemplify the connexions of pneumonia with blood disease to which I have directed your attention. Yet these cases, ugly as they seem, generally do well—in fact I have no record of any fatal case—and this without any very active treatment. Youth is in their favour; and if the spread and obstructive influence of the disease is checked by large warm poultices, or even blisters, the eliminating processes aided by mild mercurials and salines, sometimes with ammonia, and the strength sustained by frequent liquid nutriment and moderate quantities of wine—the issue will generally be favourable. I very much doubt that the same success would attend a much more energetic practice, whether of the antiphlogistic or of the stimulating kind.

Note added in 1872.—The following extract from our recent work on "Pulmonary Consumption" (p. 335) will explain the view which I take of the utility of stimulants and other sustaining measures in the treatment of asthenic inflammations, and will further show the grounds on which I did not hesitate to add my name to the recent Declaration against the abuse of alcoholic stimulants that has excited so much comment:—

"Whether the inflammation be pneumonic or bronchial, it throws out bioplasms or sarcophytes, which, if they languish and congregate, block up the tissues and interfere with respiration and circulation; but if kept alive and active, may migrate and clear out of the affected tissues and membranes in the form of pus and mucus-cells and other excretable matter. Now, we may in some measure promote this result by the judicious use of stimulants and nutriment in such forms and quantities as the patient will bear. Often the stomach is weak, and cannot bear much or solid food, and then beef-tea and other soups and broths should be given in small quantities and at short intervals, together with the diluted wine or spirit most agreeable to the patient. . . . After such attacks of inflammation as have required the use of antimony and salines, or even after those lower forms benefited by carbonate of ammonia, the operation of dilute mineral acids, especially the nitric, is often very grateful to the palate and stomach, cleansing the tongue and restoring the appetite and the power to take and digest solid food; and the sooner this can be effected the better. It may sometimes be commenced during a remission of the febrile symptoms in the morning, even when salines are still necessary in the evening and night; and if the remission increases to intermission of the fever, quinine, salicine, or calumbo may be added to the morning dose. This should be our aim—to attempt as early as possible to change the treatment from the antiphlogistic to the tonic and sustaining, still

retaining the aid of nocturnal soothing salines and moderate counter-irritation to keep in check any remains of the inflammatory irritation.

"I feel quite sure that this is a much safer and more successful practice than that which has been much recommended of late, giving strong tonics, such as iron and quinine, boldly throughout an inflammatory attack, without regard to their immediate effects of increasing pain, cough, tightness of breath, and heat of skin.(a) I am equally opposed to the practice of keeping patients with pneumonia and bronchitis in a state of constant semi-intoxication with brandy, in quantities much greater than are necessary merely to sustain the failing powers. No doubt patients do sometimes recover under this treatment; but their recovery is more tardy than that from a more moderate and rational plan; and convalescence and subsequent health are often impaired by the craving for, and indulgence in, stimulants, which this practice produces. I have known several, and have heard of more, cases of dipsomania which dated their origin from this spirituous medication." It should therefore be our object, in prescribing stimulants in the treatment of disease, not to exceed the quantity necessary for the temporary weakness, and to diminish or withdraw them by degrees in proportion as this is removed.

(To be continued.)

ORIGINAL COMMUNICATIONS.

OVARIOTOMY—ANTISEPTIC DRESSINGS—RECOVERY.

By W. NEWMAN, M.D. Lond., F.R.C.S. Eng.

S. A., aged 32, was admitted into Stamford Infirmary, June 13, 1871. Married; one child, 5 years old. Menstruation regular until the last three months; since that time has been every fortnight. Enlargement of abdomen for the past twelve months, steadily increasing. Thin, but not unhealthy-looking. Abdomen uniformly enlarged—thirty-six inches in circumference at umbilicus. Dulness on percussion over lower three-fourths of abdomen, both in front and in flanks; this unaltered by any change of position. Fluctuation very evident. More resistance to deep pressure in left than in right iliac region.

Vaginal Examination.—Cervix small and os uteri healthy. Much resistance to be felt at roof of vagina, and there seems to be more downward bulging and resistance to the finger on the left than on the right side.

July 3.—I performed paracentesis of the abdomen, removing thirteen pints of greenish-yellow fluid; sp. gr. 1028; alkaline; coagulated by heat to one-half of whole bulk. After the tapping a mass the size of a foetal head could be felt in the left iliac region, extending across to the mid-line and upwards to within two inches from the umbilicus. Much relief followed the tapping.

25th.—Is anxious to go home for a time. Fluid is reaccumulating. Abdomen measures thirty-two inches.

September 13.—Readmitted as in-patient; in very fair health; abdomen now measures thirty-five inches.

21st.—Menstruation ceased on 16th. Large warm water enema given this morning. 2.30 p.m.: Chloroform given and operation of ovariectomy undertaken. All the staff of the Infirmary present. The catheter passed. Surface of abdomen washed with carbolic acid lotion (1 in 20), and carbolic acid spray (1 in 100) kept up steadily throughout the whole operation. The sponges employed were all wetted with lotion of the same strength. An incision made from umbilicus to pubes through outside tissues down to the peritoneum; this covering was care-

(a) If it be not to the strong tonic and stimulant treatment (which had been certainly adopted in some of them), I know not to what to ascribe the frightful hyperpyrexia in certain cases of acute rheumatism recently described by Dr. Wilson Fox and others. He seems to have averted a fatal result in some of these cases by what appears a very hazardous measure—cold bath and ice applications; but the struggle between life and death was fearfully long and doubtful; and one feels constrained to ask, "Cannot this formidable hyperpyrexia be prevented or met by gentler means?" I never met with such a case, in my own practice, during the ten years when I had charge of patients at University College Hospital. Out of 163 cases of acute rheumatism only two died—one with peri- and endo-carditis supervening on old heart disease; the other of double asthenic pneumonia. The remaining 161 were cured after an average stay of twenty-four days in the Hospital. The chief treatment was by alkalis and colchicum, followed by bark. Local bloodletting and blisters were sometimes added when the heart was attacked; and in all cases of severe pain, opium, generally combined with calomel.

fully opened on a director. A thick-walled cyst at once came into view; no omentum or intestine to be seen. Slight and easily broken-down adhesions existed on the whole of the front part of the tumour between this and the peritoneum; no adhesions to internal organs. I tapped the cyst with large trocar, drawing off eight pints of fluid; it was then easy to draw out the greater part of the mass, and several separate hard collections of cystic growth came out also. The larger part of the solid growth was found to lie anterior to the uterus, low down in the true pelvis, and it was not possible to dislodge this by traction until I introduced two fingers into the vagina and made firm upward pressure. The difficulty apparently arose from the mass lying beneath the promontory of the sacrum. The pedicle was very long and thin, almost riband-like. This was tied in two halves by some carbolic catgut, two strong strands on either side, and then returned into the abdomen. Two points, which bled freely on the peritoneal surface, just within the pelvis, were also tied with catgut, and all the ligature-ends cut short. No ovarian fluid escaped into the abdominal cavity; all the blood was carefully sponged out. Left ovary affected; right not implicated. Wound brought together by three sutures of flexible metallic wire, which included the peritoneum; a suture of carbolic silk between each two metallic sutures. Protective and antiseptic gauze closely applied over all, and retained in place by wide antiseptic bandage. She was then lifted back into bed, still asleep from anæsthetic. Pulse 90, good volume; catheter every four or five hours. 9 p.m.: Pulse 92; temperature 98°; some pain and sickness. 11.30 p.m.: More pain, and even iced milk is rejected. Subcutaneous injection of morphia (gr. $\frac{1}{2}$).

22nd.—Has had some fair sleep. Pulse 112; temperature 99°. Complains of feeling faint. Twenty drops of brandy in iced water; nutrient enema (beef-tea and egg) every four hours; morphia injection (gr. $\frac{1}{4}$) as may be needed. 6 p.m.: Pulse 120; temperature 98.6°; retching less. 10 p.m.: Pulse 120, not wiry; skin quite moist.

23rd.—Had a very fair night. Pulse 120, fair volume; respiration 24; temperature 100.2°. 10.30 a.m.: Changed gauze and dressings; no trace of redness or discharge; no more sickness. 10 p.m.: Pulse 116; respiration 20; temperature 100.6°; skin and tongue moist. Has dozed frequently; not in pain. Has had tea and milk; no sickness.

24th.—Metrostaxis set in. 10 a.m.: Good night. Pulse 112; temperature 100.4°. Wound dressed; no redness of edges, no discharge. 9 p.m.: Pulse 110; respiration 22; skin moist. Has been troubled with flatulence; abdomen not distended. Has morphia injection (gr. $\frac{1}{6}$) about every six hours, and nutrient enema—beef-tea and brandy (egg omitted)—every four hours.

25th.—10.30 a.m.: Pulse 104; temperature 100°. Stitches removed; wound is apparently united. Abdomen rather flat than otherwise. Takes a little food (milk, etc.) by mouth. Complains of uneasy pain about lower part of abdomen. 9 p.m.: Pulse 108; respiration 22; temperature 101.2°. Says she is fairly comfortable. Metrostaxis, small in quantity, is steadily going on. Is glad to have the urine drawn off every four hours; says that this relieves the pain.

26th.—3 a.m.: Still in pain. Temperature 101.4°; pulse 120; respiration 22. 9 a.m.: Has feeling as if bowels would act; pain of bearing-down character. I made a vaginal examination, and found very manifest fluctuation in Douglas's space; some little pain on pressure upwards with the finger. Pulse 120; temperature 101.4°. Wound dressed; looks well; some little discharge on the gauze. Warm water enema given; a good quantity of liquid faecal matter followed. An hour subsequently an enema of pulv. opii gr. ij., mucilage ζ ij.; this was followed by much relief. Has no tenderness on pressure on abdomen. No symptom of active febrile disturbance; no rigor. 10.30 p.m.: Pulse 120; respiration 24; temperature 102°. Skin moist; tongue moist. Vaginal swelling as before; uterus pushed upwards and forwards. The fluctuation can be distinctly felt both by vagina and rectum. Opiate enema repeated.

27th.—10.30 a.m.: Pulse 108; respiration 20; temperature 101°. Has had a better night. Wound dressed. There has been discharge of several ounces of serous blood-stained fluid from about middle of wound; all has been taken up by gauze covering, and there is no trace of odour. Says that after retching last night she felt something give way, and soon had much relief. 10 p.m.: Pulse 104; respiration 22; temperature 100.2°. Has not been so comfortable to-day; feeling of sickness and occasional retching. Enema of warm water brought away a fair quantity of perfectly normal and semi-solid faecal matter. Skin moist, and is said to have had free perspiration.

28th.—10 a.m.: Temperature 101°; pulse 98. About one ounce

or a little more of serum on the gauze; no redness about wound. Metrostaxis (present for four days) now ceased; some hardness over pubes on right side; no pain on gentle pressure; abdomen not distended. 9 p.m.: Pulse 96; temperature 101°; respiration 22. Comfortable most part of the day; some faecal motion, and since that time watery diarrhoea and pain. Through carelessness of nurse the lower part of wound has been quite uncovered for some little time, and at lips of wound there is now some surrounding redness; no odour from discharge.

29th.—11 a.m.: Pulse 100; temperature 101°; respiration 22. Has been troubled with pain and irritable purging; tenesmus relieved by opiate enemata; vaginal swelling even more decided and more tense. 3.30 p.m.: Temperature 102.6°; pulse 108. Flushed in face, anxious and restless; never so before since the operation. 9 p.m.: Temperature 101.6°; pulse 100. More comfortable than she was at 4 p.m.; complains much of pain at the lower part of back; has some (though not urgent) feeling of sickness; no diarrhoea the last few hours.

30th.—11 a.m.: Pulse 96; temperature 102°. Says she has had very much pain about the back through the night, and has not slept well. Wound dressed; some small quantity of serous blood-stained discharge on the gauze. The abdomen in the lower third is evidently enlarged, and more firm to the touch; vaginal swelling quite as evident, and very tense. 8.30 p.m.: The conditions of local distension and of increasing general distress were so marked, that, after careful consultation with my colleagues, it was decided to break up the lower part of the wound, and allow the contained fluid to escape. Chloroform was given; the carbolic acid spray employed as usual, and I then (with antiseptic finger) broke open the lower two inches of the wound. The adhesions gave way easily, and I soon reached the abdominal cavity. The moment that the finger was free in the cavity some dark-coloured and slightly offensive blood (to the amount of three ounces or more) welled up. I touched with the finger a floating and apparently natural fold of intestine, and reached well down into the true pelvis. No firm clot or solid matter was touched. A metallic suture introduced at upper part of newly made wound; the lower part left open. Had some fair sleep, with usual morphia injection.

October 1.—10 a.m.: Pulse 98; temperature 102°. Wound dressed; some quantity of dark bloody discharge on gauze; no odour; tongue quite moist, white coating. 10 p.m.: Pulse 96; temperature 102.4°. Says she is much relieved from pain. Abdomen smaller; no pain to the touch; a large quantity of dark blood-stained discharge on the gauze.

2nd.—9 a.m.: Pulse 94; temperature 100.4°. Has had a very fair night; abundant discharge; dressings have needed changing every five or six hours; no sickness or retching for last thirty-six hours; estimated that from twelve to twenty ounces of deeply stained serum have come away since the wound was opened; vaginal swelling much as before. 9 p.m.: Pulse 92; temperature 100.2°. Abdomen more flat; has taken food well, and is in all points feeling better.

3rd.—10.30 a.m.: Pulse 96; temperature 101.2°. Complains of sorethroat. Fauces are slightly red. Tinct. ferri mur. mxxv . ex aq. ζ ij. ter die. Discharge from wound less in quantity. 9 p.m.: Pulse 88; temperature 100.4°. A good result (solid motion) and much relief followed the use of enema of warm water. Is certainly better.

4th.—11 a.m. Pulse 84; temperature 99.2°. Fairly good night. Says she is very comfortable, and her general aspect is good. Wound dressed; about two ounces of dark broken-up blood on the gauze; no odour; no pus. 9 p.m.: Pulse 88; temperature 101°. Has had some meat for dinner, and enjoyed it; has also two eggs and more than a pint of porter daily; milk, too, in fair quantity.

6th.—Highest temperature 102.4°; but pulse only 92. Vaginal examination made. The swelling is still present, but not so large or so tense. Is doing very well.

7th.—Discharge quite inodorous; but, for the first time, some distinctly puriform fluid wells up through the wound. This may be due to some internal change, but more, I think, to an inadequate covering of the lower part of the wound.

9th.—Says she is quite comfortable. Abdomen much flattened; discharge distinctly pus; about one ounce on gauze night and morning, but quite without odour.

13th.—Doing very well; discharge is more watery now; quantity much as before. Vaginal examination made: the uterus is almost, if not quite, in normal place; still some fluid to be noted in Douglas's space; not at all tense.

15th.—Was much disturbed yesterday by screams of another patient. Temperature ran up to 103°, and she had racking headache; no abdominal discomfort, and no disturbance about

the wound. Headache relieved by twenty-minim doses of the tinct. digitalis. Is better on the whole to-day.

19th.—Headache gone; wound now filling up, and discharge scanty and inodorous. The vaginal swelling can no longer be detected, and uterus is evidently in normal position. She has pain and tenderness in left groin; for about two inches along line of femoral vein there is some little thickening; a local phlebitis. This crept on downwards to posterior tibial vein, and for some few days the left foot was œdematous.

21st.—Up for first time to-day; antiseptic dressings discontinued.

27th.—Sits up regularly, and is gaining strength; eats and sleeps well.

November 6.—The wound in abdominal wall not quite filled up; only a few drops of discharge (pus) now each day. She can stand upright, walk a few steps, and will shortly leave the Infirmary.

Remarks.—The above case is, I believe, the *first* in which the antiseptic treatment has been fairly applied in the operation of ovariectomy. My best thanks are due to Professor Lister for his great kindness in affording me this past summer the opportunities of watching the daily application and the marvellous results of antiseptic dressings. General and special Surgery will alike, I doubt not, profit by his teachings. The whole operation was undertaken and carried out from first to last under an abundant cloud of carbolic acid spray (1 to 100). Certainly this may be conceded: that the employment of this antiseptic spray had no prejudicial influence, and did not provoke mischief when freely brought into contact with a large serous cavity; no symptom of acute peritonitis was noted. The selection of the catgut ligature for the pedicle in preference to the more commonly used clamp was, I think, an error, and it is not impossible that the serious complication of large internal hæmorrhage may have been due to the slipping of some one of the ligatures employed. Further, too, I think it open to grave question whether it would not have been more wise to have introduced—say for the first twenty-four hours—a tent of carbolised oiled lint at the lower angle of the wound. The success that followed on the breaking-up of the wound, so as to allow the free escape of the effused blood, is of much interest. In this I only followed the teaching of well-known operators; but it can hardly be too much to claim for the antiseptic dressing a very material share in the recovery that followed in spite of the opening up to external influences of a very large collection of blood. That putrefaction did not happen was surely due to the careful exclusion of the external atmosphere as such; and as certainly, had septic changes once occurred, the patient could hardly have recovered. The question was carefully thought over more than once, whether it would not be best to puncture or incise the collection in the vaginal pouch of peritoneum. The main reason which decided me not to adopt this course was the certainty that the antiseptic treatment would then have been impossible, and I am heartily glad that the event has justified the decision so arrived at. The details given in the above paper are condensed from far more copious notes, and for these, taken constantly every three hours for more than a fortnight, as well as for most careful personal attention, my very best thanks are due to my friend Mr. A. T. Gibbings. But for his sedulous care, the ultimate result would have been far less favourable.

Stamford.

ON

LIGATURE OF THE SUBCLAVIAN ARTERY.

(A REPLY TO DR. BEACH'S CRITICISM.)

By Staff Assistant-Surgeon F. P. STAPLES.

THE number of the *Medical Times and Gazette* for November 18, 1871, contains an adverse criticism on a method I advocated some time ago for a more facile deligation of the subclavian artery than that in common use. Before noticing its details, I may remind your readers that the operation recommended differs from that commonly practised by the skin incision being made along the upper side of the subclavian triangle of the neck, or, in other words, along a line parallel to the normal course of the omo-hyoideus.^(a)

Some advantages were claimed for what your correspondent

(a) It was not intended in the first paper, nor is it now, to institute in the written description of the proceeding a comparison of it with any of those methods by which large skin flaps are carried over the posterior triangle; nor with the methods by perpendicular or semilunar incision.

has been pleased to term an innovation, of which the principal were as follows:—

1. The skin incision, not being immediately bounded by the unyielding clavicle, admits of easy retraction in both directions, consequently giving more space at the bottom of the wound, and thus free access to the vessel.

2. The risk of hæmorrhage obscuring the final steps of the operation from accidental wound of the supra-scapular vessels is lessened.

3. That the omo-hyoideus, fully exposed as it is in the incision recommended, is a more recognisable and a truer guide to the artery than the edge of the anterior scalenus.

The criticism deals with the last only, and against its successful adaptation to the operation under notice urges three objections, which may be briefly stated thus:—

1. The occasional want of, or other anomaly in the course of, the omo-hyoideus, and the probability of the case requiring operation being the occasional one where the anomaly obtains.

2. The chances of the Surgeon's embarrassment, by the anomaly.

3. Increased risk for the patient resulting from embarrassment.

With regard to the first objection, I have to thank Dr. Beach for placing his experience on record, but will remark that, as the course of the omo-hyoideus must ever remain normal in an extremely large proportion of cases, the difficulty will present itself to the Surgeon about to operate as remotely problematical. Assuming, however, its existence in a case under operation, are the 2nd and 3rd points in the objection—viz., embarrassment of the Surgeon and increased risk to the patient—inevitable?

An anomalous distribution of the parts in the posterior triangle of the neck is calculated to disconcert the Surgeon, no matter by what method he essays to ligature the subclavian artery; and I need scarcely observe that the absence of the posterior belly of the omo-hyoid muscle is by no means the most embarrassing of these anomalies.^(b) Practically, however, it is the most misleading that is likely to occur in the course of the operation recommended; yet a careful consideration of it, based upon not a few dissections, scarcely seems to confirm the opinion that from its presence need necessarily follow frustrated efforts of the Surgeon or increased risks to the patient. The discovery of the anomaly will be made—(I am alluding to the absence of the posterior belly of the omo-hyoideus, and will pass over the other irregularities of the muscle as no more applicable to this than to any of the other methods in use)—immediately the deep cervical fascia has been divided, while the important parts in the space are undisturbed; then, in using the incision recommended, and keeping in the direction of the skin wound, a few scratches, if there is not much fat, will expose the vessel if placed normally, and if it is placed low down it will bring the Surgeon on to the body of the plexus, and by following this to its inner edge there ought to be no reasonable difficulty in finding the artery.

If, however, the efforts of the Surgeon are impeded, as stated to be likely in the criticism, although I think I have shown there need be no reason for such embarrassment, I may remark that in using the incision recommended he is not deprived of the assistance to be derived from the edge of the anterior scalenus.

A Surgeon is, no doubt, at liberty to draw his own conclusions from his anatomical labours, and to warn his Professional brethren of the difficulties by which his path has been impeded, and, on this understanding, the criticism should have passed unnoticed had the impeding embarrassments and promises of uncertainty resulted from a trial of the method criticised; but, as such is not the case, I have thought it necessary to occupy so much of your space to show that the condemnatory objections need create no alarm, and that they are based upon a remote probability, which, if accidentally present, need neither be embarrassing to the Surgeon nor full of risk to the patient.

Puchmuree, Central India.

THE South Shields Board of Guardians have voted £100 to Dr. Thompson, and £75 to Dr. Denham, for their extra services during the prevalence of small-pox in the town and district.

Ferguson's "Surgery," Allan Burns' "Observations on the Diseases of the Heart, etc., and on the Unusual Origin and Distribution of some of the Larger Arteries of the Human Body." Edinburgh, 1809.

THE RISE AND PROGRESS OF YELLOW FEVER IN BUENOS AYRES IN 1871.

By J. H. SCRIVENER, M.D. Lima,

A SHORT HISTORY OF THE INTRODUCTION OF YELLOW FEVER INTO THE PORT OF BUENOS AYRES IN 1858, AND OF ITS REAPPEARANCE AND PROPAGATION IN 1871.

YELLOW fever was imported into Buenos Ayres in 1858 and in 1871. In March, 1858, I received a note from Dr. Alsina (then Governor of Buenos Ayres) requesting me to be present at two post-mortem examinations at the Recoleta (the public cemetery of the city). This invitation I willingly accepted, as Dr. Alsina was aware that I had practised in Lima during the prevalence of yellow fever in that city; and as a pestilence was then raging in Buenos Ayres, about the nature of which Medical men were undecided, he wished me to ascertain if it was really the disease. I went to the cemetery, where I found the President of the College of Physicians and a number of its members, besides several Physicians of different nations. I had at that time retired from my Profession, and was holding the appointment of her Britannic Majesty's Acting Consul in Buenos Ayres.

On making the post-mortem examination of these two bodies, we found the same pathological signs which presented themselves in those who had died from yellow fever in Lima; we therefore came to the conclusion that it was the same disease.

The yellow fever prevailed in Buenos Ayres for about six weeks in 1858, and was confined to certain streets running parallel with the river. It disappeared suddenly with a strong south-westerly wind (called a *pampero*), after having carried off between 600 and 700 victims. The importation of this fever was clearly traced to the Royal Mail Steam Packet *Camila*, for three persons on board that vessel, among whom was the purser, died from it.

It is a remarkable fact that, previous to the appearance of yellow fever in Buenos Ayres, it had prevailed for many years in Rio Janeiro; yet, notwithstanding the uninterrupted intercourse between Rio Janeiro and the port of Buenos Ayres, it was not brought to the latter city till the end of March, 1858. The same fact was observed with respect to the yellow fever in Lima; for that disease prevailed for several years in the port of Guayaquil on the Pacific coast, and though there was frequent and uninterrupted intercourse between that port and that of Callao (six miles from the city of Lima), it was not imported into Lima until 1852.

During the outbreaks of yellow fever in 1842 and 1845 in Guayaquil, there were instances of persons who had the fever on board the northern steamers, and who disembarked in the port of Callao, and arrived in Lima, where they were attended by Medical men and by members of the family with whom they were staying, but yet no other person was attacked with the disease.

It has been remarked in Lima that it has been since the discovery of gold in California, and the constant rush of people and shipping from the Atlantic to the Pacific, that the epidemics of 1853, '54, and '55 have taken place in Peru; and it is remarkable that, since the arrival of great numbers of emigrants from Europe, the epidemics of 1866, '67, and '71 have occurred in Buenos Ayres.

It is impossible to know the sanitary condition of the numerous vessels that visited the River Plate ports during the periods referred to; we cannot, therefore, affirm anything with certainty on this subject. We know that some of them came from the ports of Brazil, where the yellow flag was hoisted half-mast high as the signal of cholera and yellow fever; but we are ignorant of the number of these vessels which arrived with their sickly crews, neither have we any means of ascertaining it, for every captain touching at Buenos Ayres had an interest in not divulging any facts that might subject his ship to the quarantine laws. Certainly there were vessels which came from the ports of Paraguay and Corrientes during those periods, where cholera and yellow fever prevailed.

The Buenos Ayres *Standard* attributes the importation of yellow fever to two causes: it states that a passenger in confinement at the Lazaretto of Ensenada borrowed a horse, rode into town, took to his bed, and recovered; but that his family died, then most of the people next door died from the disease, and so it spread through the whole district of San Telmo, the dirtiest and most populous in the city. It also states that at the same time a vessel with immigrants from Genoa, which had touched at Barcelona, had become infected there; that the cap-

tain threw overboard fourteen persons who had died of the fever, but, on entering the port of Buenos Ayres, he only presented his papers from Genoa, and landed his passengers, many of whom were doubtless infected.

Such facts, then, as these, which I have thus briefly related, show, I think, a striking resemblance in the growth of yellow fever in different latitudes in the south-west coast of Peru and the shores of the River Plate between 1849 and 1871.

The individual who conveyed the yellow fever to the town of Charcas, in Peru, was a soldier-deserter from the coast, and a native of Pisco. This man caught the contagion in Pisco, where he went, according to report, in search of a dead man's effects, and was carried home in a litter, a distance of six leagues. Those who came in contact with him took the fever, which soon became general in the towns and villages in the highlands of Peru. According to official reports, one-half of the population of Cuzco (the ancient capital of the Incas), consisting of 40,000 souls, fell victims to the disease.

It would appear to be clearly proved, by the preceding accounts, that the yellow fever was propagated by contagion. How can we explain, then, why persons arriving from an infected port with yellow fever, as in the case of those who arrived at Lima from Guayaquil in 1842 and 1845—several years previous to the development of the disease in that city—did not propagate it? Then, again, why vessels that came from the infected ports of Brazils to the River Plate ports previous to 1858 did not import it, whilst the soldier-deserter from the coast, a few years after the periods referred to, imported it into the towns and villages of the highlands of Peru; and a passenger from the Lazaretto of Ensenada, or more probably from the Genoese vessel, into the city of Buenos Ayres?

Dr. Jackson, in his work "Remarks on the Epidemic of Yellow Fever," throws no light on the subject. He says that "certain inexplicable conditions in the atmosphere facilitate the propagation of contagious diseases among the community; others are indifferent, as neither facilitating nor opposing; and some may be considered as negative, inasmuch as a disease inherently contagious does not spread, or spreads only in a very limited manner, and reluctantly, as it were, under the implied condition. The fact is obvious; the efficient cause is unknown; the ultimate cause is the preservation of the human race from extinction under the occurrence of a mortal contagious malady."

We have heard, from the best authority, that many of her Britannic Majesty's ships on the West Indian and North American coasts, whose crews were suffering from yellow fever, were cured from it, and the disease entirely removed, by the vessels going to a temperature of 60° of Fahrenheit. Yet we find, from the Medical writers in the Andes of Peru, that the disease struck down with the same severity and rapidity the miner in the highest and coldest mountains as the agriculturist in the balmy and warm temperature of the valleys. It seems to have been equally contagious in every climate and temperature in the highlands of Peru. It is estimated that the yellow fever proved fatal to one-fourth of the indigenous race of Peru.

I was exercising my Profession in Lima when the pyrexial disorders of 1852 and 1853 broke out; but they were only, as Dr. Archibald Smith justly observes, "the nascent and growing stages" of that mature yellow fever which burst forth with violence in January, 1854.

There were no primary and progressive stages of yellow fever previous to its outbreak in Buenos Ayres, but there were certain inexplicable conditions in the atmosphere which attracted the attention of the inhabitants. The weather was extremely sultry, and the thermometer of Fahrenheit ranged between 96° and 104° in the last days of December and the commencement of January; there was a density in the air which had not formerly been experienced; there had been a great drought for several months, and the river shrank on several occasions to an unusual distance from the shore. It is true that there were several sporadic cases of yellow fever in December of the previous year, but they created little or no alarm; they were, nevertheless, the harbingers of the greatest pestilence that ever afflicted the city.

Medical men, both native and foreign, were undecided as to the nature of the epidemic at its outbreak; some were of opinion that it was a typhus fever, others that it was icteroid typhus, and others declared it to be yellow fever.

I was in Buenos Ayres towards the conclusion of the fever in May last, and saw many who had been attacked with it, and being acquainted with it in consequence of my attendance on the sick in Lima in all its stages and forms, felt interested in obtaining from Medical men and reliable persons, who attended upon the sick, an account of the stages and forms of

the disease in that city. I am particularly indebted to Dr. Christiani and the Rev. Mr. Lett, who were present from the beginning to the end of the pestilence, for much valuable information on the subject.

It appears, from an account published by the Rev. T. E. Ash, B.A., Chaplain to the British Legation in Buenos Ayres, that "the yellow fever made its appearance in that city in the first week of last January, but at the beginning the only persons attacked by it were a few Italians, who were entirely ignorant of the nature of the disease; that if the alarm of that pestilence had been properly sounded by the authorities, the Medical men, the clergy, and the press, it would have helped considerably to crush out the incipient danger, and thereby saved some thousands of lives."

But, with due deference to this gentleman's opinion, I beg to observe that, if the alarm of the pestilence had been properly sounded, it could not have prevented the dreadful effects. That mysterious agent, yellow fever, or its epidemical influence, existed in the atmosphere, and no human means could have interrupted its course or impeded its pernicious effects. The district of San Telmo suffered more from the fever than any other quarter of the city, from causes only partially known. We know that if the apartments of the sick are crowded and ill-ventilated, they may be supposed to be charged with offensive material in a higher proportion than the common atmosphere, inasmuch as it has there less opportunity of being diffused; and it appears that such was the case in the district of San Telmo. "It was supposed," continues Mr. Ash, "that the ravages of the plague would be confined to San Telmo; hence no precautionary measures were taken. No person of note had succumbed to the fever."

We learn from this gentleman and the press that the disease progressed during the month of February; "that it passed from the parish of San Telmo to the Calle Paraguay and near to the Calle Florida; that the registered deaths in the beginning of the month did not exceed twenty daily; that the mortality increased rapidly towards the close of the month, and the deaths were from forty to fifty daily; that several persons of note had died of the fever, among whom were the venerable Irish pastor, Father Fahey, and the old and respected Dr. Ventura Bosch."

It appears that in March the pestilence spread with frightful rapidity, and that the greatest terror prevailed in all quarters of the town. The press endeavoured to calm the fears of the inhabitants by publishing fewer deaths than took place. The Government and public authorities were indefatigable in their efforts to adopt prompt measures suited to the exigency of the case, and a Lazaretto was established near the Once de Setiembre. We learn from Mr. Ash's statement that "the gravediggers at the South Cemetery were unable to keep pace with the mortality, and as many as seventy coffins were one night left overground; that by dint, however, of high wages, a larger number of workmen was obtained, who, in gangs of day and night service, aided by the moonlight, succeeded in getting through their dismal work." "In the middle of March," continues Mr. Ash, "the plague may be said to have become general. The parish of Socorro, considered one of the healthiest of the city, was infected. In Calle Callao, our widest street, numerous cases occurred, and the most airy and best-ventilated parts of Buenos Ayres were the first and most severely attacked, whilst the centre for the time escaped. Governor Castro closed all the schools in the town. The mortality of the first week of March reached seventy daily, and on March 8 rose to 115. Physicians recommended everyone who could to leave the city. Those whose business required their presence in the town were advised to sleep in the suburbs. The panic had, unhappily, communicated itself to all classes, and it was said that more than half of the Physicians had fled. Those who remained were overburdened with work. It was remarkable that the epidemic followed the tract of those streets which had been flooded in March of last year. The houses in those parts had been mostly left in a filthy condition, the inhabitants returning to them after the floods had subsided, while piles of rotting clothing, etc., remained infecting the locality for some time after. And now the month of March again brought heavy rains, the Tercero (a rapid stream which runs through certain streets when there is a heavy rain) rose, and it is said that some of the people sick of the fever were drowned in their beds."

Mr. Ash also states that "there was much superstition among the lower classes, who fancied that the priests and Doctors were killing them by throwing powders in the streets every night. They refused the ordinary Medical attendance, and in some cases adopted the most ridiculous remedies, such

as applying the entrails of chickens to the stomach of the sick person. The Lazaretto was now full; but the poorer people had such a horror of it, that its occupants were only those who were removed thither by the police—it was a by-word that no one left the place alive, and even the most wretched denizens preferred dying amid squalor and misery to being sent to what they looked upon as the vestibule to the cemetery. Towards the close of March the deaths reached 350 per day, and swept from among them several representative men. A second panic now ensued, greater than the first—waggons, carts, and every kind of vehicle were seized at any price to convey fugitives and furniture into the country. Some went with canvassed tents, and others in covered bullock carts; others took the railways to the remotest points, and many went away to ranchos on the Indian frontier."

All who have written on this great pestilence have stated that nothing could exceed the gloom and desolation that pervaded the city in April—that the streets were silent and desolate, save where a hearse appeared followed by a solitary coach; pieces of crape were hung from nearly every door; no signs of life were visible from the windows of the opened houses; the stillness of death reigned in every quarter, for there were no persons, no carts, no carriages, no movement of any kind in the streets. The mortality was now returned at 400 daily. The hotels were closed, as well as the chief coffee-houses, and even the clubs; and the city, as Mr. Ash states, "was like a ship abandoned at sea."

A Popular Committee had been formed, for providing accommodation and even comfort for the poorer classes, and were the means of saving many persons from a premature end. They published the following circular on April 20:—"There are barely 30,000 souls left in town, of whom 7000 are sick, and the death-rate is from 400 to 500 daily."

It appears that the pestilence reached its climax on April 10, when there were 503 deaths according to the official mortality-list, and 540 according to Mr. Ash's account, who states that the gravediggers toiled by the light of lanterns, and more than 1000 were interred on that day. Here it is worth relating that of 300 gravediggers employed not one died.

The epidemic had raged for 100 days, calculating from January 1 to April 10, when it commenced rapidly to decline, the mortality decreasing to one-half. It must be taken into consideration that at that period of the decrease the population was reduced to one-third—that is, about 60,000 inhabitants—the rest having taken up their quarters in the villages near the city and at their estates in different parts of the country.

From the commencement of May there was a great decline in the epidemic, and, subsequent to the 10th of that month, there were but from four to six new cases daily. It was at this date I arrived at Buenos Ayres and found that the city was thinly populated, although the inhabitants were returning rapidly to their homes. A new case, however, of the disease showed itself occasionally at the beginning of June, after the Medical Board had declared that it had ceased to exist.

It is estimated by the *Standard* that the yellow fever proved fatal to 26,200 persons in Buenos Ayres, but the official returns of deaths are 13,400: the former statement is considered as exaggerated, and the latter far below the true number. It is probable that we shall never know the accurate number; nor can we reasonably expect to do so, when we consider the misery and confusion which prevailed on the occasion. It is positively known that more than 10,000 Italians fell victims to the epidemic; they were of the lowest class of society, and extremely filthy in their habits. They slept in houses called *conventillos*, like sheep in a penfold (for which they paid two-pence the night), and sixty of them were carried out dead from one of these houses. Thousands of the poor native class fell victims to the disease. Many of them were so suddenly and violently attacked that they had not the means of sending for a Medical man. There was also a great number of this class who had no confidence in Medicine; and then, again, when a Doctor was sent for, he frequently could not be found. We may therefore confidently assert that more than half of this class perished without Medical attendance. I think, perhaps, that I am within bounds when I state that not a thousand of the well-to-do class fell victims to the epidemic.

It appears to me a noteworthy fact that the first outbreak of yellow fever in Buenos Ayres should have been so severe and fatal, as compared with those of Lima and Rio Janeiro, considering the latitudes in which both are respectively placed. We learn from Dr. Ravenna (now of the former city, and formerly of the latter) that the epidemic began in a very mild manner in Rio Janeiro, and went on increasing in strength till the

third year, when it became most fatal. It was known by the name of "the polka," since, like the popular dance of the same title, it appeared to be so much the fashion that almost everyone affected by it took part in it.

Having given a brief account of the yellow fever in Buenos Ayres, and its importation into that city, I shall now endeavour to relate the forms in which that epidemic presented itself, according to the accounts given to me by Dr. Christiani and the Rev. Mr. Lett, who attended upon hundreds of sick on that appalling occasion. On looking over Dr. Daza's treatise "On the Epidemic in the Highlands of Peru," Dr. Archibald Smith's work "On the Rise and Progress of Yellow Fever in Lima," and my own observations during its prevalence in that country, I find that, according to the testimony of these gentlemen, the epidemic took the same forms, and was accompanied in general by the same series of symptoms, as those observed in the persons whom it attacked in Buenos Ayres.

The yellow fever presented itself in Buenos Ayres in three forms—1st, the benignant or simple hæmorrhagic form; 2nd, the bilious or icteric form; 3rd, the nervous or ataxic form.

Signs of the First Stage.—The invasion was sudden, and commenced with fever, lassitude, disinclination for food, headache (which was chiefly confined to the forehead, accompanied with a sense of stricture as from a binding of a cord), slight nausea, or vomiting of a green and yellow hue, pains in the thighs and loins, frequently very acute in the latter. This train of symptoms frequently appeared within the first twenty-four hours.

Symptoms of the Disease in—1. The Benignant or Simple Hæmorrhagic Form.—After the primary symptoms of invasion had passed, the patient presents the following signs of the disease:

—Prostration of vital forces, greater or lesser, according to the intensity of the fever. There is a great change in the countenance—it is more or less flushed; sometimes florid and comparatively bright, sometimes livid and sullen. There is a great variation in the pulse—it is sometimes full and strong, and then, again, hard and small; it is always frequent, varying from 90 to 120 beats per minute. There is great restlessness in some cases; the headache is very violent, and occasionally attended with a sense of heaviness and mental drowsiness; the eyes are more or less disturbed; the lips are often dry, and sometimes parched and pale. The tongue becomes white and foul, but red at the point and borders; it sometimes becomes rough, dry, and parched, and covered with a yellowish tinge. There is considerable thirst, and the bowels are much confined. The heat of the body is dry and ardent; the respiration is frequent, and from time to time the inspirations are deep and prolonged; the urine is usually scanty and high coloured. A deep-seated pain is frequently felt in some part of the body, but more particularly in the loins.

The above symptoms go on increasing until the sixth, seventh, and eighth days. They are occasionally prolonged to the tenth or fifteenth, accompanied almost constantly, from the third to the fourth day, with mulberry-coloured spots, which present themselves on the skin; they are of different sizes, from that of a flea-bite to that of a pea. They first appear on the breast, then on the abdomen, from whence they generally spread all over the body. The patient is very restless during the earlier days of the fever—he is sleepless or slumbers lightly, and has occasionally mild delirium.

The fever generally comes to a crisis between the eighth and fifteenth days, and when favourably it declines by degrees, which is known by the moderate heat of the body, a slight perspiration, less frequency and greater softness in the pulse, a free and easy respiration, restlessness and headache disappearing, more expression in the eyes, the tongue assuming its natural appearance, thirst declining, the appetite returning, and the urine more abundant.

When the fever is to terminate fatally then all the symptoms become gradually worse: the pulse becomes progressively smaller, the breathing hurried, the heat of the skin from being moderate becomes ardent, the head is confused (and deafness often accompanies this symptom), the lips and tongue are dry—there are frequently open chinks on the latter, covered with an exudation of blood, or a dark stain; the voice fails, speech is broken and slow; the eyes are sunk, with a fixed look; the hands and feet are tremulous, and bathed in a cold sweat; the pulse ceases to be felt, and death closes the scene.

2. The Bilious or Icteric Form.—This typical form presents, according to Dr. Daza, two distinct modifications—viz., the hæmorrhagic-icteric, and the non-hæmorrhagic-icteric or congestive. He describes the latter, which he designates the "bilious":—"From the fourth to the sixth day, up to which time the symptoms are just the same as in the preceding (benignant

variety), this bilious form begins to show itself by a greater prostration of strength, so that the patient is unable to move himself; the pulse is small and frequent; the heat of the body is dry and burning; breathing agitated; the voice weak, and the manner of utterance much altered; the skin of the face, neck, and breasts presents a colour which varies from an opaque yellow to the brightest tint of the broom blossoms. This yellow tinge is more conspicuous in the white of the eye, which, as the disease advances, grows more intensely yellow. The headache is ordinarily attended with a troublesome sense of heaviness; the tongue is covered with a white or yellow coat, and in continuation becomes dry, arid, chapped, and covered with a dark or blackish stain, the same as the lips; there is a bitter taste in the mouth, retching and vomiting of a green and yellow colour, and such is the gastric irritability that it is generally necessary to apply a sinapism to the epigastrium in order to prevent what is drank from being rejected by vomiting. This form is one of the most fatal, and has caused the greatest consternation in towns and villages, where it has been confounded with the yellow fever, on account of the rapidity with which it snatches away its victims, and also because in some cases the yellow fever is so strongly pronounced that it stains the clothes and bed-covers even after death."

Vomiting was frequent in those who were attacked with the fever in Buenos Ayres. The matter ejected was frequently of a dark brown or black colour, resembling turbid coffee; it was not accompanied with retching or straining. The urinary secretions were much affected; they were, in some cases, entirely suppressed, and when that took place the case was almost always fatal. There were many who died from hæmorrhage. Mr. Lett assured me that he had seen many cases of this form, and that the greater part of them were females; that the blood spurted out of the mouth with violence, and at times was ejected by mouthfuls; that the blood exuded from many parts of the surface of the body in great abundance, more particularly from below the arm-pits; that some who were apparently dying from hæmorrhage recovered, but of those whose bodies were covered with dark or livid spots, of the size of a sixpence, not one recovered; that in many cases in which the fever came to a favourable crisis the individuals suffered from abscesses in different parts of the body; that petechiæ, as well as suppression of urine, were present in half the cases, and hæmorrhage very frequently from the nose; and that very few recovered who had suppression of urine.

3. Nervous or Ataxic Form.—There were some cases of this variety of the epidemic; it was the most fatal, but, happily, much less frequent than the preceding. Mr. Lett assured me that he had seen several cases of it, but they were of only a few hours' duration. In fatal cases of the disease, according to Dr. Daza, the following symptoms present themselves:—"The eyes are turned or squint, and the patient's whole frame is seized with tremblings. The tongue is sometimes cold and pale; the headache is in most cases intolerable; appetite totally gone; there is a little thirst. The wasting of the body is very observable in this modification of the disease. Should he survive the fourth or fifth day, his convalescence will be extremely protracted."

There were many bodies in the forms we have enumerated that stained the ground with a yellow colour.

It will be seen in this brief account of the different stages and forms of yellow fever, and for which I am indebted to Medical men and other reliable persons, that the general features of the disease in Buenos Ayres were as follows:—

1. In the more severe cases livid or black spots appeared on the tongue; blood very commonly exuded from the gums and spurted out from the mouth, particularly in females.
2. In a great majority the skin took on the yellow colour of the flower of the broom, either during life or after death.
3. The urine was suppressed in many cases, and the bowels were very confined in all.
4. Many affected with petechiæ of a dark colour were carried off on undetermined days; many died from hæmorrhage of the stomach, uterus, intestines, and surface of the body.
5. Mulberry-coloured spots on the skin were observed in most cases.

It would have been of great interest if the Medical men of Buenos Ayres had drawn up pathological tables of post-mortem cases, as was so frequently done during the prevalence of the yellow fever in Lima. Their treatment of the fever was in accordance with that employed by Medical men in those countries where the disease prevails.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

ACUTE DIFFUSE PERIOSTITIS AND OSTEITIS OF HUMERUS, INDUCING DEATH OF A LARGE PART OF THE BONE—RECOVERY, WITH A VERY USEFUL ARM, AND WITH VERY SLIGHT DEFORMITY.

(Under the care of Mr. HULKE.)

A BOY, aged 11, was admitted into Percy Ward January 6, 1871, with a considerable brawny swelling of the arm and redness, great pain and tenderness, most marked towards the shoulder. Pulse 120; temperature 101°. This was attributed to a fall a week before, which, four days later, was followed by rigors, sickness, and loss of appetite, with the local symptoms detailed. He was of a scrofulous family. Acute periostitis being diagnosed, on the next and following days incisions down to the bone were made, with the object of limiting its extension by affording a free exit for the products. No pus escaped, but the general swelling and the fever diminished.

On January 19 deep fluctuation was thought to be felt over the neck of the humerus, and an incision was made there; it led to rough bone, but gave vent to no pus.

At the end of the month he was able to get up. The inner and upper part of the arm remained swollen and thickened.

On February 5 an abscess pointed, and was opened, over the bicipital groove. This was followed by increased swelling and redness of the front and outer side of the upper arm and shoulder. A probe passed into the abscess ran towards the head of the bone. He could lift the arm from his side with the other hand without pain; but owing to the great swelling it was uncertain whether this was not a movement of the scapula with the humerus. When the scapula was fixed, which could only be imperfectly accomplished, owing to the great tenderness, on rotating the arm a distinct crepitus was perceptible; but it could not be certainly established whether this was in the shoulder-joint, or whether it proceeded from separation of the diaphysis and epiphysis. Mr. Hulke took the latter view, and, being anxious to prevent an extension of the inflammation from the shaft to the head of the humerus and shoulder-joint, which the prolonged presence of the dead end of the shaft might occasion, on February 15 laid open the abscess, found the shaft separated (as he had suspected) from the head of the bone, and cut off about two inches of the upper end, which were dead, bathed in pus, and enveloped in a tube of thickened periosteum, the inner surface of which was already lined with new bony tissue. The joint was left intact. The posterior surface of the shaft nearly to the elbow was dead, but the necrosis evidently did not comprise the whole cylinder, and as it was perfectly tight, it was left to be exfoliated. Some time later an abscess pointed through the triceps a little above the olecranon. After this the swelling greatly lessened, and the abscess closed, the incision through which the necrosed end of the shaft had been removed remaining open.

In April this was enlarged, and a sequestrum about four inches long pulled out. The wound now closed, and in the following July he left the Hospital with a perfectly movable shoulder-joint, very slight deformity, and a strong useful arm.

TWO CASES OF AMPUTATION.

(Under the care of Mr. HULKE.)

Case 1.—A mechanic's wife, aged 27, was admitted into Bird Ward, November 18, 1870, with great swelling, tenderness, and severe pain in the right knee, aggravated by the slightest movement. The tibia was displaced backwards and rotated outwards, as is usual in old-standing disease of this joint. During the preceding ten years the knee had been repeatedly inflamed, though never so severely as now. The present acute symptoms had lasted eight weeks. Her father, mother, a brother, and a sister had died of phthisis. The joint was fixed in a McIntyre's splint, and the limb swung; the knee painted with iodine, and the pain relieved with anodyne. This treatment was followed by improvement, but towards the end of December the condition of the joint grew worse, her rest was much broken, she lost flesh, and her strength declined. Mr. Hulke, therefore, amputated the limb above the femoral condyles on January 4, by Teale's method. The raw surfaces were washed

with a watery solution of chloride of zinc, the flaps joined with silk sutures soaked in carbolised oil, and the stump covered with a square of lint dipped in the same. Her temperature rose on the fourth day to 101.2° in the armpit, and then fell. On the tenth day her appetite failed, she had retention of urine, she felt depressed, and manifestly flagged. On the sixteenth and following day she vomited several times, and now the urine was observed to be of a dark smoky colour. No blood-discs could be detected in it, and by boiling with nitric acid no albuminous precipitate was obtained. Its specific gravity was 1034. These symptoms were unaccompanied by any rise of temperature or acceleration of pulse. Suspecting them to be due to the absorption of a poisonous quantity of carbolic acid from the oiled lint with which the stump was covered, this was discontinued, and they immediately ceased. After this she made steady progress, and left the Hospital towards the end of February. When last seen, a short time ago, she had an excellent stump, and had grown stout.

Case 2.—An emaciated, goitrous woman, aged 21, of a scrofulous family, was admitted into Regent Ward, February 14, 1870, with enlargement and contraction of the left knee, backward displacement and outward rotation of tibia, and great pain, increased by the slightest movement. She said that five years ago, after a fall, the knee became swollen and painful, and it had ever since continued more or less so, obliging her lately to use crutches. Six days after her admission an abscess was found in the ham and calf. This was opened with antiseptic precautions, and dressed in the same manner; but it extended, and required fresh incisions to drain it thoroughly. The discharge became very offensive and more abundant. The pain and other inflammatory signs in the joint increased. Her sleep was much broken by starting of the limb; her appetite, never good, failed; her temperature rose, and her pulse became quicker. Under these circumstances Mr. Hulke removed the leg by Teale's method, sawing through the femur just above the condyles. The flaps and the stump were treated in the same way as in the last case. Recovery was retarded by repeated diarrhoea, and at the end of March the femur, over which the large square anterior flap had at first hung very loosely, protruded through its centre by inducing ulceration. No part of the edges of the flap had been lost by sloughing, but, owing to the very feeble state of the girl, their union was very slow. A few days later the soft tissues were pushed back a couple of inches, and the projecting bone was sawn off. The cancellous tissue of the piece cut off was inflamed, soft, and full of pus; the exterior of the cortex was overlaid by porous masses of new bone. After this the condition of the stump and her general state improved; but at the end of April an abscess formed in the outer side of the thigh, which remained long open, and threw her back again. It finally closed in June, on the 15th of which month she went home convalescent, with a soundly healed stump on which she could already bear some pressure.

WESTMINSTER GENERAL DISPENSARY.

TREATMENT OF SYPHILIS BY MERCURIAL FUMIGATION, WITH A DESCRIPTION OF A NEW AND CHEAP VAPORISER.

(Under the care of Mr. CHURCHILL.)

CASES of accidental inoculation of syphilis upon the hand of the Medical attendant, though fortunately rare, deserve to be recorded as beacons to warn the unsuspecting of the danger they incur by neglecting to use proper precautions to protect themselves from the possible absorption of syphilitic material through a crack or wound of the hand.

T. L., a Medical student, was attending occasionally at the Westminster General Dispensary for the purpose of receiving instruction in the dispensing of medicines and the treatment of disease. He was particularly anxious to obtain some information with regard to the pathology and treatment of syphilitic disease, and with this view he had been allowed to watch the progress of treatment in selected cases, with the endeavour, if possible, to discover the changes in character of the primary sore. He had been in the habit of manipulating the sores, hoping to satisfy himself as to the distinctive differences between the Hunterian and the soft or non-infecting chancre, and to ascertain how far it was possible for a soft chancre to become indurated, so as to resemble, if not to constitute, a true infecting chancre. It has been asserted by some authorities that a soft sore under irritation may become indurated, and, as such, a focus of constitutional infection. Those who discredit the dual character of the syphilitic poison also assert that a hard

sore may produce a soft chancre on an uncontaminated subject, depending to a great extent upon the temperament or constitution of the individual infected. The assertion that hard sores are much rarer in females than males would seem, if true, to justify to some extent the doctrine of the unity of the syphilitic virus. All observers admit that sores which are to all appearance soft are occasionally followed by constitutional symptoms, and that sores of the true Hunterian type are not always followed by secondaries. Also, in syphilitised subjects, inoculations with matter taken from a hard sore will occasionally produce a sore resembling a soft chancre, but this the dualists affirm is not identical with the soft chancre. Supporters of the other doctrine admit that the poison of syphilis has developed into two well-marked varieties, which, as a rule, "breed true." "The two diseases are, for all practical purposes, entirely dissimilar, differing in symptoms, in prognosis, and treatment" (*Vide* Mr. Bradley's "Notes on Syphilis and on the Unity of the Syphilitic Virus," p. 38.) The only point that remains to be determined is, how far these two diseases, "entirely dissimilar," have divaricated, according to the evolutionary hypothesis, from a single original stock. That gonorrhœal urethritis is, and always has been, a distinct disease, seems to me as certain as the admitted distinctions between acute and croupous laryngitis, although, according to some evolutionists, a "traumatic urethritis" was the parent of all forms of venereal disease.

The account T. L. gave of himself, referred to in the last issue of the *Medical Times and Gazette*, was as follows:—In addition to the ordinary routine work of a Medical student in the dissecting-room, he had undertaken to assist the pathologist in post-mortem examinations; and while others carefully sucked or cauterised wounds inflicted during dissection, it was his boast that no harm had ever come from previous wounds. He supposed that his system was innocuous to the intrusion of septic particles or other products of decomposition. He had witnessed in others the poisonous effects of the absorption of deleterious matter; and though aware of the risk he incurred by dissecting with open wounds, he was, like many others, indifferent, because fortifying himself by a false hope. Surgeons of far greater experience, and maturer years, in their zeal to instruct, are perhaps unmindful of the potency of the syphilitic poison. Too great care cannot be taken to guard against the possible entrance of syphilitic matter by such unexpected channels. That the disease was not contracted by venereal indulgence was evident by the appearance of the primary sore on the palmar surface of the thumb, and the implication of the axillary glands on the left side, as also by the absence of any scar or mark on the penis and of inguinal glandular swelling; last, but perhaps not least, was the evidence of the patient himself, who most positively denied that he had exposed himself in any way to the possibility of infection by impure or muliebral contact.

Unaware of the cause of the small blister on the palmar surface of the thumb, T. L., in his attempt to heal the sore beneath by bland ointments and lotions, was really fostering the development of constitutional symptoms, little suspecting that he would have the opportunity of studying (!) in his own person a disease the cause of which he was hoping to investigate more fully in others. He went to the sea-side for change of air, hoping that the follicular ulceration of tonsils and palate and the sore on thumb would heal as his health improved. It was not until his return to town that his suspicion was aroused as to the specific nature of the disease. It should be mentioned that he consulted about this time some Surgeons of eminence; but whatever their suspicions may have been, no specific treatment was adopted. He was afterwards advised to take fifteen grains of iodide of potassium and four grains of Plummer's pill daily, and to dress the sore with black wash. About this time ulcerating tubercles appeared on the legs and back; an eruption also appeared on the scalp, and he lost a good deal of hair. The sloughs on the tonsils and palate were some time separating, and he suffered for about twelve months from sorethroat. T. L. consulted Mr. Henry Lee, who advised the mercurial fumigation treatment, which was commenced at once—*i.e.*, as soon as the eruption became fully developed. He continued this treatment every night for three months, when it was omitted in consequence of all sores having healed, as also the sorethroat. It was now the middle of winter, and he was unable to carry out effectively the mercurial treatment, on account of early lectures at the Hospital requiring him to expose himself to the cold morning air. The sorethroat returned, and he resumed the fumigation for another two months, when he was pronounced to be cured of the disease.

For the successful administration of mercurial fumigation so much self-denial on the part of the patient is required, that he too frequently stops the use of the bath before the disease has been entirely eliminated from the system. Such a partial employment of the mercurial bath has given rise to a scepticism with reference to its efficacy as a powerful anti-syphilitic remedy. T. L., fully aware of the danger of partially curing his disease, carried out the treatment most systematically, and is now rewarded by the comforting assurance of a renovated constitution.

The plan adopted of administering the baths under the bed-clothes has two important advantages not possessed by the ordinary method of administration under a cane chair—*viz.*, 1st, that the patient's body is placed in a mercurial atmosphere so long as he remains in bed; 2nd, that he is enabled to apply the fumigating process to the throat, larynx, nasal passages, and bronchial mucous membrane, by respiring the vaporised air for a limited time under the bed-clothes; 3rd, that the luxury combined with the greatly increased warmth obtained by this method of administration commends itself to the approval and satisfaction of the patient, not enjoyed by other methods. As a corollary, patients have been more ready to carry out to successful termination this method of treatment by mercurial fumigation. A cradle is necessary to support the bed-clothes, and raise them from the bath. For poor patients, unable to purchase a vapour bath, I have had constructed a metal tray for holding the water, with a raised portion in the centre, surrounded by water, on which the calomel is deposited. The tray fits into a watchman's "candle-lamp." A spirit-lamp may be fitted into the socket made for the candle; and the

apparatus is complete. Hitherto, the expense of the apparatus has seriously interfered with the introduction of this powerful anti-syphilitic remedy among the poorer classes of society, who are, perhaps, more subject to the ravages of this destructive disease. The difficulty having been overcome, it is to be hoped that the method of treatment will be more universally known and adopted. I have used this method of fumigation, and found it most successful in cases where the wife has contracted syphilis from her husband, and *vice versa*. The process of cure may with advantage be carried out simultaneously. This vaporiser will no doubt prove of great service in the sick-room, and in pulmonary complaints, for fumigating purposes, and for volatilising drugs previous to inhalation. The apparatus complete, as shown in the figure, may be obtained from Messrs. Baker, surgical instrument makers, High Holborn.

ROYAL INFIRMARY, EDINBURGH.

ASCITES COMPLICATING OVARIAN DISEASE.

(Under the care of Dr. MATTHEWS DUNCAN.)

M. R., AGED 51, a widow, who has had seven children, was admitted to Ward XVI., on November 13, complaining of pain and swelling in the belly, and indigestion. She first remarked the swelling of her belly eight or nine weeks ago;

it has increased rapidly since then, and gives rise to pain and inconvenience. Her monthly periods were regular up to the time of the commencement of her present illness, but they have been absent since then.

Present Condition.—The belly measures forty-five inches, the tape being passed round it over the most prominent part, which is the umbilicus. On palpation and percussion in the usual manner the swelling is found to be caused by fluid, free in the peritoneal sac. No cardiac or other local disease could be discovered to account for the presence of the ascitic fluid.

November 17.—Patient was tapped to-day. Twenty-two pints of fluid of a greenish colour were drawn off. It is found to have a specific gravity of 1020; reaction alkaline; when heated, or on adding nitric acid, it almost entirely coagulates. On keeping this fluid, no coagulum is formed, but a deposit is observed, which on microscopic examination is seen to contain round granular cells, varying in size, and generally possessing a nucleus and granular contents. Some of these cells are four times as large as an ordinary red blood-corpuscle. After the tapping, a hard, irregular, nodulated mass is felt, occupying the right iliac fossa, near the site of the right ovary; it is freely movable.

Remarks.—This patient was sent into the Hospital, said to be suffering from ovarian dropsy. The great bulk of the fluid, however, was at once made out to lie free in the abdominal cavity, to be what is ordinarily called ascitic. Cases of ovarian dropsy are generally accompanied by some amount of ascites, but in the great majority of them it is trifling, in small quantity. On manipulating over an ovarian cyst, the woman lying on her back, you can generally make out the rounded margin of the cyst-wall, where the dulness of it should end; but the dulness of the free fluid in the abdominal cavity may run into it, and you may thus be unable to distinguish between the two. Place the woman on her side, however, and then the dulness is observed to end at the rounded margin of the tumour, the ascitic fluid having gravitated towards the other side, and what was before dull on percussion is now found to be resonant. Instead of the ovarian dropsy, it was the ascites which predominated in this case. On tapping, it was found to measure twenty-two pints and a half. After tapping was performed, an ovarian tumour was detected, which before was not to be recognised. The large amount of ascites was probably owing to the disease being, in all likelihood, malignant. Malignant disease seems to cause a great deal more irritation of the peritoneum than simple ovarian tumour. In ordinary cystic disease of the ovary we occasionally observe tubercular peritonitis to be present along with it more frequently than would happen should there be no irritation of the peritoneum, such as is caused by an ovarian tumour. The opinion that the case before us is probably malignant in its character, is founded on the following considerations:—1st. The cachectic condition of the patient—the sallow, anæmic appearance of her face. In advanced ovarian dropsy which is not malignant you have considerable emaciation present, especially about the face, neck, and breasts; but otherwise the general appearance may be healthy. 2nd. The feeling and history of the tumour itself. It has a very irregular, hard, nodulated feeling; no big cyst present. There is no definite shape, but merely a series of irregular lumps. It is growing slowly. The age of the patient (51) gives some countenance to the diagnosis.

ELECTION OF M. MAREY.—This distinguished physiologist, whose sphygmograph has imparted such an impulse to physiological research and practical Medicine, has just been elected, by a large majority, into the Section for Anatomy and Physiology of the Académie de Médecine.

THE FRENCH LIBERATION OF TERRITORY SUBSCRIPTION.—This patriotic subscription, which must excite sympathy in the breast of every one capable of love for his country, is being pursued with great energy, and must, at all events, realise a considerable sum of money. The Medical journals had first thought of opening their columns to receive the names of those *confrères* who might feel disposed to contribute to a separate subscription. At a meeting of Medical editors, however, it was thought better to abandon the projected Medical Press Committee, in order not to multiply too much the centres of reception. All *confrères* are urged to use the great influence they possess in increasing the lists to be opened at the different municipalities. The ladies, however, with whom the idea of voluntary subscriptions originated, do not feel disposed to give up their separate action; and a committee is being formed at Paris, having Madame Wurtz as president, and Mesdames Nélaton and Barth as vice-presidents.

SATURDAY, FEBRUARY 17, 1872.

THE CONTAGIOUS DISEASES ACTS.

It was shown in an article in our last number that opinions as to the Contagious Diseases Acts may be ranged under three heads. First of all there are the *implacables*, represented by Mr. Jacob Bright, whose doctrine is that the repression of prostitution is a restraint of civil liberty, and that the fear of syphilis is so potent an aid to continence that we cannot afford to stamp out a disease which has such happy moral results. We will not waste our readers' time by undertaking the superfluous task of arguing against these propositions.

The second class are those whose prime idea is the stamping out of disease *simpliciter*; and the third consists of those who wish to repress prostitution, and who objected to the Acts at first in fear lest the machinery for eradicating physical disease might be so worked as to be converted into a protection and public patronage of vice.

Now, we think we shall receive the assent of every sane and respectable householder and ratepayer in the United Kingdom when we say that it is high time that controversy should cease. No case has been fairly made out of oppression, or false accusation of respectable women, since the Acts have been put into partial operation. They who began by advocating the removal of physical evils, now point triumphantly to the good moral results of the Acts; and they who are eager for the repression of prostitution because of its immorality cannot (if they are of sound mind) object to measures for curing disease as well. There is, therefore, the happiest occasion for a compromise; both parties may unite in strengthening the hands of the Home Secretary, and in obtaining the sanction of the Legislature to an Act in which the maximum of moral and of physical repression shall be combined.

Before specifying the general nature of the Bill which Mr. Bruce on the evening of the 13th obtained leave to bring into the House of Commons, we cannot help reinforcing our argument for a compromise—for the union of all rational men in getting the best Bill which public opinion and the Houses of Parliament can be got to sanction—by a very short statement of the manner in which things got into their present mess.

We lay the chief blame of the *imbroglio* on those members of our own Profession who, in their laudable zeal for wiping out syphilis, began by introducing the thick end of the wedge first, and shaped their measures in such a way as to awaken the prejudices and alarm the moral sense of the community. It is not too much to say that a large part of the middle classes

have a vague, but overwhelming notion, that a frightful state of immorality prevails in Paris. They have heard of prostitutes furnished with certificates of health after examination; thus they have conceived an idea of a "French system" of open immorality, and their bristles erect themselves of their own accord at the very notion of such a French system, or any part of it, being introduced into "moral" England—that "happy" land which, as they suppose, a "silver streak" divides from the abominations of French sensuality, just as our forefathers used to boast of it as a barrier against wooden shoes, slavery, and a diet of frogs.

We lay the blame, then, of the present inveterate opposition to the Acts on the way in which the matter was first handled; on the well-meaning attempt to make it an isolated question of disease—a mere Medical question. The results would have been far different if the moral side, which the advocates of the Acts are now fain to put forward, had been acted upon from the first. If the ancient common laws of the land had been put in force for the regulation of prostitutes as such, the physical treatment might have been added with very little trouble.

Let us call attention to a few facts gathered from recent returns and from Mr. Bruce's speech, which will illustrate our meaning.

We are told that in the year 1865 there were 1770 prostitutes in Plymouth, of whom 1249 were under 21 years of age—under the age at which the English law allows men to dispose of their persons and property as they choose. Now, pray, mark what follows! Of these 1249 wretched children, *two* were under 13 years of age, *twelve* under 14, 109 under 15, 89 under 16, 207 under 17, 227 under 18, and so forth—altogether 1249 under 21, and out of these 419 children under 17 years of age.

The advocates of the Contagious Diseases Acts point to these figures with justifiable pride, and assure us that the operation of these Acts had in six years (1871) reduced the total number of prostitutes in Plymouth from 1770 to 503, and that of these only one was under 17 years of age. We are thankful for the result, come by how it may be.

But what a sarcasm! Here, in "moral" England, with its "streak of silver sea" fencing it off from French abominations—with bishops, parsons, Dissenting ministers, magistrates, sanitarians, philanthropists, grievance-mongers, reformers, missionaries, district visitors, and every kind of functionary, official and voluntary, to look after the morals of the people—here, in Plymouth, one of the largest towns in England, 419 children are allowed to prostitute themselves. And this hideous blot is at last wiped out. How? By love of God? No. By love of your neighbour? No. By preachers and the fear of hell? No. But by a committee of Surgeons, who preach fear of the pox!

We say now, what the *Medical Times and Gazette* has said before over and over again, that nine-tenths of the good achieved might have been gained and *kept* if the moral instincts of the community had been tenderly handled; if there had been no ground for talking of the introduction of a "French" system; and if the ancient existing laws against vagrants (of which a summary, prepared *ad hanc rem*, appeared in our columns three years ago) had been put in force. This is now admitted; and here we may call attention to one grotesque feature in the administration of law in England.

Anyone who has undertaken the task of endeavouring to enforce sanitary law must be aware of the invincible obstacles interposed by some magistrates; and how, if the Act appealed to is susceptible of an interpretation which shall render it nugatory, this interpretation is stolidly brought forward as a bar to the efficient working of the law. This has been the case with the Vagrant Acts. These were quite sufficient, as we have said, to inflict "heavy blows and great discouragement" on prostitution and syphilis, had the police acted upon them and the magistrates interpreted them in their proper

spirit, and had the Home Secretary or Lord Chancellor (or other personage on whom the responsibility rests) taken care to keep police and magistrates to their duty. But no!—this Act was "interpreted" in such a way as to be useless, till a change came over the spirits of the Liverpool magistrates.

"The Vagrant Act," says Mr. Bruce, in his speech on Tuesday evening, "*had been interpreted in different ways.* In Liverpool *lately* it had been applied with great vigour for the first time, and with results of a very striking kind. In a report recently issued by a committee of magistrates in Liverpool it was stated that the number of women convicted under the Vagrant Act previous to 1870 varied from sixty-five to 500 annually. In 1871, however, the magistrates, acting under the direction of the stipendiary magistrate, Mr. Raffles, determined that the act of importuning in itself justified the apprehension and punishment of the offender. The result had been that in 1871 the number of women so charged under the Vagrant Act was 3388, and the change in the appearance of the streets of Liverpool had been very remarkable. The present Bill proposed to enact that every common woman who in any public street importuned persons should be liable to be dealt with under the Vagrant Act, and that for this purpose the Vagrant Act should extend to Scotland and Ireland. For the first offence under that Act, the offender, as a disorderly person, was liable to three months' imprisonment; for the second offence, as a rogue and a vagabond, to six months' imprisonment; and for the third, as an incorrigible rogue, was liable to be tried at Quarter-Sessions and sentenced to twelve months' imprisonment. In the opinion of the Liverpool magistrates, the power of committal for still longer periods would be useful."

Of course it would. But what is the use of Acts if magistrates exert their perverse ingenuity in giving them a colourless interpretation?

We must now condense into few words the gist of Mr. Bruce's Bill. He said that the Government had reluctantly come to the conclusion that it was impossible to maintain in a limited district the main principle of the Act—viz., compulsory periodical examination—while it could not be extended to the whole country. And this he held to be impossible in the present state of public opinion, of which the Acts went far in advance. Under these circumstances the Bill proposed to substitute for the present Acts certain general stringent provisions, which he explained, for clearing the streets and preserving decency, for detaining diseased persons in custody for other offences, for the more effectual protection of young girls and women, and for repressing disorderly houses and the harbouring of diseased women.

We are exceedingly sorry at the sacrifice of the periodical examination. This examination is attacking prostitutes from the physical side, and is quite justifiable, if made, as it should be an appendix to moral repression. Women who publicly offend against order and morality cannot claim "civil rights."

In conclusion, we must express our hope that the question will be settled for the present; that all parties will agree in accepting the best Bill which can practicably be had; and we believe, for our own part, that if Mr. Bruce's Bill be carried in its present shape, public opinion will demand the addition of the compulsory examination clauses before two years are past.

ELECTION OF EXAMINER AT THE COLLEGE OF SURGEONS.

ON the last day of this month the Council of the College of Surgeons will elect an examiner in the room of Mr. Cock, retired. Two members of the Council and two Fellows not on the Council have been nominated. For a long time it was the custom to elect the senior member of the Council who was willing to serve as an examiner. Then it was felt that there might be Fellows, not members of the Council, who would make better examiners than anyone on the Council. At any rate, it seemed desirable to increase the number of Fellows from whom the candidates could be selected; and a sort of understanding has latterly been arrived at that half the members of the Court of Examiners should be members of Council, and

half not so. It remains to be seen whether this rule will work well. There are evident disadvantages in excluding from the Court of Examiners senior members of Council who have attained a position in the Profession which would make their names an additional value to the diploma, and who may have better qualifications for the office of an examiner than anyone not on the Council. And it seems absurd that the fact of being elected to the Council by the suffrages of the Fellows should be a disqualification for the 'examinership. It would seem to be far better if the simple endeavour were made to select the best available man for the office without the least reference to his being a member of Council or not.

In the present election, if the rule of having half the members of the Court of Examiners elected from Fellows who are not on the Council be adhered to, one such Fellow must be elected; and two have been nominated—Mr. Campbell De Morgan and Mr. Callender. Two members of Council have also been nominated—Mr. Spencer Smith and Mr. Birkett. There are three senior members of Council to these gentlemen—namely, Sir James Paget, Mr. Prescott Hewett, and Mr. Charles Hawkins;—but these three gentlemen have expressed their inability or unwillingness to act as examiners. Accordingly, the two members next in order of seniority who are willing to serve have been nominated.

There can be no doubt that all the four gentlemen we have named would make good examiners. But the Council have to consider some delicate questions in making a choice of one from among four good men. It is not desirable that teachers should examine their own pupils; therefore, for this and other evident reasons, it is not desirable to have more than one examiner from one school. As Mr. Lane, of St. Mary's, is already an examiner, this may be some objection to the election of Mr. Spencer Smith; but as Mr. Hilton, of Guy's, is also one of the Court, the same objection holds against Mr. Birkett; and as Mr. Savory is also an examiner, Mr. Callender is in the same position as Messrs. Smith and Birkett. Mr. De Morgan is free from any objection on this score, and his position as a teacher and a Surgeon to the Middlesex Hospital will give great weight to his candidature. Nor is he a member of Council; so that his election would maintain the principle of the equal division of examiners between members of Council and other Fellows. On the other hand, the fact that a man passes successfully through the ordeal of an election is in general a proof of competency and knowledge of business.

Whatever the choice may be, we have no doubt it will be a good one—indeed, it must be so if any one of the four gentlemen nominated be elected. And the task of selecting the best of four good men must be a difficult task; for, supposing the Professional qualifications to be equal, questions of tact, and temper, and knowledge of the world, and knowledge of students, and common sense, will all arise, and ought to have their due weight with the electors. These things the Council will necessarily consider, and we may safely leave them to arrive at a just decision.

VISUAL QUALIFICATIONS OF CANDIDATES FOR THE PUBLIC SERVICES.

It is very desirable that some fixed rule should be laid down as to the degree of short sight which disqualifies a Medical man for admission to any of the public services. It is no doubt essential that care should be taken not to admit as a recruit for the ranks any man who cannot see the bull's-eye on a target up to 500 or even 1000 yards; it is also well that combatant officers should possess vision sufficiently acute to enable them, with the naked eye, to distinguish objects such as cavalry from artillery, at moderate fixed distances; and we believe it to be laid down that officers are not to be admitted as students in the Staff College who do not possess good

sight; but as an ordinarily near-sighted man can, with properly adjusted field-glasses, see just as well as a man who enjoys long sight, and as field-glasses are part of the regular equipment of every staff officer, we hardly think that short-sightedness *per se* should be held to be an absolute disqualification for even that branch of military service.

We consider it still less essential that a Medical officer should possess a range of vision such as to enable him to count Snellen's test-dots at a distance reducing them to the size of the bull's-eye on a rifle target at 500 yards. In the schedule sent from the Army and Indian Medical Departments to candidates for those Services, this principle is recognised, and a moderate degree of myopia is not objected to; but the candidate must be able to dissect or perform a Surgical operation without glasses. This is reasonable enough; but a recent instance has been communicated to us in which several candidates for the Indian Medical Service were rejected because their vision was below the standard laid down as essential for recruits for the ranks. One of the gentlemen so rejected, we are informed, was afterwards accepted for the Army Medical Service on appearing before a special Board at Whitehall-yard, where the requirements as to sight appear to be more moderate than at the India Office; and subsequently, to make the matter still more surprising, on the application of a little force *ab externo*—at the instance, we believe, of a gentleman of Indian descent, of very high Professional attainments—all the candidates previously rejected on account of defective vision were, by the self-same Board, on being reassembled at the India Office, admitted as fit!

This very obvious self-contradiction might, of course, have been avoided by a more liberal construction of existing rules; and we hope that, a precedent having now been authoritatively established at the India Board, there may be no more rejections of ordinarily myopic candidates for admission to the Indian Medical Service.

THE WEEK.

TOPICS OF THE DAY.

THE meeting of the General Medical Council is, we believe, definitely fixed for the 29th of the present month. We hear that there is very little chance of any scheme for a Conjoint Examining Board for Ireland being submitted to the Council with the unanimous consent of the Irish Examining Bodies. In Scotland, the scheme approved by the Edinburgh Royal College of Surgeons and the Scottish Corporations generally differs entirely from that offered by the University of Aberdeen. In England, the scheme which has been agreed to by the two Royal Colleges and by the Universities is essentially imperfect, inasmuch as it has been framed in such a manner that the Corporation, which under Act of Parliament grants by far the largest number of Medical licences of any "Medical authority" in the kingdom, is unable to take part in it. Out of these apparently irreconcilable elements, if the General Medical Council can construct the lasting fabric of a uniform test and admission to the Medical Profession, it will truly deserve a meed of praise such as it has not been its lot hitherto to receive. For ourselves we are not sanguine. We are fully convinced that it would be better to go on with our present somewhat time-worn, but tolerably effective machinery, than to erect a different standard of examination in each of the three kingdoms, and favour the introduction to the Medical Register of a number of Medical men practising with one qualification, which will be the undoubted effect of the sanction of the General Medical Council being obtained for the imperfect scheme of the two Royal Colleges.

The Report of the Syndicate of the University of Cambridge, which, it will be recollected, was in favour of the scheme of the Royal Colleges of Physicians and Surgeons for a Conjoint Examining Board, has been received favourably at a meeting of

the Senate of the University; but at the time of our writing it had not been finally adopted.

The disturbances which took place at the installation of Sir William Stirling Maxwell as Rector of the University of Edinburgh have led to the rustication of one student and the admonition and continuance in the University on probation of several others. We hope that the University authorities are satisfied with the constant hot water in which they are kept by their infringement of the laws of decency by the admission of women to the Medical school of their University.

The Solicitor-General for Scotland has pronounced against the legality of the election of Mr. Ruskin as Rector of the University of St. Andrews, on the ground that it contravenes a clause in the Scottish University Act, which prevents any Principal or Professor of a University being eligible for the office of Rector. Mr. Ruskin is Professor of Fine Art at Oxford. The office, therefore, falls to Lord Lytton, Mr. Ruskin's Conservative opponent, if he be inclined to accept it.

Professor Huxley has resigned his seat on the School Board. We are glad to announce that Professor Huxley's health has greatly improved since he left England, and that his friends fully expect that his illness, which was the result of overwork, will have been fully recovered from before his return from the East.

A deputation from the Poor-law Medical Officers' Association, and from the British Medical Association had an interview with Mr. Stansfeld on Tuesday. The deputation was introduced by Mr. Corranec. The object of the deputation was to obtain the insertion of clauses in the forthcoming Sanitary Bill, which would place the Medical relief of the poor on a more satisfactory footing, reorganise the Poor-law Medical Service, extend the Dispensary system, and provide for the payment of drugs out of the public money. Mr. Stansfeld's reply was deemed satisfactory by the deputation.

The disappearance of the Russian agent of the Messrs. Blews, and the statement that the mystery is explicable by supposing that the unfortunate man is suffering from a second attack of a form of insanity which compels people to get away on some pretext from their connexions and friends, and to wander about without any ostensible purpose, are of some Medical interest. Wander-madness, like lycanthropia, has no place in modern mental pathology as a separate diseased state, but the impulse to get away from the restraints of society, and from their ordinary surroundings, is a common one to mad people. There are two classes of cases of this kind—one of persons of unsound mind, who lose themselves, or do not recollect or realise their connexion with familiar places, like the solicitor who passed his own house twice when wandering about in the night, and knew it, but to whom it never occurred that he should go in. Others leave their homes intentionally, and even use stratagem to throw their friends off the scent. To this class, no doubt, the case of Mr. Blews' agent belongs.

Professor Rolleston, of Oxford, has been elected a Fellow of Merton College. The Linacre Professorship of Physiology, held by Professor Rolleston, was endowed out of the revenues of Merton in 1854.

Mr. Bazalgette, the engineer to the Metropolitan Board, has replied to the charge brought by the City Commissioners of Sewers, that the main drainage scheme in the City, at least, is grievously incomplete, and that in all 562 sewers in the City have direct or indirect outlets into the Thames. The substance of Mr. Bazalgette's reply is, that when the works are completed all cause of complaint will be removed, and that many of the sewers that now remain are small and insignificant.

UNIVERSITY OF LONDON.

The Senate of the University has resolved to take the opinion of Sir Roundell Palmer and Mr. Cozens Hardy upon the claim

made by the Treasury, that the receipts and payments on account of the Brown Trust Fund be included in the accounts rendered to the Audit Department. The Senate has also declined the offer made by Dr. Crisp of his Museum of Comparative Pathology for purchase on behalf of the University.

ROYAL COLLEGE OF SURGEONS.

The following is an abstract of the unconfirmed minutes of the meeting of the Council on the 8th inst.:—It was resolved to present addresses of congratulation to her Majesty and to H.R.H. the Princess of Wales on the recovery to health of H.R.H. the Prince of Wales. The report of the Court of Examiners since November 17 was read, and the Council adopted the recommendations of the Court, that lectures on anatomy in the University of Cambridge be in future recognised to the same extent as in other Medical schools; and that two courses of lectures on general anatomy and physiology, each of four months' duration, be recognised as equivalent to one course of the required attendance on such lectures, on the understanding that the second course will be an extension, and not a repetition of the first. Mr. Clark was elected an Examiner in Dental Surgery; and Messrs. H. Spencer Smith, J. Birkett, G. C. De Morgan, and G. W. Callender were nominated for election to the Court of Examiners, and Thursday, the 29th inst., was fixed for the election. The Council determined to appoint at their next ordinary meeting a committee of five members, in addition to the President and Vice-Presidents, to consider and report on the conditions upon which members of twenty years' standing should be elected to the Fellowship under Section 5 of the Charter of 1852. Mr. Simon, in pursuance of his notice of the 11th ult., moved—"That, on the occurrence of a vacancy in the Court of Examiners of this College, due notice be given of such vacancy by advertisement in such journals and at such times as the President shall decide, and that Fellows desirous of being considered candidates be invited to send in their names to the President"; and the motion having been seconded by Mr. Erichsen, Messrs. Simon and Hawkins demanded that the names of those voting for and against the motion be entered on the minutes—viz., majority for the motion, twelve: Sir William Fergusson, and Messrs. Hilton, Clarke, Hawkins, Smith, Simon, Holden, Erichsen, Wilson, Lee, Wells, and Critchett; minority against the motion, three: Messrs. South Curling, and Birkett. Mr. Erichsen gave notice of the following motion at the next ordinary meeting of the Council—viz., "That a return be prepared by the Court of Examiners, and presented to the Council at its ordinary meeting in May next, of the number of candidates who have been rejected at the Primary and Pass Examinations for the Membership during the three Collegiate years from July, 1868, to July, 1871, stating the numbers who have been rejected and who have passed from each School, and that a similar return be presented to the Council each year at its quarterly meeting in July."

At a meeting of the Board of Trustees of the Hunterian Collection of the College, on Saturday last, the 10th inst., Mr. Cæsar H. Hawkins, F.R.S., Serjeant-Surgeon to her Majesty, and late President of the College, and Sir John Lubbock, Bart., F.R.S., M.P., were unanimously elected trustees of the Collection confided to the care of the College by Government, in the vacancies occasioned by the decease respectively of Mr. George Grote, F.R.S., and Sir Roderick Impey Murchison, Bart., F.R.S.

The skeleton of the Porbeagle shark taken on the coast of Sussex in November last is now completed, and the specimen exhibited in the Hunterian Museum. The great skill and practice of the articulator, Mr. James Flower, have succeeded in overcoming most of the difficulties usually found to attend the preparation of the skeletons of cartilaginous fish; and careful measurements and drawings of the animal having been taken before it was dissected, every part is now preserved in its natural position. "Of course," says Professor Flower, the dis-

tinguished Conservator, "it has been impossible to prevent a certain amount of shrinking of the cartilages;" but this has been guarded against as much as possible by various ingenious expedients adapted to the different construction of the parts that had to be dealt with. The soft cartilaginous skull, where most difficulty was expected, has been preserved in its natural form by drying in a matrix of plaster of Paris made exactly to fit all its cavities and depressions, and the spinal column has been kept very nearly of its normal length by inserting thin slips of wood between each of the bodies of the vertebræ. Besides the skeleton, several excellent and instructive preparations have been made of the soft parts of the animal.

In concluding his course of lectures on Dermatology, on Wednesday last, the 14th inst., Professor Wilson reminded his audience that the day was the anniversary of the birth of John Hunter, on whom, in his peroration, he pronounced the following eloquent eulogium:—"Hunter," he said, "was a man to whose comprehensive mind every work of the Creator was interesting and important, in whose sight nothing was too small for observation, and nothing created in vain, whether the humblest plant or animal of the highest order of organisation. In the field of pathology in all its departments his zeal and faith were equally energetic and pure, whether he was investigating what may be termed the physiology of pathology, as in his grand labours on the blood, on inflammation, and on syphilis, or whether he was illustrating morbid changes in the integuments. He has left behind him, in the splendid museum, which will for ever be a chaplet to his fame, many valuable specimens of dermatological interest; and if his spirit be with us and round about us this day, as I doubt not it is, I am fain to hope that he will not look disapprovingly on our present occupation. I believe it to be impossible that he could do so. No whole would seem perfection to him without the perfection of its parts, for the soul of Hunter was essentially all-absorbing and universal."

THE OUT-PATIENT GRIEVANCE.

AS in all other places of the kingdom wherein there is a Hospital or Dispensary, the evils attendant on the indiscriminate relief given to out-patients is felt at Bath. The evils are patent enough; what is the remedy? It is proposed by the governors of the Bath United Hospital "that (except in cases of accident or urgency) no Hospital relief be administered without a subscriber's recommendation; but the recommendation entitling the bearer to Medical relief shall not state if it is to be administered to him as an in- or out-patient; for it is believed that while the subscriber is the best judge of the social suitability of the applicant for treatment, the Medical staff is most competent to determine if the patient can be treated as suitably out of the house as in it." It was thought that this resolution would throw to some extent the onus of selecting proper persons for Medical relief on the subscribers, and on the Medical staff the onus of placing the persons recommended on the in- or out-door patient list. It is evident, however, that this is a mistake, for the governors will certainly not take the trouble to inquire into the real position of the applicant for a letter. The subject is one of extreme difficulty, and, as yet, no adequate remedy has been proposed.

SOMETHING FOR THE NAVAL MEDICAL SERVICE.

"THE smallest donation thankfully received," may apply to the Medical officers of the navy; but they have never had anything like a spontaneous relief or reward. The little they have obtained has been wrung, as it were, at the knife's point from the officials at the Admiralty. We now learn that the unmeaning rank of Acting Assistant-Surgeon in the Royal Navy has been abolished, and in future all officers on entering the service will have their regular commissions in the same way as do their brethren in the army. They will, in fact, receive the rank of gentlemen, if they are not treated as such.

LOCAL SANITARY ADMINISTRATION.

ON Thursday, the 15th inst., a deputation of the Social Science and British Medical Associations waited on Mr. Stansfeld, at the Local Government Board, Whitehall, with reference to Mr. Stansfeld's proposed Sanitary Bill. The deputation comprised a large number of veteran sanitarians, and the aspect of Chadwick, Liddle, Aldis, Farr, and others, afforded practical proof that regard for the health of the community is not incompatible with the good health and energy of the individual sanitarian. Dr. Lyon Playfair and Mr. Hastings were the chief speakers, and their object was to impress on Mr. Stansfeld the necessity of county sanitary boards, intermediate between the purely local and the central or metropolitan sanitary authority. Mr. Stansfeld received the deputation very courteously, but was not able to promise that he would take the county as a sanitary unit at present, though he said that it was far from impossible that such a scheme might be matured in process of time. We hope that all parties will join in strengthening the hands of the Government, and assist in getting the best Bill which the Legislature can be got to pass. It is quite clear that the parish Surgeon must be the primary Medical Officer of Health. His board of guardians must require him when attending fever or diarrhoea to take cognisance of preventible causes. If there be a *registration of sickness*, the exploration of causes of disease *must* follow. As to the authority that shall superintend large combined works of drainage, water-supply, and the like, whether county or metropolitan, it involves no principle, but must be settled as public convenience may dictate. On the ground of distributing patronage fairly, we should like to see eminent provincial Physicians—Rumsey, Budd, Trench, Davies, Philipson, Middleton, Osborne, Wiblin—employed; and do not see the need of abstracting them altogether from private practice.

ELIMINATION OF ALCOHOL.

DR. A. DUPRÉ, of Westminster Hospital, has recently presented a very important paper to the Royal Society "On the Elimination of Alcohol." Obviously, one of three results may follow the ingestion of that liquid—either all the alcohol may be oxidised, and none eliminated unchanged; or a portion only may be oxidised, and the rest eliminated unaltered; or all the alcohol may be eliminated unchanged. If all the alcohol be eliminated unaltered, it follows that if a certain amount of alcohol be administered daily, the quantity eliminated would increase from day to day, till eventually a state of equilibrium would be attained, and the amount eliminated each day would equal the amount ingested. If, on the contrary, all the alcohol were either oxidised or eliminated within a period of twenty-four hours, no increase in the daily elimination will take place as a consequence of the alcohol diet. The author undertook two series of experiments, in which the quantity of alcohol eliminated by both kidneys and lungs was determined. His results are thus summed up: "The amount of alcohol eliminated per day does not increase with the continuance of the alcohol diet; therefore all the alcohol consumed daily must, of necessity, be disposed of daily; and as it certainly is not eliminated within that time, it must be destroyed in the system. The elimination of alcohol, following the ingestion of a dose or doses of alcohol, ceases in from nine to twenty-four hours after the last dose has been taken. The amount of alcohol eliminated, in both breath and urine, is a minute fraction only of the amount of alcohol taken."

Dr. Dupré confirms M. Lieben's observation that a substance exists in the urine of man, and in the urine of various animals, which is not alcohol, though it yields iodoform. The author found, that after six weeks of total abstinence, and even in the case of a teetotaler, that this substance, the precise nature of which has not been determined, is eliminated in the urine, and perhaps also in the breath. The quantity met with in the urine is very small, and it was found that after the

elimination due to the administration of alcohol had ceased, the amount of the substance eliminated in a given time at first remained below the quantity normally excreted, and only gradually rose again to the normal standard. The presence of this body in urine must throw great doubt on many of the previous determinations of alcohol in urine. It passes over with the first portions of the distillate, it yields acetic acid on oxidation, gives the green reaction with bichromate of potash and sulphuric acid, yields iodoform, and its aqueous solution has a lower specific gravity and a higher vapour tension than pure water.

CONVERSAZIONE AT THE LONDON INSTITUTION.

ONE of the *conversazioni* of the London Institution was held at Finsbury-circus on the evening of the 14th instant, and proved highly successful, both in the excellence of the subjects exhibited and the number of ladies and gentlemen who assembled to enjoy them. The examples of the Fine Arts shown attracted general attention, especially Mr. White's sketches of Mexican scenery and vegetation, the wonderful photographs by Mr. Good, and not less the sketches taken in India and on the route in the recent eclipse expedition. Specially interesting to us were the scientific objects. Messrs. Hopkin and Williams exhibited specimens of several of the rare metals and their salts; Messrs. Zimmerman showed a new form of voltaic battery; Messrs. How and Messrs. Beck had on the table a number of microscopes, mainly binocular; and Mr. Browning demonstrated the hydrogen spectrum with one of his instruments. The *conversazione* was rendered still more attractive by a lecture delivered in the course of the evening by Mr. Norman Lockyer, F.R.S., F.R.A.S., "On the Sun." The learned astronomer confined his remarks to the solar atmosphere, giving the most recent views on its composition, on the nature of its spots, and so on. The enormous value of the spectroscope as a scientific instrument was pointed out; and it was shown by the lecturer, in reference to his late valuable researches on the spectra of various densities of a given gas—say hydrogen—how a new means of research was put into the hands of the physicist and chemist in this foundation of a process of quantitative spectral analysis. The lecture was illustrated by magnified photographic views of the sun's atmosphere, some of which were taken during the recent eclipse, by the spectra of various substances, as well as by several other experiments of different kinds.

THE ILLEGAL PRACTICES OF A PHARMACEUTICAL CHEMIST.

WITH reference to the case of Andrews *v.* Davies, recently decided in the County Court at Shrewsbury, the plaintiff stated that he was a certificated pharmaceutical chemist. He possessed, according to his own admission, a foreign diploma of Doctor of Medicine, and had been convicted under the Medical Act for "wilfully and falsely using the title of Doctor of Medicine, implying that he was recognised by law as such." Now, whether this conviction would be affirmed or not if it were brought before the Court of Queen's Bench, one thing is certain, that according to the Pharmaceutical Chemists Act (15 and 16 Vic., cap. 56, sec. 11), "No person who is a member of the Medical Profession, or who is practising under the right of a degree of any University, or under a diploma or licence of a Medical or Surgical corporate body, shall be entitled to be registered under this Act; and if any registered pharmaceutical chemist shall obtain such diploma or licence, his name shall not be retained on the said register during the time that he is engaged in practice as aforesaid." And by the 12th section, "If any person, not being duly registered as a pharmaceutical chemist, shall assume or use that name in any part of Great Britain, or shall assume, use, or exhibit any name, title, or sign implying that he is so registered, or that he is a member of the said Society, he shall

be liable to a penalty of £5." One object of the Medical and Pharmaceutical Acts is to draw a broad line of demarcation between the Medical Profession and the trade of a chemist and druggist; and no person is allowed to combine the two. He cannot be a member of the Medical Profession and of the Pharmaceutical Society; and even if a chemist and druggist obtains a recognised degree or diploma, he must cease to be a member of the Pharmaceutical Society. *A fortiori*, if a man has been "wilfully and falsely using a title implying that he is recognised by law as a Practitioner in Medicine," and has thereby fraudulently induced people to confide in him, he is doubly amenable to the law. Mr. Andrews' occupation, even as a chemist and druggist, will, it would seem, henceforth be gone; for under the 31 and 32 Vic., cap. 121, sec. 1, no person shall "sell or keep open shop for retailing, dispensing, or compounding poisons, or assume or use the title of 'chemist and druggist,' or chemist, or druggist, or pharmacist, or dispensing chemist or druggist, in any part of Great Britain, unless such person shall be a pharmaceutical chemist, or a chemist and druggist within the meaning of this Act, and be registered under this Act, and conform to such regulations as to the keeping and dispensing of such poisons as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council." It is to be hoped that this may be a caution to all prescribing druggists who aspire to a position to which they are not by law entitled, instead of remaining content with an avocation in itself at once respectable and lucrative. Infraction of the law cannot be tolerated to the detriment of the Medical Profession and the public at large. Mr. Andrews has been attempting to sit between two stools—the stool of Medicine and the stool of a vendor of drugs. Between the two he must come to the ground.

LAMBETH WATER AGAIN.

Dr. MacCORMACK, Medical Officer of Health for Lambeth, is reported to have made, on the 12th instant, an analysis "of the Southwark and Vauxhall Companies' water, drawn whilst the water was on from the main, from the house, 4, Walnut Tree-walk, Kennington-road," and states that, "having examined it by the two most modern and delicate processes, and having got results by both which confirm each other in the most striking manner, he has no hesitation in repeating that the water was totally unfit for human consumption, and little better than extensively diluted sewage. Of the two, the Lambeth water was a trifle worse than the Vauxhall, but both were much worse than many waters which have been already condemned, and the wells closed."

A CONTRAST.

At the meeting of the Leicester Town Council last week the following little episode took place:—Mr. Councillor Cottingham complained that Mr. Howse received £70 for inspecting cattle, whilst the Medical Officer received only £15 for similar services rendered to human beings. No one seemed to think that the Medical Officer received too little, but all agreed that the cattle inspector received too much. It was eventually decided not to raise the salary of the human Doctor, but diminish, if possible, that of the cattle doctor—that he be paid a fixed salary, instead of per case.

PRESENTATION TO MR. DUNN.

WE learn that Mr. Dunn has been presented with a silver cup by the Strand Theatre company, in recognition of his long and valuable services. The presentation was made on the stage of the theatre, accompanied by a very appropriate speech from Mr. Arthur Swanborough. The cup bore the following inscription:—"Presented to R. William Dunn, by Mrs. Swanborough, the ladies and gentlemen of the Strand Theatre company, as a slight mark of their respect and esteem."

HOSPITALS FOR SMALL-POX.

It is curious to observe the various ways in which small-pox is propagated and encouraged even by those whose interest as well as duty should lead them to adopt an opposite mode of conduct. Here is a sample of the way in which "things are not done" in the important episcopal city of Lincoln:—At a late meeting of the Local Board, letters were received from the Clerks to the Local Boards of Sheffield, Norwich, Nottingham, etc., in answer to applications for information relating to small-pox Hospitals. The Hospital at Nottingham, to hold 120 persons, it was stated had already cost £2000, and it was not known what the ultimate cost would be. A report was also read from the Lincoln Dispensary, complaining of the apathy of the Board in providing accommodation for persons suffering from small-pox. Dr. Harrison, who was present, stated that during the present year thirteen cases had come under his notice. Three of the patients had died, and seven were well. The disease was of a very mild form. He further stated that twelve out of them would have been sent to Hospital. Hereupon one of the Local Board said, amidst some cheering, "I should act very differently with my family." Another gentleman did not think there was any necessity for a small-pox Hospital at all. There had always been during his life a few persons suffering, but there was no cause for alarm, as the city was too healthy, sweet, and clean. He did not think anyone would go into the temporary Hospital; he should not allow his family to do so; and none but the veriest paupers would go in. He moved that no further steps be taken in the matter. This, being seconded, was carried. This is the way to shelve a question; but it speaks little for the sagacity and common sense of the Lincoln Board that they should thus, by a side wind, ignore their duty.

TESTIMONIAL TO A SURGEON.

ON the occasion of Dr. Alfred Harvey leaving the scene of his late practice, and the patients to whom he had administered for many years, a social gathering took place at "Simpson's," in the Strand, on Monday evening last. The dinner was served up in Simpson's best style, and the company, numbering nearly fifty influential gentlemen, passed a most pleasant evening. After the banquet, the chairman, Dr. Cross, presented Dr. Harvey with a splendidly illuminated testimonial and a purse of sovereigns. The testimonial bore the following inscription:—"We, the undersigned patients and friends of Dr. Alfred Harvey, whilst sincerely expressing our regret at his retirement from the neighbourhood of the Strand, embrace this opportunity to present him with this testimonial and a purse of sovereigns, and testify our appreciation of the admirable manner in which he has discharged his important duties for upwards of thirty years, and also record with gratitude the invaluable services rendered by the ability displayed in his Profession, and by his uniform courtesy and kindness; and trust that the satisfactory results which have attended his efforts here will command for him the same high esteem and regard where he is now located." Dr. Harvey acknowledged the compliment in a few eloquent words.

ST. PANCRAS MEDICAL ARRANGEMENTS.

THE Board of Guardians of St. Pancras have determined to abolish the infirmary of the workhouse as a receptacle for cases of acute sickness. It will in future be used for cases of chronic disease only. Some changes have also been made in the Medical staff of the institution. Dr. Hill has been appointed Medical officer of the whole establishment, at a salary of £200, with residence, etc., and an allowance of £25 per annum for a deputy to act in his absence. With a view, if possible, we suppose, of offering some check to the number of inquests held in the workhouse infirmary, Dr. Hill, by his contract, is required to pay over all fees for post-mortem examina-

tions and coroners' inquests to the Board of Guardians. Without expressing any opinion as to the policy of such a measure, it may fairly be doubted if the arrangement be legal.

RADCLIFFE STUDENTSHIPS.

WE have much pleasure in publishing the following announcement. The offer, we are sure, will be received as a boon by the students of the favoured schools, and is highly creditable to the Radcliffe Trustees:—

"The Radcliffe Trustees, anxious to aid one or more advanced students in the scientific study of preventive or curative Medicine, offer £10 a month, for three months, to a student of St. Bartholomew's, Guy's, or St. George's Hospital desirous of working for that time in Oxford. He will have opportunities of studying physics, chemistry, geology, the higher parts of biology, clinical and sanitary Medicine. Candidates must be recommended on intimate personal knowledge by the Dean or Secretary of their Medical schools, and will not be submitted to an examination. Their names must be sent to Sir James Paget, Sir William Gull, or Dr. John W. Ogle, on or before February 20. The first election will be in the last week of February. There will be an election of another student in April. Candidates are requested to state in their application during what months other than the long vacation they would prefer to reside.—Oxford, January 31, 1872."

THE SICK POOR OF THE HOLBORN UNION.

ONE of the first questions which the newly constituted Holborn Board took into consideration was the rearranging and remodelling of its workhouse buildings. It has been determined by the Board to concentrate the whole of the paupers in two of the houses, instead of as heretofore in six. This work of improvement began last year. The whole of the buildings, with the infirmary, sick-wards, and administrative offices, will, when completed, accommodate 1500 inmates; and the total outlay, including all outgoings, will be less than £40 per bed, whilst other parishes are expending nearly £100 per bed upon their new establishments. The Holborn Guardians deserve the commendation, not only of their own, but of all other rate-payers in the metropolis, when it is remembered that a saving of £1 only per head on all the paupers of this metropolis would amount to no less than £150,000.

CHOLERA IN THE THAMES.

THE Sub-Committee of the Thames Shipping Inspection Committee, in their report, state that there has been, up to the present time, no appearance whatever of cholera. They have, however, met from time to time, that they might be in a position to watch the course of the disease, and to take immediate action in the event of its making its appearance among us. Mr. Harry Leach's offer to act as Advising Medical Officer to the Committee has been accepted, and, immediately on the appearance of cholera in the River Thames or the metropolis, Mr. Leach will be engaged as principal Medical Superintendent, at a monthly salary of fifty guineas. The Sub-Committee have, from time to time, received communications respecting the progress and extent of the cholera on the Continent. The Honorary Secretary is at the present time in communication with the authorities, to arrange that official reports should be supplied them.

SMALL-POX JOTTINGS.

SEVEN fresh cases of small-pox had occurred in the Islington Medical district during the past week, as against five the week before. There had been two deaths from the disease.—It was reported to the Hackney Board of Guardians that no deaths of patients belonging to that union had occurred in the Small-pox Hospital at Homerton during the past week, but notice had been received of the discharge of five from that establishment.—The Medical Officer reported to the Holborn District Board of Works that during the previous fortnight one death had occurred from small-pox, and two fresh cases

were brought under notice.—Small-pox, of a very malignant type, has been prevailing for some time, and still prevails in Philadelphia to an alarming extent. In New York there has been during the winter a constantly increasing number of deaths from small-pox every week, but the disease as yet is not of so virulent a character as in Philadelphia.—In Nottingham, since November 20 last, 362 patients have been admitted to the small-pox Hospitals; of this number 189 were discharged, 121 still remain under treatment, and 52 died. But it is stated on reliable authority that there have been 150 deaths during the above period in private houses, making the mortality from this disease alone over 200. No person who had been vaccinated took the disease. Public vaccinators are now appointed. Nottingham and Wolverhampton are now the two highest in the bills of mortality.—Four fresh cases of small-pox were reported to the Kensington Board of Guardians last week, and two deaths.—The Medical Officer, in his report to the St. Olave's Board of Works last week, states "that during the past twelve months 157 cases of small-pox had occurred in the district; of these 144 had been vaccinated, 13 had not. Of the 144, 8 died, or at the rate of 5.7 per cent.; of the 13 unvaccinated 10 died, or at the rate of 76.9 per cent. These all referred to the Poor-law Medical practice of the district; as to private practice, a difficulty was experienced in getting at the returns, but the number of cases was estimated at 40, all of which must have recovered, as no death had been certified."—During the past fortnight 18 fresh cases of small-pox were reported at Wakefield, and 6 patients in the Small-pox Hospital.—The returns of small-pox cases in Aberdeen, made up to the 8th inst., show—Total number admitted to the Hospital since the opening 69, 1 new case admitted, 51 remaining under treatment, 7 patients discharged cured, and 11 deaths. The disease is greatly on the decline.—There were 7 deaths from small-pox during the past fortnight in the Hackney district.—In Poplar, in the past week, 3 deaths had occurred from the disease in the Union, and 11 fresh cases brought under notice. In the same period 66 persons were vaccinated at the public stations. In the North-street Infirmary 13 small-pox patients are under treatment.—The last quarterly return of deaths in Sheffield shows 360 from small-pox. The disease was epidemic in Sheffield during 1863-64, and again in 1868-69. During the ten years 1861-70 the fatal cases in Sheffield and Eccleshall Bierlow districts were no less than 1252. The present epidemic is, however, more severe than any in recent years.—In Halifax, from January 3 last to the 16th inst., 89 cases of small-pox were reported, and 8 deaths.—The Irish Registrar-General, in his report on the third quarter of the year 1871, states that, of the 19 cases of small-pox reported from Waterford, "all recovered except one, which was directly imported from Liverpool, and complicated with purpura hæmorrhagica. I attribute the providential escape of this city from the threatened epidemic to the perfect vaccination of all the children in this district, and also to the great amount of revaccination performed on the appearance of the first case of small-pox and previous to it." But small-pox had been very prevalent in Ireland during the quarter.—The small-pox epidemic in Edinburgh shows no sign of diminution, and in the eight principal towns of Scotland during the past month the disease is still increasing, the deaths having risen to 461 in January, as against 354 in the previous month.—Small-pox appears to be decreasing at Brigg, Lincoln, 2 fresh cases only having been reported in the last week.—The Medical Officer of Health of Wolverhampton states, in his report to the Sanitary Committee, just issued:—"As far as at present can be ascertained, principally from statements made by friends of the deceased, 151 of the deaths from small-pox occurred in those who were confessedly unvaccinated; 106 were stated to have been vaccinated, but many of these were probably unvaccinated. Of 69 no information was obtained."—In the metropolis, during the week ending last Saturday,

68 deaths occurred from small-pox, showing an increase on the week previous of 16.—In the four Small-pox Hospitals at Hampstead, Islington, Homerton, and Stockwell, 34 deaths were returned last week, against 37 and 27 in the two preceding weeks.—In Dublin, last week, 47 deaths from small-pox were reported, against 40 and 47 in the previous fortnight.—A newspaper reporter at Ryde was, on Tuesday, fined by the magistrates 2s. 6d. and costs, for selling a local newspaper which had been exposed to infection from a person in his house suffering from small-pox, without having previously disinfected it.

MEANS FOR DISINFECTION.

THE City Commissioners of Sewers have resolved upon the construction of a room for infected articles, a room for the storage of articles after disinfection, a shed for a truck, and a furnace for burning infected flock, etc., on the ground in Golden-lane purchased for mortuary buildings, etc.

FROM ABROAD.—GUNSHOT WOUNDS OF THE BRAIN.

PROFESSOR PODRAZKI, of the Joseph Military Academy of Vienna, has narrated in two recent numbers (December 9 and 16) of the *Wiener Medizin. Wochenschrift* an interesting case of gunshot wound of the brain followed by recovery.

Early in October, 1869, a youth aged 15 was accidentally shot in the head by a pistol, and on Professor Podrazki seeing him next day he found a round wound one centimetre in diameter, situate at the internal end of the left arcus superciliaris, into which he could pass the end of his little finger. At its bottom he found some coagula, and could feel a slight pulsating movement. The bony edges of the wound were sharp and jagged, and the surrounding skin was blackened by the powder. The lad, who was robust and healthy, lay pale and senseless, the pupils being widely dilated and in nowise sensitive to light. The breathing was stertorous, and the pulse, which was very compressible, beat only 54. A small quantity of slightly blood-coloured serum flowed from the wound. Both extremities were completely paralysed on the right side, and the urine had passed away involuntarily. The Practitioner who had first seen him had passed a probe some five or six inches long into the track of the wound (which ran horizontally backwards) without coming in contact with the ball. The diagnosis here was easy, all the symptoms indicating that the projectile had probably done extensive injury to the left anterior lobe of the brain, and that this had been attended with a considerable extravasation of blood either into the substance of the brain or between its surface and the bony coverings. Where the ball might be could not be conjectured. Of course, the prognosis was highly unfavourable. The treatment was expectant, ice being applied to the head, strong soup administered, and cold-water clysters given as an occasional aperient. Searching for the ball was out of the question, and the locality of the wound prevented the patient being placed in a position favouring the action of gravity.

In a few days the patient's consciousness gradually returned so that he became able to answer questions, but only after long consideration, as if he were in search for words, and then very slowly—in complete contrast with his ordinary quick and lively speech. In about a week some pain in the head appeared, accompanied by a pulse of 130, regular morning vomiting, and sleepless nights. There was occasional delirium, and the palsied limbs were very tremulous. The discharge from the wound consisted in part of genuine pus and in part of serous fluid. This condition of things had several times alternated with a remarkable remission of disquieting symptoms, when suddenly, about the middle of November, a soft, pale-red tumour made its appearance, projecting from the wound, but gradually became covered over by the granulations and skin, which formed over it a tolerably firm cicatrix. At first only of the size of a hazel-nut, it gradually but slowly increased.

Simultaneously with its appearance the condition of the patient exhibited a most marked improvement, his pulse going down to 80, his consciousness being clear, his sleep and appetite excellent. Even the paralysis exhibited decided improvement.

On December 12—two months after the accident—Professor Podrazki was alarmed at learning that the Surgeon in attendance had mistaken this tumour lying over the healed wound for an encysted tumour, and had proceeded to remove it. Alarmed, however, by the large quantity of black blood that issued on an incision of the skin, he desisted from the attempt. The author, on arriving, found a hernia cerebri of the size of a small walnut, which had become covered by a firm cicatrix. This having been cut through, as stated above, the pure cerebral mass projected. An attempt at returning this having been attended by the sinking of the pulse from 90 to 54, and by the patient becoming faint and cyanotic, it was determined to leave it as it was, only covering it with oiled lincn and wadding. At the same time a remarkable appearance was discovered a little above the external occipital protuberance—a small, elastic tumour, the size of a bean, which, on pressure, yielded somewhat and felt painful. Spontaneous pains had, it seems, all along been occasionally felt here. The bones appeared entirely intact; but as this small tumour corresponded pretty nearly to the spot at which the ball coursing along the inner surface of the bones might be expected to reach, the question arose whether the swelling was not connected with the presence of the ball, and whether trephining would not be justifiable in order to secure its removal and to give issue to the pus, which possibly was the cause of the hernia cerebri. This procedure Professor Podrazki considered too conjectural, and at all events not to be had recourse to unless symptoms of cerebral compression came on. The patient at that time was improving every day, the paralysis having much diminished, so that he was able to sit up for some hours daily. He had, however, entirely lost the power of memory for recent occurrences and for things that had happened only a few hours, while remote events were well recollected. His visual power was also to some extent enfeebled. It was resolved not to interfere. There was a continuous flow of a clear, serous fluid (cerebro-spinal?) from the wound made by the incision, and the hernia cerebri—or, as Professor Podrazki prefers calling it, the prolapsus of the brain—continued to increase, until it had attained the size of a walnut, projecting over the incision-wound. By July, 1870, complete cicatrization had taken place, and a photograph is given of the lad's appearance at that time. The tumour measured two inches in length, and was one inch and a half in thickness, being quite transparent, and very elastic in its anterior part. At its base the sharp edge of the bony aperture could be felt, surrounded at its lower portion by somewhat pointed osteophytes. Compression employed for some minutes diminished the size of the tumour remarkably, this becoming soft, and having a faint pulsation, while the usually excessively distended skin was thrown into folds. This pressure, however, threw the patient into a state of syncope, his pulse becoming remarkably slow. The tumour evidently only in part consisted of cerebral substance, the remainder (in its anterior portion) being cerebro-spinal fluid; and the author resolved, in consultation with Hofrath von Pitha, to resort to puncture. This he executed in November, 1870, by means of Dieulafoy's *aspirateur pneumatique*, and the tumour immediately diminished to half its size, while the remainder was, by means of gradual and gentle pressure, entirely returned, without any symptoms of cerebral pressure being produced. A pad was applied to retain it. Quite recently the author has heard from the lad's friends that nothing now remains of the tumour, the forehead being quite even, the aperture in the bone being filled up with a firm cartilage-like substance. The general health is excellent, and the patient is able to walk about, though only slowly, as the power of the right foot is not yet quite restored, although the

paralysis of the arm has completely disappeared. Speech is still slow and difficult, and has become remarkably deep. The intellectual power has not diminished.

Professor Podrazki observes that the friends of the lad regard him as cured, but for the Surgeon he is still a subject of anxiety; and it is only in a qualified manner that he reports the case as a "recovery." Indeed, in some interesting general observations with which he prefaces the narrative of this case, it is evident that the greatest caution must be observed in delivering our prognosis in this class of injuries. We have only space to briefly allude to some of the remarks in question. Sometimes, it is observed, death takes place only weeks or months after gunshot wounds of the head, either in consequence of secondary inflammation having been set up, an abscess having formed in the track of the wound, or from decomposition of extravasated blood. As long as the ball remains within the skull, life is permanently menaced, although the wound may have completely healed and all cerebral disturbance have disappeared. Various authors have recorded cases in which, even years after apparently complete recovery, death has taken place, either suddenly without preliminary symptoms, or under an apoplectic attack, or with a gradual loss of strength. In the great majority of cases acute encephalitis or meningitis occurs, the patient dying with symptoms of compression of the brain from the formation of matter, or with those of pyæmia. Sometimes death takes place quite suddenly when all seems to be going on quite well. This was so in a soldier from the Italian war, who, standing upright by his bed and questioned as to his ailments, laconically replied that he had a ball in his head. And so it proved. The pulsations of the brain were visible through an aperture in the frontal bone. His pulse beat only 44, but otherwise he seemed very well, and was making decided progress, when, on standing up, he fell down suddenly, dead. An abscess was found in the anterior lobe of the brain, and the ball lay at the bottom of it. In other cases the ball sinks by its own weight through the soft mass of the brain until, coming in contact with some important part, it at once causes death. Sometimes it reaches the base of the skull, where it remains long without doing mischief, or may become eliminated—although this is one of the rarest of occurrences. Patients are placed in the greatest danger by attempts being made to search for the position of a ball by means of a probe; for this may easily, without being perceived, penetrate uninjured portions of the soft mass of the brain, and give rise to immediate death. Whenever the probe is used all pressure must be abstained from, the instrument being left to glide along. The occurrence of prolapsus or hernia cerebri, which usually takes place only some weeks after the occurrence of the injury, adds much to the gravity of the prognosis. According to Bruns, about two-thirds of those who exhibit this die, and Professor Podrazki's experience leads him to consider this a too favourable statement. The seven cases which have occurred in his Clinic of the Joseph's Academy between 1854 and 1870 have all died.

PARLIAMENTARY.—HABITUAL DRUNKARDS—REGULATION OF MINES
—ABOLITION OF CAPITAL PUNISHMENT—PREVENTION OF CONTAGIOUS DISEASES.

IN the House of Commons, on Thursday, February 8,

Mr. Donald Dalrymple, stating that he was in possession of certain facts to prove the feasibility of the object in view, moved that a Select Committee be appointed to consider the best plan for the control and management of habitual drunkards.

The motion was agreed to.

On Monday,

Mr. Bruce brought in his Mines Regulation Bill.

A Bill for the Abolition of Capital Punishment was read a first time.

On Tuesday,

Mr. Bruce brought in his promised Bill for the Prevention of certain Contagious Diseases and for the better Protection of

Women. He prefaced his statement by a sketch of existing legislation on this subject, and of the agitation it had excited. To illustrate the working of the Act, he quoted largely from the Report of the recent Commission, adding that, though opinions might differ on the balance of their moral results, as to their physical operation in the diminution of disease and vice there could be no question. However, the Government had reluctantly come to the conclusion that it was impossible to maintain in a limited district the main principle of the Act—viz., compulsory periodical examination—while it could not be extended to the whole country. And this he held to be impossible in the present state of public opinion, of which the Acts went far in advance. The present Bill proposed to enact that every common woman who in any public street importuned persons should be liable to be dealt with under the Vagrant Act, and that for this purpose the Vagrant Act should extend to Scotland and Ireland. For the first offence under that Act, the offender, as a disorderly person, was liable to three months' imprisonment; for the second offence, as a rogue and vagabond, to six months' imprisonment; and for the third, as an incorrigible rogue, was liable to be tried at Quarter-Sessions and sentenced to twelve months' imprisonment. The next provision of the Bill was borrowed from a recent clause in the later Poor-law Acts, which enabled the Guardians when any paupers within the workhouse were discovered to be labouring under contagious diseases to detain them until they were cured. The Bill proposed to apply the same rule to women of the class referred to. All such women committed under the Vagrant Act, or generally as disorderly persons, would, if found to be suffering under contagious disease, be liable to be detained in the prison infirmary or in some certified Hospital until they were cured, or for a maximum period of nine months. No compulsory examination would in that case be necessary. Besides those who were committed to prison summarily as disorderly women there was a considerable number of women committed to prison for other offences, where the evidence showed that they were leading an immoral life. It was, therefore, proposed that the committing magistrate, in all summary cases where he was satisfied a woman was leading a disorderly life, should certify the fact, and in the event of the prisoner being found to be suffering from contagious disease she would be detained in the same way as the class of prisoners last described. There were special reasons why women of the class in question should not be permitted to return to their miserable calling while suffering from contagious disease, and, therefore, he limited his proposal to these two classes of cases. The prison Surgeon would report the existence of disease, and the report would be sent by the gaoler to the justice, who would make an order for the detention of the patient. The woman thus detained in prison after the term of her sentence might by order of the justices be removed to a certified Hospital, but if not sooner cured her detention would not exceed nine months. As an additional precaution, the chief Medical officer of the prison infirmary or certified Hospital would be required each month to transmit a certificate that further detention was necessary. The justice, however, would have the power of discharging a woman either from the prison infirmary or the certified Hospital, although not cured, if he were satisfied she intended to abandon her former life. The expense of sending the woman from the infirmary to the Hospital and from the Hospital to her home would be borne by the prison authorities. He now came to that portion of the Bill specially devoted to the protection of women. The existing law made punishable with penal servitude for life offences of a certain description upon children under 10 years of age, and he proposed to extend the age from 10 to 12. The same offence committed upon a child between 10 and 12 was at present a misdemeanour punishable with penal servitude for ten years, and he proposed to extend that protection to children under 14. At present the obtaining possession of a girl under 21 by false pretences or representations was a misdemeanour punishable by imprisonment for two years. He knew no reason for limiting these cases to women under 21, and he proposed that the punishment should equally apply when the offence was committed against women of any age. With regard to disorderly houses, the law at present was that if the landlord of a disorderly house allowed women whom he had cause to believe diseased to frequent his house he was guilty of misdemeanour, and liable to a fine of £20 or six months' imprisonment. The recommendation of the Commissioners, which he had adopted, was that whenever a woman was found in a disorderly house, the landlord, whether he knew it or not, should be liable to the same punishment. He proposed that the harbouring of children under 16 should be declared a mis-

demeanour punishable summarily before a magistrate by six months' imprisonment, or, upon indictment, with two years' imprisonment, in each case with or without hard labour at the discretion of the judge. He also proposed that the parochial authorities should be enabled to prosecute the keepers of disorderly houses without its being necessary that they should first be called upon to act by two ratepayers. He also proposed to make the landlord of a disorderly house liable if he knew it, to be kept as such, although he might not be resident in it, and although he might take no part in the management. He proposed, further, to give the landlord power summarily to determine the tenancy of a disorderly house, whatever the terms of the lease might be. The last provision of the Bill referred to common lodging-houses, the keepers of which would be deprived of their licences and subjected to punishment if they knowingly permitted them to be frequented by persons of immoral life. The greater part of these provisions were founded upon the recommendations of the Commissioners, and some had been suggested by an examination of the general law. Mr. Bruce did not disguise his regret at having to take what he evidently considered to be a backward step, but the advantages of the Acts, he urged, were overbalanced by the agitation which had been carried on, its flagrant exaggerations and misrepresentations, and the distressing spectacle of female modesty broken through by taking part in these discussions. He hoped that the operation of the Bill would create a fund of experience which at some future time might help to establish more efficient means of repression.

A short discussion followed the explanation of the Bill, in which Mr. Jacob Bright touched on some of the most unsavoury parts of the subject, described the first commencement of this legislation as an "infamous Act," and based his opposition to it on the principle of "civil liberty." This plea was ridiculed by Dr. Dalrymple and Dr. Brewer, who eulogised the sanitary benefits of the Acts. Sir J. Pakington, Sir J. Elphinstone, and Sir J. Trelawny denounced in strong language the timid and unworthy policy of the Government in abolishing Acts of which they approved, and the latter sharply attacked Mr. Jacob Bright for his prejudiced opposition to the Acts. On the other hand, Mr. Mitford, Mr. Henley, Mr. Rylands, and Mr. Otway denied altogether the sanitary and moral benefits of the Acts, and supported their repeal.

BRADFORD FEVER HOSPITAL.

THE wealthy and populous town of Bradford has recently placed some of its money at interest in a manner which reflects credit on itself, whilst conferring great benefit on some of its poorer inhabitants. It has erected an admirable Fever Hospital.

Next to hunting out and destroying the sources from which fevers spring, no doubt the best thing is to provide for the proper treatment of cases when they occur, and this seems to have been the thought of Mr. Alfred Harris (the founder), Sir Titus Salt, and an unknown donor, who in 1869 subscribed the handsome sum of £11,800 towards this object. Since that time the subscriptions for building, etc., have amounted to £22,520, and with this money the committee formed for that purpose have just thrown open for the reception of fever patients the best-adapted series of buildings, perhaps, in the kingdom.

The Hospital, which is planned on the pavilion system, and provides for the separation of the contagious fevers, stands upon a hill, in the centre of about eight acres of ground, far away from private houses, and within a mile of the town. It consists of four wards, arranged side by side in a row, and about thirty feet apart. Each ward contains ten beds, and to each bed is allotted 2300 cubic feet of space. The floors are of polished oak, and the walls of Parian cement—hard, smooth, white, and shining. Ventilation is obtained by orifices in the windows, walls, and roof, and by a simple contrivance is placed beyond the control of patients.

Corresponding to each of the four wards is a private and convalescent ward, with nurses' sitting-room, supplementary kitchen, scullery, lavatories, baths, night-chairs, and water-closets. At twenty yards distance from the row of wards, and at right angles to the last of them, is a separate building—consisting of two wards, each containing eight beds, with two corresponding rooms for convalescents, nurses' sitting-rooms, offices, etc.—for the treatment of scarlet fever exclusively. Again, at right angles to this, and parallel to the four

large wards, stands the administrative block, in which are nurses' dining and sleeping apartments, kitchen, bakehouse, servants' offices, etc., rooms for the resident Medical officer and matron, with all the requirements of a well-appointed modern dwelling-house. The whole series of buildings, which are connected by a thoroughly ventilated covered way, form a quadrangle, enclosing a space of ground which is laid out as a garden. Communication between the different wards and the house is supplied by telegraphic apparatus.

At other parts of the grounds are placed wash-houses, disinfecting chamber, post-mortem room, mortuary, stable, and coach-house. In the latter is a comfortable modern ambulance for the conveyance of patients from their homes. Provision is made for ventilating the main sewer leading from the Hospital, by conducting a shaft from it into the chimney of the engine-room, and each separate water-closet, slop-sink, waste-pipe, etc., in addition to being double trapped, is fitted with a ventilating-pipe placed between the two traps, and carried on the outside to the top of each building. Dirty linen, etc., on removal from patients, after being immersed in disinfecting fluid, is thrown down a shaft communicating with a brick chamber, placed in the open air, whence it is taken to the wash-house.

The architects, Messrs. Andrews and Pepper, frequently availed themselves of the personal instruction and advice of Drs. Murchison and Bridges, of London, and of Dr. Bourne, formerly Physician to the Bradford Infirmary, on points connected with the sanitary arrangement of the Hospital.

PSOAS PARVUS.

By J. BESWICK PERRIN,

Demonstrator of Anatomy at King's College, London.

THE natural history of this muscle is simple; it is either *psaos parvus* or nothing. Its modifications are of a minor character, being differences only in degree of development. According to Douglas, it was first discovered by John Riolan, and described by him in his "Anthropographia" in 1649. Some thirty-two years later, Brown, in his treatise of the "Muscles of the Human Body," mentions the *psaos parvus* (so called by Bauhine) as "occurring in some bodies, arising fleshy, the length of a little finger, and terminating in a slender and plain tendon above the *psaos*, and ends with the *psaos* and *Aleon*, and embraceth them firmly." Bartholino describes it as "found in a strong and fleshy man at the Hague, three fingers in breadth at its origin, terminating, also, fleshy at the upper margin of the *os ilii* at the origin of the *iliacus internus*." Molin found it also, and stated that it appears not very frequently. J. Baptiste Morgagni, in his "Adversaria Anatomica Omnia" states:—"Miror quoque, cur *psaos parvus*, qui haud ita perrarò inveniri solet, ab eodem Verheyenio ne memoraretur quidem à te vero, et plerisque alteram *illius* extremum unde potissimè ejus usus notitia pendet, ignorari esse in osse pubis implantatum, quemadmodum Cowperius docet, et ego pluries inspiciens deprehendi." Albinus gives a very accurate drawing of the *psaos parvus*.(a) Douglas says "it arises fleshy from the upper vertebræ of the loins laterally."(b) As regards its insertion, he coincides with the elder Monro in assigning it to the ilio-pectineal ridge. Riolan states that he never could find this muscle in women. Douglas pithily remarks that it is often missed in the human body, but never in a dog. It is needless to multiply the opinions of ancient authors. It is generally recognised by modern anatomical writers as a muscle sometimes found—some, however, describing it without any reservation, as if a persistent muscle. In the last edition of Quain's "Anatomy" there is the following honest statement made in reference to the *psaos parvus*:—"Although well developed and constant in animals, it is most frequently absent in the human subject. It was found in only one of twenty bodies examined by Theile with special reference to its existence. When present, it is liable to many changes in the place of origin: thus, it may be connected only with the first lumbar vertebræ, or with the second, and the intervertebral substance above it, and it has been observed to commence by two parts or heads separated by

an interval." Its average proximal attachment is best considered as described by that most accomplished and accurate of all anthropotomists, Ellis—viz., to the sides of the bodies of the twelfth dorsal and first lumbar vertebræ, and the fibroid disc between them. Not that this is the statement alone of the latter observer, but for the simple reason that he is the most able exponent of average human anatomy.

Now, for several years past I have had my attention directed to the frequency of occurrence of this muscle, and have carefully examined every human subject brought into the dissecting-room during this period of time. During the winter session 1868-69 I found it in only two subjects—a male and a female—out of twenty-nine. It was present on both sides, and well developed. In the male subject it attained to an unusually large size, almost equal in bulk to the *psaos magnus*. In the session 1869-70 I found it in no less than fifteen out of twenty-nine subjects—thus, in nine males and six females. It occurred on both sides in six males, in two on the right, and in one on the left only. In the female subjects it was present on both sides in five, and on the left only in one. During the session 1870-71, of thirty subjects, it occurred only in six, all males—in four it was present on both sides, in one on the left, and in the remaining one on the right side. In twelve subjects which came under my notice whilst acting as temporary assistant to Professor Flower at the Royal College of Surgeons during the April and May Anatomical Examinations of 1870 and 1871, I found the *psaos* once only in a male on both sides out of six in 1870, and twice only in the six of 1871; the latter occurred in spare female subjects—in one on the left side, and in the other on the right side. Out of twelve subjects—seven males and five females—during the present session 1871-72, the *psaos parvus* was present on both sides in four males and in two females.

From these statistics of 112 subjects examined, the *psaos minor* was found in thirty-two—twenty-one males and eleven females—its presence in the former being twice as frequent as in the latter; and the rate of its occurrence is in one out of every three and a half of the aggregate number.

The proportion of male to female subjects during the above-mentioned periods was pretty nearly equal.

There is considerable discrepancy between the assertion of Theile, that it occurred in one only out of twenty subjects, and the collated facts which I have described. But, however glaring the apparent difference, when analysed it will be seen that Theile may not have been very far from the truth. During the 1868-69 session I met with only two specimens in the twenty-nine subjects, while in the succeeding session fifteen occurred out of the same number of subjects. Again, in the present session, of the twelve subjects alluded to the *psaos minor* was found in six. These facts show the fallacy of limited statistics. The only way to arrive at an approximation of the truth is to multiply the number of observations. Again, it is quite possible that thirty subjects, or even twice that number, might be examined, and the *psaos minor* not be found in a single one. And it is very probable that this muscle may be less frequently met with in one race than another—a condition of great importance, and by no means made the most of.

The average attachment of the *psaos minor* is decidedly that described by Ellis. There are, however, considerable fluctuations in size met with, both of the proximal muscular part and the distal tendinous, even with the average attachments. Beyond these it shows its vagrant or metamorphic character, sometimes by excessive aggregation, at others by extenuation. Again, there is not always coequality in the *psaos* of the two sides—for example, in one female subject, moderately muscular, I found it arising musculo-tendinous from the sides of the bodies of the fourth and fifth lumbar vertebræ and the disc between them on the right side, while the left specimen was attached proximally to the first and second lumbar vertebræ and disc.

In several specimens the proximal belly was attached to the sides of the last dorsal and two upper lumbar vertebræ, simulating exactly the arrangement I met with of this muscle in the great ant-bear (*Myrmecophaga jubata*) and in the Tamandua ant-bear.(c)

Galton has described a similar arrangement in the *Dasyppus seveinectus*,(d) and Professor Humphry in the unau, pangolin, and manis.(e) In the mole (*Talpa Europea*) it arises from the last dorsal and first lumbar vertebræ, as in the average arrangement in man. Percival describes its proximal attachments

in the horse as follows:—"To the heads of the sixteenth, seventeenth, and eighteenth ribs, to the bodies of the three posterior dorsal vertebræ, and to those of all the lumbar vertebræ." With minor modifications of no material interest, I have found the psoas parvus in several species of the dog, the cat, the squirrel, the hare, the rabbit, the mouse, the Norwegian rat, the guineapig, the hedgehog, and the napu (*Tragulus Javanicus*). In some of these, this muscle is so closely associated with the psoas magnus as to be scarcely separable from it as a distinct muscle.

I have described in the kinjajou(f) and *Paradoxarus typus* that there is a further extension backwards of the psoas minor to the third lumbar vertebra, but the actual substantive breadth is equalised by the elision of the last dorsal vertebra attachment. In the caracal there is a still further posterior extension to the fourth lumbar vertebra. It is very probable that the divided proximal belly occasionally found in the human subject is a retrograde fissured homologue of the continuous sheet of the carnivor psoas minor. Professor Humphry has described a specimen of the psoas parvus in the *pteropopus*, with an anterior extension—viz., two or three lower dorsal co-existing with a third lumbar vertebra posterior extension.(g)

The most remarkable variety of this muscle which I have met with is a purely digastric one; it occurred in a muscular male subject. The proximal belly extended from the last dorsal to the second lumbar vertebra, terminating in the usual, but rather stronger, tendon. From the outer and distal aspect of this tendon a larger additional muscular belly arose, one inch and a half broad, and six inches long, somewhat wedge-shaped. The distal extremity converging somewhat, was finally implanted upon the anterior aspect of the psoas magnus tendon, below Poupart's ligament. The intervening tendon, instead of being lost in this distal belly, arched inwards to its usual termination at the ileo-pectineal eminence and brim of pelvis; this occurred only on the right side, the left being normal. So far as I am aware, there is not another case on record of such an anomalous variety of this muscle in the human subject. This peculiar arrangement approaches somewhat in character to that met with in the common seal. Meckel has given a very good description of it: "Le petit psoas est pour le moins douze fois plus volumineux que les deux précédents réunis. Il est partagé en deux chefs: l'externe, qui est le plus grand, naît principalement des apophyses transverses de toutes les vertèbres lombaires; tandis que l'interne, plus petit, vient des corps de la plupart des vertèbres lombaires inférieures. Le premier s'insère au fémur en dehors du grand psoas en dedans de l'iliaque; le second se fixe à l'eminence iléo-pectinée en dedans du grand psoas, qui est par conséquent embrassé par les deux chefs du petit psoas."(h) This is one of several eccentric varieties of muscles which I have met with in the human subject, finding an analogue in the seal.

As regards the minor varieties which the proximal belly presents in different subjects, they are merely differences in degree rather than in kind. The distal attachment affords a subject-matter of considerable interest. The long, slender, and flattened tendon, which is the resultant of the proximal muscle, usually continues an uninterrupted course to its pelvic marginal attachment, arching over the inner border of its greater associate, and intervening between it and the external iliac artery. Not unfrequently the tendon has expanding from its outer side, while lying on the great psoas, a strong aponeurotic fascia which covers the subcrural ligament portion of the ilio-psoas, and, passing under that ligament, becomes gradually lost in the iliac fascia. This fascia varies materially in different specimens. The most important, however, is that attachment which is effected by the direct continuation of the principal tendon into the pelvic fascia. In several specimens I have dissected the tendon from its ilio-pubic ramus attachment, and found that the greater part of its tendinous fibres expanded directly into the pelvic fascia, making the muscle into a tensor of the pelvic rather than of the iliac fascia. The general direction of the muscle being towards the pelvic cavity, and its occasional continuity with the pelvic fascia, afford just and sufficient grounds for the hypothesis that the true function of this muscle is as a direct antagonist to that of the levator ani, which may be considered as its segmented distal belly. As a tensor of the iliac fascia, it is a useless expenditure of *vis musculi*; as a flexor of the pelvis on the thorax, it is an

insufficient and almost useless vagrant; but as a tensor of the pelvic fascia, and antagonist to the levator ani, its presence in the animal economy is no longer a subject of vague wonder.

It would seem from the assertion of Professor Macalister(i) that this muscle is subject to variations in the chimpanzee. In a specimen which he dissected, he found the psoas minor present on both sides, one-thirteenth the size of the ilio-psoas. He further remarks that it was not found by Vrolick, Wilder, or Wyman. In a specimen which I dissected during last summer at the College of Surgeons, there was not a vestige of the psoas minor on either side. I found it, however, on both sides in the douroucouli—a monkey equally anthropoid in its muscular anatomy with the chimpanzee. It seems to be a very persistent muscle throughout the mammalia, from the ornithorynchus to man, and to preserve a considerable uniformity in its disposition. The question arises, Is the muscle in a transitional elevation character, or has that character been played out, and is it now in a gradational abortive stage? If the former, it is of a directly antagonistic character to other vagrant muscles which play their parts out more rapidly in the transition from lower to higher animals, and affords a characteristic illustration of the slow process of muscle-change. The latter is, however, much more probable—that it is in a state of degradation—for the following reasons:—1st. From its comparative rarity in the human subject, and its vagrancy in the chimpanzee, compared with its persistence in mammals lower in the scale of creation. 2nd. From the analogous evidence afforded by other muscles which have passed through the digastric into the monogastric stage. 3rd. From the tendency manifested in high grades of organisation to reduce the expenditure of muscular energy to the lowest degree consistent with efficiency, by accommodation; this effect being produced by transition of muscular into ligamentous tissue.

REVIEWS.

Diarrhœa and Cholera treated by means of the Spinal Ice-bag.
By JOHN CHAPMAN, M.D., &c. London: Baillière and Co. 1871. Pp. 54.

THIS pamphlet contains the farther experience of Dr. Chapman in the treatment of diarrhœa and cholera by means of the application of ice to the spine. The author first published a statement of his method, of its results and of the principles upon which it is founded, in a larger volume, which was noticed by us in this journal for November 3, 1866. Since then Dr. Chapman has been able to add largely to his materials, and the present time seemed an appropriate one for bringing the whole question once more before the Profession. Cholera is still hanging ominously upon the skirts of Europe, and we are now spared—perhaps but for a time—to put our houses in order and to reckon up our means of defence; we are disposed, therefore, to measure the attention to be given to this pamphlet less by its size than by the pressing importance of the subject of which it treats. Our readers are probably familiar with Dr. Chapman's views of the causation, pathogeny, and consequent treatment of diarrhœa and cholera, urged, as they have been, with the author's well-known earnestness, ingenuity, and forcible reasoning. Dr. Chapman holds that summer diarrhœa, choleric, and Asiatic cholera are but varieties of one process, differing, as it would appear, partly with the intensity of the chief cause, partly with the favourable or unfavourable sanitary conditions which surround the patient. Moreover, he holds that this cause is not a poison, by which he distinctly means that the cause is not a material particle or particles transmitted from sick to healthy persons. The question, he says, is not one of the introduction of new matter, but of the states of the old matter; and among these states its temperature is, in his eyes, of chief importance. In support of this hypothesis Dr. Chapman brings much evidence to show that the appearance and severity of cholera have, accidental conditions apart, coincided with an increase in the heat of the atmosphere. He believes that one immediate effect of this increase of temperature is to produce hyperæmia of the spinal cord and sympathetic nervous system, which, in its turn, sets up diarrhœa or cholera according to its intensity. The application of this is, that, in order to combat these changes, we must interfere with the chain of events, and, by removing the hyperæmia of these nervous centres, thus remove the immediate antecedent of the intestinal disorder. This end, of

counteracting the effects of heat upon the centres, is to be attained by means of the application of cold to them or as near to them as possible, and this is most conveniently done by placing bags containing ice in the course of the spinal column. The author, having proposed this method of treatment, has in the next place to determine its actual value in practice; he accordingly completes his case by bringing forward a large body of evidence to show that his method, when carried out by attendants with the minute care he has a right to enjoin upon them, is, if not uniformly, at any rate very largely, successful. Dr. Chapman's chief arguments may, then, be summed up in this wise:—1. That cholera and summer diarrhoea are effects of the same cause, acting with varied intensity. 2. That this cause is high temperature. 3. That we need not assume the existence of a special material poison. 4. That high temperature sets up cholera by producing irritation of the spinal cord and sympathetic system, with hyperæmia. 5. That such irritation and hyperæmia can be combated by means of cold, and of ice in particular, applied over the spinal column in a certain careful way. 6. That by this means, therefore, we can and do succeed in removing the choleraic state. These arguments are enforced at somewhat greater length in the pamphlet before us and are supported by an extensive array of facts in the preceding volume. It is unnecessary for us to point out the extreme importance of these statements; and, although very complicated and presenting not one but many vulnerable points, we must say that they are backed by very strong evidence used with much knowledge and skill—so much so, indeed, that they cannot be overlooked but claim our instant attention. In order to see our way through this difficult and complex question, then, let us see how far these six heads of arguments are independent, or how far the existence of any one of them depends upon the certainty of the remainder. It appears to us that they are not all necessary to each other, but the following points may be considered separately:—First, whether summer diarrhoea and cholera are the same thing in different degrees; secondly, whether one or both of these are not due to a material poison; thirdly, whether they are due rather to high temperature with extremes of atmospheric variation; fourthly, whether hyperæmia of the spinal cord and sympathetic system is a *conditio sine qua non* of cholera and choleric; fifthly, whether such hyperæmia (if present) can be reached and removed by ice applications to the exterior; sixthly, whether such applications are a means of cure; and seventhly, whether, if so, they cure by removing the hyperæmia aforesaid or by some other process. Now, these arguments need not all be true, and especially may we separate the therapeutic from the pathological portion of them. We cannot but be pleased to think that the evidence is most strong in support of that one position in which we are most immediately interested—namely, that the ice treatment is successful. This, surely, is the main point; and in the face of the miserable results obtained under the use of other methods, we cannot but form a favourable estimate of the alternative treatment here proposed. Whether this alleged success acts in the way suggested seems to us less certain. (a) The pathological views of Brown-Séquard, upon which Dr. Chapman in great measure relies, have scarcely been strengthened by recent observations; but, on the other hand, Brown-Séquard is no mean ally in framing a hypothesis. When we pass on to the question of causation, we must confess that we are now constrained to part from Dr. Chapman altogether. We cannot venture to deny all truth to his position, nor to deny the value of so bold and independent an attitude in its influence upon contemporary speculation; but we are constrained to say that as yet an overwhelming weight of evidence is against the author. That the nervous system may be the system primarily attacked, and may be the secondary source of all the bodily disorder, is possible, or even probable—at least, this view is quite as reasonable and tenable as some others of which we hear a good deal; but if Dr. Chapman denies that cholera depends in any way upon the introduction of a material poison from without, we hesitate to follow him. A high and very variable temperature may be one factor, and the conditions of the ground-water (investigated by Dr. Pettenkofer) may be another; but the introduction of some specific material poison into the system from

(a) We are disposed to think the effect upon the cutaneous nerves, with consequent reflex overtone or paresis of the vessels in the meninges of the nerve-centres (Nothragel, Loven) must be counted as a main element. And, although we fortunately have no experience of cholera thus treated, yet in fairness to Dr. Chapman we ought to say that we have found the ice-bag very useful in some other disorders. For example, we have found it strikingly successful in maniacal conditions, when applied to the cervical region; in sympathetic vomiting, likewise; and in some other conditions too numerous now to mention.

without seems to us to be almost indisputable. The observed course of cholera through Europe can scarcely be interpreted so favourably as Dr. Chapman seems to think, though we speak with deference on this matter, as Dr. Chapman has certainly looked as thoroughly into the matter as other authors. Again, the well-known cases of well-poisoning, such as that of the fountain at Constantinople and of the Broad-street pump, investigated by Snow, carry something like conviction with them. Still, we would say again, that the theoretical part of the treatise before us is one thing, and the practical part another; and we think that in our present helpless state we are bound to give attention to the treatment which seems to have produced results which, so far, promise so well. The ice treatment, like any other therapeutical process of an active kind, requires minute care in the use, and should be practised by a skilled Physician. We do not know what Dr. Chapman's engagements will allow him to do, but we would urge that, if unfortunately the occasion should arise, he should be requested to undertake the management of a certain number of patients in connexion with an assessor from the Privy Council and with a staff of efficient nurses and assistants. If the issue equal or even approach the expectations of the author, we shall indeed have great reason for thankfulness.

GENERAL CORRESPONDENCE.

THE INFLUENCE OF OCCUPATION IN THE CAUSATION OF SKIN DISEASE.

LETTER FROM MR. BALMANNO SQUIRE.

[To the Editor of the Medical Times and Gazette.]

SIR,—One of the expressed purposes of the statistics that are annually collected by the Registrar-General's department is to ascertain what kind and degree of influence is exerted by the various occupations of the British population in the causation of disease. But inasmuch as the returns take cognisance only of such cases of disease as terminate fatally, no information is afforded by them respecting the important class of cases that come under the heading of diseases of the skin.

More definite information on this point than has yet been collected is especially desirable for two reasons—the one being that the subject of the causation of diseases of the skin is to a great extent perfectly unknown ground. That it is so is pretty clear from the great diversity of causes that are found assigned, in the works of various writers of repute, to eruptions which make up so large a bulk of the sum total of cutaneous cases—as, for example, do eczema, psoriasis, pityriasis, lichen, strophulus, acne. The other of the two reasons in view is, namely, that a special influence in the causation of cutaneous disease has from time immemorial (although without any definitely established foundation) been always attributed to certain occupations. Thus, certain forms of impetigo, lichen, eczema, and psoriasis are commonly considered to be the product of special occupations, and this belief is expressed in the terms “grocer's itch,” “baker's itch,” etc. Like many popular beliefs on Medical matters, it is endorsed by a very general Professional assent—I mean that the term and the conclusion to which it commits the user of it is common not only with those who follow the occupations of baker or grocer, but is also a household word with ourselves.

Under these circumstances, I assume that it would be interesting to your readers if I lay before them statistics which I have compiled with some care from the notes of my charity practice and from those of my colleague, Mr. George Gaskoin, the conclusions expressed in them exhibiting the results arrived at from a year's work. In presenting them, I do not propose expressing any individual opinion as to the correctness of the popular views to which I have alluded, further than by saying that such views, whether existing in the Profession or out of it, have been as often ascertained to be the expression of the collective credulity as of the collective wisdom. Nor shall I profess that the results arrived at in the subjoined tables, although they represent a large number of cases, are to be considered as by any means conclusive. I shall, therefore, refrain from attempting to draw any general conclusions from them; the more so that I think the functions of a collector of statistics and those of a commentator on their results are best kept separate. In short, I will not mar the value of my figures by tacking any theory on to them.

It will be observed that they are absolutely deficient in one important respect: they do not show what particular diseases

of the skin were found to be most distributed amongst particular occupations. I have, of course, the materials for this also at command, but to import this consideration into the matter would involve the always ticklish question of the accuracy of the diagnosis made. Now, the figures as they stand are, as I believe, unimpeachable; they represent the comparative frequency of skin disease (as the term is generally interpreted) amongst the various occupations of the population, as enumerated by the last published census. They do not, by attempting to show too much, impair the confidence they may otherwise lay claim to, and in the form in which they are presented they are capable of correcting and of being corrected by any other observer's investigations of the same subject, since they broach only the broad question of the relative frequency of skin disease of all kinds amongst occupations of every kind. I am, &c., BALMANNO SQUIRE.

9, Weymouth-street, W., February 1.

* * * We are sorry that we cannot afford space for Mr. Squire's careful and ingenious tables "Showing the Influence of Occupation in the Causation of Skin Disease," but may state that in Table 1, showing the occupations of men, the comparative liability to skin disease is represented by the following numbers—that is, dividing the census-number of persons engaged in each given trade by the number of applicants at the Hospital, the results are as follows:—Bakers, 1 in 322; carvers and gilders, 1 in 300; cellarmen, 1 in 175; cigar makers, 1 in 360; clerks, 1 in 244; dyers, 1 in 55; gasfitters, 1 in 310; gardeners, 1 in 142; hatters, 1 in 350; jewellers, 1 in 235; leather-cutters, 1 in 51; masons, 1 in 230; musicians, 1 in 350; paperhangers, 1 in 120; school teachers, 1 in 230; shopmen, 1 in 60; tanners, 1 in 290; travellers, 1 in 230; umbrella makers, 1 in 220; warehousemen, 1 in 260; weavers, 1 in 35; wood carvers, 1 in 160; box makers, 1 in 190; fur-workers, 1 in 190; milliners and dressmakers, 1 in 74; needlewomen, shirt makers, and sewing machinists, 1 in 270; shopwomen and assistants, 1 in 43.

[We look upon the numbers as altogether too small to represent the relative frequency of skin disease amongst various classes in London as a whole, but rather of that part of London whence Mr. Squire's patients came. We have erased all occupations which yielded fewer than one case of skin disease for 360 persons; but what we retain shows that Mr. Squire is on solid ground, as is evident from the preponderance of cases of skin disease amongst dyers, amongst bookbinders, hatters, tanners, leather-cutters, weavers, fur-workers, all of whom have to deal with animal products—including musicians, who (if they do not play the bagpipe, and so delight in a national efflorescence) may be said to handle catgut and horsehair.—ED.]

PENSIONS FOR POOR-LAW MEDICAL OFFICERS.

LETTER FROM MR. J. COLVILLE.

[To the Editor of the Medical Times and Gazette.]

SIR,—As Mr. Corrance has kindly promised to introduce a Bill this session for the benefit of Poor-law Medical Officers, and as I believe the President of the Local Government Board will not be unfavourable to any measure that will be of service to them, may I ask Mr. Corrance through your valuable journal to do so as early as possible in this session, that his Bill may not at a later period be shelved. I have been a Poor-law Medical Officer myself, and know something of the unpleasant things Medical men have to submit to; but the position would be much improved if the Medical Officer had a pension to look forward to, and I think that every gentleman who has given up a great portion of his time for twenty years ought to be entitled to claim one, although he may have been engaged in private practice also. I have a friend, about 50 years of age, who finds the work too much for him, and would gladly resign if he had a pension; but as he expects an Act will be passed by-and-bye, he goes on working to the injury of himself, and certainly the poor would benefit by being under a younger man. I believe, myself, that no one should be allowed to hold a Poor-law appointment after 55 years of age, and that a pension should be granted to every man who had served for twenty years, to be graduated according to the time of service, so that his age did not exceed 55.

The guardians of unions generally wish the Government to take the matter up, as they are averse to paying the pension directly out of their rates; and the proper

course for the Local Government Board to take would be to get an Act passed enabling them to pay the pensions out of the Consolidated Fund, as they now do half the salaries, and that each parish should be charged a small percentage on their rates as a contribution for keeping up the fund. This arrangement, I believe, would satisfy everyone, and I trust the present session will not pass without its becoming law.

I am, &c., J. COLVILLE.
Sloane-street, February 15.

A REJOINDER FROM DR. DONKIN.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the *Medical Times and Gazette* of to-day's date the reviewer of my work on "Diabetes and Bright's Disease" has replied to my strictures on his review, which recently appeared in this journal.

In his letter of to-day there is not one single word which is, strictly speaking, a reply to my letter, except a carping over a couple of trifling typographical errors which have escaped correction. It follows, therefore, that the verdict of every impartial reader must be against him on the points at issue between us.

In to-day's issue he censures my book as being quasi-scientific. I must, therefore, carefully analyse and dispose of the only additional evidence he has advanced in support of this opinion.

It never was my intention to cram my book with a lengthened dissertation on the chemistry of the urine, whether healthy or morbid, or to give an elaborate detail of the various methods in use for the detection and estimation of urine-sugar, or to compete with works on Medical chemistry fully embracing this subject. On the contrary, my work being of a purely clinical character, as stated on the title-page, I condensed my observations on this particular point to what is simply *essential* for the use of the Practitioner.

I find, on a reference to the book itself, that I have devoted about two hundred pages exclusively to the subject of "diabetes," but only four of these are devoted to the examination of diabetic urine. It appears to me, therefore, not a little remarkable that "Reviewer" has restricted himself, almost exclusively, both in his critique and in his reply to-day, to what I have already shown, and shall now further show, to be a few misrepresentations of what is contained in these four particular pages only, instead of entering into a philosophical analysis of the numerous propositions I have advanced, and questions I have argued, in relation to the symptoms, pathology, natural history, and treatment of diabetes. These certainly are the subjects towards which we ought to direct our concentrated attention, in order to obtain a more definite and accurate acquaintance with, and a more powerful control over, this mysterious and formidable disease. To obtain this knowledge is infinitely more important than wasting time in idle arguments on a subject now so perfect and well understood as the examination of diabetic urine. But the mind of "Reviewer" seems to be incarcerated within the precincts of the laboratory, and unable to appreciate the value of clinical investigation, observation, and experiment. He has only advanced one argument, or rather quasi-argument, against my work; this I shall now dispose of, and then I am done with him.

In referring a second time to the detection of urine-sugar, he quotes from my book *a portion of a sentence only*, suppressing the remainder, which conveys my meaning of the whole. Thus, he observes that I teach that specific gravity, taken in conjunction with quantity, supplies "a very reliable guide as to the quantity of sugar voided in any particular case of disease." This, he says, is a guide on which I seem exclusively to have relied. But why suppress the remainder of the sentence, which is continued thus: "and an index by which we can safely predicate whether the quantity is *small* or *large*; but when it is considered necessary to determine the *exact* quantity of sugar in any given case, we must have recourse to a more definite procedure." Surely this is plain enough; and in the next two sentences I recommend, for this purpose, the polarising saccharometer of Soleil as the simplest and most ingenious method of examination. The assertion of "Reviewer," that I have relied exclusively on specific gravity, in conjunction with quantity, in the estimation of sugar, is followed by the irreconcilable imputation that I rely on specific gravity alone; and, moreover, to show me that this is an unsafe guide, I am referred to the lectures of Dr. Bence Jones on Pathology (which, I assure him, I have carefully studied)—as

if I had stated anything contrary to a fact so well known to every Medical student.

Now, in reply to the whole of this misrepresentation, I must observe that, if "Reviewer" will examine several tables and observations contained in my work, he will find that I have demonstrated that specific gravity alone is no indication of the presence of diabetic sugar, and that the urine may be saccharine even when its density is below 1010². But the quantity and specific gravity of the urine, when taken in combination, afford a most valuable clinical index of the severity of the disease, and a means of closely approximating, though not of exactly determining, the quantity of sugar voided in any given case of diabetes. To this everyone will bear testimony who has had much clinical experience of this affection. Hence the table constructed by Dr. Henry, and carefully corrected by the painstaking sagacity and ample experience of the late Dr. Prout. It was from this table, published in the latest edition of Dr. Prout's work "On Stomach and Renal Diseases," p. 26, that I roughly estimated the quantity of urine-sugar voided in the first two cases only subjected by me to the skim-milk treatment, and published in the *Lancet* so far back as October 23, 1869, and recently included in my work. But it is necessary for me to state that all the subsequent estimates of the quantity of urine-sugar given in my book are the result of accurate and careful examinations.

I am, &c.,

February 10.

A. T. DONKIN, M.D.

BALSAM OF COPAIBA IN SMALL-POX AND SCARLATINA.

LETTER FROM DR. A. ROWAND.

[To the Editor of the Medical Times and Gazette.]

SIR,—I should feel obliged by insertion in your journal of the following remarks on the treatment of small-pox and scarlet fever by balsam of copaiba:—From our knowledge of the effects of the balsam on the skin and mucous membranes, I was induced to try it, in four- or five-drop doses, mixed in ʒij. syrup, and ʒij. mucilage of gum arabic, three or four times a day, in the confluent small-pox of a person who had never been vaccinated. It caused no nausea, but, on the contrary, created a keen appetite, which continued till recovery. No pitting took place, and no local application was used but glycerine and water. I tried the same mixture in scarlet fever, with most satisfactory results. Under its use, the tongue and sorethroat got rapidly clean and well, followed by a keen appetite, and by none of the usual sequelæ. The secretion of urine was copious, and began to increase in quantity after two or three doses. At first it was of the colour of ale and a little ropy, but by the third day quite clear and normal. My theory of the action of the remedy is, that it alters or destroys the character of the virus, and eliminates it out of the system by the skin and kidneys more particularly; for the recoveries have been unusually rapid. In both cases I prescribed milk, beef-tea, wine, and spirits, according to need.

I am, &c., A. ROWAND, M.D.,

Visiting Physician and Surgeon to the Marine and Emigrant Hospital, etc., Quebec.

61, St Louis-street, Quebec, January 26.

ELIMINATION IN SMALL-POX.

[To the Editor of the Medical Times and Gazette.]

SIR,—Without desiring to reopen the question of Dr. Johnson's pathology of cholera, one can hardly allow the publication of his last utterance to pass unnoticed, inasmuch as, in the portion of his paper devoted to treatment, a general pathological principle is enunciated at variance with what is generally taught nowadays in our Medical schools. The West Kent Medico-Chirurgical Society were therein instructed that "the main principle to bear in mind is, that the discharges are as essentially curative as is the cutaneous eruption of small-pox." One really would like to know Dr. G. Johnson's method of treating small-pox. Are the patients at King's subjected to the humorous and humoral treatment of closed doors and windows, roaring fires, red blankets, red curtains, hot drinks, *et hoc genus omne* of former days? Surely they ought to be, if the Professor believes his own eliminative theory. If we are at all correct in our classification of the fevers, the Professor can hardly object to the following amplification of his statement:—"The discharges of typhoid are as essentially curative as the cutaneous eruption of small-pox, the cutaneous and pharyngeal sym-

toms of scarlet fever, and the membranous infiltrations in diphtheria, etc." But to confine ourselves to the presumed analogy with small-pox. Does anyone besides Dr. Johnson believe that the eruption of small-pox is essentially curative? Some ten years ago, at least, we used to be taught that the eruption was one of the phenomena of the disease, just like the pain in the back, vomiting, pyrexia, etc., and *not* the phenomenon of the familiar Daimon, Nature, doing her best to expel the offending virus by the skin. If anything is to be done with the eruption, the principle rather should be to limit it by free ventilation and light clothing; for it is an undoubted fact that the intensity of the disease corresponds with the diffuseness of the eruption. In a case of severe confluent variola, think what a large abscess would be formed were all the pus collected at one place, the severity of the secondary fever depending largely upon the immense formation and septicæmic nature of the pus! And yet we are asked to believe that this is essentially curative.

I should not have ventured to criticise such a distinguished member of the Profession had anyone else taken up the gloves, but I cannot find any comment upon this antiquated pathology in this week's issue.

I am, &c.,

M. B.

A MODEL SELF-SUPPORTING DISPENSARY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your article on "The Evils of Provident Dispensaries," in your last week's issue, induces me to give you the outlines of a scheme which I have personally carried out for the last five years with great success. My connexion with several "societies" which had their head-quarters at Liverpool, Dudley, Lichfield, Birmingham, etc., but which were carried on by local agents in this neighbourhood, led me to adopt my present scheme, in consequence of the flagrant impositions which came under my notice almost daily.

The collectors were sometimes irregular in their payments to me; at other times I found out certain persons had been paying into the society some time before I was made aware of the fact; I consequently lost the benefit of their payments in the interval between the quarters. The collectors also assumed to themselves a position of considerable importance, while one or two of the societies collapsed, leaving the unfortunate members in the lurch. Members did not much like the fortnightly visits of these collectors; and I did not see why the Doctor should get but 3s. per annum, when the members paid 4s. 2d.

These collectors, anxious to increase their percentage of income, took in many persons who were in a position to pay for their Medical attendant in the ordinary way, while the Doctor was powerless, and was never consulted as to admissions or rejections. These and many other circumstances induced me to give up my connexion with these societies altogether, and I determined to have a dispensary of my own. After some consideration, I framed the following set of rules, which have worked very well, and given no trouble whatever:—

1. Subscriptions of members of this Dispensary must be paid in advance, and benefits do not commence till one month has elapsed from date of entrance.
2. Benefits do not include month of confinement, diseases of pregnancy, enthetic disease, or Surgical dentistry.
3. Any member wishing to withdraw from the Dispensary must give six months' notice of that intention.
4. Members must find their own bottles, leeches, trusses, instruments, bandages, etc.
5. If any member requires medicine or attendance while the subscription is in arrears, the same will be charged for in the ordinary way.
6. Members are requested to attend at the surgery from nine to ten o'clock in the morning; and if they require to be visited at their own homes, they will prevent delay or disappointment by sending their messages, if possible, before nine o'clock in the morning, so that arrangements may be made.

These rules are not publicly advertised, and the Dispensary relies for publicity upon its members. Each member or household has a small memorandum-book, in which are entered these rules, the names of the subscribing members, and the dates of their payment, and when the next payment is due. The subscription is 3s. per head per annum, and the money is brought to the surgery the day upon which it is due by the members or some person on their behalf. A charge of 3d. is made at the time of entering for the small book and the entrance. Half a year's payment in advance is generally made, though a dis-

cretionary power is exercised in the case of very poor persons, so as to make it in their case a quarter's payment in advance, especially where a large family are members.

The month of accouchement is not included, for obvious reasons, and the diseases of pregnancy refers only to miscarriage and abortion. Enthetic disease and Surgical dentistry are optional matters, so far as I am concerned, and thus I am able to charge for attendance in some special cases of syphilis, secondary or tertiary. In cases of fracture I make a small charge for bandages and the use of splints. Other matters connected with the remaining rules speak for themselves.

By these means I am enabled to refuse admission to any person who I think is in a position to pay as a private patient. The members generally pay regularly and punctually, and, as they bring their payments to the surgery, it causes little trouble.

I thought these few facts might assist some Practitioners who wish to start something of this sort, and there may be many like myself, who do not care much for their connexion with these collecting societies. I shall be glad to reply to any question which I may not have sufficiently explained.

I am, &c., JUNIUS MEDICUS.

REPORTS OF SOCIETIES.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

THURSDAY, FEBRUARY 8.

Dr. DRUITT, President, in the Chair.

A SPECIAL meeting was held to hear a paper from Mr. W. Acton on the question, "Whether the Contagious Diseases Acts shall be Repealed, Continued, or Extended to the General Population?" founded on the minutes of evidence lately given before the Royal Commission.

Mr. ACTON said, it was first necessary to define a "prostitute." The police took it to mean a woman residing in a brothel, or soliciting in the public streets, or who was informed against. Before taking action, the police required not simply one, but several proofs combined. There was thus little danger of respectable women being molested. The Commission, in fact, admitted that the police had discharged their duties with moderation and caution. He (Mr. Acton) next described the condition of the prostitutes in London and large towns as terribly diseased and degraded. They infected the men of the army and navy, and under the voluntary system did not present themselves at Hospitals until the evil had gone to extreme lengths, and they left before they were cured. He (Mr. Acton) regretted that the Commission had not taken evidence as to the prevalence of venereal disease among the civil population, as one-half of the out-cases at Hospitals were of this character. Another regrettable omission was the absence of any comparison between the British and foreign armies. This deficiency he endeavoured to supply from statistics obtained by himself, and showed that there was much less disease in Paris and Brussels. Mr. Acton next gave a succinct history of the Contagious Diseases Acts, which were first applied to the peculiar conditions of the army and navy. The marked diminution in the more serious forms of disease where the Acts had been introduced was shown by statistics; also that there was now less public solicitation, and that it had been the means of reclaiming women from their evil courses. Formerly, at Plymouth, girls as young as 13 were found in houses of ill-fame, whereas now there was not one known under 17. Allusion was next made to the formidable resistance raised against the Acts, which had led Parliament to refer the whole question to a Royal Commission, and this had given birth to the present report and minutes of evidence. Mr. Acton replied *seriatim* to the objections most worthy of notice. He said that, did he believe that the Contagious Diseases Acts had an immoral tendency, he would give them up, at once and for ever, notwithstanding the value he set upon them on sanitary grounds. Even Mrs. Butler admitted that fallen women could not be left as they were. She was in favour of providing Hospital accommodation for them, and would detain them, not by legal compulsion, but by Hospital regulations. That the examining of prostitutes was not repulsive to the women was evident from the fact that they flocked to Hospitals, where exposure was greater, in preference to being treated privately at home. The recommendation of the Committee, that the periodic examination of the

women should be discontinued, Mr. Acton looked upon as evidently a compromise among the members of the Commission. In conclusion, Mr. Acton hoped that forthcoming legislation would not undo the good that had been effected, but would extend it.

A vote of thanks was accorded to Mr. Acton for his able, careful, and temperate paper.

Dr. DRYSDALE would propose that the State should provide voluntary accommodation for venereal patients, as it now did for scarlet fever, small-pox, and other infectious diseases. He would allow a divorce to wives who had been infected by their husbands.

Mr. HOLLAND said that it was not essential that the examination should be made by men; it might very well be left to women. It was not giving the women a certificate that they were safe.

Dr. MOUNT said, in reply to one of the previous speakers, that India was no more under martial law than England. The Act had been worked in Calcutta with good results. Colonel Playfair had told him that at Aden, also, the system had eradicated syphilis. He was, however, of opinion that no legislation should be imposed until the people had been educated up to it. He would like to see a compromise agreed upon, and leave the rest to the march of time.

Dr. GIBBON said that a compulsory system of dealing with lewd women had long been in force at Cambridge. They were sent to the "Spinning House," which had been set up from funds left by Hobson, the famous horse-dealer, whose "choice" had passed into a proverb.

Mr. MILTON thought it shameful that innocent women and children should be allowed to suffer from a disease which might be exterminated if prostitutes were submitted to examination.

Dr. WEBSTER was opposed to any extension of the Acts to the civil population, for in Paris the system left a very large amount of disease still rife, and was a great incitement to immorality.

Mr. DEAKIN maintained that, by the old law of the country, the police had power over prostitutes, and that by the Contagious Diseases Acts this power was restricted and surrounded with special precautions.

The CHAIRMAN said it was satisfactory to find that the advocates of the Acts were conceding the points which had been urged against them on the ground of morality. Under certain aspects the examination was disgusting. But it was shown from the evidence that the authorities were not content with physical treatment, but also supplied the women with means of escape from their disgraceful trade. It appeared beyond doubt that these Acts had had a beneficial moral result; that was enough. It might be considered a national disgrace that prostitution had been allowed to go such lengths, and that it was now repressed, not on account of its own horrible nature, but because of the disease it happened to bring with it; still, it was repressed, and that was enough for the present. He admitted there had been on his part—he would not say a change of opinion, but a change of front on this subject.

Mr. ACTON hoped the progress of opinion made during the last twelve months would continue. He should like to see all parties joining hands. The great amount of disease in Paris was among those whom the system did not reach, and who brought disease and vice to that city from every part of the world.

OBITUARY.

CHARLES TOWNSEND, M.R.C.S., &c.

WE record with deep regret the death of the above Surgeon, which occurred at his residence, Pakenham-road, Edgbaston, on the 29th ultimo. Mr. Townsend entered the Profession as a pupil to Mr. Pye Chavasse; he was afterwards a student at University College. He became a Member of the College of Surgeons and a Licentiate of the Apothecaries' Society in 1844. Soon afterwards he obtained the appointment of Resident Surgeon-Accoucheur to the General Dispensary, which office he held for three years. On relinquishing this appointment, Mr. Townsend commenced general practice, and was elected as one of the Honorary Surgeons of the Birmingham and Midland Eye Hospital. He was a skilful operator; he was kind and courteous to his colleagues and the officers of the Hospital, and was greatly esteemed by his patients and a large circle of friends. He was married in 1854, and has left a widow and four children.

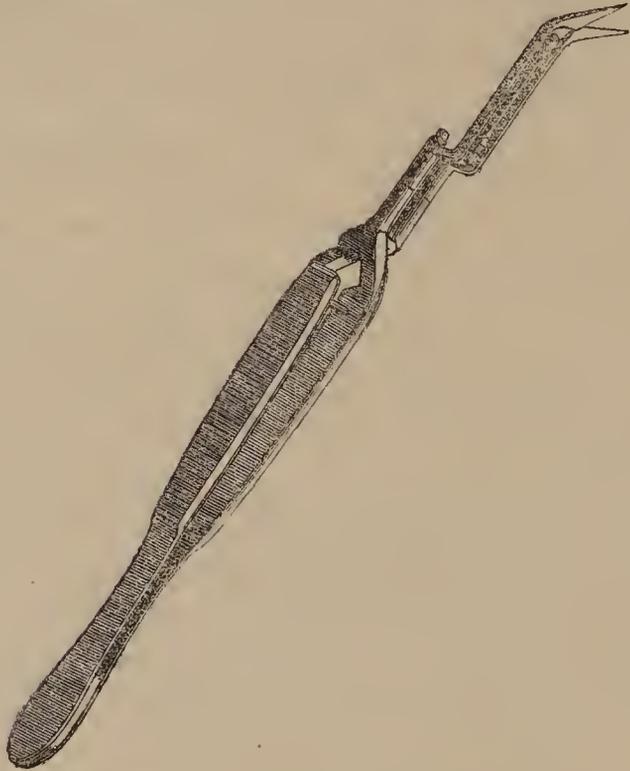

NEW INVENTIONS.

FORCEPS SCISSORS FOR OPHTHALMIC SURGERY.

By CHARLES HIGGENS, F.R.C.S.,

Assistant-Surgeon to the Central London Ophthalmic Hospital.

THE idea of these scissors was first suggested to me by Mr. Baker. The handle of the instrument is like that of a pair of ordinary forceps, but the two sides cross each other. The cutting blades are placed at an obtuse angle with the handle, and work upon a rod-pivot placed between the shanks of the blades. The blades are open when the instrument is not in use, and are closed by pressing the handle between the finger and thumb, in the same manner as forceps are closed.

Originally, the instrument was made for dividing those thick portions of opaque capsule sometimes left after operations for cataract, which are too tough to be torn through with needles, and the removal of which with forceps is attended with so much danger to the eye. It will be found useful, too, for cutting the iris in iridectomy and for enlarging corneal incisions. As the action of the scissors is quite simple, the necessity of those awkward back-handed positions is obviated. The inconvenience of these positions every ophthalmic Surgeon must have experienced occasionally in using ordinary scissors. The instrument is made by Messrs. Krohne and Sesemann, Duke-street, Manchester-square.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, February 8:—

Dobie, Stanley Locker, Irthington, Carlisle.
Jackson, Francis Edward, Chertsey, Surrey.
Stoney, Percy Butler, St. Bartholomew's Hospital.

The following gentlemen also on the same day passed their first Professional examination:—

Dalton, Charles Bernard, Guy's Hospital.
Morton, Albert Samuel, London Hospital.
Walker, William Newman, University College.

UNIVERSITY OF DUBLIN.—TRINITY COLLEGE.—The following gentlemen have passed the examination for the degree of Bachelor of Medicine, held on the 6th and 7th inst.:

Browne, Valentine E.	Mease, Andrew Leslie.
Elliott, Charles N.	Thorhill, Hayman.
Kelly, Thomas J.	Walsh, Samuel.
Maddock, William.	Woodhouse, Stewart.

At the examination for the Mastership in Surgery, held on the 9th and 10th inst., but one candidate passed—

Ferguson, William Claudius.

At the Spring Commencements, held in the Examination Hall of Trinity College on Shrove Tuesday, the following degrees in Medicine and Surgery were conferred:—

Baccalauri in Medicinâ.

Elliott, Carolus Nelson.	Thorhill, Hayman.
Maddock, Wilhelmus.	Walsh, Samuel.
Mease, Andreas Leslie.	Woodhouse, Stewart.
O'Farrell, Nicolas Sweetman.	

Magister in Chirurgiâ.

Ferguson, Wilhelmus Claudius.

Doctores in Medicinâ.

Bradshaw, Wilhelmus Hanna Delamaine.
Nason, Johannes Wilhelmus Washington.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BRIGSTOCKE, CHARLES ARTHUR, M.R.C.S., L.S.A.—Medical Officer and Public Vaccinator for the Calne Union.

DUNSMURE, JAMES, jun., M.D., F.R.C.S.E.—Extra-Physician to the Meadows House Royal Hospital for Sick Children.

PLAYFAIR, WILLIAM, M.D. Edin., F.R.C.P. Lond., F.R.C.S.—Physician-Accoucheur and Physician for Diseases of Women and Children at King's College Hospital, Lincoln's-inn-fields.

POORE, GEORGE VIVIAN, M.D. Lond., M.R.C.P. Lond.—Assistant-Physician to Charing-cross Hospital, *vice* Alexander Silver, M.D. Univ. Aber., M.R.C.P. Lond., promoted to Physician.

RIX, BENJAMIN, M.R.C.S.E., L.S.A.—House-Surgeon to the Infirmary, Tunbridge Wells.

MILITARY APPOINTMENTS.

MEDICAL DEPARTMENT.—Assistant-Surgeon Alexander Minty, M.B., from the Rifle Brigade, to be Staff Assistant-Surgeon, *vice* Brodie Cruickshank, M.B., appointed to the 80th Foot; Assistant-Surgeon George Ryan, from the 19th Foot, to be Staff Assistant-Surgeon, *vice* William Francis Burnett, appointed to the 68th Foot.

RIFLE BRIGADE.—Surgeon-Major Alexander Scott Fogo, M.D., from the Royal Artillery, to be Surgeon, *vice* Augustus Patrick Meyers Corbett, M.D., who exchanges.

ROYAL ARTILLERY.—Surgeon Augustus Patrick Meyers Corbett, M.D., from the Rifle Brigade, *vice* Surgeon-Major Alexander Scott Fogo, M.D., who exchanges.

ROYAL MALTA FENCIBLE ARTILLERY.—Surgeon Ludovico Bernard, M.D., to be Surgeon-Major.

BIRTHS.

ARGLES.—On February 8, at Hermon Lodge, Wanstead, the wife of Dr. Argles, of a daughter.

COATES.—On February 5, at Moutpellier House, Great Malveru, the wife of F. W. Coates, M.D., of a son.

FAUGHT.—On January 6, at Morar, Gwalior, India, the wife of J. G. Faught, Staff-Surgeon, of a daughter.

KIDD.—On February 13, at 23, Northbrook-road, Lee, S.E., the wife of Leonard Kidd, M.B., Surgeon Army Medical Staff, of a daughter.

PEARLESS.—On February 14, at The Vicarage, Sevenoaks, the wife of Chas. D. Pearlless, M.R.C.S., L.R.C.P., of a son.

SMITH.—On February 6, at 68, Harley-street, W., the wife of Dr. Gilbert Smith, of a daughter.

SNELL.—On February 13, at 8, Castle-gate, Nottingham, the wife of Enoch Snell, Surgeon, of a daughter.

MARRIAGES.

ARCHER—NASH.—On February 8, at Royston, Herbert Ray Archer, M.B., son of Wm. Archer, F.R.C.S., of Boyne-terrace, Notting-hill, to Georgiana, daughter of the late Wm. Thos. Nash, Esq., of Royston.

COLLET—LAMB.—On February 8, at St. Stephen's Church, Bayswater, Henry, second surviving son of Henry James Collet, M.D., Worthing, to Agnes, eldest daughter of Robert Boyd Lamb, Esq., 45, Prince's square, Bayswater, late H.B.M. Consul, St. Thomas, W.I.

EARLE—MACDONALD.—On February 8, at St. Peter's Church, Southampton, Nathaniel Earle, M.A., M.B., of The Sock, Winchester, to Annie Augusta Hay, only daughter of Dr. Donald Macdonald, Bengal Medical Service.

HEUDE—ROUGHTON.—On February 8, at St. James's, Paddington, William Wentworth Heude, M.D. Edin., Surgeon-Major H.M. Madras Army (retired list), and only son of the late Captain William Heude, 46th Madras N.I. (H.E.I.C.S.), to Emily Wood, fourth daughter of James Roughton, Esq., late of Barrow-upon-Soar, Leicestershire.

LELAND—COLLETT.—On February 8, at the parish church, Charmouth, J. S. Leland, M.D., of Kirkby Stephen, Westmoreland, to Nannette Emma, eldest daughter of Henry Collett, Esq., of Richmond, Surrey.

TURNER—DUKE.—On February 12, at St. Mary-in-the-Castle, Hastings, Richard Turner, Surgeon, Lewes, to Elizabeth Blackman Duke, eldest daughter of the late Walter Duke, Surgeon, Hastings.

WALKER—HINDLEY.—On February 8, at St. Stephen's Church, Shepherd's-bush, Joseph Walker, M.D., of 22, Grosvenor-street, to Isabel Phoebe, youngest daughter of the late Charles Hindley, Esq., of East Acton, Middlesex.

DEATHS.

- BEEVOR, CHARLES, F.R.C.S., at 129, Harley-street, on February 8.
 BRADBURY, BECKETT, M.D., at his residence, Huddersfield-road, Oldham, on February 1, aged 48.
 BREWER, ELLEN GERTRUDE, youngest daughter of Alexander Brewer, Surgeon, of Ebbw Vale, Monmouthshire, at 201, Queen's-road, Dalston, on February 8, aged 16.
 EVANS, KATHERINE BRORONE, relict of the late Thomas Evans, M.D., formerly of Stockwell-park House, Surrey, at her residence, Rumsey House, Kidmelly, on February 10.
 JONES, JOHN, Surgeon, at Tir Bach, near Swansea, on February 5, aged 48.
 RODEN, ROSEANNAH MARY, the wife of William Roden, M.D., F.R.C.S., at Morningside, Kidderminster, on February 1, aged 50.
 WILLEY, EDITH, the dearly beloved wife of Henry Willey, M.B., of Bromley, Kent, at Winchester, on February 7, aged 23.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

- BIRKENHEAD BOROUGH HOSPITAL.—Assistant House-Surgeon. Candidates must be registered Medical Practitioners. Applications to the Chairman of the Weekly Board, on or before February 26.
 BIRMINGHAM QUEEN'S HOSPITAL.—Resident Physician and Medical Tutor. Candidates must be Graduates in Medicine of a University of Great Britain or Ireland. Applications, with diplomas and testimonials, to Mr. H. C. Burdett, on or before March 22.
 BLOOMSBURY DISPENSARY.—Resident Medical Officer. Must be duly qualified. Applications to the Secretary, on or before February 17. Election on the 19th.
 KENT AND CANTERBURY HOSPITAL.—Dispenser and Assistant House-Surgeon. Must be duly qualified and registered. Applications to Mr. T. Southee, on March 15. The duties will commence on March 31.
 KING'S COLLEGE.—Assistant Physician for Diseases of Women and Children. Applications to Mr. J. W. Cunningham, Secretary.
 MARGATE ROYAL SEA-BATHING INFIRMARY.—Resident Surgeon. Must have some legal qualification to practise. Applications to the Secretary, on or before February 29.
 MIDDLESEX HOSPITAL, W.—Physician. Full particulars may be obtained upon application to Mr. H. M. Evans, Secretary-Superintendent, on or before February 20.
 NORTH WALES COUNTIES LUNATIC ASYLUM, DENBIGH.—Assistant Medical Officer. Must be duly qualified and registered. Applications and testimonials to Mr. John Robinson, Clerk to the Visitors, on or before February 20.
 SALOP AND MONTGOMERY COUNTIES LUNATIC ASYLUM.—Medical Superintendent. Must be duly qualified to practise Medicine and Surgery. Applications and testimonials to the Clerk to the Visitors, on before March 1.
 VICTORIA HOSPITAL FOR CHILDREN, GOUGH HOUSE, QUEEN'S-ROAD, CHELSEA.—Assistant-Surgeon. Must be F. or M.R.C.S.E., and not practising pharmacy. Applications to the Secretary, on or before February 28.
 WEST KENT GENERAL HOSPITAL, MAIDSTONE.—Physician. Must be duly qualified. Applications and testimonials to the Secretary, on or before February 19. Election on February 27.
 WESTMINSTER GENERAL DISPENSARY, GERRARD-STREET, SOHO, W.—Hon. Surgeon. Must be F. or M.R.C.S.E., not practising pharmacy or midwifery. Applications and testimonials to the Secretary, on or before February 19. Election on the 22nd.
 WESTMINSTER GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified and registered. Applications and testimonials to the Secretary, on or before February 19. Election on the 22nd.
 WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Mr. M. Norris, on or before March 1. Election on the 7th.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

- Caxton and Arrington Union.—Mr. Thomas G. Brook has resigned the First Caxton District; area 12,217; population 2400; salary £68 5s. per annum.
 Chorlton Union.—The Sixth District is vacant; salary £90 per annum.
 West Derby Union.—Mr. John S. Gratton has resigned the Walton District; area 8940; population 5717; salary £50 per annum.

APPOINTMENTS.

- Acbridge Union.—Alworth M. Bayliffe, M.R.C.S. Eng., L.S.A., to the Eleventh District.
 Driffield Union.—Wm. Wood, M.R.C.S. Eng., L.S.A., to the Middleton District.
 East Preston Union.—Cleveland Smith, M.R.C.S. Eng., L.S.A., to the Broadwater District.
 Manchester Township.—J. F. W. Tatham, L.R.C.P. Edin., L.F.P. & S.Glas., to the St. Michael's District.
 Newark Union.—Richard H. Dawson, M.R.C.S. Eng., L.S.A., to the Clifton District.
 New Winchester Union.—Julian Willis, M.R.C.S. Eng., L.R.C.P. Edin., to the Third District.
 Rothbury Union.—James M. Pringle, M.R.C.S. Eng., to the Whittingham District.
 St. Pancras Parish.—Ferdinand A. Purcell, M.D. Queen's Univ. Ire., M.R.C.S.E., to the Seventh District.

DR. W. L. PLAYFAIR has been appointed Professor of Midwifery at King's College, and Senior Obstetric Physician in King's College Hospital, vacant by the retirement of Dr. Priestley.

DR. WIMBERLEY has been appointed Physician and Surgeon to the Coventry General Hospital.

THE cholera still continues in St. Petersburg and Revel.

THE Bethnal-green Board of Guardians have resolved to appoint an officer for the enforcement of the vaccination laws in the parish.

A DEPUTATION from the Thames Shipping Inspection Committee, accompanied by Dr. Dickson and Dr. Letheby, have had an interview with the President of the Local Government Board, and urged that in the Public Health Bill the port of London should be constituted a distinct sanitary district, and that power should be given to the authorities to raise money for a systematic supervision of the shipping.

THE Royal Artillery Hospital at Cannanore, by order of Lord Napier, is to be closed, and the establishment discharged from the date of the removal of the E Battery, 20th Brigade. The Artillery sick, in future, are to be treated in the Hospital of the European infantry regiment stationed at the same cantonment. This is the fourth regimental Hospital that has been closed during the past twelve months.

MR. CHARLES R. ROWE, late Medical Officer to the Wimborne Division of the United Patriots National Benefit Society, has been presented with an illuminated address, a very handsome chased silver inkstand, and a massive silver pencil and penholder, in recognition of the very efficient way in which he had discharged his duties in connexion with the Society for a number of years.

A PETITION to Parliament, signed by 106 Physicians, Surgeons, and general Practitioners of Liverpool, was presented to the House of Commons on Tuesday, praying that the Contagious Diseases Acts of 1866 and 1869 may be immediately repealed, and that no future legislation may be enacted on the subject, which, whether by registering prostitutes, providing for the compulsory examination of women, or otherwise, shall recognise prostitution as a necessity.

AT a public meeting held at the Town Hall, Durham, the Mayor in the chair, Mr. John Pratt, Surgeon, was presented with a testimonial, consisting of a gold centre-seconds stop-watch and appendages, and a purse of gold, for his public services to the poor during the prevalence of the late outbreak of small-pox.

ROYAL COLLEGE OF PHYSICIANS.—The following lectures of the present year will be delivered at the College, Pall-mall East, on each of the following Wednesdays and Fridays, at five o'clock:—Goulstonian Lectures, by Dr. Hensley, "On the Mechanism of Respiration, Circulation, and Digestion," on February 23, 28, and March 1; Croonian Lectures, by Dr. Bristowe, "On Disease and its Remedial Treatment," on March 6, 8, and 13; Lumleian Lectures, by Dr. Quain, "On the Diseases of the Muscular Walls of the Heart," on March 15, 20, and 22.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—SESSION 1871-72.—The next meeting will be held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Saturday (this day), February 17, at 7.30 p.m., Robt. Druitt, M.R.C.P. Lond., F.R.C.S., President. Dr. MacCormack, Medical Officer of Health for Lambeth, will be balloted for as an Ordinary Member. Mr. Sneade Brown, of 28, Oxford-square, Hyde-park, will be balloted for as an Associated Member. Dr. Albert J. Bernays, Professor of Chemistry, St. Thomas's Hospital, will read a paper on "The Precautions which should surround Toxicological Investigations in Medico-legal Cases, and on Evidence in Courts of Law."

THE MURDER OF TALBOT IN DUBLIN.—It may be interesting to some of our readers to learn that, at the Commission of Oyer and Terminer, on February 9, Robert Kelly, the hero of the recent deplorable miscarriage of justice in Dublin, whose first trial assumed such unexpected medico-legal features, was tried for shooting at Head-constable Mullins with intent to murder, and was found guilty. Mr. Justice Morris sentenced the prisoner to fifteen years' penal servitude, and in passing sentence took occasion to remark that it was owing only to Providence that he was not on his trial for actual murder. If the policeman had died, the Court said the learned judge would have had no option but to sentence him to death.

HEALTH OF SCOTLAND.—3174 deaths were registered in the eight principal towns during January, of whom 1607 were males and 1567 females. Allowing for increase of population, this number is 121 above the average number for the month of the last ten years, and is the highest number recorded in January since the commencement of the Registration Act. A comparison

of the deaths registered in the eight principal towns shows that during January the annual rate of mortality was 23 per thousand persons in Perth, 31 in Paisley, 33 in Glasgow, 34 in Greenock, 36 in Edinburgh and in Aberdeen, 45 in Dundee, and 46 in Leith. Of the 3174 deaths registered, 1178, or 37 per cent., were of children under 5 years of age. In Perth 18 per cent. of the persons who died were under 5 years of age; in Paisley, 29 per cent.; in Edinburgh and in Dundee, 32; in Leith, 36; in Aberdeen, 37; in Glasgow, 41; and in Greenock, 44 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 1039 persons, thus constituting 32 per cent. of the mortality. This rate was exceeded in Edinburgh, Dundee, and Leith from the prevalence and fatality of small-pox, and in Aberdeen from small-pox and measles combined. Small-pox appears to be still on the increase, the number of deaths from that cause having risen from 354 during December to 461 during January. The deaths from small-pox therefore constituted 44.5 per cent. of the whole mortality for the month. In Leith 39.5 per cent. of the deaths were caused by small-pox; in Dundee, 36.3; in Edinburgh, 24.4; in Perth, 18.0; in Aberdeen, 15.2; in Paisley, 2.3; and in Glasgow 1.9 per cent. No deaths were recorded from that disease in Greenock.

THE following is a list of Medical candidates of H.M.'s British Army who were successful at the competitive examinations held at London in August, 1871, and at Netley in February, 1872, after having passed through a course at the Army Medical School, Netley:—

Order of merit	Names.	Studied at	Total No. of marks.
1.	Cottle, E. W.	Oxford and London	5118
2.	Ash, R. V.	London and Aberdeen	4625
3.	Connolly, P. S.	Dublin	4510
4.	Dwyer, C. E.	Dublin	4447

17.	Donovan, J.	Dublin and Cork	2300

STRYCHNIA IN VOMITING.—M. Debauge observes that although nux vomica and strychnia have been employed in the treatment of various affections of the digestive organs, he is not aware of any account of strychnia being used for the relief of obstinate vomiting occurring in hysteria, pregnancy, suppressed menses, and disease of the uterus. This form of vomiting is dependent for the most part on asthenia, and occurs in debilitated subjects; and sometimes, after resisting all sedative remedies, it is arrested by the impression made on the gastric mucous membrane by stimulant drinks. In obstinate cases, however, these do not suffice, and then strychnia becomes a valuable remedy, and may be to this end administered internally and hypodermically.—*Lyon Médical*, January 7.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Questioner.—The subject of the lines by "Martialis Junior" is not one that we can admit into our columns.

Fox's Palatable Cod-liver Oil with Quinine.—A Medical correspondent, who has derived great benefit from this preparation, asks us to make the fact public, and recommend it to such of our readers as may (themselves or their patients) be suffering from debility and imperfect nutrition.

Hoffmann's Anodyne, or, as we now call it, the spiritus ætheris sulphurici compositus, contains some ethereal oil, in addition to sulphuric ether and alcohol. It was invented by the celebrated Frederick Hoffmann, Professor at Halle, who called it his *mineral anodyne liquor*.

American.—Between the claims of Morton and of Jackson to the credit of the discovery of the anæsthetic properties of ether inhalation, we feel it impossible to decide. At first we believed Morton was the man; subsequent evidence induced us to give our vote to Jackson; and there we stop. Both evidently worked in common, and drew their suggestions from the same facts.

MEDICAL EVIDENCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Since communicating with you on this subject, a singular confirmation of my remarks has been made by Baron Martin, in the case of Christiana Edmunds. He said: "A poor woman, by the way, was seldom afflicted with insanity, but it was common to raise a defence of that kind when people of means were charged with the commission of crime. He had heard a Doctor say 'that all mankind were mad, more or less; but that had little to do with the case under consideration.' The state of mind which excused crime was well fixed in our law; there were many diseases of which the mind was liable as well as the body. There was the idiot who was born without any mind whatever. Again, there was the raving madman; and if he had a homicidal tendency, he would be no more responsible than a tiger. But the most numerous cases of the kind were of persons subject to delusions."

As in the case of the idiot the judge has mentioned, which shows how the law was framed, mind was then considered as an abstract principle, independent of brain function. If it is the law, so much the worse for the condition of the law, as it proves incontestably that such a law must have been made during a period of entire ignorance as to the true function of the brain during health and disease. The sooner such a law is remodelled in conformity with our increased knowledge on a subject of such vital importance as the abnormal conditions of brain function shown in insanity, the more will the law, if so amended, command the respect of the intelligent of the nation. It is unfortunate that Medical men should not be more on their guard when giving their evidence in a court of justice. One authority used these words—"He regarded hers as a case on the borderland between crime and insanity."

This mode of expression may be poetical and imaginative, but its very ambiguity and indefiniteness are eagerly caught at, and used with a species of morbid avidity by the non-Professional mind. Its captivating sound, words signifying nothing, are so convenient as to be used in the peroration of the leading article of the *Times* on this case. It is, no doubt, oftentimes the case, that it demands great power of mental acumen and analysis to discover the phases of insanity; but is it expedient or even politic to put such weapons into the hands of those who are too ready to use them without scruple, to the disadvantage of our Profession—one which necessitates the exercise of special mental powers to become competent in the mastery of abnormal states of cerebral function? Such men as Drs. Forbes Winslow, Maudsley, Connolly, Woodward, and others of the same class, know full well the difficulties that have to be encountered in battling successfully with diseased function of brain, without embarrassing the case by expressions so indefinite at such a time and place as a court of law. Mark the consequence! Mr. Serjeant Ballantine says—"A more noble Profession than that of Medicine, as it is constituted in this country, never had existed. He knew of none for which he entertained feelings of higher respect and consideration."

Mr. Serjeant Ballantine, having delivered himself of this patronising eulogy, thought that was quite sufficient in justification in knocking down that which he had so exalted, so that the fall would be proportionately great; for he continues: "It was on that account that he (Mr. Serjeant Ballantine) felt indignant when men used the honourable character attached to that Profession to propound views before a jury not calculated to elucidate the question under consideration. He could not help thinking they rather went into the witness-box confident in their own powers of verbiage, which did not convey any clear ideas." Until very recently the patho-physiological treatment of the insane was but imperfectly understood; we are now, as it were, raising the veil which has enshrouded cerebral affections in such profound mystery. Dungeons of the most dismal description, iron cages, manacles, chains, and all sorts of demoniacal devices were resorted to for the treatment of the insane. These are now things of the past. Mental diseases are now treated mentally. But the law which has drawn forth such trite and pertinent remarks from Baron Martin and Mr. Serjeant Ballantine was framed in olden times, and coeval with that period when the insane were treated as wild beasts. Having been a pupil of Sir Charles Bell, I have, since 1835, made the brain and nervous system my special investigation. So late as 1836 the insane catacombs in Baltimore had human victims chained hand and foot, and fed in the manner of the tigers, lions, and leopards of the Zoological Gardens. Would that the Medical Profession could return the eulogy of Mr. Serjeant Ballantine with regard to the present state of the law as regards the insane. Insanity is admitted by the most competent authorities to be too often hereditary, as are other abnormal functions. How is this affected when the taint of the disease has to be propagated through such a tortuous and infinitesimally minute channel of communication? Imagine a microscopic sperm-cell uniting with an equally minute germ-cell; this union producing a vital electric shock, accompanied by a nervous vibration or undulatory state of special nervous molecules, the medium yet undiscovered

—as were the capillary nerves, until lately demonstrated by Dr. Lionel Beale—this shock is conveyed to the ovaria, causing the throwing-off of a minute ovum, which travels through the Fallopian tubes to the uterus, where it germinates and goes through all the phases of embryologic existence. The marvel is, after such a complicated process, that the original taint of the father should be so preserved as to retain and manifest all its characteristics in the future child. No one who has made brain diseases his study but must be aware that the disappointment consequent on the affections being frustrated in the object of their choice is one of the most fruitful sources of insanity. It was the affection for her Medical adviser which developed into an active existence the latent insanity of Christiana Edmunds. It should not be forgotten that at the middle age of woman's life she is specially susceptible of morbid attachments, when there is a predisposition from hereditary or other causes. In this instance the Medical man was the victim of this mentally diseased woman's fancy. It is one of the perils attendant on the exercise of the Medical Profession—one which demands the most enlarged charity to one thus unfortunately situated. Had it not been Dr. Beard, it would have been someone else. The immediate or proximate cause of the development of insanity in Christiana Edmunds was at a period when the change in the function of the uterus takes place, which is so frequently accompanied by mental aberration.

I am, &c., ROBT. H. COLLYER, M.D.

199, Brompton-road, S.W., January 22.

Infection.—Yes. The 29th and 30th Vict., cap. 90, section 39, enacts that —“If any person knowingly lets any house, room, or part of a house, in which any person suffering from any dangerous infectious disorder has been, to any other person, without having such house, room, or part of a house, and all articles therein liable to retain infection, disinfected to the satisfaction of a qualified Medical Practitioner, as testified by a certificate given by him, such person shall be liable to a penalty not exceeding £20. For the purpose of this section, the keeper of an inn shall be deemed to let part of a house to any person admitted as a guest into such inn.”

Malta.—Several articles have lately appeared in *Public Opinion* (Malta), calling the attention of the authorities to the absolute necessity for sanitary legislation in that place. It is clearly shown that the drainage is very bad, the water-supply insufficient, and the prevalence of zymotic and preventible diseases excessive. One writer on the subject says, “I would gladly compare the mortality of this island with other places, could I have access to statistics: but, as I have before remarked, for reasons only known to the authorities they are scrupulously withheld.” If this be the fact, and we see no reason to doubt it, the authorities are evidently afraid of exposures.

EPILEPSY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Commencing like a child's story-book, “Once upon a time” some writer—either Sir W. Gull or Dr. Druitt—stated that on claret it was easy to command the capricious spirit of composition, and on such stimulant mentally to create a new and happy being without tonsils, coccyx, thymus, or indigestion. Possibly so; but after the fatigues of the Professional day, commend a theoretical teetotaler to a glass of gin-sling, a specimen of which stands at one's elbow, the prescription very simple—R. gin ʒj., sugar ʒij., lemon ʒj., ice *quantum suff.*, soda-water ʒviii.; M.—an excellent tippie in moderation, and highly recommended as a fever drink by several learned coroners. Under this seductive influence the pen runs easy. Work makes the workman; by writing we learn to write; and the congenial theme of the moment has not been ridden too hard—a rich mine of discovery lies still unexplored. From the Registrar-General's Returns it appears that in England annually about 3000 people die of epilepsy, the majority of fatal cases being younger amongst females. Turning to the Army Medical Department records, it appears that on home service, in 1869, out of 239 soldiers admitted into Hospital 1 died, and 96 invalided; no case in the Household Cavalry. Abroad the numbers treated amounted to 150 (about), of whom 3 died at Bermuda, Madras, and the Cape. Excepting Japan and New Zealand, instances occurred at each foreign station—Madras (28), Bombay (37), the Cape (17), and so on. In the navy the admission higher generally; it appears, in 1868, out of 94 cases on home stations, 1 died, 45 invalided. In both services the numbers treated on home stations considerably in excess of those abroad. The recruit on enlistment often conceals any mention of an epileptic tendency—a condition easily re-induced by drink and sexual excesses; and a scoundrel hoping to obtain his discharge will cunningly feign disease. Instead of convulsions connected with constitutional disease, cerebral or spinal organic lesions, catalepsy, or an infinity of phases pitiable and demanding sympathy, our hearts hardened by previous impostures, we look out for other reasons, and with distrust and disgust proceed to diagnosis. One decrepid Assistant-Surgeon may, perhaps, be sitting with his wife, brooding over the addition of twins, and the order to go abroad which will break up his little world of domestic happiness; another playing whist, his hand full of trumps; or a third cramming up temporary knowledge for examination—when the summons arrives to visit a soldier in a fit. The cry of “Wolf”—no matter how often repeated—must never be ignored; always put in an appearance. The man may be drunk—ten chances to one he is—but, on the other hand, he may be dying. On one occasion, at country quarters, whilst on the stage dressed up as a ferocious bandit, flourishing pistols, and calling “Revenge!” “Despair!” “Ha ha!” and so forth, I had the luck to be called away to an impostor feigning epilepsy—and in long boots and Spanish curls one had to go. [This is in strict confidence; in those days we were wild and wayward, but (with slow promotion) we are not wayward now.] Late at night, in a barrack-room, about ten men disturbed from sleep are holding down on his bed Private Adam Elijah Walker (soldiers have such patronymics), who is struggling, plunging, cursing, and yelling; in fact, going through the stereotyped antics. If, like the justice, “in fair round belly with good capon lined,” beware of a kick—the opportunity is too good to be lost; the inclination pardonably tempting. Or, if fool enough to put your fingers near his mouth, our interesting patient is perfectly justified in indulging the luxury of a sharp bite. Do not put a cork between his teeth—it may stick in his throat; use a strong spoon; even then you may injure the jaw. They say an Italian recently swallowed either a soup-ladle, a carving-knife, or a two-pronged fork, but—credat Judeus!—tell it to the Marines

or the *British Medical Journal*. Put Walker on the floor, clear the space all round, remove all restraint (although pressure in certain directions sometimes will avert an attack). After lightning comes the thunder. If the fit be genuine the accumulated nerve-force finds relief in jactitation of the muscles. Let him turn and roll and gnash his teeth. One man is sufficient to remove obstacles, and quietly to steer erratic movements. Supposing the symptoms feigned, Adam Elijah, taking every care not to hurt himself, must occasionally open his eyes to arrange the next move: the pupils will be sensitive, and any allusion to a hot poker or a cold drenching will, as we say in the army, “be noted.” Whereas a *bond fide* victim will have a pale, cadaverous face, likewise a cold skin, our friend's Cockney countenance will be flushed with exertion, the body hot, the tongue not bitten; the atmosphere will exhale an aroma of pine-apple rum, and a pinch of snuff or pepper will induce sneezing. *Difficile est satiram non scribere*. Now, changing the vein, and treating the subject as it deserves—most seriously—no disease appears more disheartening than epilepsy, where it is impossible to conquer the *fons et origo mali*. All honour to Radcliffe, Russell Reynolds, Beaman, Sieveking, and others who have done their share of exhaustive research and careful observation, leading to successful treatment. As in the street, the railway-carriage, or the ball-room, the practised Physician notices phthisis, cancer, neuralgia, renal, cardiac, or ovarian disease impressed on different faces, so when the eye rests on a tall, pale, handsome woman, with chiselled rigid features, peculiar chin, and a reserved, quiet manner, epilepsy somehow suggests itself, especially if the eyeballs are prominent. Take the case of a high-minded lady, who, going the round from one Physician to another, improves for a time, only to relapse. Fond of her husband, her children, and her home, perhaps placed in a position requiring brilliant powers of conversation, ready tact, and energy, in vain she struggles against failing memory and listless torpor. It may happen at an important dinner-party when that terrible fear comes on, she sees those vivid colours, hears the dreaded air from *Faust*; there may be a pleasing tingling of the feet, a cold sensation about the stomach, a creeping along the back, a numbness of the hand, or throbbing of the temples; like Mathias in the tale of the Polish Jew, she hears the bells. She hears no more—for the rest is a blank.

The barrack clock strikes one; outside the sentry lustily shouts “All's well”; the fire and the lamp burn low, and the “bright moon that tips with silver all the fruit-tree tops” peeps in pleasantly between the curtains. However, before laying down the pen, although fully alive to the value of large doses of bromides and iodides, also of the preparations of arsenic, iron, zinc, strychnine, and quinine, the advantages of electricity, climate, general hygiene, etc., I cannot believe that any man can baffle this eccentric subtle disease unless he is a good sound GENERAL PRACTITIONER.

P.S.—The above prescription can only be accurately dispensed at a military mess.

Etiquette.—It was the custom of the great Dr. Johnson, when shown into a room where there were books on shelves, always to spend the spare time in looking over the titles and dipping into the volumes. It is something to know what books there are on any given subject. Books on a table, put out evidently to amuse visitors, of course are meant to be freely handled; but it is a violation of etiquette to scan too closely the books on a man's study-table, so as to seem to pry into the subject of his immediate studies. The offender is probably a very young man.

Practitioner.—Our columns are far too full at present. But let us say that no experiment in the laboratory, and no vivisection, can do away with the *bond fide* results of clinical observation. A man who has been living, “not wisely, but too well,” with a skin the colour of a Ribston pippin, and a paunch as tight as a drum, takes five or ten grains of calomel, and a black draught next morning. By this he is relieved of a hatful of offensive scybala and a good flow of greenish-yellow bile. Can this be disproved because a dog, with perhaps an almost empty state of abdominal veins, does not, after calomel, secrete more bile than usual through a fistulous hole leading into its gall-bladder? In giving the calomel or other mercurial to increase the secretions of the liver, of course we assume, and ought to have sufficient evidence, that the liver is too full, and has bile to be got rid of.

USEFUL ADVICE TO SUFFERERS FROM CONSTIPATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As constipation *par excellence* constitutes one of the most troublesome and most common afflictions of mankind, I feel obliged to give publicity to the following experience, although it is not a very pleasant subject to write upon in public. A few days ago, I made as it were by accident the experience that defæcation is greatly forwarded by a pressure on the perineum between the anus and the end of the os coccygeum. In case of difficult defæcation, or imperfect depletion of rectum, the patient should put his hand on his back, and hence lower it gradually until it will have reached the last vertebra of the spine. In this manner he will enable himself without any inconvenience to exert with his finger a pressure on the right spot. If the pressure be supported by rotatory and rubbing movements of the finger, and by the natural internal pressure, its effect will be all the greater. A careful application of my advice will undoubtedly prevent many diseases of the bowels, especially piles, dilatation of the rectum, prolapsus of this organ, etc. I am, &c., H.

COMMUNICATIONS have been received from—

Dr. WHITMORE; Mr. HEWITT; Mr. SNELL; M.B.; Mr. BAYNTUN; Dr. JORDAN; Mr. T. PIPER; Dr. MACCORMAC; Dr. C. C. RITCHIE; Mr. HARTLEY; Mr. METCALFE JOHNSON; Dr. STEVENSON; Mr. MATTHEWS; Dr. VINEN; Dr. POWELL; Mr. MAUNDER; Mr. PERRIN; Mr. D. A. SCOTT; JUNIUS MEDICUS; Mr. F. CHURCHILL; Mr. H. MORRIS; Dr. J. RUSSELL; Dr. HAMILTON; Mr. H. S. HEATH; Sir JAMES PAGET; Mr. PEARLESS; Dr. OGLE; Mr. WOOLCOTT; Mr. COLVILLE.

BOOKS RECEIVED—

Photographic Clinique of the Hospital for Diseases of the Skin, No. 1—Report of the Commissioners of Sewers, with Return of Amounts Paid to the Metropolitan Board of Works—Wolff on Zymotic Disease—Harley

on the Urine and its Derangements—St. Thomas's Hospital Reports, vol. ii.—Fergus on the Sewage Question—Convocation Report on Intemperance—Hoyle on Our National Resources and How they are Wasted—Fourth Report on the Operation of the Contagious Diseases Acts—Bayes on Typhoid Fever, with Cases—Curran's Further Evidence in favour of a Hill Residence for European Soldiers in India—Burke's Observations on the present Epidemic of Small-pox—Penning's Notes on Nuisances—MacCormac on Consumption.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Notes and Queries—Dark Blue, February—Madras Monthly Journal of Medical Science—Bath Express—Lincolnshire Chronicle—Lincoln Gazette—Pharmaceutical Journal—Dublin Journal of Medical Science, February—Medical Press and Circular—Standard.

APPOINTMENTS FOR THE WEEK.

February 17. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. Dr. Albert J. Cornays, "On the Precautions which should surround Toxicological Investigations in Medico-legal Cases, and on Evidence in Courts of Law." ROYAL INSTITUTION, 3 p.m. Mr. Wm. B. Donne, "On the Theatre in Shakespeare's Time."

19. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Victor de Méric, "Casts and Drawings on a Case of Congenitally Deformed Hands and Feet." Dr. C. Bell Taylor, "Observations on the Contagious Diseases Acts, with an Analysis of the Statistical Results as deduced from all the Parliamentary Papers which have been issued on the subject from the commencement to the present time."

20. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited.—Dr. C. T. Williams, "Malformation of the Chest (a Living Subject);" "Ulceration of the Vermiform Appendix, causing Local Peritonitis." Dr. Moxon, "Expansion and Softening of Small Grey Tubercle." Dr. Nunneley, "Congenital Occlusion of Hepatic Ducts." Dr. Greenhow, "Embolism and Softening of the Left Anterior Cerebral Lobe; Aphasia." Mr. W. Adams, "Depressed Fracture of the Skull in a Child, with Injury to the Brain;" "Circumscribed Abscess in the Inner Condyle of the Femur opening spontaneously." Mr. Gay, "The Head and Neck of a Femur excised for long-standing Disease of the Joint." Dr. Pye-Smith (for Dr. Shepherd), "Malformed Heart of a Child." Mr. Durham, "Hydatid Tumour of the Thigh." Mr. Waren Tay, "Tumour of the Arm; Congenital Hypertrophy." Mr. W. Haward, "Fibrous Tumour of the Testicle." Dr. Andrew Clark, "Disseminated Melanosis." Mr. Thomas Smith, "Axillary Aneurism, for which the Subclavian Artery had been Ligatured."

ROYAL INSTITUTION, 3 p.m. Dr. W. Rutherford, F.R.S.E., "On the Circulatory and Nervous Systems."

21. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

SOCIETY OF ARTS, 8 p.m. Meeting.

22. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Odling, F.R.S., "On the Chemistry of Alkalies and Alkali Manufacture."

23. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Mr. Bryant, "On Two Cases of Recto-Vesical Fistula treated by Colotomy." Mr. Warrington Haward, "On Cases of Distension of the Antrum." Dr. H. Weber, "On a Case of Hyperpyrexia in Rheumatic Fever treated by Cool Baths and Affusions." Dr. George Johnson, "Case of Syphilitic Paralysis of Third Nerve cured by Full Doses of Mercury after Failure of Large Doses of Iodide of Potassium."

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Meeting.

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Goulstonian Lectures—Dr. Hensley, "On the Mechanism of Respiration, Circulation, and Digestion."

ROYAL INSTITUTION, 9 p.m. Mr. H. Leslie, "Social Influence of Music."

VITAL STATISTICS OF LONDON.

Week ending Saturday, February 10, 1872.

BIRTHS.

Births of Boys, 1210; Girls, 1282; Total, 2492.

Average of 10 corresponding weeks, 1862-71, 2264.6.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	764	760	1524
Average of the ten years 1862-71	754.1	740.9	1495.0
Average corrected to increased population	1645
Deaths of people aged 90 and upwards

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Popula- tion, 1871.	Small-pox.	Measles.	Scarlet Fever.	Diphtheria.	Whooping- cough.	Typhus.	Enteric (or Typhoid) Fever.	Simple continued Fever.	Diarrhoea.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.70 in. The highest was 29.84 in. on Wednesday at noon, and the lowest 29.49 in. on Monday morning.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

† Through an error which was discovered on the revision of the enumerated numbers at the Census Office, the correct population of Manchester at the middle of 1871 was 351,171, and not 356,099, as published in recent Weekly Returns. The number for the middle of 1872 (352,759) shows, therefore, an increase of 1271 upon the corrected number for 1871.

ORIGINAL LECTURES.

LECTURES ON
EXCISION OF THE HIP-JOINT.By HENRY HANCOCK, F.R.C.S.E.,
Senior Surgeon to Charing-cross Hospital.

GENTLEMEN,—Paul of Egina appears to have been the first to recognise the propriety of excising joints for disease. "If," says he, "the end of a bone near a joint be diseased, it must be excised."

Avicenna was the first to draw especial attention to the possibility of excising the head of the thigh-bone, but he did not approve of the proceeding, observing, "But if the head of the thigh-bone be diseased, it is better to abstain from operation."

The Germans claim the honour of priority in the performance of this operation for Schmalz, of Pirna, in Saxony, who was called to the daughter of a priest at Stürve, who had for six months suffered from disease of the hip-joint. The girl appears to have been in a most unfavourable condition for operation. Not only was the head of the *left* thigh-bone displaced upwards and backwards, but the right hip-joint was suppurating, although the head of the thigh-bone still remained in the cotyloid cavity, the child being in the last stage of weakness and hectic fever. Schmalz, having by the probe discovered that the neck of the right femur was carious, made up his mind that excision of the head of that bone was, although a doubtful, still the only method which held out a hope of doing good. He therefore made an incision four inches long over the great trochanter, exposing the latter. "To my great astonishment," he writes, "I found the neck of the bone detached from the trochanter. I required neither bone-forceps nor saw, but, seizing the neck with a strong pair of pincers, after rotating it strongly, I extracted it with the head with very slight hæmorrhage. Nature had thus performed excision of the head of the femur." Schmalz continues—"The patient recovered. I observed that the leg operated upon became as short as the other, the femur having been drawn up by the action of the muscles. Both sides of the pelvis are the same height, whilst the entire pelvis is slightly inclined forwards. Near the left hip-joint the elevation caused by the luxated bone may easily be felt. On the operated side this elevation of course is absent, but the great trochanter occupies nearly its normal situation. The two feet are turned slightly outwards, the legs are equal in length, and the child totters somewhat in walking."

After reading the above, we can scarcely agree with those who describe the case as a mere trial, and assert that no real excision of the joint or of the head of the femur appears to have been performed until April, 1821, when Mr. Anthony White, of Westminster Hospital, successfully removed the head and neck of the femur.

No one can reasonably doubt that Schmalz's operation was undertaken with the full intention of excising the head and neck of the femur, nor can we understand how the mere fact of the neck being separated from the trochanter whilst the head of the bone remained in its proper situation can by possibility deprive him of the credit due to his having initiated this operation. I knew Mr. Anthony White well; I had the advantage of being one of his pupils. If he were now living he would be the first to acknowledge the priority of Schmalz, for no one more thoroughly despised attempts to assume credit due to others than he did. Mr. White frequently talked to me of this operation, and regretted that it was not more generally adopted. He claimed, it is true, to be the first *English* Surgeon—he never claimed to have been the *first* Surgeon who performed it. Whilst, therefore, the priority is due to Schmalz, the operation was performed for the second time in Europe, and for the first time in this country, by Mr. Anthony White, in the year 1821.

The patient, John West, when 9 years old, slipped down stairs and slightly hurt his left hip. After a few weeks, he was observed to limp in his gait, and complained of pain and stiffness in his groin; and subsequently he lost the power of locomotion, had the usual symptoms of hip-joint disease, and the head of the thigh-bone became displaced and rested far back on the dorsum ilii. He suffered very acutely, and underwent the usual treatment of cupping, blistering, etc., with all kinds of constitutional remedies for many months, but without benefit, and after a time suppuration in the joint took place,

which was evacuated from the front and upper part of the thigh. Temporary relief was thus obtained, but during two years a succession of similar abscesses formed around, and small portions of bone were frequently protruded through the sinuses which remained, and more especially from those formed over the pubes. At the end of the third year he was in the greatest possible state of emaciation; no longer enduring acute pain, but exhausted by the previous suffering, and by an overwhelming discharge from numerous apertures. The integuments over the displaced bone had become at various parts absorbed, and the bone was readily found at these points to be in a state of superficial caries. The knee had long been embedded and immovably fixed on the inner side of the opposite thigh, and the right side, on which he could alone lie, was cruelly galled with bedridden ulcerations. The formation of fresh abscesses had for some months ceased, and further diseased processes were not apprehended.

In the month of April, in consultation with Mr. Travers, it was decided to remove the head of the bone. An incision was made through the integuments, beginning about an inch above the point where the head of the femur was deposited, and then carried down the centre of the bone, to a point as far as was considered necessary for sawing through it. The integuments were then separated on each side, making their dissection as close to the bone as possible. The straight saw was then used, and the femur divided without difficulty about two inches below the top of the great trochanter, and including the little trochanter. So closely adherent was the upper portion of the bone to the ilium, that Mr. White was compelled to introduce a spatula between the sawn ends, and use it as a lever, by which he was enabled to detach the subjacent parts, and to finish the operation. A very small quantity of blood was lost, and the boy suffered less than was anticipated. The bone had lost but very little of its original form; the round ligament and the cartilage were gone, and the head of the bone was slightly affected by superficial caries. Neither the finger nor the probe could detect any morbid condition of the ilium, but the original site of the acetabulum could not be found. The knee was now gently raised outwards, the removal of the fixed head of the femur admitting of that movement. Such is the history of this celebrated case. We can scarcely credit the temerity of one who evidently has never performed this operation in his life deliberately attempting to detract from its merit and describing it as a mere excision for deformity.

Here we have the patient in the greatest possible state of emaciation, exhausted by previous suffering and an almost overwhelming discharge from various apertures, with the integuments ulcerated and the bone to be felt in a state of caries, with the knee embedded in the opposite thigh, and the opposite side of his body cruelly galled by bedsores.

True it is that the formation of fresh abscesses had ceased for some months, and that further diseased processes were not apprehended; but still the discharge and the numerous apertures remained, the ulcerated integument remained, the bedsores remained, the caries of the head of the bone remained; yet we are told that this operation, undertaken for the sole and express purpose of removing this carious bone, for enabling the various wounds and sinuses to heal, was nothing but "a proceeding for getting rid of the deformity resulting from an arrested hip disease."

Had the author in question consulted Mr. White's own paper in the *Lancet*, he would have found Mr. White distinctly stating: "Considering that the strength of the boy from the profuse discharge kept up by the caries of the bone was never likely to be restored, I was induced, after mature reflection, to propose an operation for the removal of the femur as far as it should be found in a state of caries, which, from the examination with the probe, appeared to extend probably a little lower than the great trochanter." Clearly showing that Mr. White's object in recommending the operation went far beyond the "mere removal of deformity."

This case, moreover, is interesting, not only from its being the first operation of the kind ever undertaken in this country, but from the opposition offered to its performance; for, proceeds Mr. White, "my colleague, the late Mr. Morel, saw the case, concurred in the proposition, and offered to be my assistant." However, the late Mr. William Smith, member for Norwich, to whom the mother of the boy was known, informed the late Sir Everard Home of the proposed proceeding. The boy, at his request, was conveyed to St. George's Hospital, and after an examination of the case with his colleagues, a written document signed by him and them was given to the mother of the boy, declaring that the contemplated operation would not only be useless, but impracticable, and most likely, if attempted,

attended with loss of life. "I was not present," says Mr. White, "at this consultation, and only knew of it by being shown this document or protest by the child's mother. Of course after such a published declaration I abandoned the case altogether." And no wonder! for the proceeding can scarcely be regarded as either courteous or liberal. But, fortunately for the interests of science, after an interval of some months, Mr. Travers, whilst attending at Mr. Smith's house in the city (to which the boy had been removed with his mother), was requested to look at him, and being told of the proposed operation by the mother, at once saw and understood the principles and plan of the procedure.

What a striking contrast does Mr. Travers' conduct present. He at once wrote to Mr. White, not only expressing his entire concurrence in the measure, but also kindly offering to assist him in carrying it into effect, notwithstanding the formidable protest which had been published shortly before. Fortified, therefore, by the opinion of this distinguished Surgeon, Mr. White performed the operation in April, 1821, and removed the head, neck, and trochanters, the caries being superficial, and not extending lower than the lesser one. The patient rapidly acquired strength and flesh, and in a few weeks every sinuous opening had healed.

In 1823, Hewson, of Dublin, removed the head of the femur for caries; but the patient died three months after from abscess penetrating the cotyloid cavity into the pelvis. In 1829, Schlichting divided a sinus and extracted the head of the femur, which was detached and carious. The patient recovered in six weeks.

These examples were followed by Heine (of Wurtzburg), Gluge, Vogel, Textor, Sedillot, and others. But brilliant and successful as was White's case, the operation was entirely lost sight of and neglected in England, and, with the exception of a case said to have been performed by the late Sir Benjamin Brodie, for twenty-four years it was performed exclusively in Germany.

We read in Le Fort's treatise that, up to the year 1862, notwithstanding Bonino's celebrated work on the subject, it was performed for the first and only time in France by Ph. Roux in the year 1847. It has never been repeated since; as the operation performed by Maisonneuve was not a *resection*, but a *section* through the great trochanter to create a false joint for the cure of ankylosis. Even so late as 1861, Malgaigne is reported in the *Gazette Médicale* to have declared that it was impossible to discuss the merits of this operation, as they knew nothing about it, nobody having done it or seen it done.

Nor does the proceeding appear to have found more favour in Scotland. As recently as November 25, 1865, we find Dr. Donald MacGregor, of Glasgow, thus writing to the *Lancet*:—

"A successful excision of the hip-joint has been so rarely, if ever, accomplished in Scotland, that I trust the following case may not be uninteresting:—A youth, aged 17, strumous, suffered from rheumatic pains in his hip, which increased so much that in the course of a month he was obliged to give up work. Matter subsequently formed, and the discharge continued for several months. Hectic fever ensued, the patient was fast sinking, and, to save his life, Dr. MacGregor excised the joint.

"He made an incision six inches long over the great trochanter. This was followed by a gush of blood, not from any large vessel, but from general oozing, and was easily arrested. The capsular ligament was partially destroyed, but the ligamentum teres was entire. The head of the bone turned out; the bone was sawn off through the great trochanter, and in so doing the saw passed through a large abscess in the cancellated structure of the bone. The acetabulum was healthy, and no vessel required a ligature. The whole neck of the femur was carious. For fourteen weeks the patient walked on crutches; in five months he was able to walk with the aid of a stick only."

At length, Mr. Anthony White found a worthy successor in Sir William Fergusson. This distinguished Surgeon, in 1845, not only resuscitated the operation, but, by his success and precepts, gave the proceeding so great an impulse that it has now taken a deep and doubtless a permanent root in the domain of British Surgery. To Sir William Fergusson, therefore, a credit scarcely inferior to that of White is justly due. He has just reason to be proud of many notable achievements during the progress of his career, but I very much question whether he has ever done anything by which he has conferred greater benefits upon mankind than by the revival and re-establishment of this operation, whereby many, previously doomed to protracted and irremediable suffering and a miserable death, have been relieved—frequently saved. A case attended by such results can scarcely be passed by unnoticed:—

"J. C., aged 14, was admitted into King's College Hospital November 20, 1844. Always enjoyed good health until the January preceding, when he first experienced severe pain in the left groin, which continued unabated notwithstanding the use of leeches, blisters, seton, etc. Between three and four months afterwards the pain became most harassing in the left knee. Early in October a large collection of matter formed over and behind the great trochanter, which burst spontaneously, and there has been continued discharge ever since. The condition of the limb is such as is usually noticed in the advanced stage of hip-disease. It appears considerably shorter than the sound one, and is much bent both at the knee- and hip-joints.

"There is constant pain in the knee, but there is little in the hip unless the limb be moved, or the head of the femur forced against the pelvis. After remaining in the Hospital three months the distortion of the limb had increased, and in consequence of lateral curvature in the lumbar region of the spine, with corresponding obliquity in the pelvis, as well as further flexion at the hip and knee, the shortening was more apparent than ever. The heel of the affected side was between four and five inches above the other. The shaft of the femur sloped obliquely downwards and inwards, and the knee rested on the inner side of the thigh of the sound limb. The head of the bone could be felt through the soft parts lying on the dorsum ilii, and so isolated that the finger could be passed round it in all directions.

"There were several small sinuses contiguous to the large one, but it could not be ascertained that any of them led to diseased bone or communicated in any way with the pelvis. There was a large circular sore over the great trochanter, and a profuse discharge of thin matter. The patient made no complaint of pain unless the limb was moved, but seemed weaker and more dejected than when first admitted. He could lie with comparative comfort only on his right side. Pulse varied from 100 to 110; appetite indifferent; tongue very red; cheeks frequently flushed; had profuse night sweats; and the feet and face were slightly oedematous.

"On March 1, 1845, a longitudinal opening, about six inches long, was made in the line of the femur, extending from over the head of the bone to a little below the trochanter major, and the tissues were separated from the shaft of the bone a little below that process, so as to permit a curved needle to be used for the introduction of a chain-saw. This latter step was attended with considerable difficulty, owing to the depth and obliquity of the bone, and, when accomplished, proved to be of little value; for after several trials the instrument broke, and Sir William was compelled to adopt another mode of procedure. With a sharp-pointed bistoury he separated all the soft parts from the neck of the bone and the trochanters, and then, by causing the knee to be moved across the opposite thigh, and using the femur as a lever, the head and portion of the bone thus isolated was so thrust out of the wound that he could with facility apply the ordinary saw for the requisite section. Not being satisfied with the condition of the interior of the bone at the surface exposed by the saw, he enlarged the opening and removed about three-quarters of an inch more, then closed the wound with a few points of uninterrupted suture, and covered it loosely with a pledget of lint. No vessel of sufficient magnitude to require a ligature was divided. The cotyloid cavity was filled with a fibro-gelatinous mass, similar to the lining of a sinus.

"There was scarcely any shock succeeding to the operation, and the chief complaint was pain in the knee, which for some days after was more severe than at any former period. The symptomatic fever was very slight, and disappeared entirely within the first ten days. In ten weeks, the wound having almost closed, the splint was removed, and the patient allowed to move about the wards upon crutches. He continued to improve in strength, and ultimately moved about without trouble or pain, and wearing his clothes as in perfect health.

"The length of bone removed was four inches and a quarter, measured through the curve of the neck and shaft, and the limb is now (June 24, 1845) about two inches and a half shorter than its fellow. The cartilage was almost entirely removed from the head of the bone, and the surface was in a state of ulceration. The trochanter and rest of the shaft seemed in a healthy condition, with the exception that the cancellated tissue was loaded with a dark-coloured fluid of an oily consistency, and seemingly mingled with imperfectly formed pus."

It was scarcely to be expected that a proceeding apparently so heroic and formidable should have escaped severe criticism and opposition even from the most distinguished among us. This opposition was not confined to Sir Everard Home and his

colleagues, but of later date its most strenuous opponent was Mr. Syme. His objections appear to be founded upon the coexistence of disease in the acetabulum when present in the head of the femur; upon the supposed impossibility of eradicating the disease when so coexistent; and upon the apparent severity of the operation, which he characterises as "bloody" and "formidable," "not only useless but hurtful."

Mr. Syme admits that in hip disease the result depends chiefly upon the state of the bones composing the joint. "If they are carious *he must die*; if they are not, *he may recover*." Notwithstanding this admission, he continues—"Some operations have been lately performed in London with the view of remedying caries of the hip-joint by cutting out the head of the thigh-bone, but this proceeding must have originated and been conducted in forgetfulness of the well-known pathological fact, that when caries attacks the surfaces of a joint it is never limited to one of the bones which compose the articulation. If the articulating surface of the head of the thigh-bone be carious, it follows as a matter of absolute necessity that the acetabulum must be in a similar condition. But as the acetabulum does not admit of removal in the living body with any prospect of safety or advantage, no benefit can be derived from taking away a part of the articulation, and therefore excision of the head of the thigh-bone for caries of the joint should be regarded as no less erroneous in theory than objectionable in practice. In the London operations the hip-joints must have been either carious or not, and the proceeding either useless or unnecessary. It is very probable that in some of these persons the head of the thigh-bone might have been cut out during the suppurating stage without *preventing* recovery. But in what respects they would have derived benefit from the operation it is not so easy to see."

Mr. Skey, in his work on "Operative Surgery," also remarks—"This operation is rarely justifiable, or, when performed, answers any good purpose."

On the other hand, the operation has been advocated by Mr. Anthony White, Sir William Fergusson, Messrs. Gant, Holmes, Knox, Price, Smith, Walton, Dr. Bonino, and others; but without exception, prior to the year 1857, when I submitted my views to the Profession, writers upon excision of the hip-joint restricted the operation to cases in which dislocation of the head of the femur had obtained, and the head of the bone created irritation by acting as a foreign substance amongst the soft tissues of the hip; and all laid considerable stress upon the necessity that, for the operation to succeed, the amount of disease in the acetabulum and pelvic bones must be extremely small. In the year 1844 Dr. Bonino writes—"Any operation undertaken when the cotyloid cavity is affected is worse than useless, as we only remove a portion of the disease, leaving behind, perhaps, the portion most likely to lead to a fatal result. Such indeed seems to have been the cause of death in some of those operated upon."

Sir William Fergusson, in his paper read before the Medico-Chirurgical Society in 1845, alluding to a case operated upon by Sir Benjamin Brodie, observes—"In Sir Benjamin Brodie's case the head of the bone was in the acetabulum at the time of the operation. The patient died within a few days after—apparently the direct effect of that proceeding." And again, in a clinical lecture, delivered March, 1848, noticing the ease with which the acetabulum may be reached, he says—"I do not by this imply that I should not be deterred from operating, had I indubitable proof that the bones of the pelvis were affected; on the contrary, I would hesitate to resort to such a proceeding under the circumstances."

In the year 1848 Mr. Henry Smith laid down the following rules:—"If, then, there be dislocation of the thigh-bone, and the head of that bone be found to be extensively diseased, and there is no disease of importance in the pelvic bones, and no communication between the abscesses about the hip, nor any with the pelvis or abdomen, etc., then will it be both justifiable and proper to have recourse to this operation. It is only under peculiar circumstances that resection of the head of the femur should be attempted; the disease must be in its last stage. It is necessary that dislocation of the thigh-bone from its socket should have taken place, and there must be evidence of the disease being confined chiefly to the upper part of this bone, and of a non-complication to any great extent of the pelvic bones."

Sir Benjamin Brodie, in 1850, after pointing out that the head of the femur may sometimes be felt lying on the dorsum illii, seemingly almost immediately beneath the common integuments, says—"In such a case it has been proposed to make an incision on it, and remove the head and neck of the femur by the saw. It would appear that this operation has been actu-

ally-performed with some degree of advantage, and I do not doubt that circumstances may occur to make it worth while to have recourse to it. But it is to be observed at the same time that all that can be thus accomplished is the removal of one portion of the disease, and that it is the largest portion of it, in the bone of the pelvis, which is necessarily allowed to remain. The operation cannot be performed without a certain degree of local disturbance, and more or less loss of blood; and taking all these things into consideration, I conceive that we should not recommend it, except when some unequivocal advantage may be expected from it."

Mr. Knox, whose celebrity as an anatomist all admit, wrote, in 1851:—"In making this seemingly bold attempt for the speedy cure of a hitherto intractable disease, Surgeons were no doubt quite aware, or, at all events, ought to have known, that the caries affecting the femur was most usually a morbid affection, not confined to the bone, but was a disease affecting simultaneously in many cases the pelvic bones entering into the composition of the joint; that the os innominatum, in fact, was quite as liable to constitutional or scrofulous caries as the femur itself; that both are, unhappily, most frequently simultaneously affected; and that the removal of the femoral portion of the disease (the pelvic part being beyond the reach of excision, at least, if not of any Surgical treatment) by no means warranted the inference that disease in the pelvic portion would in all cases be arrested, and a speedy cure be effected."

Mr. Erichsen, also, in 1857, in allusion to cases wherein the pelvic bones are much involved, the acetabulum carious, rough, and probably perforated, says—"The treatment of this form of hip disease is in the highest degree unsatisfactory. Excision of the hip-joint is of course not practicable, on account of the amount of osseous disease and the extensive implication of the pelvic bones."

Among the other objections which have been raised is the possibility of mistaking disease of the sacro-iliac synchondrosis or of the pelvis itself for hip-joint disease; and another, upon which Mr. Coulson lays great stress, "That in this disease it is not the articular symptoms which produce death, but the exhaustion of the frame and strength, which the Surgeon, looking at the local cause only, imagines to arise from resistance to an incurable local malady; whereas the local malady and hectic are but symptoms indicative of the same disease; so that, to whatever extent the local malady may aggravate the general symptoms, as it is not the cause of these symptoms, so neither will its removal prove the remedy."

(To be continued.)

LECTURES ON THE COMPARATIVE ANATOMY OF THE ORGANS OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—At the commencement of the first course of lectures on Comparative Anatomy which I had the honour of delivering in this theatre, I recalled the fact that these lectures are intimately associated with the Museum; that their annual delivery was one of the conditions upon which the Hunterian collection was entrusted by the nation to our College, and that it was expressly stipulated that they should be "illustrated by the preparations."

I have endeavoured to fulfil this condition both in the choice of a subject and in the method of its exposition. It has been proposed, with the help of the specimens in the Museum, to take a general survey of the structure of the animals belonging to the highest class of organised beings, and, taking human anatomy as a point of departure, to trace out the deviations from, and resemblance to, the best-known form of vertebrate structure, in descending through the series of animals composing the class of mammals.

The object of this course is twofold—(1) The greater interest which it may be presumed the audience likely to assemble in this building will take in the portion of the animal kingdom to which we ourselves, in bodily conformation, are most nearly related; and (2) Because it is one of the special features of this Museum that, as the anatomy of man is more fully illus-

trated than that of any other species, so, in ascending the series of organised beings, the more nearly we approach to man the more completely and in greater detail do we find the various modifications of structure demonstrated by specimens.

Last year the characters, structure, functions, and modifications of the teeth occupied our attention. Certain practical reasons were given why these organs were most conveniently considered apart from the other buccal structures with which they are physiologically and locally connected; for they are, in fact, nothing more than extremely modified papillæ of the mucous membrane of the mouth, and in the main, though not exclusively, subservient in their function to alimentation. Their chief distinction from the remaining parts of the great and complex system of what are comprehensively called "digestive organs" is their intense hardness, owing to the impregnation of their tissues with earthy salts, and the firm connexion which they contract in the process of their development with the bony framework of the jaws. Their preservation and examination is consequently a far more easy and simple process than that of the remaining parts of the same system, which, following the arrangement of the Hunterian physiological series, will next engage our attention.

Certain portions of the membrane lining the internal surface of the alimentary canal near its commencement are raised into papillæ of various forms, the epithelial covering of which may be very greatly developed, and even acquire the hardness and consistence of horn. Such parts are then called "odontoids." (a) With the exception of these, all the structures to be spoken of in this course are of a very perishable nature, being composed of various combinations of connective, epithelial, muscular, and glandular tissue, and can only be studied either upon freshly dissected specimens, preparations preserved in spirit or some antiseptic fluid, and in some cases only, and in a partial and imperfect manner, in dry preparations. Consequently, far greater difficulties beset an acquisition of a knowledge of their form and arrangement in different animals than is the case with the more durable and easily examined bones and teeth.

The preparations of these parts which are put up in such a manner as to afford satisfactory information upon the points we wish to know, are, even in this Museum, very far less numerous and complete than those of the other structures to which I have just referred, and in the case of animals of considerable size, the difficulty and expense of mounting the visceral organs in spirit quite precludes the possibility of being able to afford permanent demonstrations of their form and structure. When we turn to books for information we find similar difficulties. The obstacles in the way of procuring many animals in a state fit for examination, and the amount of time and labour in dissecting the softer tissues before they can be described, has necessarily rendered their study less attractive than many other branches of anatomical investigation. We have undoubtedly much valuable information on this subject in the numerous general treatises on comparative anatomy, among which I may specially mention the excellent series of dissections contributed by Daubenton to Buffon's "Histoire Naturelle," the "Leçons" of Cuvier and of Meckel, and the more recent work of Owen on the "Anatomy of Vertebrates," together with the valuable notes of John Hunter, which remained unpublished till about ten years ago, (b) and to which I shall frequently refer. And there are also many most important special monographs on groups or particular species, especially of our domestic animals; but these are scattered through such a vast number of different works and journals that their examination and collation is often a matter of great labour, and there is constant danger of overlooking even some of the most valuable. I have endeavoured to seek out and give references, as far as possible, to all of these which contain important information upon the subject of the present course, but to do so in the exhaustive manner that I should have desired would take far more time than, unfortunately, I have at my disposal. One of the greatest difficulties in obtaining information from these monographs, and from books generally, arises from the different methods of dissection and description of particular organs, and the different systems of nomenclature adopted by anatomists. This absence of any uniform method makes it often impossible, unless assisted by figures, to comprehend or make any use of many of the published descriptions.

Perhaps the most important source of information upon

(a) Milne-Edwards, "Leçons sur la Physiologie et l'Anatomie comparée de l'Homme et de Animaux," tome vi., p. 101. 1860.

(b) "Essays and Observations on Natural History, Anatomy, Physiology, Psychology, and Geology." Edited by R. Owen. Two vols. 1861.

the subjects now coming before us has been the opportunity of examining the bodies of animals which have died in that magnificent and admirably managed institution—the menagerie of the Zoological Society in the Regent's-park; and I must here express my sense of gratitude for the readiness which the administrators of the Society, and especially the able secretary, Mr. Sclater, invariably show in consulting the interests of science wherever any such opportunities occur. We owe to the Zoological Society the materials from which have been prepared the larger proportion of the specimens that will be brought before you in illustration of the present course.

These various sources of knowledge having been laid under contribution, I still feel that the materials at my disposal are very insufficient for the task I have undertaken, and that, with many serious omissions, I can only hope to give a somewhat more connected and detailed account of certain modes of viewing these structures than has been before attained, and to supply a want which I myself, and I believe others, have frequently felt. I say *certain modes*, for to treat the subject exhaustively there are many ways of entering upon it which must be almost entirely omitted from this course. For instance, the histological structure of all the organs to be spoken of offers an endless field of research, which, as applied to three or four species of animals only, now occupies the time and energies of a host of workers qualified by special training to advance this most important branch of the subject. Then, a complete review of the present condition of knowledge of the physiological functions of the organs concerned in digestion in these same three or four animals alone would occupy a far longer time than that allotted to this present course. Witness the thirty-six lectures on the "Physiology of Digestion," lately published by Professor Schiff, (c) and which still only embrace a portion of the subject—that relating to the division of the system situated above the pylorus.

Morphology in what may be considered its coarser aspect—as taught, in fact, by ordinary dissection and by museum preparations—must (in accordance, I take it, with the original design of these lectures) be my principal aim; endeavouring, indeed, to indicate, wherever it is practicable, its bearings upon the other branches or aspects of the subject. The search after the purpose which every modification of structure subserves in the economy is always full of interest, and, if conducted with due caution and sufficient knowledge of all the attendant circumstances, may occasionally lead to important generalisations. But we must always bear in mind that adaptation to its special function is not the only cause of the particular form or structure of an organ; but that this form, as we see it, having in all probability been arrived at by the successive and gradual modification of some other different form, from which it is now to a greater or less degree removed, has other factors besides use to be taken into account. To take the case of the digestive organs, which may be considered as machines which have to operate upon alimentary substances in very different conditions of mechanical and chemical combination, and to reduce them in every case to the same or precisely similar materials, we might well imagine that the apparatus required to produce flesh and blood out of coarse fibrous vegetable substances would be different from that which had to produce exactly the same results out of ready-made flesh or blood; and in a very broad sense we find that it is so. Take a very large number of carnivorous animals belonging perhaps to different fundamental types, and a very large number of herbivorous animals, and, striking a kind of average, we shall find that there is pervading the first group a general style, if I may use the expression, of the alimentary organs different from that of the others. There is a specially carnivorous and a specially herbivorous modification of these parts. But if function were the only element of modification, it might be inferred that, as one form must be supposed to be best adapted and perfect in its relation to a particular kind of diet, that that form would be found in all the animals consuming that diet. But how different is this from being the case! Take the horse and the cow, for instance—two animals whose food in the natural state is precisely similar, and yet how different the structure of their alimentary canal and the processes involved in the preparation of their food! Take, again, the seal and the porpoise—both purely fish-eaters, who seize and swallow precisely the same kind of prey, in precisely the same manner—and see what a different arrangement of alimentary canal! If the seal's stomach is adapted in the best conceivable manner for the purpose

(c) "Leçons sur la Physiologie de la Digestion," par Maurice Schiff. 2 vols. 1867.

it has to fulfil, why is not the porpoise's stomach an exact *fac-simile* of it, and *vice versa*? We can only answer, the seal and the porpoise belong to different groups of animals, formed on different primitive types, or descended from differently constructed ancestors. Just as we see in different parts of the world the same operations of agriculture and other industry carried on by very different instruments, and in very different manner, the result produced being at all events approximately the same, so we see a similar variety in animal structure; and the few modifications which seem required in the digestive process, from the comparatively small variety in the condition of the different alimentary substances met with in nature, carried on with almost endless variety in the instruments used. This principle will meet with abundant illustration throughout the course.

If all the minor modifications of the structure of the digestive organs are exclusively related to the special substances they have to operate upon, few things would be more remarkable than the facility with which animals will adapt themselves, when necessity requires it, to very different conditions of diet from those to which they are ordinarily accustomed. Thus, among wild animals there are many instances known of the food being changed from purely vegetable to purely animal matters, according to season and opportunities; (d) and among domestic and captive animals numerous experiments show how species purely carnivorous by nature will live apparently an indefinite time on bread or other vegetable substances; and herbivorous animals, on the other hand, can be fed on flesh without any apparent disturbance of their nutrition.

John Hunter found that a tame kite, when gradually brought to feed on bread alone, would thrive on it as well as on meat; and he kept a sea-gull for twelve months on barley. (e) Schiff found that rabbits would live perfectly well on the flesh of frogs, and, as is well known, in Iceland, when the natural food fails, cows and horses are fed for a considerable time exclusively on fish. I have also heard of the flesh of dead whales being used for the same purpose in the North of Scotland.

Schiff appears to have proved by numerous experiments related in his lectures above referred to, (f) in opposition to previous views, that the gastric juice secreted by the stomach of a carnivore, and by that of a herbivore, is identical in its chemical and physiological properties, as tested by its power of converting alimentary substances into peptones; and, moreover, that the product of digestion (the peptone), elaborated by the stomach of a herbivore and injected into the stomach of a living carnivore, is directly absorbed without undergoing any metamorphosis recognisable by reagents, and that analogous results are furnished by the converse experiments of nourishing a herbivore with the product of the digestion of a carnivore. And when we consider the identity or close similarity of the chemical composition of the principal animal and vegetable alimentary substances, this is not much to be wondered at.

In discussing the subject of the relation of food to the construction of the digestive organs, it must be borne in mind that the vegetable substances occasionally taken either voluntarily by wild animals habitually carnivorous, or those used in the

experiments just named, never belong to the class which mechanically and physically are either by their bulk or hardness most removed from animal tissues, but are succulent parts of plants, fruits, or pulpy farinaceous substances acted on by the digestive organs with almost the same facility as flesh itself. The alimentary canal of the carnivorous or omnivorous animals would not suffice to contain the necessary volume, or to act with sufficient intensity upon aliment presented in the comparatively innutritious and bulky form it is taken in by the pure grass-eaters, and it is among these latter that the principal deviations from the ordinary type of structure of the digestive organs will be found. Hence the mechanical, rather than the chemical, constitution of the food must be looked to in endeavouring to find a relation between the aliment of an animal and the conformation of the parts destined to act on that aliment.

The digestive apparatus of mammals, as in other vertebrates, consists mainly of a tube with an aperture placed at or near either extremity of the body—the oral and the anal orifice—and with muscular walls, the fibres of which are so arranged as by their regular alternate contraction and relaxation to drive on wards the contents of the tube from the first to the last of these apertures. The anterior or commencing portion of this tube is greatly and variously modified, in relation to the functions assigned to it of selecting and seizing the food, and preparing it by various mechanical and chemical processes for the true digestion which it has afterwards to undergo before it can be assimilated into the system. For this end it is dilated into a chamber or cavity called the mouth, and supported by a movable framework, which usually carries the teeth—especially hard organs, for the purpose of cutting, tearing, or grinding the alimentary substances into small particles. I hardly need in this theatre define the different parts known as the lips, cheeks, palate, fauces, and tongue, but must be permitted to recall your attention to two or three peculiarities connected with these structures as we know them in man.

One of these is the elevation of the mucous membrane of the front part of the hard palate into a few irregular wavy transverse ridges, which are interesting as presenting, slight or rudimentary indications of structures which we shall find far more strongly marked in nearly all mammals, and in some attaining a remarkable importance in relation to the functions of this portion of the alimentary canal. With regard to the tongue I would mention a pair of fringed projecting ridges or folds of the mucous membrane on the free part of the under surface, commencing near the apex, and diverging as they pass backwards on each side of the frænum. These are by no means constant, and are not described in ordinary works of anatomy, though, as in the specimen now exhibited, sometimes perfectly well marked. Also a group of nearly vertical fissures, with intervening raised ridges, placed on the sides of the organ, just in front of the attachment of the palato-glossal fold. These vary greatly in their condition and development, and generally pass insensibly into the well-known simple vertical linear arrangement of the papillæ common to the whole lateral border of the organ; but their import will be more clearly understood after the examination of the tongues of several other forms.

In connexion with the buccal cavity we shall have to consider an extensive and complex glandular apparatus which pours its secretions into it—secretions which constitute the fluid commonly known as saliva.

The whole apparatus consists of organs which have been variously classified, either according to their supposed function, their minute structure, or their general arrangement with regard to the other organs and tissues near which they are placed. As the first two methods still to some extent contain elements of uncertainty, it is most convenient for the present purpose to continue the old anatomical grouping into two classes:—1. The small glands embedded in the mucous membrane or submucous tissue lining the cavity, and which are of two kinds—the follicular and the racemose. 2. Those in which the secreting structure is aggregated in distinct masses removed some distance from the cavity, other tissues besides the lining membrane being usually interposed, and pouring their secretion into the cavity by a distinct tube or duct, which traverses the mucous membrane. To the latter alone the name of "salivary glands" is ordinarily appropriated, although the distinction between them and the smaller racemose glands is only one of convenience for descriptive purposes, their structure being more or less identical; and as the fluids secreted by all become mixed in the mouth, their functions are, at all events in great part, common.

(d) As one of the most recently recorded voluntary changes of diet among wild animals in adaptation to change of circumstances, I cannot forbear extracting the following interesting account, on the authority of Mr. T. H. Potts (see *Nature*, October 19, 1871, page 489), which has since been corroborated from other sources (*Ibid.*, February 1, 1872):—The kea of New Zealand (*Nestor nobilis*), one of the family of *Trichoglossinae*, or brush-tongued parrots, called "mountain parrots" by the settlers—whose habit had previously been to range over shrub-covered heights and rock-bound gullies, gathering their subsistence from the nectar of hardy flowers, from the drupes and berries of shrubs, and also, perhaps, from insects found in the crevices of rocks or beneath the bark of trees, so that their aliment, though not wholly vegetarian, was yet such as called forth no display of boldness to procure a sufficient supply—since the establishment of sheep-farms in the districts they inhabit, were first observed to visit the "meat gallows" of the back-country squatters, and to feed upon the flesh of the dangling carcasses of the recently killed sheep. But a still greater change soon came over their habits; for not only the dead flesh of the newly introduced mammals became an object of their search, but they were next observed to attack the living sheep. The birds are described as coming in flocks, singling out a sheep at random, when each alighting on its back in turn tears out the wool and makes the sheep bleed, till the animal runs away from the rest of the flock. The birds then pursue it and continue to attack it, apparently for the sake of the blood that flows from the wounds, till in many cases the unfortunate animal dies of exhaustion.

(e) In this case the muscular tissue of the gizzard acquired an abnormal development, as shown in the preparation still in the museum (*Physiological Series*, No. 523). This experiment may have been in Hunter's mind, when he writes, in one of his occasional notes, lately collected and published by Professor Owen—"I dare say the different manner of living gives rise to the different formation of the viscera"—(*Essays and Observations*, vol. ii., page 2)—in other words, modification of function precedes and causes modification of structure.

(f) Vol. ii., lecture 25.

Under the name of *salivary glands* are commonly included—
 1. The *parotid*, situated very superficially on the side of the head, below or around the cartilaginous external auditory meatus, and the secretion of which enters the mouth by a duct (often called *Steno's* or *Stenson's*) which crosses the masseter muscle, and opens into the upper and back part of the cheek.
 2. The *submaxillary*, situated in the neck near or below the angle of the mandible, and sending a long duct forwards to open in the forepart of the floor of the cavity of the mouth below the apex of the tongue. These are the most largely developed and constant of the salivary glands, being met with in various degrees of development in almost all animals of the class of mammals. Next in constancy is (3) the *sublingual*, closely associated with the last-named, at all events in the locality in which the secretion is poured out; and (4), the *zygomatic*, found out in some animals, in the cheek just under cover of the anterior branch of the zygoma, its duct entering the buccal cavity near that of the parotid.

The intimate structure of these different glands is not altogether alike, and even that of the homologous glands of different animals, in those few in which it has been examined, does not appear entirely to correspond; (g) making any classification which may be proposed according to their structure in one animal by no means applicable to all.

The most obvious function common to the secretion of these various glands, and to that of the smaller ones placed in the mucous membrane of the lips, the cheeks, the tongue, the palate, and fauces, is the mechanical one of moistening and softening the food, to enable it the more readily to be tasted, masticated, and swallowed, though each kind of gland may contribute in different manner and different degree to perform this function.

Moreover, the saliva is of the greatest importance in the first stage or introduction to the digestive process, inasmuch as it dissolves or makes a watery extract of all soluble substances in the food, and so prepares them to be further acted on by the more potent digestive fluids met with subsequently in their progress through the alimentary canal.

In addition to these functions, it seems now well established by experiment, that saliva serves in man and many animals to aid the digestive process, particularly by its power of inducing the saccharine transformation of amylaceous substances.

The special properties of the secretions of the different glands above named has naturally been a subject of laborious and repeated investigation by physiologists. It seemed at one time to be established, that the starch-transforming property was only acquired when the secretions of the various glands were mixed together in the mouth; and that when each was taken pure, as secreted, this power was not exhibited. But more recent experiments have clearly shown that this is not the case, as human saliva taken direct from the parotid duct, or directly from the submaxillary duct, without any admixture with each other or with the buccal mucus, possesses the diastatic power in a high degree. It has also been shown that the secretion of these glands, in the few animals in which it has been examined, possesses this property in an extremely varying intensity. In the dog and cat it is, indeed, present, but feeble and slow of action; in the sheep, the ox, and the horse it is scarcely more strongly pronounced, though, it must be remarked, experiments by different observers do not always coincide on these points; in the guinea-pig it is said to be more active than in man; in the rabbit, while it is not present in the secretion of the submaxillary gland, a peculiar small lobule near the parotid, called the *masseteric*, possesses the property in a particularly active degree. Even at some periods of life, as in early infancy in man, and in the corresponding time in most, but not all animals, this power does not exist in the saliva of glands which afterwards exhibit it in the highest degree. Moreover, this and other properties of the saliva are modified by different conditions of the constitution, and by the influence of the different nerves by which the glands are supplied, as is frequently demonstrated by experiments.

These results, limited as they are at present to a few species of animals, are of great importance to us, as showing how the function of a part may be modified according to the necessities of its possessor without any apparent alteration in its structure, (h) and should serve as a wholesome caution in

(g) See Heidenheim, "Studien der Physiologische Institut zu Breslau," Heft iv. 1858.—Abstract in *Brit. and For. Med.-Chir. Review*, July, 1868, p. 260.

(h) I have said *apparent* alteration of structure, so as not to exclude alterations not recognisable by any known means of research, or only by such minute investigations as have as yet been applied to comparatively few of these tissues, and probably still await confirmation.

drawing inferences from the large or small development of any particular gland, since its secretion may serve very different purposes in the economy of different animals.

Even the distinctions that seemed tolerably clearly established by Bernard, between what may be called the mechanical functions of the secretion of the parotid and the submaxillaries, the former being exclusively related to the functions of mastication, and the latter to deglutition and taste, and also the views of the same great physiologist upon the special stimuli required to call the secretion of each into action, are said by other experimentalists to require considerable modification. (i) There is little doubt, however, that, as a general rule, in mammals the parotid saliva is most watery in its composition, and that of the submaxillaries, and still more the sublingual, contains more solid elements, and is more viscid; so much so, that some anatomists consider the latter, together with the small racemose glands of the cheeks, lips, and tongue, as *mucus* glands, retaining the name of *salivary* only for the parotid. (k) We shall find these peculiar properties developed in a most remarkable degree in some animals—as, for example, the great secretion of excessively viscid saliva which lubricates the tongue of the anteaters and armadillos, associated with enormously developed submaxillary glands; while, on the other hand, the parotids are of great size in those animals which habitually masticate dry and fibrous food.

After the preparation which the aliment has undergone in the mouth—the extent of which, as we shall see, varies immensely in different forms, being reduced almost to *nil* in such animals as the seals and cetaceans, which, to use the familiar expression, "bolt" their food entire—it is swallowed, and is carried along the œsophagus by the action of its muscular coats into the stomach.

In the greater proportion of mammals this organ is a simple dilatation of the alimentary canal, forming a bag having much the same general shape as that so well known in man; but in others it undergoes remarkable modifications and complexities, the description of which will naturally occupy a prominent part of the course.

The walls of the stomach are thickly beset with tubular glands, which are now generally considered to belong to two distinct forms, recognisable by their structure and different in their function—the most numerous and important secreting the gastric juice (the active agent in stomachic digestion), and hence called peptic glands; the others only concerned in the elaboration of mucus. The relative distribution of these glands on different regions of the walls of the stomach varies greatly in different animals, and until it has been ascertained we shall not be able to form a correct idea of the mode in which the organ performs its functions. In man, as is well known, the peptic glands are distributed everywhere except in the portion next to the pylorus; in many animals the arrangement is quite the reverse. I ought to mention that although the distinction commonly made between the peptic and mucous glands seemed as well established as any fact in physiological anatomy, doubts have recently been thrown upon its validity. (l) But however this may be, there can be no question but that large tracts of the stomachal mucous membrane in many animals do not secrete a fluid having the properties of gastric juice.

The action of this fluid is mainly exerted upon the azotised or nitrogenous elements of the food, which it dissolves and modifies so as to render them capable of undergoing absorption, converting them into substances technically called peptones. In this form a certain portion is absorbed by the bloodvessels of the stomach, but the greater part passes through the pylorus into the intestinal canal, where it comes in contact with the secretion of a vast number of small glands, called the "crypts of Lieberkuhn," somewhat similar to those of the stomach, and also of several special glands of a different character—namely, the small racemose, duodenal, or Brunner's glands, the pancreas, and the liver.

The intestinal canal varies greatly in relative length and capacity in different animals, and it also offers manifold peculiarities of structure—sometimes being a simple cylindrical tube of nearly uniform calibre throughout, but more often being subject to alterations of form and capacity in different portions of its course; the most characteristic and constant being the division, as in man, into an upper and narrower, and a lower and wider portion, called respectively the *small* and *large*

(i) See Schiff, *op. cit.*, tome i.

(k) Henle, "Handbuch der Systematischen Anatomie des Menschen," vol. ii. 1862.

(l) By Ebstein (Pflüger's Archiv., iii., 535).—See abstract in *Journal of Anatomy and Physiology*, May, 1871, p. 407.

intestine—the former being divided quite arbitrarily and artificially into *duodenum*, *jejunum*, and *ileum*; and the latter into *colon* and *rectum*.

One of the most striking peculiarities of this part of the alimentary canal is the extremely frequent presence of a diverticulum or blind pouch—*caput cæcum coli*, as it is called in anthropotomy, generally abbreviated into *cæcum*—situated at the junction of the large and small intestines: a structure in which we shall find immense variety of development, from a mere rudimentary bulging of a portion of the side wall of the tube, to a huge and complex sac, exceeding in capacity the remainder of the intestinal canal. When greatly developed, as in many herbivorous animals, it cannot fail to exercise some important influence upon the digestive process, and has been compared by some physiologists to a second or complementary stomach.

Considerable light has been thrown upon its function by the ingenious observations of Schiff,^(m) which are of such interest in relation to comparative physiology that it will be worth while to give a brief abstract of them.

He maintains, in the first place, that the gastric juice can exert no peptic or digestive influence, unless the blood from which it is secreted is previously charged with some "peptogenic" substance. Most aliment soluble in water affords such peptogenic substances. The action of these substances upon the secretion of the stomach is the same, whether they are absorbed by the stomach itself or by the large intestines, or injected into the blood, but not if absorbed by the small intestines. In the latter case the peptogens appear to lose their property in the mesenteric glands, or at least before they reach the thoracic duct. The nourishment of ruminants, although it contains a large quantity of matters soluble in water, is very refractory to the action of pepsine; it requires, therefore, a very energetic gastric juice to digest it, and to produce this much peptogenic substance must be introduced into the blood before peptic digestion can take place. This is accomplished by the abundant secretion of saliva, during the double mastication, dissolving the soluble parts of the food, and by the extended absorbing surface of the first three stomachs, which allow a large quantity of peptogenic matter to be taken up, and a considerable preparation of active gastric juice to be made, by the time the food finds its way into the fourth or true digestive compartment.

Now, the ruminants, as we shall see, have all small cæca, but the herbivorous animals, which have simple stomachs, and do not ruminate, as the horse and the hare, have enormous cæca; and this organ Schiff conceives, and appears to have proved experimentally, has the same function in permitting the absorption of peptogenic substances into the blood which the first compartments of the stomach perform in the ruminant—only, of course, it is the residue of the food after passing through the stomach and small intestines, from which all the peptogenic substances have not been extracted, which continues to give them off for the elaboration of material for the digestion of fresh food taken into the stomach; so, though the process is analogous, it is not quite the same.

The large superadded non-digestive compartments of the stomach, combined with total absence of cæcum, in the hippopotamus afford a striking illustration of these views, to which we shall probably return at a later part of the course.

The cæcum of man presents so remarkable a deviation from the normal type of this organ that it will be desirable to recall your attention for a few moments to its characters. Fortunately its development is quite conclusive in showing its relation to that of other animals. It is at first a simple conical projection from one side of the intestinal tube. It gradually lengthens, and, as it does this, the terminal portion, not keeping pace in its growth with the base, becomes narrower in calibre. This is the condition it presents in the preparation before you, taken from a foetus between the sixth and seventh months. The three longitudinal bands so characteristic of the adult human colon are scarcely visible, but as they become developed it will be seen that they all terminate in the narrow apex of the cæcum. For the sake of better understanding the changes that subsequently take place, and comparing them with those that occur in other animals, it will be desirable to give them definite names. One, which lies on the side of the colon into which the ileum enters, may be called *postero-internal*; this is the least strongly developed. One on the front side of the ascending colon is the *anterior*; this is the widest. The other is the *postero-external*. These divide the colon and cæcum into three tracts, which may be designated *anterior*, *external*, and *posterior*. Now, the further changes that take

place to convert the cæcum of the foetus into that of the adult are the gradual narrowing of the whole of the cæcum, except the basal portion—or, perhaps, instead of narrowing, I should say comparative arrest of growth—until it assumes the form of a slender tube of uniform calibre, commonly called the vermiform appendage, while the basal portion grows with the rest of the large intestine, and constitutes what is commonly called the cæcum. But simultaneously with this change another takes place, which completely alters the formation of the organ. This consists in an apparent shortening of the lateral longitudinal tracts, especially the postero-internal and the postero-external, while the wall of the intestine constituting the external tract continues to grow out of proportion to the other parts. Hence it results that the true apex of the cæcum, or the vermiform appendage, as it is now called, is drawn (as it were) upwards and slightly backwards (supposing the colon in its normal position in the upright body), and is placed in a somewhat varying situation near to the entrance of the ileum; and the bulging of the external tract forms a kind of false cæcum with a rounded apex, which does not in reality correspond either to the true apex of the infant's cæcum, or to that of the large majority of animals.

It is important to recall these changes in the human cæcum, because we shall find several stages of them permanently retained in the adult state in certain animals.

Besides the external form of the intestinal canal, we shall have to consider the various modifications of its lining surface, especially in relation to the different contrivances for increasing the absorbing surface, without adding to the general bulk of the organ—such as the villi and the valvulæ conniventes of man, and folds having similar functions in many animals—and also, as far as they are known, the modifications of the various glands which pour their secretion into its interior.

Of these, as in the case of the buccal cavity, there are many which are embedded in the mucous membrane lining the cavity, and others which form distinct organs, communicating their secretion by means of more or less elongated ducts. Of the former, I have already mentioned the crypts of Lieberkuhn and the duodenal racemose glands. The crypts are found in all parts, from the stomach to the anus; but the former, as their name implies, are confined to the pyloric extremity of the intestine.

Other structures in the mucous membrane, about the nature of which there is still much uncertainty, are the solitary and the agminated glands, the latter known commonly by the name of "Peyer's patches." These were formerly supposed to be secreting organs, which discharged some kind of fluid into the intestine, but are now more generally considered to belong to the group of structures of somewhat mysterious function of which the lymphatic and lacteal glands are members. The solitary glands are found scattered irregularly throughout the whole alimentary tract; the agminated, on the other hand, are always confined to the small intestine, and most abundant in its lower part. They are subject to great variation in number and in size, and even in different individuals of the same species vary in character at different periods of life, becoming, like the mesenteric glands, atrophied in old age, though not to the same degree(n)—a point which must be borne in mind in noting their condition in the dissection of animals.

A few observations upon the general characters of the remaining parts of the digestive apparatus must be reserved for the next lecture.

BABY FARMS.—The existence of a "baby farm" was discovered a few days ago in Marseilles by a novel species of detective. A mastiff was seen carrying the arm of a newly born infant in his mouth, and his movements being watched, led to the arrest of a woman who confesses to have exercised this calling for thirty years.

A SUCCESSOR TO THE "ZOUAVE."—Mr. Strong, an American, has set up business in Marseilles for miraculous cures, like the Zouave Jacob. Mr. Strong refuses payment, and his curative mode consists in laying the hands, etc. An interminable procession of invalids daily wend their way to Mr. Strong's villa on the sea-side, and the doctors intend to petition against what they call the "thaumaturgist."

YELLOW FEVER has been committing ravages among the shipping at Pernambuco, and the port has been declared infected. Cholera has broken out in Revel, and also in Cerigo, one of the Ionian Islands.

ORIGINAL COMMUNICATIONS.

CASE OF PERFORATING ULCER OF THE STOMACH—DEATH UNDER PECULIAR CIRCUMSTANCES.

By ROBERT DRUITT, M.R.C.P. Lond., etc.

THE following case was mentioned by me the other evening at the Association of Officers of Health, in illustration of Dr. Bernays' remarks on the necessity for greater care and formality in conducting post-mortem examinations for Medico-legal purposes:—

About 11.30 p.m., August 30, 1862, I was asked to go round to the "Home School," a charitable boarding-school for girls, in Market-street-mews, Mayfair. I went, and was shown a girl lying on a bed perfectly dead, and so cold as to give me the impression that she had been dead for some hours. The contents of the stomach were running out of the mouth, and the abdomen intensely distended and tympanitic.

I was told that deceased was named Elizabeth S., 13 years of age, and of habitually bad health; that she had been that day with all the school-children of the district, in vans to take their annual holiday in Richmond-park; that she was very sick on her way home, was helped upstairs, and put to bed directly. My visit was within half an hour.

The next morning I learned to my surprise that the schoolmistress had sent, after I left, for a well-meaning clergyman, whose wife, a kind of fussy Lady Bountiful, accused me, on the schoolmistress's testimony, of having neglected any means for the recovery of the child, who, she said, was alive during my visit and spoke afterwards. This woman also declared that the child had died of cholera, and that the corpse must be removed immediately; so the poor clergyman was walking about for half the night till he got it removed to the mortuary of the St. George's Workhouse in Mount-street. This was probably the result of some brandy-and-water with which the mistress was relieving her hysterical feelings, even during my visit.

Of course an inquest was held, and I received a summons and order to make a post-mortem examination; but as I was in some respects a party accused, I was glad to obtain the presence of Mr. W. Fuller, of Piccadilly, Dr. Bloxam, and his assistant, Mr. Walker.

The post-mortem examination was made forty-two hours after death. The body rather thin; depending parts livid; pupils dilated; yellowish liquid running out of mouth; no marks of injury. On cutting into the distended abdomen a large quantity of gas escaped. Small intestines distended, pinkish; stomach not very distended, and of dusky hue. Various parts of the intestines down to the bladder were covered with a greyish layer, which looked at first sight like recent exudation, but was easily wiped off, and put by for examination.

After this preliminary inspection of the abdominal cavity, the chest was examined, and there were found general adhesion of both lungs to pleurae; tubercular deposit in both apices of lungs and in left bronchial glands; small vomica in right apex. Liver healthy, but adherent to diaphragm; gall-bladder full. Stomach dusky, thin, and unhealthy-looking; evident marks of ulceration on anterior surface of lesser curvature; no general signs of irritation of the mucous membrane, but an oval ulcer, one inch by half an inch, which had at one point gone through the peritoneum by a very small oblique aperture just admitting a probe. The stomach contained a large mass of food, which was removed for examination. The intestines were adherent to each other and to the peritoneum at several points. There was an old diseased and ulcerated patch near the vermiform appendage, a considerable ulcer in the transverse colon, and one cicatrised in the descending colon. The large intestine contained some healthy faeces at its upper extremity, and no liquid.

The contents of the stomach consisted of well-masticated food, including bread, muscular fibre, apple in large quantity, chicory, watercress, lettuce, with one or two vegetables that I was not able to identify; but the most remarkable portion was a quantity of hazel-nut kernels, well masticated, and swallowed along with their brownish husk, which is a beautiful microscopic object.

The case was evidently that of a child with scrofulous disease of the stomach and other organs, who, out on a picnic,

employed her time in eating apples and nuts; the stomach became distended with flatulence, and gave way at a diseased spot, blowing out its gas into the peritoneal cavity, and with it a small quantity of masticated nut-kernels, which, at a first glance, had a curious resemblance to a coating of lymph. But it is clear that the person who was accused (however ignorantly and falsely) of not taking proper steps to avert death was not the person to whom an order for making a post-mortem examination should have been directed.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,

Student of Guy's Hospital.

No. III.

(With Photo-lithographic Plates.)

The Production of the Percussion, Tidal, and Dirotic Waves—Conditions influencing the Development of each—The Analysis of Pulse-Tracings.

HAVING now a fixed phraseology by which to describe the various parts of a pulse-tracing, and having briefly indicated the theories held to account for their production, the schema may be appealed to in support of these statements. The first point requiring proof is, that the vertical upstroke is due to percussion. The first nine tracings on the plate accompanying this paper were obtained from the schema. Fig. 1 was obtained from the descending aorta with the capillaries moderately dilated; in this tracing, immediately after the sudden vertical upstroke, an almost equally sudden fall of the lever may be seen, followed immediately by another abrupt rise and succeeding slower collapse. The tracing tells its own tale; it is evident that the first elevation of the lever cannot be produced by the passage of a wave of fluid through the artery, for if it were, the collapse would be slow and gradual; it is probably produced by the jar transmitted through the blood-column, and imparted to the arterial wall. In Figs. 4 and 5, from tracings of the brachial, the percussion upstroke is not so markedly separated from the remainder of the tracing, though the second elevation of the lever is probably caused by the tidal wave. That this elevation of the lever is not the dirotic wave or diastolic expansion, but is due to some vibration of the blood-column during systole, is proved by Fig. 5. In this case the cardiac systole was prolonged: this is indicated by the prolonged and sustained expansion of the artery, after the second elevation of the lever; it, therefore, cannot be the dirotic wave which occurs after the closure of the aortic valves and during diastole, but must probably be due to the interval elapsing between the transmission of the percussion-stroke and the tidal wave.

Figs. 7, 8, and 9 were obtained from the radial artery; Fig. 7 will be discussed hereafter; in Figs. 8 and 9 the percussion-stroke may be well seen, markedly separated from the tidal wave, more so even than in Figs. 1 and 2. Compression is added to percussion in Fig. 9, the outlet being blocked by the contracted capillaries; the percussion-wave is therefore transmitted more slowly, as the distal end of the blood-column is well-nigh immovable, and cannot be jerked forward. In another series of experiments, tracings were obtained from the aorta, brachial, and radial arteries, in which the rapidity, duration, and force of the systole were equal. The time that intervenes between the transmission of the percussion and tidal waves gradually increased, as the distance from the heart at which the tracings were taken increased; for while the percussion-impulse is transmitted through a column of fluid, the walls of which are rigid, almost instantaneously (Dr. Sanderson calculates 90 feet per second), the tidal wave is much slower; accordingly, the percussion-wave is transmitted almost instantaneously throughout the system, and the tidal wave follows it at an interval which increases with the distance of the artery from the heart.

Again, proof of the first upstroke being due to percussion may be obtained by altering the mode of contraction of the heart in the schema, making it less sudden in its commencement; the percussion-wave may by this means be decreased by diminishing the sharpness of the contraction, so that at last no part of the upstroke is vertical, but the whole oblique and the apex rounded, owing to the disappearance of the percussion-wave, the tidal wave alone remaining. The percussion-

wave may also be done away with by obstructing the aortic orifice, the contraction of the heart remaining the same as in the normal tracing; the upstroke becomes sloping, having also a rounded summit, and the tidal wave alone remains. A similar tracing may be obtained as a pathological condition.

Observations made on the human subject give similar evidence. One of my fellow-students, Mr. T. Eastes, kindly assisted me in these and other experimental tracings; the tracings in the next section of the plate are from his pulse. In Figs. 10, 11, and 12, taken from the external carotid, brachial, and radial arteries respectively, both the percussion and tidal waves are well marked; the tidal wave is seen to diminish in size the farther the artery is from the heart, so that in the radial pulse the two almost become merged in one, and the tidal wave is only just discernible. It may also be noticed that the tidal wave follows the percussion-wave at a shorter interval in the carotid than in the brachial; and a shorter interval in the brachial than in the radial.

Admitting, then, the presence of percussion as an element in a tracing, that of the tidal wave will not require much proof. The fact of the production of a wave having a sloping upstroke and rounded summit, and requiring a short interval of time for its transmission through a system of tubing, is plainly shown by the well-known experiment of Marey's, quoted by Dr. Sanderson in his lectures on the Arterial Movements, in which three polygraphic levers are applied to coils of tubing, at increasing distances from a bag representing the heart, contracted by the hand; the levers writing above one another and simultaneously, on a revolving cylinder. By this means it was found that the maximum of distension was obtained in the distal portion of the tubing later than in the proximal; that the expansion was more gradual and the wave smaller in the same position. Similar results may be obtained from experiments made with the schema. In these it is seen that the tidal wave is larger in the aorta than in the brachial, and in the latter than in the radial, and also its relative proportion to the percussion-wave is found to diminish. Thus, in the aorta it is larger than the percussion-wave, in the brachial nearly the same size, and in the radial considerably less. Again, by referring to the plate it will be noticed that it is larger when the capillaries are in a normal condition—*i.e.*, in a state intermediate between dilatation and contraction—than when they are either fully dilated or tightly contracted; for in the former state it passes along without fully distending the wall of the vessel; in the latter the tension, being already raised almost to its utmost, will not permit a much further increase.

Before leaving the subject of percussion and tidal waves, it must be stated that both are not always present in the same pulse; in fact, perhaps in the larger proportion they are not. The tidal wave may be merged in the percussion-wave; that this really takes place, experience will soon teach. In a series of pulses, the tidal wave, well marked in some, is diminished in others, till it becomes only just perceptible, and at last completely disappears. This has been before referred to as taking place in the different arteries in one subject. It may be seen to occur in the radial arteries of different subjects by referring to the plate. In Fig. 17 both are clearly discernible; in Fig. 18 the tidal wave has become much less marked; in Fig. 21 it has almost completely disappeared, and can only be discovered by the most careful scrutiny; as a slight fulness in the downstroke succeeding the primary expansion, it is most easily seen in the last wave in this figure.

Again, the percussion-wave may be lost, or merged in the tidal wave. This takes place where the action of the heart is less sharp and sudden than usual, or the arterial tone particularly good. In Fig. 20, where the contraction of the heart commences more gradually, the upstroke is sloping, and the tidal wave alone remains. If the upstroke had been vertical, there would have been the usual interval between the percussion and tidal waves. The presence, then, of the percussion-wave depends on a sharply contracting heart and in deficient arterial tone. It is produced both by hypertrophy and under excitement, and is found in any condition which increases the sharpness of the cardiac contraction, or often as a normal element.

Thus far we have only studied those phenomena of the pulse that occur during systole, and we have arrived at that point in the pulse-tracing which corresponds to the closure of the aortic valves. The next event that occurs is what has previously been described as dicrotism or the diastolic expansion. The fact that dicrotism, or, to adopt Dr. Sanderson's more preferable term, the "diastolic expansion," does really occur in the human pulse, and is not due to an imperfection in the instrument employed to obtain a pulse-tracing, has been proved by

M. Landois by aid of his sphygmoscope. In this instrument the column of gas supplied to a fine burner is acted upon by the pulse, the movements of which are imparted to the flame, which may be seen to undulate, each increase in the flame corresponding to the main upstroke in a tracing being followed by a smaller one coincident with the diastolic expansion.

The theories that have been formed to account for dicrotism are almost innumerable. Albers attributed it to a second contraction of the heart; Galen, to the vibrations produced in the walls of the arteries by the afflux of blood; Parry and Hammernjk consider it to be due to the alteration in the length of the arteries, which are curved during systole and straight during diastole; Volkmann thought the contraction of the heart was transmitted by two waves of unequal rapidity—one in the blood, the other in the arterial walls; Marey ascribed it to the check received by the blood in the descending aorta by the bifurcation of the common iliacs, causing a rebound throughout the whole arterial system, except in the lower extremities, where he said it was absent; Naumann ascribed it to the stopcock action of the semilunar valves sending a shock throughout the blood column, similar to that noticed in a column of water on suddenly turning off a tap. Koschlakoff gives some interesting results on the production of dicrotism, as shown by pumping a stream of water through elastic tubing. From these he argues that dicrotism depends on a disturbed equilibrium of tension of the artery, and occurs in its walls. Dr. Sanderson holds that the maximum of distension occurs in the peripheral arteries and arterioles at a time when the larger arteries are contracting; that, while in the "largest arteries the expansion is ebbing, in the smallest it is culminating, so that for an instant the pressure is greater in the latter than in the former: there is but one effect possible. The restoration of equilibrium must take place by increase of pressure towards the heart, and diminution towards the periphery. This restoration of equilibrium constitutes the second beat." Again, Dr. Sanderson remarks that dicrotism is characteristic "of that condition of the circulation in which the arterial pressure is diminished while the venous is increased," and that a small amount of blood expelled from the ventricle, or dilated capillaries allowing free passage of the blood, increase it. I shall not attempt in this place to disprove any of the foregoing theories, but shall proceed to state those which I have been led to form, and the reasons which directed me to them.

It has been stated above that dicrotism is due to the contraction of the distended elastic walls of the aorta, which takes place immediately on the termination of systole. During the contraction of the heart the blood-column is first urged forward, but soon checked by the resistance it meets with in the smaller arteries and capillaries; but as the heart continues to contract, the blood forced out of it must go somewhere, and, accordingly, makes room for itself in the arterial system by distending the elastic coat of the aorta; this, by its contraction, which takes place immediately on the termination of that of the heart, returns to the blood the motive force expended in its dilatation, thus closing the aortic valves, and producing the dicrotic wave in the arteries. I shall endeavour to prove that dicrotism is merely supplemental to the heart's action, and is, indeed, a second tidal wave passing through the arteries, produced by the aortic contraction.

It will be noticed that, though in most of the tracings in Pl. i. obtained from the schema the diastolic expansion is faintly perceptible, yet in none does it attain to its usual importance. The reason of this may be found in the fact that the tubing used in the construction of the schema consists of thick vulcanised indiarubber; it is but slightly distensible, and not to be compared with the beautifully soft, elastic coat of the arteries, more especially of the aorta; and therefore, though well calculated to exhibit the effects of percussion, is incapable of transmitting a well-marked dicrotic wave. Proof of this I have obtained in the following manner:—A thin, easily distensible indiarubber bag has been introduced into the ascending aorta just above the aortic valve, in hopes of imitating the distension of the elastic coat of the human aorta and its effect. The bag has been surrounded by netting to prevent its over-distension. Now, on watching the aortic valve in the schema, it may be seen to become extremely tense immediately after the termination of the systole, and then, during the remainder of diastole, tension is diminished; the elastic bag is also seen to become greatly dilated during systole, and to contract during diastole. On applying the finger to it, a double beat is distinctly felt—one apparently produced by systole, the other by the recoil from the valves. The tracings represented in the accompanying woodcut were obtained from the schema thus

modified. All of them are characterised by a well-marked dicrotism, although the force, rapidity, and duration of the cardiac contractions were the same as before. The dicrotism, therefore, must be due to the alteration in the elasticity of the aorta. The effect of percussion on the pulse-wave is less strongly marked, owing to the increased distensibility of the aorta; for, instead of the blood being moved forward as a solid column, the lateral resistance being less than that offered to its onward

FIG. 5.—Capillaries dilated; contractions slow.

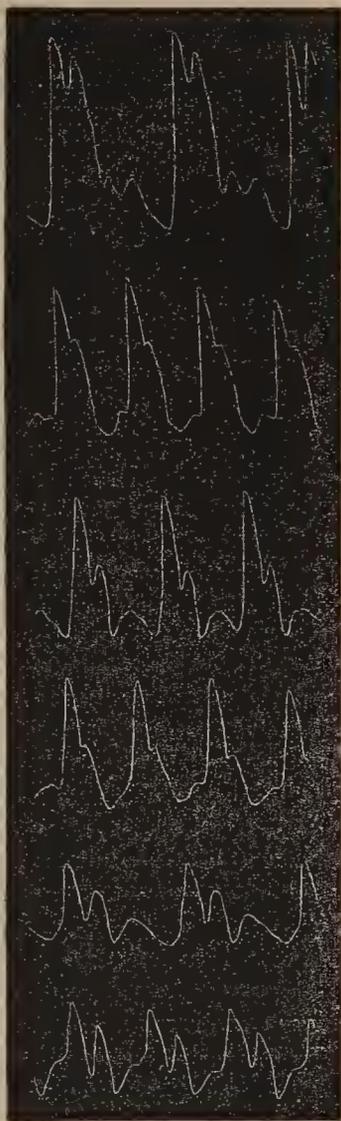

FIG. 6.—Capillaries dilated; contractions rapid.

FIG. 7.—Capillaries normal; contractions slow.

FIG. 8.—Capillaries normal; contractions rapid.

FIG. 9.—Capillaries contracted; contractions slow.

FIG. 10.—Capillaries contracted; contractions rapid.

movement, some force is lost in the lateral distension of the column. The percussion-impulse is, therefore, best transmitted in rigid tubing. It is, however, by no means lost now, though not so exaggerated as previously. In Fig. 5, previous to the dicrotic upstroke, a slight rise and fall of the lever may be seen; this is probably due to the vibration imparted to the blood by the shock produced by the closure of the aortic valves and the rebound that takes place from them. It is, indeed, a second percussion-wave, and is followed by a second tidal or dicrotic wave. It is often seen in tracings obtained from the schema, or from the human pulse.

That dicrotism occurs at the termination of the systole and closure of the aortic valves is demonstrated by Fig. 5, Pl. i., where, the systole being prolonged, the diastolic expansion is delayed till its termination. During the downfall of the lever, which occurs throughout the remainder of diastole, there is seen another slight undulation; this, again, is due to the elastic coat of the aorta, and is usually seen in the human pulse. It is virtually a second dicrotic wave, and is produced by another slight expansion and contraction of the aorta. The expansion is caused by the recoil of blood from the capillaries, increased tension being produced in the proximal arteries, requiring a secondary contraction of the elastic coat.

From the above results the primary cause of dicrotism may be deduced, but there still remains the question to be solved—Under what conditions does it vary? This, again, has been one of the most disputed points in sphygmography; but by the aid of the schema I think we shall be able to answer it to a great extent. Three terms have been used to describe the various degrees of dicrotism. When the aortic notch, that is, the point from which the diastolic expansion commences, does not reach as low as the respiratory line—*i.e.*, the line drawn through the bases of the percussion upstrokes—the pulse is said to be *hypo-dicrotous* (an example of this may be seen in

Fig. 4, Pl. ii.); when the aortic notch is level with the respiratory line, the pulse is called *dicrotous* (as in Fig. 5, Pl. ii.); and when it falls below the line, *hyper-dicrotous* (as in Figs. 6 and 7, Pl. ii.). The first two of these terms do not well convey the intended meaning, and are liable to misconception, for any pulse in which the diastolic expansion is perceptible is dicrotous, and in these papers I propose to use the term *dicrotous* instead of *hypo-dicrotous*; and, when wishing to indicate that the aortic notch reaches the respiratory line, the term *fully dicrotous* will be employed; the expression *hyper-dicrotous* being retained, with its original meaning.

(To be continued.)

CHLORAL IN EPILEPSY.

By NATHANIEL ALCOCK, L.C.P.I.,
Assistant-Surgeon 35th Regiment.

THE speculations as to the vascular condition during epilepsy, drawn from experimental pressure upon the arteries leading to the brain, and from the results of hæmorrhagic anæmia of that organ, and the belief that the most immediate cause in the induction of a fit is a sudden contraction of the vessels, are in a great measure borne out by the action of chloral in antagonising the epileptic seizure. It is now very widely accepted that the rigors preceding the hot and sweating stages of intermittent fever are coincident with spasm of the capillaries of the system. If, then, it can be shown that epilepsy is interchangeable with this fever paroxysm, it may reasonably be inferred that the immediate precursor in either case is the same; and if, in addition, it appears that such interchange of symptoms occurs during the lessening violence of the epileptic disease, it would point to the conclusion that the rigors are a diminutive of the fits; and, finally, if such reduction of morbid force succeed the use of a given drug, it may fairly be attributed to the action of that substance.

Private D., 35th Regiment, otherwise perfectly healthy, is subject to occasional epileptic fits, originated, in the first instance, by a blow on the head from a falling block on ship-board, and which are easily reinduced by the abuse of stimulants. Was admitted on December 16, at 9 p.m., at the conclusion of a fit.

On the 17th, had a fit at midnight.

On the 18th, had a fit at 3 p.m., and got fifteen grains of chloral, with half a drachm of ether, at 8.30 p.m.

On the 19th, began to take bromide of potash, eight grains three times a day, and at 3.30 p.m. had, instead of a fit, an attack exactly resembling ague, the duration of the rigors and hot stage being about three-quarters of an hour, and being succeeded by profuse sweating. Chloral, twenty-five grains at bedtime.

On the 20th the rigors recurred at 3 p.m. Chloral was repeated at night, and the rigors returned at 3 a.m.

On the 21st the rigors were postponed to 9 p.m.

On the 22nd they were averted.

On the 23rd the chloral was omitted, and at 6 p.m. on the following day the fits relapsed in the *epileptic form*, with complete unconsciousness. All treatment being suspended, the rigors reappeared no more, but the fits subsiding with a regular cadence of prolonged intermission and lessened intensity, ceased altogether in about ten days. From this it seems probable that epilepsy and rigors are but major and minor degrees of the same condition, and that chloral has the power of relaxing the offending capillaries.

Private S., 73rd Regiment, hereditarily epileptic, was under treatment on August 13 for blistered feet, and, seeing a man in the same ward seized with epilepsy, was thrown into a fit. During seven weeks the fits recurred, always in the evening, and at uncertain intervals, never exceeding four days.

From October 4 to 8 five grains of chloral were given three times a day; yet a fit was repeated on the 8th.

Continuing the small doses daily up to the 12th, half a drachm of chloral was given two hours before the expected relapse, and the fit was thereby postponed.

This was repeated on the 13th and 14th with success; but, notwithstanding the exhibition of the medicine on the 15th, a fit occurred at 8.30 p.m.

For the three succeeding days eight grains were given three times a day; and on the 19th half a drachm two hours before the time of the anticipated attack. The fit was averted, but in its stead a profuse perspiration broke out.

On the day following, after a similar dose, and at the same time, diaphoresis again took place.

On the two succeeding days, the same amount of the medicine being given, neither a fit nor sweating occurred.

On the day following, two hours after the administration of the chloral, a very slight fit was developed.

All treatment was then suspended, and for more than two months the attacks have not been renewed. The influence of chloral in combating the epileptic propensity is therefore powerful.

Sheffield.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

LONDON HOSPITAL.

CASES OF LUMBAR COLOTOMY IN MR. MAUNDER'S CLINIC.

Case 1. Malignant Stricture of Rectum.—Case 2. Tertiary Ulceration of Rectum.

THE plan of clinical instruction adopted by Mr. Maunder is both didactic and suggestive, and is carried out partly at the bedside and partly in the theatre. Every new case is thoroughly investigated with the class, the history is listened to, the leading facts commented on, and the proper value assigned. Then the objective and subjective symptoms are noted and investigated, the posture of the patient being especially remarked. All possible sources of error are mentioned. While this is going on the students are encouraged personally and collectively to examine and form opinions upon certain prominent features; and should the diagnosis not be evident, Mr. Maunder frankly says so, and throws out suggestions for the consideration of the students until the next visit. Dressers and others are also invited to observe certain facts, and to manipulate parts, short of causing discomfort to the patient, in order that each and all may take an interest and learn something in "going round." Questions are also asked to test the knowledge of the student. Once a week during the winter session a clinical demonstration is given by Mr. Maunder in the theatre. When possible, a case that has proved fatal, and from which the pathological specimen has been procured, is chosen for comment. In this way most is learnt; having heard the history, noted the symptoms, watched the progress of disease in the ward, and now seeing the morbid changes in the organs, the student may be said to have seen the case from beginning to end. On another occasion, a case which has been carefully investigated at the bedside, and with which the class is familiar, is more fully discussed than many circumstances will otherwise admit of, and chalk and the blackboard are called in to aid the explanation. The other method, which Mr. Maunder learnt from the late Professor Syme, consists in having a patient or patients in the theatre. This is very instructive up to a certain point (one cannot always speak freely before a patient), especially where it is desirable to contrast diseases which may be mistaken the one for the other when seen separately—as in the case of chancre; or when the same disease can be shown in different stages, as was exemplified in Mr. Maunder's first clinical lecture, as Surgeon, when three cases of disease of the knee-joint could be brought into the theatre.

For the following report we are indebted to Mr. Stanley A. Gill, House-Surgeon:—

Case 1.—G. S., aged 41, formerly a sailor, suffered from dysentery about twenty years ago. Until within nine months he was quite well, when he was seized with diarrhoea. About six weeks after this he used to pass blood in his motions. He has had very little pain, but has lost flesh very fast for the last six months, and has become very weak. Upon admission, January 9, 1872, he complained of intermittent pains at the lower part of his abdomen, and a frequent desire to go to stool, the motions being fluid, and containing blood at times. He is emaciated and feeble; his appetite is bad; his countenance expressive in a marked degree of the cancerous cachexia. Around the anus is an epithelial growth. On passing the finger into the rectum, a stricture which will just admit its tip is felt about two inches within the anus. The portion of bowel below the stricture was dilated and smooth, its walls and the strictured portion being hard and fixed. He had incon-

tinence of fæces and overflow of urine. A nutritious diet and tonic medicines were ordered.

January 12.—Mr. Maunder suggested that in the absence of urgent symptoms, such as serious obstruction, severe pain, vomiting, and hæmorrhage, nothing was at present indicated beyond the palliative treatment already prescribed by the House-Surgeon.

21st.—Has vomited twice to-day; motions still fluid and frequent.

26th.—During the last few days the vomiting has greatly increased in frequency, and he has much changed for the worse, being very feeble. His countenance is pinched. Pulse 108; very compressible. As some cough existed, Dr. Down was requested to see the case, and, having done so, saw no objection to lumbar colotomy, which Mr. Maunder suggested to the patient as the only means of checking the vomiting, and of prolonging his life possibly for three months. The operation was performed at once, and the vomiting did not recur, and the patient expressed himself relieved. He became weaker and weaker until he died, forty-three hours subsequently. Post-mortem examination was obstinately refused.

Case 2.—Mrs. H., aged 25, with an undoubted history of syphilis, has been under Mr. Maunder's observation for the last two years. When first seen she was the subject of ulceration of the rectum, hypertrophied folds of skin about the anus, associated with one or two ulcers, and hypertrophied vulva. There was also more or less frequent desire to go to stool, associated with painful defæcation and muco-sanguineous discharge. Upon two occasions outgrowths at the anus have been removed by operation. Mercury and iodine have been used in various forms, but with rather an injurious than a good effect. She has had also the opportunity of sea air and country air, but without avail. At the time of her last admission, October 28th, 1871, her symptoms were aggravated. There is a sense of bearing down; frequent desire to go to stool, resulting in a free discharge of mucus highly tinged with blood. The anus is fringed with outgrowths, ulcerated; and about an inch and a half within this aperture the rectum is becoming strictured.

January 3.—The treatment has been conducted on general principles, and the gum-elastic bougie used. She is no better, and says "her life is miserable." Mr. Curling was asked to see her, and suggested the exhibition of one grain, or even half that quantity, for a dose, of iodide of potassium, as she could not bear larger quantities, and the solution of one grain of nitrate of silver in an ounce of water to be injected.

7th.—The stomach has rejected both medicine and food. She cannot bear the injections.

25th.—She is worse rather than better, both locally and generally; suffering from frequent attacks of vomiting. Mr. Maunder suggested that lumbar colotomy afforded her a reasonable prospect of recovery, and the patient readily acceded.

31st.—Lumbar colotomy was performed in the left loin, patient being under the influence of chloroform. The patient having a tendency to obesity, and the muscles well developed; the descending colon, empty, was found at a good depth from the surface. It was secured to the wound, and opened in the usual way. When the patient was turned upon her back, milk, which had been previously injected per rectum, flowed at the wound.

February 3.—She has always been susceptible to chloroform vomiting, and suffered a good deal consequently. The traumatic fever has been high, and there is now free discharge from the wound.

8th.—Vomiting ceased some days ago; motions pass entirely by the wound; and altogether she is progressing favourably. Since the operation the sanguinolent discharge from the rectum has entirely ceased.

18th.—Doing well.

Remarks.—When contemplating colotomy on the male referred to, the operator had for his objects the arrest of vomiting, which seemed to be rapidly exhausting the patient, and also the emptying of the bowels—only partially able to empty themselves—the product of the decomposition of the contents of which was probably being absorbed and poisoning the system. The exhalations from the man were most offensive. In a thin subject the operation is easily performed; no blood is lost, and shock is avoided. Although life cannot be prolonged beyond a few weeks, sometimes only for days or hours, intense suffering is removed, and the patients are always grateful. In the case of the young woman the principle upon which the operation was undertaken was widely different. Ulcers exist, and even if they would heal cannot, by reason of the frequent

passage of fæces over them and the disturbance caused by muscular action. Mr. Maunder hoped that by diverting the passage of the fæces from the rectum to the loin for a few weeks, the repose thus given to the diseased bowel would have a curative result.

LEEDS INFIRMARY.

At a recent visit to this fine institution, we had an opportunity of seeing the following interesting cases in the wards under the care of Dr. Allbutt:—

First, we saw a man about 30 years of age, who had suffered some time from epileptic fits, beginning with an aura from the right thumb. He described it as a kind of internal quivering. This runs up his arm in about sixty seconds, when he becomes unconscious; but he can stop every fit by tightening a cord which he wears round his wrist, so that a fit never occurs unless his cord breaks. Dr. Allbutt has had a steel band with a screw made for him, which can be tightened without fear of giving way. The cause of his first coming to the Infirmary was a terrible supra-orbital neuralgia of the left side, which had lasted nearly six months, in spite of all treatment at the Belfast Infirmary and elsewhere. This neuralgia seemed to have partially replaced the epilepsy, as during its continuance the threatenings had been less frequent. Under the daily use of ten cells of Elliott's constant battery for three weeks his agonising pain had been entirely cured, and was relieved after the first or second application. There still remains some occasional aching in a slight degree, but nothing to inconvenience him. Dr. Allbutt had also among his patients a man suffering from intense neuralgia of the first and second branches of the trigeminal nerve, and who had a white lock of hair on the same temple about the size of his forefinger. The constant current had utterly failed to give him the slightest relief, but Dr. Allbutt gave us to understand that such a failure was quite exceptional in his experience. Another patient is liable to epileptiform attacks confined to the left side of the face and the tongue. There is never any loss of consciousness nor any movement of the limbs, but the left arm is sometimes a little numb and heavy. The attacks, on his admission, were occurring many times daily, and lasted about a minute or a little more, but they have given way very much under the use of bromide of potassium.

The principal methods of electro-therapeutics were introduced into this Hospital some time ago by Dr. Clifford Allbutt, and we saw several patients under this kind of treatment. Among others was a case of bad sciatica of long standing, which had been treated with twelve to twenty-five cells of Weiss's constant battery for about a fortnight. There was now but little pain remaining, and the weak and wasted leg was recovering favourably under gentle faradism.

In a neighbouring bed was a very remarkable case of progressive muscular atrophy, in which the unusual course of the disease had left the hands and forearms as yet intact. These parts were, in fact, finely developed and very powerful, while the upper arms and scapular muscles were much wasted. The triceps extensor in both arms was fairly preserved, but both biceps muscles had vanished, or nearly so. The legs showed the same peculiarity; the thighs being much weakened, while the parts from the knees downwards were scarcely affected at all. Galvanisation of the sympathetic in the neck had been carefully practised for some time, with not the slightest improvement, but a fortnight's use of faradism had enabled the man to rise from bed and walk about the ward. These, Dr. Allbutt assures us, are the results he has always obtained in the very numerous cases of progressive muscular atrophy which have been under his care.

In other parts of the ward Dr. Allbutt showed us a case of cirrhosis of the liver, in which we could detect only a bare finger's breadth of dulness; a massive tumour occupying the left half of the abdomen, of slow growth, and not attended with rapidly advancing cachexia, wasting, or pain, and which Dr. Allbutt guessed to be enchondromatous; and thirdly, a case of much interest, in which marked cachexia, constant vomiting after food, and a tumour in the cardiac region of the stomach in a middle-aged man suggested malignant disease, while, on the other hand, an indistinct resemblance to the spleen and a history of residence in the tropics suggested ague-cake and paludal cachexia. A course of quinine quickly settled the matter by removing the cachexia, the vomiting, and the tumour in a few days.

We saw, also, a boy about 10 years of age, who has been in the

Infirmary under Dr. Clifford Allbutt's care for many weeks. The symptoms are amaurosis (complete), vomiting, and headache; there is also some loss of balance and control over the legs, as is well seen when the boy is made to walk in the ward. Dr. Allbutt told us that the boy had presented the choked disc in both eyes in a marked form, but that this state had now been followed by atrophy of both nerves. He was quite blind. Dr. Clifford Allbutt believes that there is a tumour in the vermiform process of the cerebellum; and we may refer to his discussion of this point in the fifth chapter of his volume on the "Ophthalmoscope in Diseases of the Nervous System."

MEDICAL EVIDENCE.

IN another column will be found an interesting paper read by Dr. Bernays before the Association of Medical Officers of Health, on the precautions which should surround toxicological investigations in Medico-legal cases, and on evidence in courts of law. Although not a Medical man, Dr. Bernays, from his well-known scientific attainments, and from his wide experience as a lecturer on chemistry at a large metropolitan Medical school, is entitled to speak with authority on such important questions as those he has mooted in his paper. The evidence offered by experts in courts of justice—we are now speaking of the evidence of experts generally, and not solely of that of Medical experts—has of late given rise to a widespread opinion that the success of a cause depends not on its merits, but on the length of purse of plaintiff and defendant. Long lists of eminent witnesses have been seen arrayed against one another, and, as it seemed to the general public, offering under oath the most contradictory statements.

As for the evidence of Medical witnesses, it has been a by-word and term of reproach, especially among lawyers, though very unjustly. Solicitors and barristers are guided by custom and precedent, whilst we are thankful to say the Medical Profession is day by day becoming more guided by science and reason. A Medical man who goes into the witness-box as an expert, the wider his experience and the greater his knowledge, the greater is his diffidence in committing himself absolutely on particular points. The object of a barrister is, however, to get the expert to give unqualified answers to the questions put to him, and, if possible, to convert the witness into an advocate. Medical men should, however, never forget the obligation they are under, not only to speak the truth, but the whole truth. We well recollect a circumstance that occurred at the outset of our Professional career, illustrating the kind of evidence a Medical

man is expected to give. We had been accidentally witness to an unprovoked assault made upon an officer in the army at a place of public amusement, by a man with whom the officer had no previous acquaintance. The man, in consequence of some supposed insulting expression in the officer's face, deliberately spat upon him. The barrister—an eminent recorder, we believe—who conducted the plaintiff's case in the police-court, tried to extract from us that such an unprovoked assault as this committed by a man who had never seen the officer before, by a person who it was now admitted had received no provocation, must be the act of a madman—the object being to get the defendant confined as a lunatic instead of being simply bound over to keep the peace. Of course the barrister, notwithstanding much bullying, that eventually provoked the intervention of the magistrate, failed in moving us from the assertion that, although the assault was consistent with insanity, yet it was equally consistent with perfect sanity.

Medical evidence may be divided into two kinds—that which is offered before the coroner's court, and that which is given in a court of justice. The former is, we need hardly say, more frequently required than the latter, and is perhaps of no less importance. Nothing can be more unsatisfactory than the manner in which both are demanded. We have the testimony of Dr. Lankester that the evidence of Medical men in his court is often utterly defective; and further, that he is not even bound to receive Medical evidence solely from Medical men—he can call upon anyone to give Medical evidence; and he stated before the Association of Medical Officers of Health, when discussing Dr. Bernays' paper, that he had on a recent occasion called upon a post-mortem-room porter to give evidence as to the existence of a clot of blood upon the brain. This is an unsatisfactory state of affairs. The law requires that in the case of a sudden or suspicious death the nearest Medical man be sent for, or the one who first saw the body after death, to make the post-mortem examination. Dr. Lankester evidently thinks that it would be much better to employ an expert accustomed to such examinations. The time is not, we hope, far distant when several experts will be attached to the coroner's court, skilled not only in pathological anatomy, but in chemistry. They should, in reality, decide whether an inquest is necessary.

A crying evil is the inefficient manner in which toxicological investigations are carried out, or, rather, not carried out. Suppose an inquest is held on a body, and the circumstances are such as to justify a suspicion of poisoning: the coroner has several courses open to him and not one is satisfactory. He may decline to order any chemical investigation on the score of expense. We know of an instance where two members of a family died with symptoms pointing most strongly to arsenical poisoning, whilst the other members of the family suffered at the same time from severe diarrhœa. The coroner adjourned the inquest, and directed (verbally) the viscera to be handed over to a well-known toxicologist. He declined to undertake the responsibility without a written order from the coroner, which would have involved the payment of a moderate fee. The coroner, simply stating that he had no funds, declined to make the order, and closed the inquest. Sometimes the coroner may be able to induce the ordinary Medical attendant to give up his fees (which seldom, if ever, exceed two guineas) to some expert, who may have to spend several days in carrying out the analyses required, and for which two guineas is miserably inadequate. In a case of apparently very great importance the coroner applies to the Home Secretary for an order for analysis. If the request be granted, the pay is certainly more adequate; but we know from experience that the request is too often refused. In the case of charges made before a magistrate the course of procedure is even more objectionable, for it is difficult to obtain more than half a guinea or a guinea for a chemical analysis and evidence. If, as in certain well-known instances, some Medical jurist of

standing and reputation be employed, an objection, ably put forward by Dr. Bernays, lies, that an investigation involving questions of life and death ought not to be entrusted to only one individual, however eminent and above suspicion he be. Dr. Bernays would entrust the investigation to a court of skilled examiners, who should conduct the investigation. We apprehend there would be difficulties in the way of this, and our experience of committees—not a slight one—is adverse to this course. The plan followed in Paris appears to us to be a good one, not very expensive, and one which almost entirely meets the wants of the case. The conduct of a toxicological investigation is entrusted to two experts—one a Medical jurist and Physician, having a thorough acquaintance with physiology; the other a chemist, who is not necessarily a Physician. They meet, examine the viscera, and make the necessary analyses after consultation. In all cases where practicable it might be further required that the analyses be done in duplicate, each one by a separate chemist, who should be required to conduct his analysis without consultation, just as the bullion-dealer sends his ingots to two different assayers, who make their reports each in ignorance of the procedure of the other; or as the two examining Medical men, in a case of lunacy, make their separate examinations and reports.

We may sum up our views as to the conduct of Medico-legal investigations thus:—The coroner and the police magistrate, in all cases in which they deem it requisite that a post-mortem examination or an analysis should be made, ought to be able to secure the services of two competent experts, one of whom should be a chemist; and these should make their investigations as far as possible in concert. Perhaps it might be necessary to employ a second chemist in the manner already indicated. Their evidence in writing should be laid before a public prosecutor, an official whose appointment cannot long be delayed. We dissent entirely from Dr. Bernays' view, that the experts ought not to be examined and cross examined in open court. A well-reasoned opinion ought to be able to withstand a severe cross-examination, and we do not see why the evidence of a Medical man in a case of life and death should be allowed to escape this severe ordeal.

The question whether the duties above indicated should be entrusted to the new Health Officers, to be created under the Sanitary Bills now before Parliament, when they become law, is a distinct consideration, of which we shall probably treat in a future article.

THE PATHOLOGICAL SOCIETY.

At the meeting of this Society on Tuesday, the President announced that the Council had come to an important resolution. They recommended the setting apart of portions of the Society's time for the discussion of certain points or abstract questions connected with pathology. With this recommendation we most heartily agree. It is high time the Society took some such step, for it is foolishness to go there night after night to see bits of bone, the sole interest of which lies in their having been excised by some distinguished Surgeon present, or of a salivary calculus which it required two men to extract, but of which beyond nothing is known.

The Society is called a Pathological Society, and yet it has of all things been most impatient of pathology. It has been wont to calmly sit down to digest a certain mass of morbid material, and has been most impatient until it has ingested the whole of it. Any remarks on an interesting subject have been promptly repressed, and the sole aim of the Society at one time seemed to be to have as many specimens as possible before it, quantity being esteemed far before quality. Doubtless this kind of work has been well done—and by this time it has been pretty thoroughly done—but it is not pathology.

It is well to encourage the younger members to bring forward specimens which may serve to give rise to a few words of pleasant discussion; but for the senior members there should

be opportunities for ventilating theories of disease and causation of disease, such as have not heretofore existed. Indeed, it was not until the Society came under the wise rule of a recent president that anything could be introduced which had not an immediate reference to morbid anatomy; now, we trust, his views are to receive a still more extended application.

But there is something still wanted. There is no time or means for examining specimens until the time for discussion has gone by. Above all, there are no means for examining a microscopic specimen save by an engine few men can work—the only one of the kind in the Society. Why some of the surplus funds are not spent in obtaining some fairly good microscopes, and thus insuring the means for examining morbid specimens, we cannot see; but we can conceive that such a plan would be conducive to the better study of pathology in the Pathological Society.

THE EXPECTED COLLISION WITH A COMET.

CRITICS and theologians have often noticed the remarkable agreement between some of the maxims sanctioned by the most Divine authority and those of the shrewdest and most practical of the Roman poets.

“ Prudens futuri temporis exitum
Caliginosa nocte premit Deus,
Ridetque, si mortalis ultra
Fas trepidat. Quod adest memento
Componere æquus; cætera fluminis
Ritu feruntur,” etc.

So sang Horace; and Mr. Creech Englished his song thus:—

“ Future Events wise Providence
Hath hid in Night from humane Sense
To narrow bounds our Search confin'd;
And laughs to see proud Mortals try
To fathom deep Eternity
With the short Line and Plummet of their Mind.”

But there is a certain class of minds on which neither Divine authority nor human wisdom makes much impression. These credulously listen to the juggling vaticinations of the mercenary quack preacher or astrologer, who undertakes to “fathom deep Eternity,” and to fix “That Day and Hour” which the Omnipotent has locked up amidst the awful things not to be made known.

Comets played a great part in the cosmical theories of a bygone day, and were supposed to create not only material cataclysms, but moral disturbances—revolution, war, etc. In Thomas Burnet's “Sacred Theory of the Earth,” comets account for the elevation of hills, the depression of ocean beds, and the Universal Deluge.

But if the theories of modern astronomers are worth anything, comets are very harmless bodies after all—mere puffs of vapour; nay, it is supposed that our earth passed through the tail of one without injury on June 30, 1861.(a)

But though actual collision with a comet may do little material harm to the earth, the Medical philosopher may fairly comment on the moral harm which the belief in it may inflict on the earth's inhabitants. At the end of the tenth century of our era an impression prevailed that the world was coming to an end. The cultivation of the earth was neglected, business languished, and whilst some men were absorbed in fear and considered all earthly occupations hopeless, others determined to enjoy the fleeting hour, and beguiled the time with licentiousness, rapine, and drunkenness.

The notion of a speedy end to the world is a phenomenon that occurs at intervals. About ten years ago the Irish inhabitants of Gray's-inn-lane were so disturbed by such a prophecy, that some went out of their senses. A similar delusion in the reign of Queen Anne caused Dean Swift to bequeath to us his “True and Faithful Narrative of what passed in London during the General Consternation of all Ranks and Degrees of Mankind on Tuesday, Wednesday, Thursday, and Friday last.” What Swift pretended to describe as happening then, would

be sure to happen now, should the popular belief in the end of the world be confirmed. Swift's pretended narrator, a mercer in Cheapside, says that he went to church with his wife—a thing he had neglected on a week-day for many years; but during their absence a fine piece of cambric was carried off by a shoplifter. The Governor of the Bank of England, it is said, directed all the fire offices to keep their engines ready to play on the building. The South Sea Stock went down. The lawyers were in great consternation.

“Our sage and learned judges had great consolation, inasmuch as they had not pleaded at the bar for many years; the barristers rejoiced in that they were not attorneys; and the attorneys felt no less satisfaction that they were not pettifoggers, scriveners, and other meaner officers of the law. . . . Most of the considerable Physicians, by their outward demeanour, seemed to be unbelievers; but at the same time they everywhere insinuated that there might be a pestilential malignancy in the air, occasioned by the comet, which might be armed against with proper and timely medicines. . . . The only persons who showed any joy were three malefactors sentenced to be hanged on the Monday following. . . . An Irish gentleman, out of pure friendship, came to make me a visit, and advised me to hire a boat on the ensuing day, and told me that unless I gave earnest for one immediately he feared it might be too late, for his countrymen had secured every boat on the river, judging that in the general conflagration to be upon the river would be the safest place.

“At length Friday came; and the people covered all the streets—expecting, watching, and praying. But as the day wore away their fears began to abate, then lessened every hour; at night they were almost extinct. . . . Great numbers now flocked to the taverns to supper. . . . The subject of all conversation was to ridicule the prophecy. . . . All the gentry were perfectly ashamed, and disowned that they had manifested any signs of religion. . . . The next day even the common people appeared in their usual state of indifference. . . . They drank, they whored, they swore, they lied, they cheated, they quarrelled, they murdered. In short, the world went on in its old channel.”

We may divide the world into two classes—those who read Dean Swift, and those who do not. The latter class have got to learn what wisdom and wit are; the former will excuse us if we have neglected Medical matters for the moment, and have brought the great Dean on the stage to show us the value of the morality extorted by fear of a comet.

THE WEEK.

TOPICS OF THE DAY.

TUESDAY'S *Gazette* announces that Sir William Gull, Bart., M.D., has been appointed Physician-Extraordinary to her Majesty. This personal tribute on the part of his Sovereign will, we are sure, not be the least appreciated of Sir William Gull's recent honours. We heartily congratulate him upon this well-deserved distinction.

The University of Cambridge has confirmed the report of the Syndicate recommending the scheme for a partial Conjoint Examining Board agreed to by the Royal Colleges of Physicians and Surgeons. Although the Universities have more or less readily given their assent to the arrangement of the Royal Colleges, we must maintain our opinion that it is not for the benefit of the Medical Profession that that arrangement in its present form should receive the assent of the General Medical Council. In the first place, the scheme is not complete, even as regards England. The Medical Authority which has the highest Parliamentary sanction, which has done more to improve Medical education and examination, and to raise the status of the Medical Practitioner, than any other, is, by the very nature of the scheme, excluded from participating in it. To suppose for one instant that by such a union, which is certainly not sanctioned by the spirit of the Act of 1858, the Apothecaries' Society will be driven to forego the exercise of its licensing powers, whilst it offers to the student a thoroughly fair and sufficient practical examination of his fitness to practise,

(a) See a notice in *Nature*, February 15, 1872.

and a licence which has the *prestige* of more than half a century, and the highest legal sanction, confirmed by repeated Acts of Parliament, is mere folly. To suppose, again, that the Royal College of Surgeons is so far independent of all public law and public opinion that it is able to refuse to examine candidates who have already obtained a legal right to practise Medicine for a diploma in Surgery, unless they also consent to be examined by, and pay a large sum of money to, the Royal College of Physicians, is to credit the College with powers which, we believe, are not conferred by its charters, and are certainly repugnant to the spirit of all previous Medical legislation. Should the General Medical Council be ill-advised enough to sanction this scheme, it will have no choice but to admit to the Register a large body of Medical Practitioners having no Surgical diploma, but possessing the licence of the Apothecaries' Society only. We need not say that this would be to accept a position against which all they have hitherto done has been a protest, and to introduce an evil which would far outweigh any good that might accrue from an arrangement between the Universities and the Royal Colleges. But there are other and still graver objections to their acceptance of this scheme. The first is, that it is now tolerably clear that it is useless to expect any conjoint action between the Irish Medical Authorities, and that the Scottish are quite disagreed as to the character of the conjoint examinations which some of them are willing to institute. Further than this, there is a strong feeling which is gaining ground amongst some of the foremost teachers and professors in Scotland, that the dead level of education contemplated by Conjoint Boards, even if it could be attained, would be a greater evil than the present multiplicity of examinations. We confess that we do not share this fear if a properly constituted and complete Conjoint Board were formed in each division of the kingdom, in which all sections of the Profession and all Medical authorities were represented, and which was subject to the constant supervision and inspection of the General Medical Council. But we are bound to take notice of an objection, the validity of which only experiment could disprove. The feeling of which we have spoken has taken shape in a memorial, a copy of which we have received from Professor Sanders, of Edinburgh, and Professor Gairdner, of Glasgow, and which, we believe, will be presented to the General Medical Council at their forthcoming session. The following is the text of the memorial:—

"The undersigned, having been informed of the recent proceedings on the part of the Universities and Corporations in Scotland, with a view to the formation of a Conjoint Board of Examination at the instance of the Medical Council, feel bound to indicate their dissent from these proceedings on the following grounds:—

"1. The reason alleged for such proceedings in the first instance—viz., the attainment of 'uniformity of qualification' (i.e., a fixed minimum of Medical knowledge and skill on the part of candidates, secured through examinations conducted upon a precisely similar plan, by examiners making precisely similar requirements)—appears to the undersigned an object neither desirable nor attainable.

"2. Even were the object in question a desirable one, it evidently cannot be secured by the measures proposed. It is inconceivable that one Board sitting in England, another in Scotland, and a third in Ireland, each Board being of very complex constitution, and holding examinations in different places, without any concert or intercommunication, could possibly secure 'uniformity' in any real sense of the word.

"3. The immense number of candidates which would have to be examined in each division of the kingdom by the Conjoint Boards, would make it absolutely necessary either greatly to enlarge the number of examiners and to subdivide them into companies (of course with a still further loss of 'uniformity' as regards results), or to work one set of examiners continuously day after day for long periods, with the practical effect of reducing their operations to a wearisome routine, incompatible with other Professional pursuits on the part of the examiners, and entailing great hardship upon candidates by want of accommodation with the sessional arrangements of the principal Medical schools.

"4. The expense of examinations so conducted would be, if thrown upon the candidates, a very serious addition to the cost of Medical education and qualification, without any commensurate results as regards the security of the public.

"5. The undersigned are decidedly of opinion that if, for the public security, an additional examination requires to be introduced over and above the nineteen at present in operation, the cost of such additional examination should in any case not be thrown upon the candidates, nor yet on the existing examining bodies, but should be defrayed by the State, as representing the public.

"6. The true object to be aimed at, whether in view of the public interest or that of the Medical Profession, is, in the opinion of the undersigned, *not* uniformity, nor yet a fixed minimum of qualification, but the watching and stimulating the existing Examining Boards, through a systematic inspection, conducted under the auspices either of Government or of the Medical Council.

"7. The undersigned profess themselves willing and anxious to facilitate to the utmost a thoroughly efficient system of examination in the Universities and Corporations with which they are severally connected, and would gladly welcome the visits of any inspectors appointed on the part of the public to secure, as far as may be, efficiency on the part of all such examining bodies in the performance of their important duties. In the case of the Universities, such a system of inspection would be quite in accordance with the system already introduced by the Universities Act of Non-Professorial Examiners. The undersigned are thoroughly satisfied with this system, and believe that an extension of it would do good.

"8. The details of such inspection should, in the opinion of the undersigned, be arranged between the State, as representing the public, and the Medical Council as representing the Medical Profession.

"9. The undersigned desire it to be understood that so far from objecting to a 'Conjoint' system of examination, they would cordially welcome any voluntary joint action of different Boards with the view of diminishing the labour and responsibility of examination, and the expense and trouble of it to the candidates. The objection that they entertain to the proposed system is, that it would not diminish either the expense or the trouble to the candidates, but would, on the contrary, increase both; while, by removing the responsibility of the practical part of the examination in some measure from the existing Boards, it would tend very much to reduce all Medical examinations to a low dead level, and would render it nearly impossible to improve them in accordance with the demands of advancing Medical knowledge."

Seeing, therefore, that there are these grave objections to the acceptance of any partial scheme which may be laid before the General Medical Council, and that it seems useless to expect any combined action in Scotland and Ireland, we think it our duty to urge on that body the responsibility which they will take upon themselves if they hastily disturb the existing machinery of Medical education and examination by tentative, imperfect, and premature alterations which may yet be proved to be *ultra vires*.

The Bill now before Parliament for the better protection of Infant Life, introduced by Mr. Charley and Drs. Brewer and Lyon Playfair, provides that it is unlawful for any person to retain, or receive for hire or reward, two or more infants under the age of one year, for the purpose of nursing or maintaining them apart from their parents, for a longer period than twenty-four hours, without first taking out a licence under the hand of a justice of the peace. This licence is to be granted by justices on their receiving a certificate from a justice of the peace, clergyman, or minister of religion, or registered Medical Practitioner, that he has caused a personal investigation to be made into the character of the person applying for the licence and his or her ability to maintain the children. The licensed person is to keep a register of the infants under his care, which he is bound to produce when required by an order from a justice of the peace. Infringement of these provisions is a misdemeanour punishable by six months' imprisonment or fine. The licence may be revoked by a justice of the peace on proof that an infant is in an unsatisfactory state of health and condition arising from the neglect or incapacity of the person so licensed. The death of an infant under

the care of a licensed person is to be reported within twenty-four hours to the coroner, who is bound to hold an inquest unless a Medical certificate be produced by the licensed person that death occurred from natural causes. No child so dying is to be buried without the coroner's certificate. The provisions of the Act do not extend to relatives or guardians of infants, nor to persons having the care of infants whose parents are abroad, nor to public homes and orphanages, nor to persons receiving children under the provisions of any Act for the relief of the poor. It seems to us that the omission of any provision for the regular inspection of baby farms is an important flaw in the Bill. Another is, that it is not extended to those establishments common enough in the manufacturing districts, where infants, whose mothers are at work in the factories, are "kept quiet" during the day.

Mr. Stansfeld's Sanitary Bill has the merit of not attempting too much. If he succeeds in establishing definite local sanitary authorities, with definite responsibility, he will have accomplished a great good. We shall take an early opportunity of making our readers acquainted with the particulars of the measure.

We reserve our comments on "the extraordinary charge of murder" brought against a solicitor, who is accused of killing his wife in 1867, by his niece and her alleged paramour, a Surgeon, who was called to attend the deceased lady. The case is evidently one which will require most careful investigation.

A further sum of £100 is to be paid to each of the eighty-five London charities under Lord H. Seymour's will.

The students of the University of St. Andrews have decided in favour of the admission of ladies to the learned professions. By this we suppose they mean the admission of women to the bar and pulpit as well as into Medicine. The Medical students at St. Andrews who have sisters and mothers, we presume would not desire to dissect at the same table with a woman.

Mr. Skey, with characteristic energy, has lost no time in informing the public, through the *Times*, of the dissatisfaction, not to say contempt, with which he regards Mr. Bruce's Bill for the Amendment of the Contagious Diseases Acts. He says that "Mr. Bruce has simply emasculated the Act, the very essence of which is the power to detect disease *in transitu*." We have already expressed our opinion that the examination of public and professed prostitutes, should it, in obedience to popular clamour, be at present abandoned, will most assuredly be re-enacted before long by Parliament. But it is clear, at the same time, that stringent measures must be adopted—on the one hand, to prevent mistakes and protect personal liberty; on the other, to repress and discountenance vice and to favour reformation. Anything like the French system of registration and legalised prostitution is abhorrent to the moral sense of England, and we are glad it is so. Mr. Skey, as the Chairman of the Admiralty Committee of 1865-66, assumes his full share of the responsibility of the advice on which the Government framed the present Acts. That they have done much good, none but fanatics would deny. The principle of the examination of public women in naval and military stations is one which cannot safely be relinquished. It is only necessary that, in their efforts to limit a preventible disease, the Legislature should take care to avoid all appearance of fostering and favouring the vice with which that disease is ever associated.

THE MURDER IN LAMBETH.

A TERRIBLE murder—remarkable for the cool determination with which it was committed—has been proved against a man, named William Chester Minor, who is described as an American Physician. This person, soon after midnight on Saturday morning, killed, by firing several times at him, a stoker named George Merritt, who was going to his work in the Belvidere-
